An example of an input data set is an Employee Master hierarchy description in which each row represents the relationship between an employee (child node) and the employee's manager (parent node). In this example:

- Employ_ID is the child node identifier and the primary key
- Mgr_ID is the parent node identifier

Employee
Employ_ID
Dept
Salary
Mgr_ID

The input data set cannot include rows with operation codes other than NORMAL.

The input data set can contain hierarchical data.

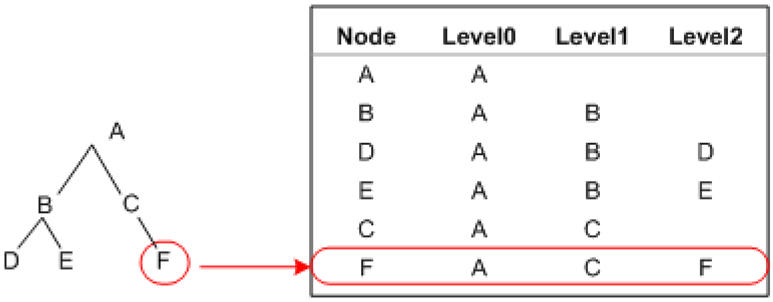
3.5.3.4.2 Editor

The Hierarchy_Flattening editor includes:

- Schema In pane which contains the source schema
- Schema Out pane which contains the target schema
- Hierarchy_Flattening transform options
  You can drag column names from the source schema to fill in values for the Parent column, Child column, Parent attribute list, and Child attribute list options.
  Data Services generates the target schema in response to the values you choose in the transform options. To refresh the target schema after you make a change to the options, choose *View* > *Refresh* or press *F5*.

3.5.3.4.3 Options

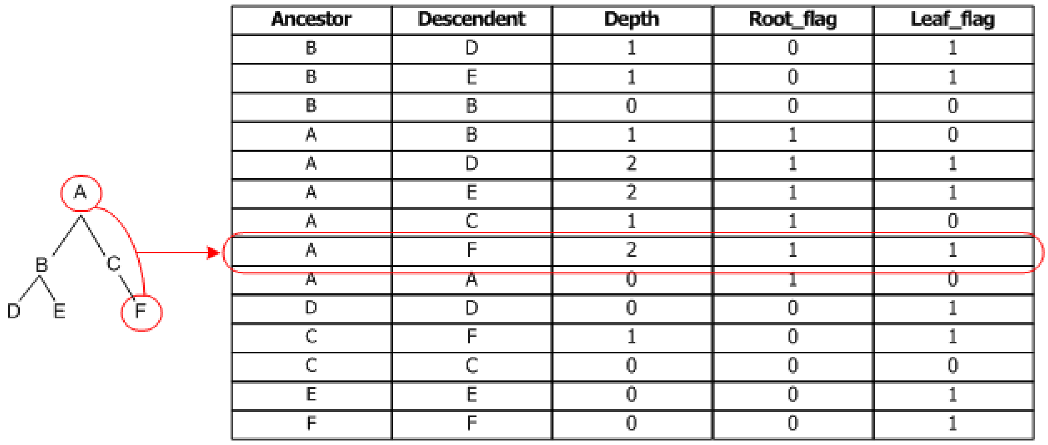
<table>
<tr><th>Option</th><th>Description</th></tr>
<tr><td><i>Child attribute list</i></td><td>Identifies a column or columns that are associated with the child column. You can drag columns from the source schema into the <i>Child attribute list</i>. The column name appears in the target schema with a prefix that identifies the column as a child attribute. The following table shows the result of adding a column named <code>POPULATION</code> to the child attribute list.
<table>
<tr><th>Flattening mode</th><th>Source column</th><th>Target column</th></tr>
<tr><td>Vertical</td><td>POPULATION</td><td>C_POPULATION</td></tr>
<tr><td>Horizontal</td><td>POPULATION</td><td>C_L1_POPULATION
C_L2_POPULATION
(one column for each hierarchy level)</td></tr>
</table>
You can specify columns including nested schemas as the child attribute.</td></tr>
<tr><td><i>Child column</i></td><td>Identifies the column in the source data that contains the child identifier in each parent-child relationship. You can drag this column from the source schema into the <i>Child column</i> box.
You cannot specify columns including nested schemas as the child.</td></tr>
<tr><td><i>Do not abort in case of cycle</i></td><td>Select to specify that a job should not abort if a cycle (circular dependency) is detected. If a cycle is encountered, warnings are written to the log files.
If left unchecked, jobs will abort if the transform encounters a cycle.</td></tr>
<tr><td><i>Flattening type</i></td><td>Indicates how the hierarchical relationships are described in the output. Choose from two options:
<ul>
<li><i>Horizontal</i> — Each row of the output describes a single node in the hierarchy and the path to that node from the root. This mode requires that you specify the maximum path length through the tree as the <i>Maximum depth</i>.



<table>
<tr><th>Node</th><th>Level0</th><th>Level1</th><th>Level2</th></tr>
<tr><td>A</td><td>A</td><td></td><td></td></tr>
<tr><td>B</td><td>A</td><td>B</td><td></td></tr>
<tr><td>D</td><td>A</td><td>B</td><td>D</td></tr>
<tr><td>E</td><td>A</td><td>B</td><td>E</td></tr>
<tr><td>C</td><td>A</td><td>C</td><td></td></tr>
<tr><td>F</td><td>A</td><td>C</td><td>F</td></tr>
</table>
</li>
<li><i>Vertical</i> — Each row of the output describes a single relationship between ancestor and descendent and the number of nodes the relationship includes. There is a row in the output for</li>
</ul></td></tr>
</table>

<table>
<tr><th>Option</th><th>Description</th></tr>
<tr><td></td><td>

each node and all of the descendents of that node. Each node is considered its own descendent and therefore is listed one time as both ancestor and descendent.



<table>
<tr><th>Ancestor</th><th>Descendent</th><th>Depth</th><th>Root_flag</th><th>Leaf_flag</th></tr>
<tr><td>B</td><td>D</td><td>1</td><td>0</td><td>1</td></tr>
<tr><td>B</td><td>E</td><td>1</td><td>0</td><td>1</td></tr>
<tr><td>B</td><td>B</td><td>0</td><td>0</td><td>0</td></tr>
<tr><td>A</td><td>B</td><td>1</td><td>1</td><td>0</td></tr>
<tr><td>A</td><td>D</td><td>2</td><td>1</td><td>1</td></tr>
<tr><td>A</td><td>E</td><td>2</td><td>1</td><td>1</td></tr>
<tr><td>A</td><td>C</td><td>1</td><td>1</td><td>0</td></tr>
<tr><td>A</td><td>F</td><td>2</td><td>1</td><td>1</td></tr>
<tr><td>A</td><td>A</td><td>0</td><td>1</td><td>0</td></tr>
<tr><td>D</td><td>D</td><td>0</td><td>0</td><td>1</td></tr>
<tr><td>C</td><td>F</td><td>1</td><td>0</td><td>1</td></tr>
<tr><td>C</td><td>C</td><td>0</td><td>0</td><td>0</td></tr>
<tr><td>E</td><td>E</td><td>0</td><td>0</td><td>1</td></tr>
<tr><td>F</td><td>F</td><td>0</td><td>0</td><td>1</td></tr>
</table>

</td></tr>
<tr><td><i>Generate cycle rows</i></td><td>

Specifies that when a cycle is encountered, the circular node will be the last in the hierarchy tree, and the tree itself will carry negative value for Leave Level (Horizontal Flattening) and Depth (Vertical Flattening).

Select this option if you would like more information about which nodes are causing the cycles. For example, you can insert a Validation transform after the Hierarchy flattening transform to check for negative values. If negative values are encountered, you can send the the data to another path for further analysis.

</td></tr>
<tr><td><i>Maximum depth</i></td><td>

(This option only applies to horizontal flattening.) Indicates the maximum depth of the hierarchy. The root node (level 0) has a depth of 0; the first level has a depth of 1, and so on.

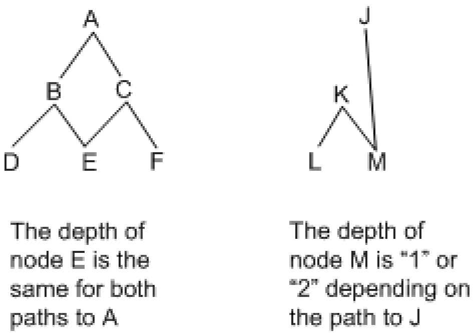
If you do not know the number of levels in your hierarchy, set <i>Maximum depth</i> to 1. When you execute the job, a warning message will appear in the execution log indicating that the <i>Maximum depth</i> is less than the actual depth of the hierarchy. Reset <i>Maximum depth</i> to the actual value reported in the warning message.

</td></tr>
<tr><td><i>Parent attribute list</i></td><td>

Identifies a column or columns that are associated with the parent column. You can drag columns from the source schema into the <i>Parent attribute list</i>. The column name appears in the target schema with a prefix that identifies the column as a parent attribute. The following table shows the result of adding a column named `POPULATION` to the parent attribute list.

<table>
<tr><th>Flattening mode</th><th>Source column</th><th>Target column</th></tr>
<tr><td>Vertical</td><td>POPULATION</td><td>P_POPULATION</td></tr>
<tr><td>Horizontal</td><td>POPULATION</td><td>P_L1_POPULATION
P_L2_POPULATION</td></tr>
</table>

</td></tr>
</table>

<table>
<tr><th>Option</th><th>Description</th></tr>
<tr><td></td><td><table><tr><th>Flattening mode</th><th>Source column</th><th>Target column</th></tr><tr><td></td><td></td><td>(one column for each hierarchy level)</td></tr></table>You can specify columns including nested schemas as the parent attribute.</td></tr>
<tr><td><em>Parent column</em></td><td>Identifies the column in the source data that contains the parent identifier in each parent-child relationship. You can drag this column from the source schema into the <em>Parent column</em> box.
You cannot specify columns including nested schemas as the parent.</td></tr>
<tr><td><em>Run as separate process</em></td><td>This option creates a separate sub data flow process for the Hierarchy_Flattening transform when Data Services executes the data flow.</td></tr>
<tr><td><em>Use maximum length paths</em></td><td>(This option only applies to vertical flattening.) Indicates whether longest or shortest paths are used to describe relationships between descendents and ancestors when the descendent has more than one parent. The option only affects the DEPTH column in the output.


The depth of node E is the same for both paths to A
The depth of node M is "1" or "2" depending on the path to J</td></tr>
</table>

Related Information

Performance Optimization Guide: Run as a separate process option [page 2153]

3.5.3.4.4 Data outputs

Horizontal flattening represents each level in the hierarchy as a column in the output, with the root listed in the first column and the outermost leaf listed in the last column. Represented horizontally, the number of levels in the hierarchy and the distance between a given node and the root node is clear.

Horizontal flattening produces the following target columns:

Column name	Description
CURRENT_LEAF	The end node described.
LEAF_LEVEL	The number of levels down from the root node where Current_leaf is found The root node has Leaf_level of 0.
LEVEL0	The descriptor for the top level node.
LEVEL1	The descriptor for the first level node If Leaf_level is 0, this value is NULL.
LEVEL **<n>**	The descriptor for the **<n>** th level node where **<n>** is the number of levels in the hierarchy If Leaf_level is **<n>** -1 or less, this value is NULL.
P_L0_ **<attribute_column>**	Attribute column associated with the node described in Level0.
C_L1_ **<attribute_column>**	Attribute column associated with the node described in Level1 when that node is the child node. If Leaf_level is 0, this value is NULL.
P_L1_ **<attribute_column>**	Attribute column associated with the node described in Level1 when that node is the parent node. If Leaf_level is 0, this value is NULL.
C_L **<n-1>** _ **<attribute_column>**	Attribute column associated with the child node described in Level **<n-1>** where **<n>** is the number of levels in the hierarchy. If Leaf_level is **<n>** -2, this value is NULL.
P_L **<n-1>** _ **<attribute_column>**	Attribute column associated with the child node described in Level **<n-1>** where **<n>** is the number of levels in the hierarchy. If Leaf_level is **<n>** -2, this value is NULL.
C_L **<n>** _ **<attribute_column>**	Attribute column associated with the child node described in Level **<n>** where **<n>** is the number of levels in the hierarchy. If Leaf_level is **<n>** -1, this value is NULL.

The following table shows an example of the target schema and data for horizontal flattening with a two-level hierarchy including country as the root node, state at level one, and city at level 2 (leaf nodes). The parent and child attributes are the same, a population value.

The table shows the three rows in the output; however, the format folds the row data onto two rows. The headings at the top of the table describe the first half of each row of data. The headings at the bottom of the table describe the second half of each row of data.

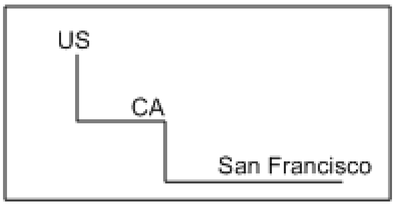
CURRENT_LEAF	LEAF_LEVEL		LEVEL0		LEVEL1		LEVEL2	
US	0		US		NULL		NULL	
		272,583,805		NULL		NULL		NULL
CA	1		US		CA		NULL	
		272,583,805		30,866,851		NULL		NULL
San Francisco	2		US		CA		San Francisco	
		272,583,805		30,866,851		30,866,851		723,959
		P_L0_POP	C_L1_POP		P_L1_POP		C_L2_POP	

In a typical data flow including a Hierarchy_Flattening transform with the same attribute for parent and child nodes, you may follow the transform with a query that would filter the duplicated attribute values. The query would pass the P_L0_ `<attribute_column>` and the C_L `<n>` _ `<attribute_column>` through as they are, then keep either parent or child attribute for the intermediate levels.

Vertical flattening produces the following target columns:

Column name	Description
ANCESTOR	The node closer to the root node in the relationship described by this row.
DESCENDENT	The node farther from the root node in the relationship described by this row.
DEPTH	Number of levels between the Ancestor and Descendent.
ROOT_FLAG	Identifies the value in the Ancestor column as the top node of the hierarchy. Root_flag is 1 if Ancestor is the root node. Otherwise, Root_flag is 0.
LEAF_FLAG	Identifies the value in the Descendent column as the bottom node of the hierarchy. Leaf_flag is 1 if Descendent is the leaf node. Otherwise, Leaf_flag is 0.
P_`<attribute_column>`	Column from the source that you associate with the parent (can be more than one P_ `<attribute_column>`). If Leaf_flag is 1, this value is NULL.
C_`<attribute_column>`	Column from the source that you associate with the child (can be more than one C_ `<attribute_column>`). If Root_flag is 1, this value is NULL.

The following graphic and table shows an example of the target schema and data for vertical flattening with a two-level hierarchy. The hierarchy includes a country as the root node, state at level one, and city at level 2 (leaf nodes).



The parent and child attributes are the same, a population value.

ANCESTOR	DESCENDENT	DEPTH	ROOT _FLAG	LEAF _FLAG	P_POP	C_POP
US	CA	1	1	0	272,583,805	30,866,851
US	SanFrancisco	2	1	1	272,583,805	723,959
CA	SanFrancisco	1	0	1	30,866,851	723,959
US	US	0	1	0	272,583,805	NULL
CA	CA	0	0	0	30,866,851	30,866,851
SanFrancisco	SanFrancisco	0	0	1	NULL	723,959

Each node is listed one time as both ancestor and descendent. The Parent attribute is null for a row describing the relationship between a leaf node and itself. Likewise the Child attribute is null for a row describing the relationship between a root node and itself.

The transform ignores any hierarchical data unless a nested schema is identified as a parent or child attribute. An attribute column containing nested data is passed through the transform without change.

3.5.3.4.5 Error conditions

If the hierarchy represented by the input data set is cyclic—some node is its own ancestor—Data Services produces a run-time error.

> i Note
>
> This runtime error does not occur if you select the *Do not abort in case of cycle* option.

No errors are produced if the input data source describes multiple root nodes.

3.5.3.5 History_Preserving

The History_Preserving transform allows you to produce a new row in your target rather than updating an existing row. You can indicate in which columns the transform identifies changes to be preserved.

If the value of certain columns change, this transform creates a new row for each row flagged as UPDATE in the input data set.

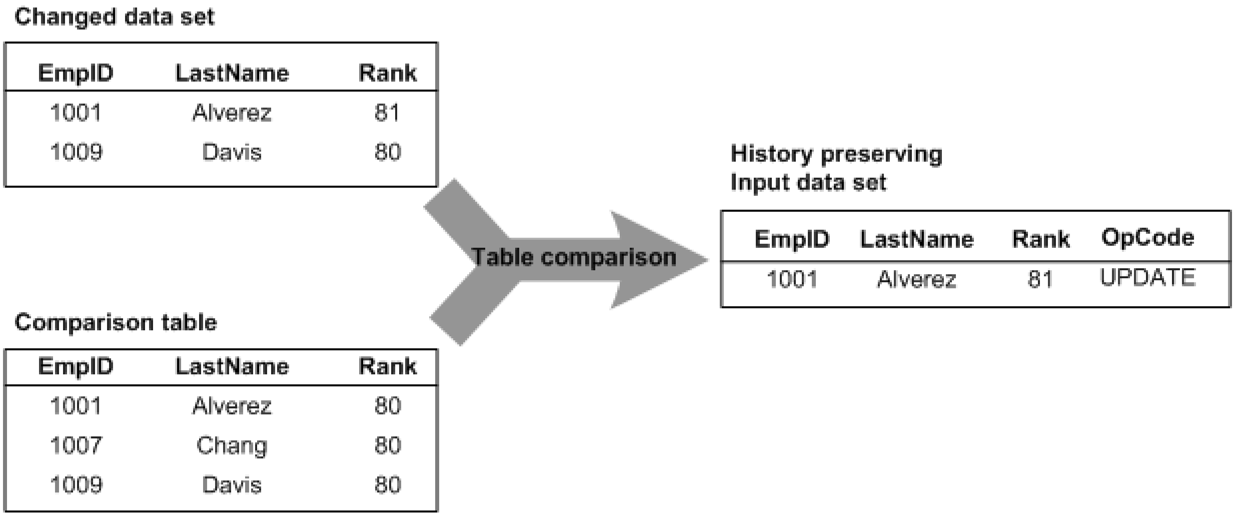
Related Information

Table_Comparison [page 1110]
real [page 1036]

3.5.3.5.1 Data inputs

A data set that is the result of a comparison between two images of the same data in which changed data from the newer image are flagged as UPDATE rows and new data from the newer image are flagged as INSERT rows.

For example, a target table that contains employee job rankings information is updated periodically from a source table. In this case, the table comparison flags changed data for employee Alverez and discards unchanged data for employee Davis. The result is a single row flagged with the UPDATE operation code.



Changed data set

EmpID	LastName	Rank
1001	Alverez	81
1009	Davis	80

Comparison table

EmpID	LastName	Rank
1001	Alverez	80
1007	Chang	80
1009	Davis	80

History preserving
Input data set

EmpID	LastName	Rank	OpCode
1001	Alverez	81	UPDATE

The input data set can contain hierarchical data. The transform operates only on the rows at the top-level of the input data set, and passes nested data through to the output without change. Columns containing nested schemas cannot be used as transform parameters.

Use caution when using columns of data type `real` in this transform. Comparison results are unpredictable for this data type.

3.5.3.5.2 Editor

The History_Preserving transform editor includes the source schema, the target schema, and transform options. You can drag column names from the source schema to fill in values for the Date columns *Valid from* and *Valid to* date column, *Compare columns*, and Current flag *Column* options. Data Services generates the target schema in response to the values you choose in the transform options. To refresh the target schema after you make a change to the options, choose ▶ *View* ▶ *Refresh* ◀ or press *F5*.

3.5.3.5.3 Options

Option	Description
Compare columns	The column or columns in the input data set for which this transform compares the before- and after-images to determine if there are changes. ● If the values in each image of the data match, the transform flags the row as UPDATE. The result updates the warehouse row with values from the new row. The row from the before-image is included in the output as UPDATE to effectively update the date and flag information. ● If the values in each image do not match, the row from the after-image is included in the output of the transform flagged as INSERT. The result adds a new row to the warehouse with the values from the new row. ● *Compare columns* cannot contain nested schemas.
Current flag—Column	A column from the source schema that identifies the current valid row from a set of rows with the same primary key. You can indicate whether a row is the most current data in the warehouse for a given primary key using this flag. The current flag *Column* cannot be the same value as the *Valid from* or the *Valid to* date column. The current flag *Column* cannot contain a nested schema. Data Services validates that you specify a current flag *Column*, *Set value*, and *Reset value*, if any are specified.
Current flag—Reset value	An expression that evaluates to a value with the same data type as current flag *Column*. Data Services uses this value to update the current flag *Column* in an existing row in the warehouse that included changes in one or more of the compare columns. Enter a value in the current flag *Column* box to enable the *Flag reset value*. For added flexibility, you can enter a variable for this option.
Current flag—Set value	An expression that evaluates to a value with the same data type as the current flag *Column*. Data Services uses this value to update the current flag *Column* in the new row in the warehouse added to preserve history of an existing row. Enter a value in the Current flag *Column* box to enable the *Set value*. For added flexibility, you can enter a variable for this option.
Date columns—Valid from	A date or datetime column from the source schema. If the warehouse uses an effective date to track changes in data, specify a *Valid from* date column. Data Serv-

<table>
<tr><th>Option</th><th>Description</th></tr>
<tr><td></td><td>ices uses this value in the new row in the warehouse added to preserve the history of an existing row. Data Services also uses this value to update the *Valid to* date column in the previously current row in the warehouse.
Data Services validates that both the *Valid from* date column and the *Valid to* date column have been specified if either is specified.</td></tr>
<tr><td>*Date columns—Valid to*</td><td>A date or datetime column from the source schema. Specify a if the warehouse uses an effective date to track changes in data and if you specified a *Valid from* date column.
This value is used as the new value in the *Valid to* date column in the new row added to the warehouse to preserve history of an existing row.
The *Valid to* date column cannot be the same as the *Valid from* date column.</td></tr>
<tr><td>*Date columns—Valid to date value*</td><td>Specify the values to use in the *Valid to* date column in the old record and the new record added to the warehouse to preserve history of an existing row.
● *New record*—You can specify one of the following values:
○ A date value specified as a four-digit year followed by a period, followed by a two-digit month, followed by a period, and followed by a two-digit day value. The default value is `9000.12.31`. A variable can also be used.
○ A variable name that contains a date value.
● *Old record*—You can specify one of the following values:
○ *Use "valid from" date of new record*—The following example shows that the new record (Key 2) column *From_Date* contains `2006.01.31` and the old record (Key 1) column *To_Date* contains this same value.
<table>
<tr><th>Key</th><th>Empno</th><th>Name</th><th>Salary</th><th>From_Date</th><th>To_Date</th></tr>
<tr><td>1</td><td>100</td><td>Chang</td><td>10000.00</td><td>2006.01.01</td><td>2006.01.31</td></tr>
<tr><td>2</td><td>100</td><td>Chang</td><td>20000.00</td><td>2006.01.31</td><td>9000.12.31</td></tr>
</table>
○ *Use one day before "valid from" date of new record*—The following example shows that the new record (Key 2) column *From_Date* contains `2006.01.31` and the old record (Key1) column *To_Date* contains a date that is one day before that value, `2006.01.30`.
<table>
<tr><th>Key</th><th>Empno</th><th>Name</th><th>Salary</th><th>From_Date</th><th>To_Date</th></tr>
<tr><td>1</td><td>100</td><td>Chang</td><td>10000.00</td><td>2006.01.01</td><td>2006.01.30</td></tr>
</table>
</td></tr>
</table>

<table>
<tr><th>Option</th><th>Description</th></tr>
<tr><td></td><td><table><tr><th>Key</th><th>Empno</th><th>Name</th><th>Salary</th><th>From_Date</th><th>To_Date</th></tr><tr><td>2</td><td>100</td><td>Chang</td><td>20000.00</td><td>2006.01.31</td><td>9000.12.31</td></tr></table></td></tr>
<tr><td><i>Preserve delete row(s) as update row(s)</i></td><td>Converts DELETE rows to UPDATE rows in the target warehouse and, if you previously set effective date values (<i>Valid from</i> and <i>Valid to</i>), sets the <i>Valid To value</i> to the execution date. Use this option to maintain slowly changing dimensions by feeding a complete data set first through the Table Comparison transform with its <i>Detect deleted row(s) from comparison table</i> option selected.</td></tr>
</table>

3.5.3.5.4 Data outputs

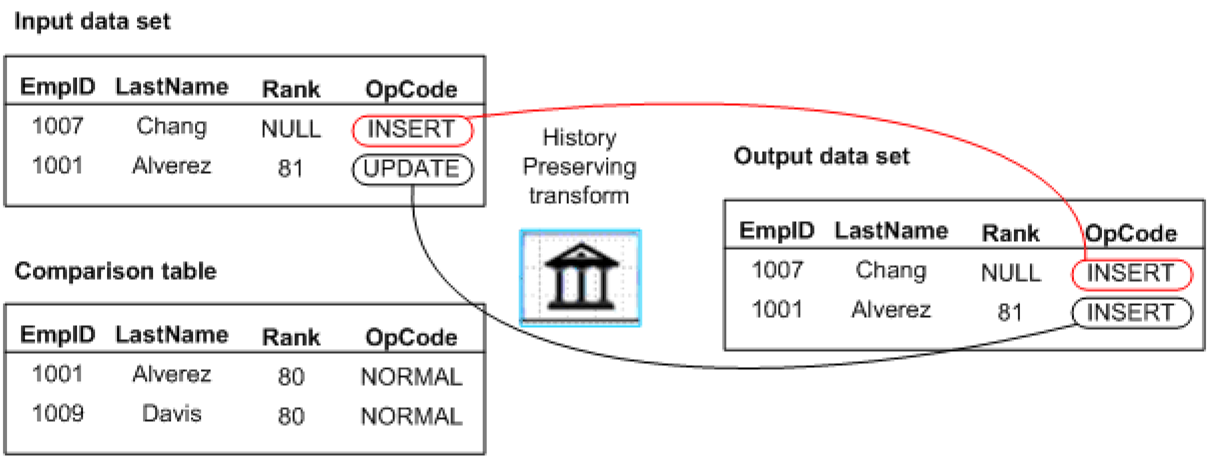
Data Outputs

A data set with rows flagged as INSERT or UPDATE.

For each row in the input data set, there are two possible outcomes from the transform:

- An INSERT row
  A new row must be added to the comparison table if:
  - Given an input row flagged as UPDATE—A value in a compare column from the input data set does not match a corresponding value in the comparison table.
  - Given an input row flagged as INSERT—The primary key from the input data set does not appear in the comparison table.

  The transform produces an INSERT row with the values from the input data set row.



Input data set

EmpID	LastName	Rank	OpCode
1007	Chang	NULL	INSERT
1001	Alverez	81	UPDATE

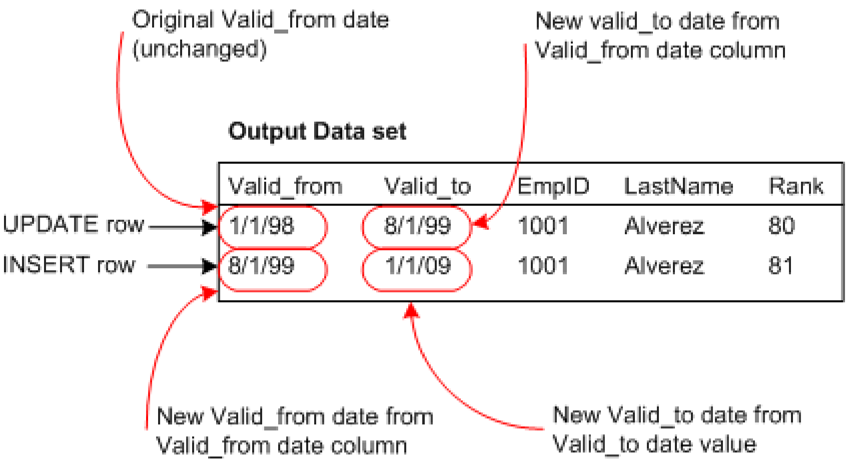
Comparison table

EmpID	LastName	Rank	OpCode
1001	Alverez	80	NORMAL
1009	Davis	80	NORMAL

Output data set

EmpID	LastName	Rank	OpCode
1007	Chang	NULL	INSERT
1001	Alverez	81	INSERT

If you specified flag values for the History_Preserving transform, Data Services includes the Flag set value in the INSERT row. In addition Data Services includes an UPDATE row to update the previously current row in the warehouse with the Flag reset value.
If you specified effective date columns (Valid to date column and Valid from date column), Data Services includes this data as well.



Valid_from	Valid_to	EmpID	LastName	Rank
1/1/98	8/1/99	1001	Alverez	80
8/1/99	1/1/09	1001	Alverez	81

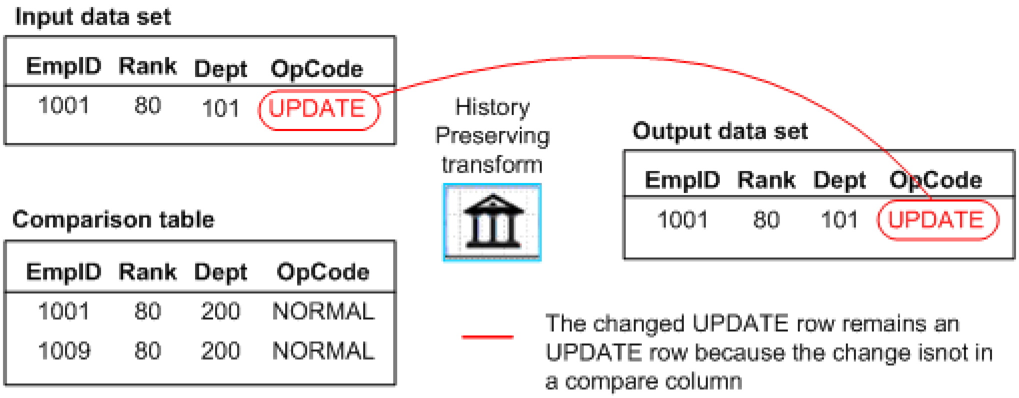
Original Valid_from date (unchanged)

New valid_to date from Valid_from date column

New Valid_from date from Valid_from date column

New Valid_to date from Valid_to date value

- An UPDATE row
  Input rows flagged as UPDATE contain changes, but not in the compare columns. The transform produces an UPDATE row with the values from the input data set row.



Input data set

EmpID	Rank	Dept	OpCode
1001	80	101	UPDATE

Comparison table

EmpID	Rank	Dept	OpCode
1001	80	200	NORMAL
1009	80	200	NORMAL

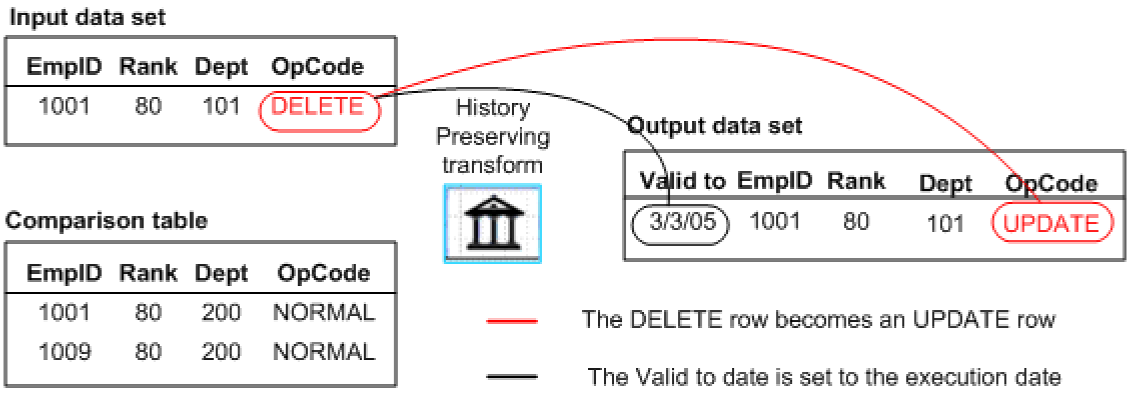
Output data set

EmpID	Rank	Dept	OpCode
1001	80	101	UPDATE

The changed UPDATE row remains an UPDATE row because the change isnot in a compare column

Input rows flagged as DELETE contain changes, but not in the compare columns. The transform produces an UPDATE row with the values from the input data set row. If you specified the effective date column *Valid to* in the History Preserving transform, Data Services sets its value to the execution date.

Input rows flagged as DELETE contain changes, but not in the compare columns. The transform produces an UPDATE row with the values from the input data set row.



Input data set

EmpID	Rank	Dept	OpCode
1001	80	101	DELETE

Comparison table

EmpID	Rank	Dept	OpCode
1001	80	200	NORMAL
1009	80	200	NORMAL

Output data set

Valid to	EmpID	Rank	Dept	OpCode
3/3/05	1001	80	101	UPDATE

History Preserving transform
The DELETE row becomes an UPDATE row
The Valid to date is set to the execution date

Nested schemas in the input are passed through without change.

3.5.3.6 Key_Generation

Generates new keys for new rows in a data set.

When it is necessary to generate artificial keys in a table, the Key_Generation transform looks up the maximum existing key value from a table and uses it as the starting value to generate new keys. The transform expects the generated key column to be part of the input schema.

3.5.3.6.1 Data inputs

A data set that is the result of a comparison between two images of the same data in which changed data from the newer image are flagged as UPDATE rows and new data from the newer image are flagged as INSERT rows.

The data set includes a column into which generated keys are added.

The input data set can contain hierarchical data. The transform operates only on the rows at the top-level of the input data set, and passes nested data through to the output without change. Columns containing nested schemas cannot be used as transform parameters.

3.5.3.6.2 Editor

The Key_Generation transform editor includes the source schema, the target schema, and transform options. To refresh the target schema after you make a change to the options, choose *View* > *Refresh* or press *F5*.

3.5.3.6.3 Options

<table>
<tr><th>Option</th><th>Description</th></tr>
<tr><td><i>Generated key column</i></td><td>The column in the key source table containing the existing keys values. A column with the same name must exist in the input data set; the new keys are inserted in this column.</td></tr>
<tr><td><i>Increment value</i></td><td>The interval between generated key values. For added flexibility, you can enter a variable for this option.</td></tr>
<tr><td><i>Table name</i></td><td>The fully qualified name of the source table from which the maximum existing key is determined (key source table). This table must be already imported into the repository. <i>Table name</i> is represented as "DATASTORE.OWNER.TABLE" where DATASTORE is the name of the datastore Data Services uses to access the key source table; OWNER, if required, depends on the database type associated with the table:
<table>
<tr><th>Database type</th><th>Owner value</th></tr>
<tr><td>DB2</td><td>Data source dependent</td></tr>
<tr><td>Informix</td><td>Informix-defined user name</td></tr>
<tr><td>Microsoft SQL Server</td><td>User name</td></tr>
<tr><td>ODBC</td><td>Data source dependent</td></tr>
<tr><td>Oracle</td><td>User name</td></tr>
<tr><td>SAP Sybase ASE</td><td>User name</td></tr>
<tr><td>SAP Sybase IQ</td><td>User name</td></tr>
</table>
</td></tr>
</table>

3.5.3.6.4 Data outputs

The input data set with the addition of key values in the generated key column, for input rows flagged as INSERT.

Use the Key_Generation transform to produce keys that distinguish rows that would otherwise have the same primary key. For example, suppose the History_Preserving transform produces rows to add to a warehouse and these rows have the same primary key as rows that already exist in the warehouse. In this case, you can add a generated key to the warehouse table and fill new key values using the Key_Generation transform.

3.5.3.7 Map_CDC_Operation

Using its input requirements (values for the *Sequencing column* and a *Row operation column*), performs three functions:

- Sorts input data based on values in *Sequencing column* drop-down list and (optional) the *Additional grouping columns* box.
- Maps output data based on values in *Row operation column* drop-down list. Source table rows are mapped to INSERT, UPDATE, or DELETE operations before passing them on to the target.
- Resolves missing, separated, or multiple before- and after-images for UPDATE rows.
- Allows you filter columns and view UPDATE rows prior to running the job.

While commonly used to support relational or mainframe changed-data capture (CDC), this transform supports any data stream as long as its input requirements are met. Relational CDC sources include Oracle and SQL Server.

This transform is typically the last object before the target in a data flow because it produces INPUT, UPDATE and DELETE operation codes. Data Services produces a warning if other objects are used.

Related Information

Designer Guide: Importing CDC data from Oracle [page 745]

3.5.3.7.1 Data inputs

All rows in the input data are set to NORMAL. This is an internal Data Services operation code.

The input data set can contain hierarchical data. Nested schemas in the input are passed through without change.

3.5.3.7.2 Editor

Use the drop-down lists in the *CDC Columns* section to select the required columns in your input schema used to sequence the input rows and map operations to the output.

If you want to sort the input using additional columns, click a column in the input schema and drag it into the *Additional grouping columns* box.

If you are using a relational or mainframe CDC source table, the `DI_SEQUENCE_NUMBER` and `DI_OPERATION_TYPE` columns appear in the input schema and are automatically removed in the output schema. To propagate these columns to the output, create additional columns that map to them prior to coming into the Map_CDC_Operation transform.

3.5.3.7.3 Options

Option	Description
Additional grouping columns	In addition to the *Sequencing column*, you can sort input on additional columns by dragging them into this box from the input schema. Sorts are prioritized based first on the sequencing column and then on the order of the columns added to this box.
Define columns to filter updated rows	Drag and drop columns from the input schema to this box to compare CDC updated rows in the before and after images. If the values in the columns differ between the before and after images, Data Services generates an UPDATE row, otherwise the rows are filtered out.
Input already sorted by sequencing column	This transform by default assumes that the input data is already sorted based on the value selected in the *Sequencing column* box. If you deselect this check box, Data Services will re-sort the input data using the value in the *Sequencing column* box. Use the re-sort capability of this transform only when necessary as it impacts job performance.
Row operation column	(Required) Specifies a column with one of the following output operation codes for each row: ● `I` for INSERT ● `B` for before-image of an UPDATE ● `U` for after-image of an UPDATE ● `D` for DELETE If you are using a relational or mainframe CDC source table, the `DI_OPERATION_TYPE` column is automatically selected as the *Row operation column*.
Sequencing column	(Required) Specifies an integer used to order table rows. If you are using a relational or mainframe CDC source table, the `DI_SEQUENCE_NUMBER` column is automatically selected as the *Sequencing column*.

3.5.3.7.4 Data outputs

A data set with rows flagged as specified by the values in the column selected as the *Row operation column*.

Rows in the input data set all use NORMAL as their internal Data Services operation code.

Rows in the output data set can have any of the following operation codes:

- INSERT
- DELETE
- UPDATE

In addition, the DISCARD option is assigned under some conditions. Discarded rows are not passed through to the output of the transform.

3.5.3.7.5 Sorting CDC data

When you apply changed data to a loader, it is important that the order of the rows is preserved. For example, if the following operations are applied to an empty target:

- INSERT into TAB1 values ('Bob', 'Boat', 3500)
- INSERT into TAB1 values ('Jane', 'BMW Roadster', 24000)
- UPDATE TAB1 set toy = 'Motorcycle', price = 12000 where name = 'Bob'
- DELETE from TAB1 where name = 'Bob'

The table TAB1 will be left with one row:

```
'Jane', 'BMW Roadster', 24000
```

If these operations are applied out of order, for example, if the DELETE occurs before the UPDATE operation, then database consistency is no longer preserved. In this example:

- The table has two rows (Bob and Jane)
- The last UPDATE statement fails because there is no row on which to perform an UPDATE

By ordering the input rows using the sequencing column, the order of the original set of operations is preserved.

The sequencing column values are also useful if you are using before- and after-images for update rows because it is possible that before- and after-image pairs may be separated, multiplied or lost depending on the design of your data flow. You can re-sort input columns as needed by using the sequencing column and any number of additional columns.

The before- and after-images of an UPDATE row have the same sequence value. Thus correctly sorted before- and after-image rows are listed in pairs.

3.5.3.7.6 Rules for resolving before- and after-image pairs

The Map_CDC_Operation transform uses the following rules to process and resolve before- and after-images:

- When constructing UPDATE rows, the value in the *Row Operation Column* is used. If there are before-images in the input stream, before- (`B`) and after-image (`U`) row pairs are combined into one UPDATE row.
  For example, given the following sample input of six rows:

Sequencing Column	Operation Column	Internal Operation Code
1	I	NORMAL
2	B	NORMAL
2	U	NORMAL
3	D	NORMAL

Sequencing Column	Operation Column	Internal Operation Code
4	B	NORMAL
4	U	NORMAL

The following four rows will be the output:

Sequencing Column	Operation Column	Internal Operation Code
1	I	INSERT
2	U	UPDATE (before- and after-images)
3	D	DELETE
4	U	UPDATE (before- and after-images)

- If there are no before-images (`B`) in the input stream, the after-images (`U`) alone produce UPDATE rows.
  Given the following sample input rows:

Sequencing Column	Operation Column	Internal Operation Code
1	I	NORMAL
2	U	NORMAL
3	D	NORMAL
4	U	NORMAL

The following four rows will be the output:

Sequencing Column	Operation Column	Internal Operation Code
1	I	INSERT
2	U (no before)	UPDATE
3	D	DELETE
4	U (no before)	UPDATE

- If a before-image (`B`) row is followed by additional `B` rows, the subsequent `B` rows are ignored until an after-image (`U`) row is encountered.
  For example, given the following six input rows:.

Sequencing Column	Operation Column	Internal Operation Code
1	U	NORMAL
1	B	NORMAL
2	B	NORMAL
3	B	NORMAL
4	B	NORMAL
2	U	NORMAL

Two UPDATE rows are output:

Sequencing Column	Operation Column	Internal Operation Code
1	U	UPDATE (before- and after-images)
2	U	UPDATE (before- and after-images)

- ○ The first two rows are processed as one UPDATE row.
- ○ The third and sixth row are processed as a pair. One UPDATE row is output.
- ○ The remaining rows are DISCARDED. For more information, see the following rule.

- If after a series of B rows, either no U rows remain or another row type is encountered, B rows are discarded. For example, given the following sample input of five rows:

Sequencing Column	Operation Column	Internal Operation Code
1	U	NORMAL
1	B	NORMAL
2	B	NORMAL
3	B	NORMAL
4	I	NORMAL

Two rows are output:

Sequencing Column	Operation Column	Internal Operation Code
1	U	UPDATE (before- and after-images)
4	I	INSERT

Designer Guide: Using before-images [page 750]

3.5.3.7.7 Filtering updated rows

You can drag and drop columns from the input schema to the *Define columns to filter updated rows* box to filter CDC updated rows.

Filter criteria: If two input rows have the same sequencing column value and operation column value (B and U), the Map_CDC_Operation transform compares the before image and after image of the seleted columns in the column filter.

If the values in the columns in the filter differ between the before image and after image, Data Services generates an UPDATE row; otherwise, the row will be filtered out. If there is no column filter, all updated rows coming from the input stream will be passed through.

LONG, BLOB, and columns selected in *Sequencing column* and *Row operation column* options are not allowed in the *Define columns to filter updated rows* list.

> Note
>
> Because the *Define columns to filter updated rows* option filters out CDC updated rows, a target table should have primary key that identifies the row to update the change record.

3.5.3.8 Pivot (Columns to Rows)

Creates a new row for each value in a column that you identify as a pivot column.

The Pivot transform allows you to change how the relationship between rows is displayed. For each value in each pivot column, Data Services produces a row in the output data set. You can create pivot sets to specify more than one pivot column.

3.5.3.8.1 Data inputs

A data set with rows flagged as NORMAL.

3.5.3.8.2 Options

Option	Description
Data field column	The name of the column that contains the pivoted data. This column contains all of the *Pivot columns* values. The data type of this column is determined by the data type of *Pivot columns*. If two or more *Pivot columns* contain different data types, Data Services converts the columns to a single data type—the data type of the first column you add to the pivot set.

Option	Description
Header column	The name of the column that contains the pivoted column names. This column lists the names of the columns where the corresponding data originated.
Non-pivot columns	The columns in the source that are to appear in the target without modification.
Pivot columns	A set of columns to be rotated into rows. Describe these columns in the *Header column*. Describe the data in these columns in the *Data field column*.
Pivot sequence column	The name you assign to the sequence number column. For each row created from a pivot column, Data Services increments and stores a sequence number. Data Services resets the sequence to 1 when creating a row from an original row. For example, if the row corresponds to the first column pivoted, the sequence number for the row is 1.
Pivot set	The number that identifies a pivot set. For each pivot set, you define a group of pivot columns, a pivot data field, and a pivot header name. Each pivot set must have a unique *Data field column* and the *Header column*. Data Services automatically saves this information.

3.5.3.8.3 Data outputs

A data set with rows flagged as NORMAL. This target includes the nonpivoted columns, a column for the sequence number, the data field column, and the pivot header column.

3.5.3.8.4 Example

Suppose you have a table containing rows for an individual's expenses, broken down by expense type.

Emp_name	Mgr_ID	Internal _Expense	Travel _Expense	Misc _Expense
AAA	1234	2000.00	5000.00	100.00
BBB	9876	3000.00	0.00	1000.00
CCC	5555	4800.00	800.00	0.00

This source table has expense numbers in several columns, so you might have difficulty calculating expense summaries. The Pivot transform can rearrange the data into a more manageable form, with all expenses in a single column, without losing category information.

Set the Pivot transform options to pivot the data such that all of the expenses are in the same column. Note that you only need one pivot set in this example.

Options	Value
Pivot sequence column	Sequence
Nonpivot columns	Emp_name
Pivot set	1
Data field column	Expense
Header column	Expense_Type
Pivot columns	Internal_Expense Travel_Expense Misc_Expense

Select *ViewRefresh* or press *F5* to update the output schema for the Pivot transform.

The output data set includes the employee name (not pivoted) and new columns for the pivot sequence, expense type (pivot header), and actual expense data. The manager ID column is not listed in either the pivot or the nonpivot column lists, so it is not included in the output.

The result is a single column of expense values that can be summarized easily.

Emp_name	Sequence	Expense_Type	Expense
AAA	1	Internal_Expense	2000.00
AAA	2	Travel _Expense	5000.00
AAA	3	Misc _Expense	100.00
BBB	1	Internal_Expense	3000.00
BBB	2	Travel _Expense	0.00
BBB	3	Misc _Expense	1000.00
CCC	1	Internal_Expense	4800.00
CCC	2	Travel _Expense	800.00
CCC	3	Misc _Expense	0.00

Suppose that instead of containing one type of data—expenses—your source table contains two types of data—expenses and days traveling both domestically and internationally—for two months.

Emp_name	Dom_Exp	Int_Exp	Dom_Day	Int_Day
AAA	2000.00	5000.00	10	5
BBB	3000.00	0.00	0	0
CCC	4800.00	800.00	15	1

You want to create a target table that has the data in two columns: expenses and days. Therefore, you want to create two pivot sets. Create one pivot set to pivot on the expense columns.

Options	Value
Pivot sequence column	Seq
Nonpivot columns	Emp_name
Pivot set	1
Data field column	Expense
Header column	Expense_Type
Pivot columns	Dom_Exp Int_Exp

Create a second pivot set to pivot on the day columns.

Options	Value
Pivot sequence column	Seq
Nonpivot columns	Emp_name
Pivot set	2
Data field column	Num_Days
Header column	Day_Type
Pivot columns	Dom_Day Int_Day

In this case, the output data set includes the employee name (not pivoted) and new columns for the pivot sequence, expense type, expense data, day type, and day data. Because you linked the pivot data, domestic and international data are contained in unique rows.

Emp_name	Seq	Expense_Type	Expenses	Day_Type	Num_Days
AAA	1	Dom_Exp	2000.00	Dom_Day	10
AAA	2	Int_Exp	5000.00	Int_Day	5
BBB	1	Dom_Exp	3000.00	Dom_Day	12
BBB	2	Int_Exp	0.00	Int_Day	0
CCC	1	Dom_Exp	4800.00	Dom_Day	15

Emp_name	Seq	Expense_Type	Expenses	Day_Type	Num_Days
CCC	2	Int_Exp	800.00	Int_Day	1

When working with multiple pivot sets, pivoted columns cannot contain a different number of rows.

If the example target table contained additional expenses (internal plus miscellaneous expenses), but only had days traveled to match domestic and international travel expenses, the expense data set would be larger than the days traveled data set. In that case, you would have to add a new artificial column containing NULL values to the input data set, and associate the day columns with those additional expenses.

Emp_name	Seq	Expense_Type	Expenses	Day_Type	Num_Days
AAA	1	Dom_Exp	2000.00	Dom_Day	10
AAA	2	Int_Exp	5000.00	Int_Day	5
AAA	3	Internal_Exp	500.00	NULL	NULL
AAA	4	Misc_Exp	75.00	NULL	NULL
BBB	1	Dom_Exp	3000.00	Dom_Day	12
BBB	2	Int_Exp	0.00	Int_Day	0
BBB	3	Internal_Exp	350.00	NULL	NULL
BBB	4	Misc_Exp	140.00	NULL	NULL
CCC	1	Dom_Exp	4800.00	Dom_Day	15
CCC	2	Int_Exp	800.00	Int_Day	1
CCC	3	Internal_Exp	1000.00	NULL	NULL
CCC	4	Misc_Exp	55.00	NULL	NULL

3.5.3.9 Reverse Pivot (Rows to Columns)

Creates one row of data from several existing rows.

The Reverse Pivot transform allows you to combine data from several rows into one row by creating new columns. For each unique value in a pivot axis column and each selected pivot column, Data Services produces a column in the output data set.

3.5.3.9.1 Data inputs

A data set with rows flagged as NORMAL.

3.5.3.9.2 Options

Option	Description
Axis value	The value of the pivot axis column that represents a particular set of output columns. A set of *Pivoted columns* is generated for each axis value. There should be one *Axis value* for each unique value in the *Pivot axis column*.
Column Prefix	Text added to the front of the *Pivoted column* names when creating new column names for the rotated data. An underscore separates the prefix name from the pivoted column name.
Default value	The value stored when a rotated column has no corresponding data. The default is "null" if you do not enter a value. Do not enter a blank.
Duplicate value	Action taken when a collision occurs. A collision occurs when there is more than one row with the same key and value in the *Pivot axis column*. In this case, you can store either the first row or the last row, or you can abort the transform process.
Input data is grouped	Select to indicate whether the input rows are already sorted based on columns specified in the *Non-pivot columns* box. This can improve the performance of the transform.
Non-pivot columns	The columns in the source table that will appear in the target table without modification.
Pivot axis column	The column that determines what new columns are needed in the output table. At run time, a new column is created for each *Pivoted column* and each unique value in this column.
Pivoted columns	The columns containing data you want rotated into the same row. A set of columns will be created for each unique value in the *Pivot axis column*.

3.5.3.9.3 Data outputs

A data set with rows flagged as NORMAL. This target includes the nonpivoted columns and a column for the combination of each pivot column and each pivot axis.

3.5.3.9.4 Example

Suppose you had a table containing contact information for each employee. Each row in the table contains data for a particular employee and contact type.

EmpNo	Type	Name	Address	Phone
100	emergency	Andrew	404 Hallam St	555-4450
100	home	Pat	125 Mercury St	555-6035
100	work	Sean	8400 Page Mill Rd	555-5000
200	emergency	Linda	126 River Rd	555-1087
200	home	David	479 Mill St	555-6914
300	work	Joanne	9500 Page Mill Rd	555-8500

Because the table can have several rows for each employee, finding information, such as a missing contact, for a particular employee may be difficult. The Reverse_Pivot transform can rearrange the data into a more searchable form without losing the category information.

Set the Reverse_Pivot transform options to pivot the data such that all of the contact information for a particular employee is in the same row.

Option	Value		
Non-pivot columns	EmpNo		
Pivoted columns	Name Phone		
Default value	Null		
Pivot axis column	Type		
Duplicate value	Abort		
Axis Value	emergency	home	work
Column Prefix	emergency	home	work

The output data set includes the employee number field (not pivoted) and two fields—name and phone—for each pivot axis. In this case, there are three pivot axes (emergency, home, and work). Therefore, there are six additional fields. In cases where there is no data for a field in the initial source, the Reverse_Pivot transform stores a null value.

The result is a single row for each employee, which you can use to search easily for missing contact information.

EmpNo	Emerg_Name	Emerg_ Phone	Home_Name	Home_ Phone	Work_Name	Work_ Phone
100	Andrew	555-4450	Pat	555-6035	Sean	555-5000
200	Linda	555-1087	David	555-6914	Null	Null
300	Null	Null	Null	Null	Joanne	555-8500

3.5.3.10 Table_Comparison

Compares two data sets and produces the difference between them as a data set with rows flagged as INSERT, UPDATE, or DELETE.

The Table_Comparison transform allows you to detect and forward changes that have occurred since the last time a target was updated.

Note that in order to use the Table_Comparison transform with Teradata 13 and later tables as the comparison table and target table, you must do the following:

- On the Teradata server, set the *General* parameter *DBSControl* to TRUE to allow uncommitted data to be read.
- In the Data Services Teradata datastore, add the following statement in the "Additional session parameters" field:

```
SET SESSION CHARACTERISTICS AS TRANSACTION ISOLATION LEVEL READ UNCOMMITTED;
```

Related Information

Designer Guide: Distributed data flow execution [page 301]
Teradata [page 902]

3.5.3.10.1 Data inputs

- The data set from a source or the output from another transform. Only rows flagged as NORMAL are considered by the transform. This data is referred to as the *input data set*.
- The specification for a database table to compare to the input data set. This table is referred to as the *comparison table*.

If the input data set contains hierarchical (nested) data, Data Services includes only the top-level data in the comparison and does not pass nested schemas through to the output.

Use caution when using columns of data type `real` in this transform. Comparison results are unpredictable for this data type.

Related Information

Operation codes [page 1068]

3.5.3.10.2 Options

To use the optional options, consider the type of data that might have changed since you last updated the target warehouse. Have individual records likely been changed more than once (for example, do duplicate primary key rows exist or might they be encountered during job processing)? If so, do you want to record all changes or just the latest information?

If the columns you specify for the *Input primary keys* option have a unique key per row, then you do not need to use the *Input contains duplicate keys* option.

If a record (row) might change more than once during job execution, consider a plan to handle duplicate keys:

- If you assume the input data set has duplicate keys, then to avoid data corruption, select the *Input contains duplicate keys* option. This option allows the Table_Comparison transform to output all duplicate key rows in the input data set columns.
- If you assume that the comparison table has duplicate keys, then to avoid data corruption, use the *Generated Key column* option. This option reads only the largest in a set of duplicated keys.
- If you use the *Generated Key column* option with the *Detect Deleted row(s) from comparison table* option, you can specify whether to detect deletes in all duplicate rows or in the row with the largest generated key.

The following table provides more detail about the Table_Comparison options.

Option	Description
Compare columns	(Optional) Improves performance by comparing only the subset of columns you drag into this box from the input schema. If no columns are listed, all columns in the input data set that are also in the comparison table (that are not of the long or blob data type or the Generated key column) are used as compare columns. You do not need to add primary key columns to the compare column list. They are always compared before the compare columns apply. The compare columns apply only if the primary key value from the input data set matches a value in the comparison table. If the primary key value from the input data set does not match a value in the comparison table, Data Services generates an INSERT row without further comparisons. If the primary key value from the input data set matches a value in the comparison table and values in the non-key compare columns differ in the corresponding rows from the input data set and the comparison table, Data Services generates an UPDATE row with the values from the input data set row.
Comparison method	Select a method for accessing the comparison table: ● *Row-by-row select* — Select this option to have the transform look up the target table using SQL every time it receives an input row. This option is best if the target table is large compared to the number of rows the transform will receive as input. ● *Cached comparison table* — Select this option to load the comparison table into memory. In this case, queries to the comparison table access memory rather than the actual table. This option is best when you are comparing the entire target table. Data

Option	Description
	Services uses pageable cache as the default. If the table fits in the available memory, you can change the cache type to in-memory in the data flow Properties. • *Sorted input* — Select this option to read the comparison table in the order of the primary key column(s) using sequential read. This option improves performance because Data Services reads the comparison table only once. To take advantage of this option, the order of the input data set must match the order of all primary key columns in the Table_Comparison transform. If this is already the case, drag the primary key columns from the input schema in the Table_Comparison transform into the Input primary key columns box. Using a sequential read, Data Services reads the comparison table in the order of the primary key columns. If you must pre-sort the input data, add a query between the source and the Table_Comparison transform. Then, from the query's input schema, drag the primary key columns into the Order By box of the query. The query's columns, in the Order By box, must match the order of the primary key columns that you drag into the Input primary key columns box of the Table_Comparison transform. In this way, you explicitly add a sort operation (ORDER BY) to the query's input data set to ensure that the input data set order will match the order of the read from the comparison table data in the transform.
Detect deleted row(s) from comparison table	(Optional) Generates DELETEs for all rows that are in the comparison table and not in the input set. Assumes the input set represents the complete data set. By default this option is turned off. Note The Table_Comparison transform can flag rows as DELETE. However, rows actually become DELETE rows only after the data flow completes all other processing • An additional section appears in the Table_Comparison editor, which allows you to specify how to handle DELETE rows with duplicate keys, if you select the following options: ○ *Generated key column* ○ *Detect deleted row(s) from comparison table* ○ *Row-by-row select* or the *Sorted input* comparison method If you choose the above options, choose one of the following for deleted rows with the same key value: ○ *Detect all rows*: Output detected DELETEs for all rows.

Option	Description
	○ *Detect row with largest generated key value*: Output detected DELETEs for only the generated key row with the largest value. ● If you select this option and the *Cached comparison table* option, Data Services always deletes the row with largest generated key value. If you do not specify a *Generated key column*, then the sub-options with the *Detect Deleted row(s) from comparison table* option are not enabled. If Data Services finds duplicate keys in the comparison table, then the DELETE output is corrupted. **Note** If you choose the *Detect Deleted row(s) from comparison table* option, then the performance of the data flow will be slower. The comparison method most affected is the *Row-by-row select*, followed by *Cached compare* table, then *Sorted input* option. For *Row-by-row select* and *Cached compare* table, Data Services processes the deleted rows at the end of the data flow. For *Sorted input*, Data Services processes deleted rows as they are encountered in the data flow. *Run as a separate process* Creates a separate sub data flow process for the Table_Comparison transform.
Generated Key Column	(Optional) Provides a method of handling duplicate keys in the comparison table. If for example, you have employee data that includes a social security number as a primary key, and multiple entries for some of these keys, specify a column in the comparison table with unique keys as the generated key column. A generated key column indicates which row of a set containing identical primary keys is to be used in the comparison. Specify an existing column name that by design contains no duplicate keys. The Generated key column option insures that: ● For an UPDATE, the output data set will contain the largest generated key found for a given primary key. For an INSERT, the output data set will contain a NULL value for the generated key, because this column is typically omitted from the input into the Table Comparison transform and set later by a Key_Generation. If an input column is used as generated key column, its value is preserved. For a DELETE, the output data set can include all duplicate key rows or just the row with the largest key value. ● If there is more than one row in the comparison table with the same primary key value and generated key value, the transform arbitrarily chooses which row to compare.

<table>
<tr><th>Option</th><th>Description</th></tr>
<tr><td></td><td><ul><li>If the input data set and the comparison table both have the column you specified in <i>Generated key column</i>, the transform does not compare the values for this column; it preserves the value.</li></ul>Without his option:<ul><li>If your comparison table contains rows with the same primary keys, the transform arbitrarily chooses which of these rows to compare.</li></ul></td></tr>
<tr><td><i>Input contains duplicate keys</i></td><td>(Optional) Provides a method of handling duplicate keys in the input data set. If you have more than one row with the same key in the <i>Input Primary Key</i> box, then select this check box. Data Services processes all duplicate rows. Inserts, updates, and deletes occur in the same order as they occur in the input table.

If your input columns have duplicate keys and you do not select this option, then the transform arbitrarily chooses which of these rows to compare during data flow processing.

This option uses additional memory to track rows with duplicate keys. It is recommended that you use this feature only as needed.</td></tr>
<tr><td><i>Input primary key column(s)</i></td><td>The input data set columns that uniquely identify each row. These columns must be present in the comparison table with the same column names and data types.

Drag the column(s) from the input schema into the <i>Input primary key columns</i> box. The transform selects rows from the comparison table that match the values from the primary key columns in the input data set.

If values from more than one column are required to uniquely specify each row in the table, add more than one column to the <i>Input primary key columns</i> box.

You cannot include nested schemas in the <i>Input primary key columns</i> list.</td></tr>
<tr><td><i>Table name</i></td><td>The fully qualified name of the source table from which the maximum existing key is determined (key source table). This table must be already imported into the repository. <i>Table name</i> is represented as "DATASTORE.OWNER.TABLE" where DATASTORE is the name of the datastore Data Services uses to access the key source table; OWNER, if required, depends on the database type associated with the table:
<table>
<tr><th>Database type</th><th>Owner value</th></tr>
<tr><td>DB2</td><td>Data source dependent</td></tr>
<tr><td>Informix</td><td>Informix-defined user name</td></tr>
<tr><td>Microsoft SQL Server</td><td>User name</td></tr>
</table></td></tr>
</table>

<table>
<tr><th>Option</th><th>Description</th></tr>
<tr><td></td><td><table>
<tr><th>Database type</th><th>Owner value</th></tr>
<tr><td>ODBC</td><td>Data source dependent</td></tr>
<tr><td>Oracle</td><td>User name</td></tr>
<tr><td>SAP Sybase SQL Anywhere</td><td>User Name</td></tr>
<tr><td>SAP Sybase</td><td>User name</td></tr>
</table></td></tr>
<tr><td><i>Filter</i></td><td>(Optional) Limits the rows from the comparison table that are considered for comparison against the input data set.
⚠ Caution
Incorrect filtering can produce false <code>INSERT</code> rows. Construct your filter expression carefully to avoid unexpected results.
Valid filter expressions may contain the following elements:<ul><li>Columns from the comparison table</li><li>Constants (integers, strings, substitution parameters, global variables, and expressions with these combinations)</li><li>Relational operators (<code>=</code>, <code><</code>, <code>></code>, <code><=</code>, <code>>=</code>, <code>LIKE</code>, <code>IN</code>)</li><li>Logical operators (<code>AND</code>, <code>OR</code>)</li></ul>ℹ Note
Data Services functions, and <code>JOIN</code> and other SQL statements can not be used in filter expressions.
Examples of valid filter expressions:<ul><li><code>TC.col1 IN (1, 2, 3)</code></li><li><code>TC.col1 >= 1 AND TC.col1 < 1000</code></li><li><code>TC.col1 = 1 AND TC.col2 = 2</code></li><li><code>col1 = 10 OR col1 = 20</code></li><li><code>TC.col1 = $V_DEPTNO</code></li></ul></td></tr>
</table>

3.5.3.10.3 Data outputs

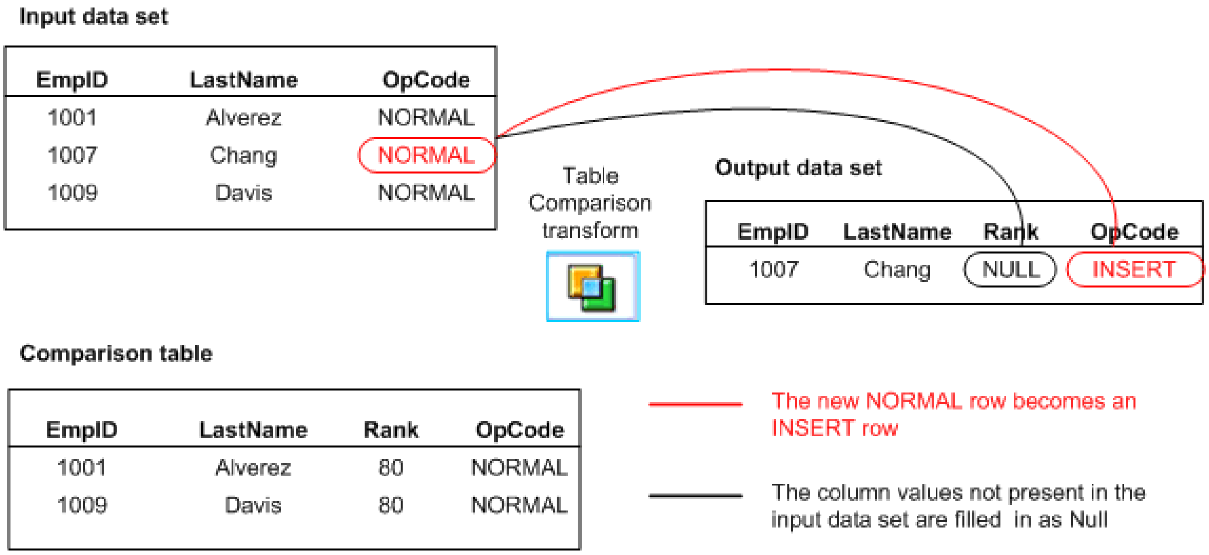
A data set containing rows flagged as INSERT, UPDATE, or DELETE. This data set contains only the rows that make up the difference between the two input sources: one from the input to the transform (input data set), and one from a database table you specify in the transform (the comparison table). The transform selects rows from the comparison table based on the primary key values from the input data set. The transform compares columns that exist in the schemas for both inputs.

If a column has a `date` data type in one table and a `datetime` data type in the other, the transform compares only the date section of the data. The columns can also be `time` and `datetime` data types, in which case Data Services only compares the time section of the data.

The transform generates a data set consisting of rows with INSERT and UPDATE operation codes, unless you are using the *Detect Deleted row(s) from comparison table* option. In this case, DELETE rows are produced. If a primary key value in the comparison table is not present in the input data set, no corresponding row appears in the output.

For each row in the input data set, there are four possible outcomes from the transform:

- An INSERT row.
  The primary key value from the input data set does not match a value in the comparison table. The transform produces an INSERT row with the values from the input data set row.
  If there are columns in the comparison table that are not present in the input data set, the transform adds these columns to the output schema and fills them with NULL values.



Input data set

EmpID	LastName	OpCode
1001	Alverez	NORMAL
1007	Chang	NORMAL
1009	Davis	NORMAL

Output data set

EmpID	LastName	Rank	OpCode
1007	Chang	NULL	INSERT

Comparison table

EmpID	LastName	Rank	OpCode
1001	Alverez	80	NORMAL
1009	Davis	80	NORMAL

Table
Comparison
transform
The new NORMAL row becomes an INSERT row
The column values not present in the input data set are filled in as Null

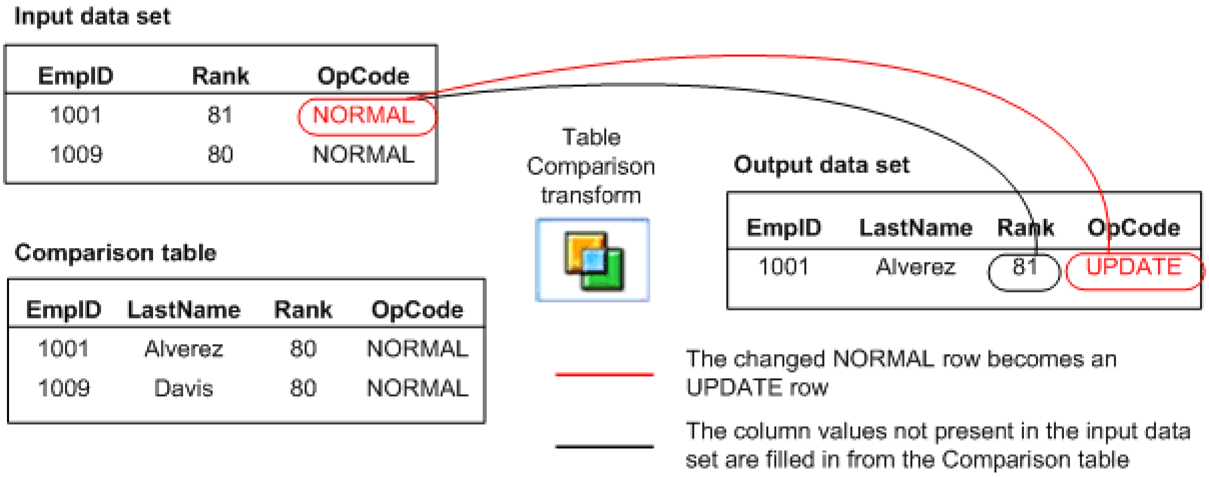
> **Note**
>
> Data Services ignores trailing blanks when it compares values in the comparison table and the input data set. However, an Oracle database server includes trailing blanks in comparisons. Therefore, the Table_Comparison transform produces an INSERT row under the following circumstances:

  - The comparison table is an Oracle table with data that had trailing blanks removed.
  - The input data contains trailing blanks.
  - You use the *Row-by-row select* comparison method. This method pushes down the comparison to the Oracle database server.

  To avoid inserting rows when the data differs only by number of trailing blanks, take either of the following actions:

  - Use a different comparison method (*Cached comparison table* or *Sorted input*) if possible
  - Add the rtrim or rtrim_blank function to remove trailing blanks from the input data.
- An UPDATE row.

The primary key value from the input data set matches a value in the comparison table, and values in the non-key compare columns differ in the corresponding rows from the input data set and the comparison table. The transform produces an UPDATE row with the values from the input data set row.
If there are columns in the comparison table that are not present in the input data set, the transform adds these columns to the output schema and fills them with values from the comparison table.



Input data set

EmpID	Rank	OpCode
1001	81	NORMAL
1009	80	NORMAL

Comparison table

EmpID	LastName	Rank	OpCode
1001	Alverez	80	NORMAL
1009	Davis	80	NORMAL

Output data set

EmpID	LastName	Rank	OpCode
1001	Alverez	81	UPDATE

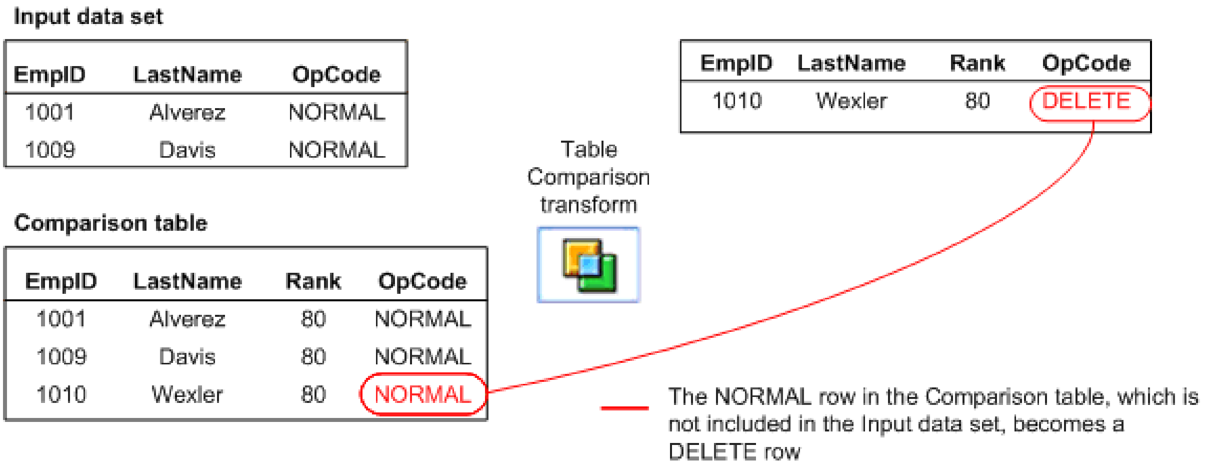
🟥 The changed NORMAL row becomes an UPDATE row

― The column values not present in the input data set are filled in from the Comparison table

> **Note**
>
> Data Services ignores trailing blanks when it compares values in the comparison table and the input data set. Therefore, if the input data and the value in the comparison table differ only by trailing blanks, the transform will not produce an UPDATE row. However, an Oracle database server includes trailing blanks in comparisons. To avoid updating rows when the data differs only by number of trailing blanks, take either of the following actions:

- Use a different comparison method (*Cached comparison table* or *Sorted input*), if possible.
- Add the rtrim or rtrim_blank function to remove trailing blanks from the input data.

- A DELETE row.
  The primary key value from the comparison table set does not match a value in the input data set. The transform produces an DELETE row with the values from the comparison table row.
  If there are columns in the comparison table that are not present in the input data set, the transform adds these columns to the output schema and fills them with values from the comparison table.



Input data set

EmpID	LastName	OpCode
1001	Alverez	NORMAL
1009	Davis	NORMAL

Comparison table

EmpID	LastName	Rank	OpCode
1001	Alverez	80	NORMAL
1009	Davis	80	NORMAL
1010	Wexler	80	NORMAL

EmpID	LastName	Rank	OpCode
1010	Wexler	80	DELETE

The NORMAL row in the Comparison table, which is not included in the Input data set, becomes a DELETE row

- The row is ignored.
  The primary key value from the input data set matches a value in the comparison table, but the comparison does not indicate any changes to the row values.

Related Information

Operation codes [page 1068]

3.5.3.11 XML_Pipeline

Processes large XML files one instance of a repeatable structure at a time.

With this transform, Data Services does not need to read the entire XML input into memory then build an internal data structure before performing the transformation. An NRDM structure is not required to represent the entire XML data input. Instead, the XML_Pipeline transform uses a portion of memory to process each instance of a repeatable structure, then continually releases and reuses memory to steadily flow XML data through the transform.

During execution, Data Services pushes operations of the XML_Pipeline transform to the XML source.

3.5.3.11.1 Data inputs

XML file or XML message.

You can connect more than one XML_Pipeline transform to an XML source.

3.5.3.11.2 Editor

Use the XML_Pipeline transform editor to specify:

- Input schema
- Output schema

The XML_Pipeline transform editor was streamlined to support massive throughput of XML data, therefore it does not contain additional options. In addition to input and output schemas, the Mapping tab shows how Data Services will map any selected output column.

When connected to an XML source, the XML_Pipeline transform editor shows the input and output schema structures as a root schema containing repeating and non-repeating sub-schemas represented by the following icons:

▦	Root schema and repeating sub-schema
▤	Non-repeating sub-schema

Within each sub-schema, mapped and unmapped columns display as follows:

▯	Column not used in output mapping
▶	Column used in output mappings

3.5.3.11.3 Rules

Rules

- You cannot drag and drop the root level schema.
- You can drag and drop the same child object repeated times to the output schema only if you give each instance of that object a unique name. You must rename the mapped instance before attempting to drag and drop the same object to the output again.
- When you drag and drop a column or sub-schema to the output schema, you cannot then map the parent schema for that column or sub-schema. Similarly, when you drag and drop a parent schema, you cannot then map an individual column or sub-schema from under that parent.
- You cannot map items from two sibling repeating sub-schemas because the XML_Pipeline transform does not support Cartesian products (combining every row from one table with every row in another table) of two repeatable schemas.

3.5.3.11.4 Limitations

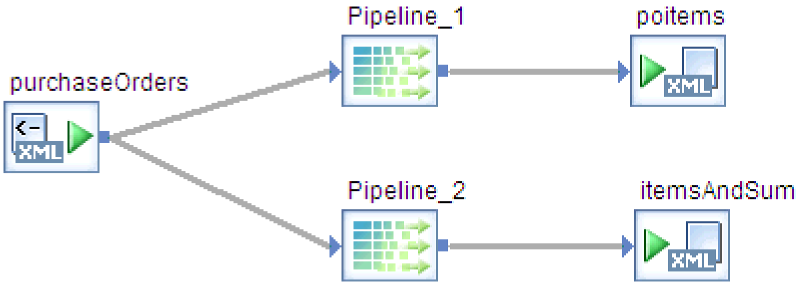
Limitations

The XML_Pipeline transform:

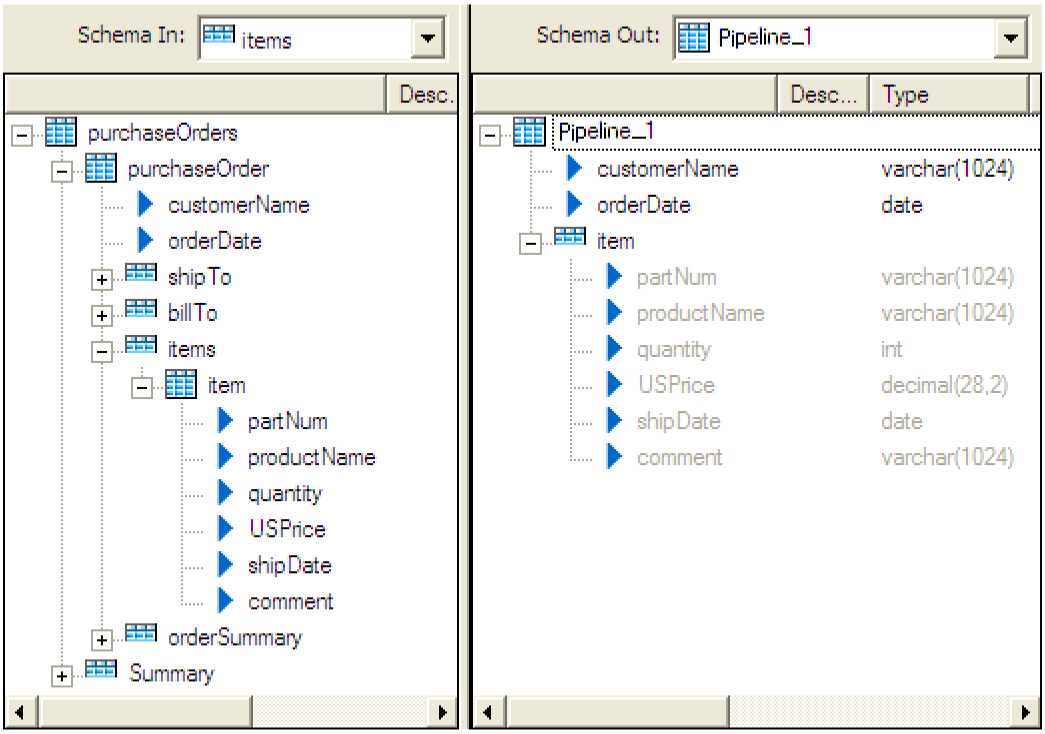
- Pushes operations to the XML source during transform execution, so you cannot use a breakpoint between your XML source and a XML_Pipeline transform.

3.5.3.11.5 Example

This simple data flow contains two XML_Pipeline transforms, but only one of them takes full advantage of the pipelining power.



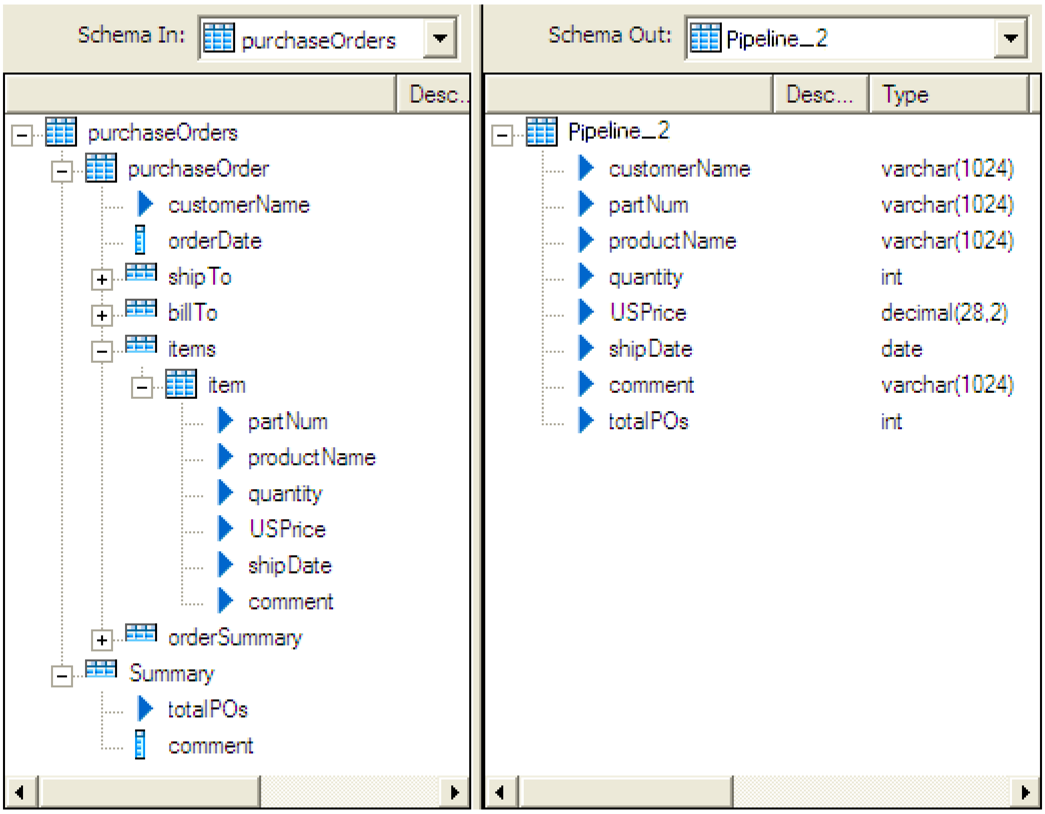
- The "XML_Pipeline_1" transform allows XML data to flow because the repeatable column, purchaseOrders.purchaseOrder.items.item is selected. The XML source produces one row after parsing one item.



Schema In: items

Schema Out: Pipeline_1

- The "XML_Pipeline_2" transform does not take advantage of the pipelining power because the purchaseOrders.Summary.totalPOs column is selected and this column occurs structurally after the repeatable column (purchaseOrders.purchaseOrder.items.item). In this scenario, the XML source must assemble the entire structure of items in memory before processing.



Pipeline_2	Type
customerName	varchar(1024)
partNum	varchar(1024)
productName	varchar(1024)
quantity	int
USPrice	decimal(28,2)
shipDate	date
comment	varchar(1024)
totalPOs	int

However, if you broke this up into two XML_Pipeline transforms, mapping the purchaseOrders.Summary.totalPOs column in a separate transform, you could connect both XML_Pipeline transforms to a Query transform and take advantage of the reduced memory consumption to get the same output.

3.5.4 Data Quality transforms

3.5.4.1 Transform configurations

The following Data Quality transform configurations are available from the *Transforms* tab of the object library. This section describes these transform configurations in detail.

Table 147: Associate transform

Transform configuration	Description
AssociateGroupStatistics_AssociateBatch	A sample Associate transform configured with group statistics.

Transform configuration	Description
Base_Associate	A base Associate transform that is used to configure an Associate transform.
Wizard_AssociateBatch	A sample Associate configuration used by the Match Wizard. This configuration should not be edited.

Table 148: Country ID transform

Transform configuration	Description
CountryID2Char	A sample Country ID transform configured to generate the two-character ISO country code.

Table 149: Data Cleanse transform

Transform configuration	Description
Base_DataCleanse	A base Data Cleanse transform that is used to configure a custom Data Cleanse transform.
Chinese_DataCleanse	A sample Data Cleanse transform configured to cleanse name, title, firm, date, email, and phone data using Chinese-based data quality rules.
Dutch_DataCleanse	A sample Data Cleanse transform configured to cleanse name, title, firm, date, email, and phone data using Dutch-based data quality rules.
EnglishNorthAmerica_DataCleanse	A sample Data Cleanse transform configured to cleanse name, title, firm, date, email, and phone data using English-based data quality rules.
French_DataCleanse	A sample Data Cleanse transform configured to cleanse name, title, firm, date, email, and phone data using French-based data quality rules.
German_DataCleanse	A sample Data Cleanse transform configured to cleanse name, title, firm, date, email, and phone data using German-based data quality rules.
Italian_DataCleanse	A sample Data Cleanse transform configured to cleanse name, title, firm, date, email, and phone data using Italian-based data quality rules.
Japanese_DataCleanse	A sample Data Cleanse transform configured to cleanse name, title, firm, date, email, and phone data using Japanese-based data quality rules.
Portuguese_DataCleanse	A sample Data Cleanse transform configured to cleanse name, title, firm, date, email, and phone data using Portuguese-based data quality rules.
Spanish_DataCleanse	A sample Data Cleanse transform configured to cleanse name, title, firm, date, email, and phone data using Spanish-based data quality rules.

Table 150: Geocoder transform

Transform configuration	Description
Geocode	A sample Geocoder transform configured to assign latitude/longitude based on an address or point-of-interest reference point.
ResultListGeocode	A sample Geocoder transform configured to provide a list of addresses or points of interest based on an address or latitude/longitude reference point.
ReverseGeocode	A sample Geocoder transform configured to assign an address based on a latitude/longitude reference point.

Table 151: Global Address Cleanse transform

Transform configuration	Description
Australia_AddressCleanse	A sample Global Address Cleanse transform configured to cleanse address data in Australia.
Brazil_AddressCleanse	A sample Global Address Cleanse transform configured to cleanse address data in Brazil.
Canada_AddressCleanse	A sample Global Address Cleanse transform configured to cleanse address data in Canada.
China_AddressCleanse	A sample Global Address Cleanse transform configured to cleanse address data in China.
Europe_AddressCleanse	A sample Global Address Cleanse transform configured to cleanse address data in multiple European countries.
France_AddressCleanse	A sample Global Address Cleanse transform configured to cleanse address data in France.
Germany_AddressCleanse	A sample Global Address Cleanse transform configured to cleanse address data in Germany.
Global_AddressCleanse	A sample Global Address Cleanse transform configured to cleanse Latin-1 address data in any supported country.
GlobalSuggestions_Address_Cleanse	A sample Global Address Cleanse transform configured to cleanse Latin-1 address data in any supported country using the Suggestion List feature.
Greece_AddressCleanse	A sample Global Address Cleanse transform configured to cleanse address data in Greece when the address data consists of Greek data.
Italy_AddressCleanse	A sample Global Address Cleanse transform configured to cleanse address data in Italy.
Japan_AddressCleanse	A sample Global Address Cleanse transform configured to cleanse address data in Japan when the address data consists of Japanese kanji, katakana, and hiragana.
Portugal_AddressCleanse	A sample Global Address Cleanse transform configured to cleanse address data in Portugal.

Transform configuration	Description
Spain_AddressCleanse	A sample Global Address Cleanse transform configured to cleanse address data in Spain.
UK_AddressCleanse	A sample Global Address Cleanse transform configured to cleanse address data in the United Kingdom.
USA_AddressCleanse	A sample Global Address Cleanse transform configured to cleanse address data in the United States.
USASuggestions_AddressCleanse	A sample Global Address Cleanse transform configured to cleanse address data in the United States using the Suggestion List feature.

Table 152: Global Suggestion List transform

Transform configuration	Description
GlobalSuggestions	A sample Global Suggestion List transform configured to generate a suggestion list for Latin-1 address data in any supported country.
UKSuggestions	A sample Global Suggestion List transform configured to generate a suggestion list for partial address data in the United Kingdom.

Table 153: Match transform

Transform configuration	Description
Address_MatchBatch	A sample Match transform configured to identify matching data records based on similar address data.
AddressJapan_MatchBatch	A sample Match transform configured to identify matching data records based on similar address data when the data consists of Japanese kanji, katakana, and hiragana.
AddressSingleField_MatchBatch	A sample Match transform configured to identify matching data records based on similar address data (when the address data is in a single field).
Base_Match	A base Match configuration that is used to configure a Match transform without necessarily performing matching.
ConsumerHouseholdResFamInd_ MatchBatch	A sample Match transform configured to identify three levels of matching data records: residence based on similar address data, family based on similar family name data, and individual based on similar given name and postname data.
ConsumerHouseholdResInd_MatchBatch	A sample Match transform configured to identify two levels of matching data records: residence based on similar address data, and individual based on similar name data.
CorporateHouseholdFirmInd_MatchBatch	A sample Match transform configured to identify two levels of matching data records: firm based on similar firm and address data, and individual based on similar name data.
FirmAddress_MatchBatch	A sample Match transform configured to identify matching data records based on similar firm and address data.

Transform configuration	Description
FirmAddressJapan_MatchBatch	A sample Match transform configured to identify matching data records based on similar firm and address data when the data consists of Japanese kanji, katakana, and hiragana.
IndividualId_MatchBatch	A sample Match transform configured to identify matching data records based on the same individual identification number data.
NameAddress_MatchBatch	A sample Match transform configured to identify matching data records based on similar name and address data.
NameDate_MatchBatch	A sample Match transform configured to identify matching data records based on similar name and date data.
NameEmail_MatchBatch	A sample Match transform configured to identify matching data records based on similar name and email data.
NameFirmAddress_MatchBatch	A sample Match transform configured to identify matching data records based on similar name, firm, and address data.
NameFirmAddressJapan_MatchBatch	A sample Match transform configured to identify matching data records based on similar name, firm, and address data when the data consists of Japanese kanji, katakana, and hiragana.
NameIndividualId_MatchBatch	A sample Match transform configured to identify matching data records based on similar name and individual identification number data.
NamePhone_MatchBatch	A sample Match transform configured to identify matching data records based on similar name and phone data.
ProductDescription_MatchBatch	A sample Match transform configured to identify matching data records based on similar product description data.
Wizard_MatchBatch	A sample Match configuration used by the Match Wizard. This configuration should not be edited.

Table 154: USA Regulatory Address Cleanse transform

Transform configuration	Description
USARegulatory_AddressCleanse	A sample USA Regulatory Address Cleanse transform configured to cleanse address data according to CASS requirements.
USARegulatoryEWS_AddressCleanse	A sample USA Regulatory Address Cleanse transform configured to cleanse address data according to CASS requirements, with Early Warning System.
USARegulatoryGeo_AddressCleanse	A sample USA Regulatory Address Cleanse transform configured to cleanse address data according to CASS requirements, with GeoCensus.
USARegulatoryNCOALink_AddressCleanse	A sample USA Regulatory Address Cleanse transform configured to cleanse address data using NCOALink data.
USARegulatoryNonCertified_ AddressCleanse	A sample USA Regulatory Address Cleanse transform configured to cleanse address data in non-certified mode.

Transform configuration	Description
USARegulatoryNonCertifiedGeo_ AddressCleanse	A sample USA Regulatory Address Cleanse transform configured to cleanse address data in non-certified mode, with GeoCensus.
USARegulatoryRDI_AddressCleanse	A sample USA Regulatory Address Cleanse transform configured to cleanse address data according to CASS requirements, with Residential Delivery Indicator.
USARegulatorySuggestions_ AddressCleanse	A sample USA Regulatory Address Cleanse transform configured to cleanse address data using the Suggestion List feature.
USARegulatoryZ4Change_ AddressCleanse	A sample USA Regulatory Address Cleanse transform configured to cleanse address data according to CASS requirements, with Z4Change.
DSF2_Walk_Sequencer	A sample DSF2 Walk Sequencer transform configured to append sequence information to your data so that, by using presort software, you can obtain walk sequence discounts.

Table 155: User-Defined transform

Transform configuration	Description
Base_UserDefined	The base User-Defined configuration that is used to configure a User-Defined transform.

3.5.4.2 Downloading blueprints and other content objects

We have identified a number of common scenarios that you are likely to handle with SAP Data Services. Instead of creating your own job from scratch, look through the blueprints. If you find one that is closely related to your particular business problem, you can simply use the blueprint and tweak the settings in the transforms for your specific needs.

For each scenario, we have included a blueprint that is already set up to solve the business problem in that scenario. Each blueprint contains the necessary project, jobs, data flows, file formats, sample data, template tables, and custom functions to run the data flows in your environment with only a few modifications.

You can download all of the blueprints or only the blueprints and other content that you find useful from the SAP Community Network website. Here, we periodically post new and updated blueprints, custom functions, best practices, white papers, and other SAP Data Services content. You can refer to this site frequently for updated content and use the forums to provide us with any questions or requests you may have. We have also provided the ability for you to upload and share any content that you have developed with the rest of the development community.

Instructions for downloading and installing the content objects are also located on the Blueprints web page.

1. To access the SAP Data Services Blueprints web page, go to *http://scn.sap.com/docs/DOC-8820* in your web browser.
2. Open the Content Objects User's Guide to view a list of all of the available blueprints and content objects and their descriptions, and instructions for downloading and setting up the blueprints.
3. Select the blueprint that you want to download.
4. Follow the instructions in the user's guide to download the files to the appropriate location and make the necessary modifications in SAP Data Services to run the blueprints.

3.5.4.3 Dynamic transform settings

Dynamic transform settings allow the user to change a transform's settings after the transform is initialized, without having to terminate and reinitialize the transform. You can pass each new setting through an input field to the transform. The transform will get an updated setting from the input field and adjust its processing to use the new setting, before processing the incoming record.

The settings a transform is initialized with are considered the transform's default settings. Dynamic setting values that are specified in the input fields are only valid for that record and do not affect any subsequent record. If the value specified for a given option is NULL or blank, then the record will be processed with the default setting for that option. If the dynamic setting is invalid, then the transform will log a warning and then use the default settings.

The dynamic input fields in Data Services are:

Transform	Dynamic input field
Data Cleanse	Option_Content_Domain_Sequence The domain must be specified as an abbreviation of the domain. The valid predefined values are: AR, ZH, CS, DA, NL, EN_US, EN_GB, EN_AU, EN_IN, FR, DE, HU, ID, IT, JA, MS, NO, PL, PT_BR, PT_PT, RO, RU, SK, ES_MX, ES_ES, SV, and GLOBAL. The Global domain is a special content domain which contains all variations and their associated properties. If a variation is not associated with domain-specific information the Global domain serves as the default domain.The Global domain is required for every content domain sequence. Be sure to add GLOBAL as the last domain in the sequence. The Content domain sequence input field may hold more than one domain. If there is more than one domain, you must separate the domains with a pipe (|). For example, to specify the domain for Spain and then for Portugal, enter **`ES_ES|PT_PT|GLOBAL`**.
Data Cleanse	Option_Output_Format The output format must be specified as an abbreviation of the domain. The valid predefined values are: AR, ZH, CS, DA, NL, EN_US, EN_GB, EN_AU, EN_IN, FR, DE, HU, ID, IT, JA, MS, NO, PL, PT_BR, PT_PT, RO, RU, SK, ES_MX, ES_ES, and SV.
Global Address Cleanse	Option_Canada_Output_Address_Language
Global Address Cleanse	Option_GAC_Dual_Address

Transform	Dynamic input field
Global Address Cleanse	Option_Standardization_Address_Line_Alias
Global Address Cleanse	Option_Standardization_Assign_Locality
Global Address Cleanse	Option_Standardization_Capitalization
Global Address Cleanse	Option_Standardization_Character_Width_Style
Global Address Cleanse	Option_Standardization_Directional_Style
Global Address Cleanse	Option_Standardization_Include_Locality_Addition
Global Address Cleanse	Option_Standardization_Locality_Name_Style
Global Address Cleanse	Option_Standardization_Output_Country_Language
Global Address Cleanse	Option_Standardization_Postal_Phrase_Style
Global Address Cleanse	Option_Standardization_Primary_Type_Style
Global Address Cleanse	Option_Standardization_Region_Style
Global Address Cleanse	Option_Standardization_Secondary_Description_Style
Global Address Cleanse	Option_Standardization_Secondary_Number_Style
Geocoder	Option_Distance_Unit
Geocoder	Option_Max_Records
Geocoder	Option_Radius
Match	Option_Field_Algorithm_Geo_Proximity_**`<logical_name>`**_Max_Distance

3.5.4.4 About Data Quality fields

Many transforms require mapped input and generated output fields. These fields are on the *Input* and *Output* tabs in the transform's editor. The available fields are documented in this section with each transform.

3.5.4.4.1 Content types

The content type identifies the type of data in the field. Setting the content type helps you map your fields when you set downstream transforms. The program searches all upstream fields and automatically maps the fields that have a content type that is relevant to the type of transform that you're currently mapping. Those upstream fields will automatically be added as mapped fields.

For example, in your data source, let's say that you have a column of data that is comprised mostly of first names called Given Name1. This field is automatically mapped to a Data Quality-recognized content type, Given_Name1. You can change the content type in the Output schema. If you are importing an XSD and DTD, you must select *Automatically Assign Content Type* to have the content type automatically assign.

You can change the content type by double-clicking on the field in the Schema Out portion of the transform, or by clicking the Content Type column on the Schema Out grid.

You can specify the content type in your source data including XML Schemas, COBOL Copybooks, flat files, Excel, and IDOC objects. If the data in a column cannot be mapped, then you will see a blank column. Content types in an XML Schema can be changed in the Local Object Library, and the change will be reflected in all data flows where the schema is used. You cannot change the content type in an XML Schema from within a single data flow.

When using some transforms, such as the Query transform, you can change the content type of an input column to a different output content type. You may want to change the content type when you will use the next transform for a different content type, for example, if you have an input column that contains city information with a content type of Locality. When you set up the Query transform, it will return state information to which you would assign the Region content type.

If you attempt to merge the contents of two corresponding columns in the Merge transform, be certain that the content types match. Otherwise, you will see a warning message when you validate.

If you have an input source on your local repository and overwrite it with one from the central repository, then your content type information will be overwritten.

If you re-import a column or table via Designer, your content types for all of the existing columns will be preserved by default. You can change this option to clear all of the content types by choosing ▶ *Tools* › *Options* ◀. Then select ▶ *Designer* › *Attribute Values* ◀. Change *Content Type* from *Preserve* to *Clear* and then the content type will be overwritten by the source data.

Available content types

The following values are available for each transform.

- <Blank>
- Address
- Address Primary Name
- Address Primary Number
- Address Primary Postfix
- Address Primary Prefix
- Address Primary Type
- Address Secondary Number

- Country
- Date
- Delivery Point
- DPV Status
- Email
- Family Name1
- Family Name1 Match Std
- Family Name2
- Family Name2 Match Std
- Firm
- Firm Location
- Firm Location Match Std
- Firm Match Std
- Given Name1
- Given Name1 Match Std
- Given Name2
- Given Name2 Match Std
- Group Number
- Locality
- Lot
- Lot Order
- Name
- Name And Firms
- Phone
- Postcode
- Postcode1
- Postcode2
- Postname
- Postname Match Std
- Prename
- Prename Match Std
- Region
- Sortcode Rte
- SSN
- Title
- Title Match Std

3.5.4.5 Associate

Description

The Associate transform works downstream from your Match transforms to provide a way to combine, or associate, their match results by using the Match transform-generated Group Number fields.

You may want to add a Group Statistics operation to the Associate transform to gather match statistics. You can combine the results of two or more Match transforms, two or more Associate transforms, or any combination of the two.

For example, you may use one Match transform to match on name and address, use a second Match transform to match on SSN, and then use an Associate transform to combine the match groups produced by the two Match transforms.

Related Information

Associate transform options [page 1134]
Association options [page 1134]
Designer Guide: Match, Association matching [page 579]

3.5.4.5.1 Content objects

Transform configurations

A transform configuration is a transform with preconfigured input fields, output fields, and options that can be used in multiple data flows. These are useful if you repeatedly use a transform with specific options and input and output fields.

When Data Services is installed, read-only transform configurations are provided for the Data Quality transforms.

You can use transform configurations in your data flows or as an example of a typical transform. After you place an instance of the transform configuration in a data flow, you can override these preset defaults. You can also create your own transform configuration, either by replicating an existing transform configuration or creating a new one.

Sample blueprints and other objects

We have created Data Quality blueprints and other content objects to help you set up Data Services jobs. We’ve identified a number of common scenarios that you are likely to perform with Data Services. For each scenario, we’ve included a blueprint that is already set up to solve the business problem in that scenario.

Related Information

Downloading blueprints and other content objects [page 1128]
Transform configurations [page 1123]

3.5.4.5.2 Associate transform options

The following options control transform-level functions.

Option	Description
Associate set name	Specifies the name for your Associate set.
Generate report data	Specifies whether to generate report data for this transform. This option is available in every transform that generates report data. *Yes:* Generates report data for this transform. *No:* Turns off report data generation. If you do not need to generate reports (in production, for example), you should set this option to No. This will improve performance.
Logical source field	Specifies the field that contains the ID for the logical source.
Physical source field	Specifies the field that contains the ID for the physical source (Reader).
Run as a separate process	Specifies whether to split transform into a sub-data flow that can improve performance and throughput by using separate memory and computer resources. *Yes:* Splits transform into sub-data flow that runs on a separate process. *No:* Keeps transform in same process as the rest of the data flow.

Related Information

Performance Optimization Guide: Distributing Data Flow Execution, Run as a separate process [page 2153]

3.5.4.5.3 Association options

This is a repeating option group: you can add as many associations as you want.

Option	Description
Association name	Specifies the name for this association. Be sure that it is unique among other associations in this transform.
Group Number field	Specifies the field that contains the group number data from the Match transform. Add as many of these as you want by clicking the *Add Row* button.

3.5.4.5.3.1 Post-association processing

Use the Post-association processing table to navigate to your operations by double-clicking the desired row in the table.

Best record

The purpose of best record post-processing is to salvage data from matching records—that is, members of match groups—and consolidate, or post, that data to a best record, or to all matching records.

Group statistics

Use group statistics to generate statistical information about your group of matching records. Find out:

- The number of records within the match group
- The sequential group order number
- The group rank, which flags one record within each group of matching records as the Master record and all other records in the group as Subordinate records.
- whether the records in a match group belong to more than one source

Group statistics are essential for generating data for match reports.

Prioritization

Use the prioritization operation to order records for processing by other post-match operations.

Unique ID

You can use the Unique ID options to assign sequential identification numbers to each new record when adding records to a data warehouse. For example, the largest number assigned in a particular project can be carried over as the beginning identification number (plus 1) to be used in the assignment of new sequential IDs. This occurs when the software processes the next source against the data warehouse file.

Output record

Use the Output record options to flag certain types of records for potential processing downstream.

Related Information

Best record options: Best Record tab [page 1136]

Group prioritization options: Priority Order tab [page 1140]
Unique ID options: Unique ID tab [page 1142]
Output flag selection options [page 1306]
Designer Guide: Match, Best record [page 562]
Designer Guide: Match, Unique ID [page 570]

3.5.4.5.3.1.1 Best record options: Best Record tab

Use the best record post-match processing operation to update your records with information from other records in a match group, among other things.

Option	Description
Best record name	Enter a name for your Best Record operation. Make sure that this name is unique within this Match transform.
Best record strategy	Choose the strategy to determine whether any action is taken on records in a match group. This is the criteria for further action. After you choose the strategy, priority, and field that you want to work with, the Match transform automatically generates the Python code for you (except for Custom). *Custom:* Choose this strategy to base your strategy entirely on custom Python code. This allows you to open the Python Expression editor and create custom Python code. *Date:* Choose Date to base your strategy on a date field. *Length:* Choose Length to base your strategy on the length of data in a field. *Non_Blank:* Choose Non_Blank to base your strategy on the completeness of data in a field. *Priority_Number:* Choose Priority_Number to base your strategy on a number.

Option	Description
	Priority_String: Choose Priority_String to base your strategy on string data in a field.
Strategy priority	These are the choices for priorities for each of the best record strategies, other than Non_Blank and Custom. Date • *Newest:* The newest date in the field will cause an action to take place. • *Oldest:* The oldest date in a field will cause an action to take place. Length • *Longest:* The longest string in a field will cause an action to take place. • *Shortest:* The shortest string in a field will cause an action to take place. Priority_Number • *Highest:* The highest number in a field will cause an action to take place. • *Lowest:* The lowest number in a field will cause an action to take place. Priority_String • *Ascending:* The string with the most ascending string order will cause an action to take place. • *Descending:* The string with the most descending string order will cause an action to take place.
Strategy field	Choose a field that contains data that you need to execute your strategy.
Posting destination	Specifies the destination record. *Master:* Post only to a master record. *Subs:* Post only to subordinate records. *Master to Subs:* Push information from the master record and post it to each subordinate record. *All:* Post to both the master and subordinate records.
Post only once per destination	*Yes:* Post only once per destination record. After data is posted to the destination record, the operation stops. *No:* Post more than once per destination. After data is posted to the destination record, the operation continues and the destination record is populated again with the next value. This option should be used when accumulating values such as total sales. Set this option to Yes when you are using the NON_BLANK strategy. Set this option to No when you are using the Longest, Shortest, Newest, Oldest, Ascending, or Descending priorities.

Option	Description
	ℹ Note This option is ignored when using the *Master to Subs* posting destination. With this posting destination, information can be posted only once.
View/Edit Python	The View/Edit Python button opens the Python Expression editor. If you chose the Custom strategy, you can create your custom Python code. If you chose any other strategy, Python viewed in the editor is read-only.

Best record action fields

Use the best record action fields table to define the actions taken on the fields based on your strategy.

Option/Option group	Description
Source field	Specifies the name of the source field in the input record.
Destination field	Specifies the name of the destination field in the output record, or the destination of this best record action. You can have the action post to the same input field, or you can post to a different field.
Custom	*Yes:* Specifies that you want to create custom Python code to perform an action on the destination field. *No:* Specifies that you want to use the same source and destination fields. When this option is set to No, the contents of the source field are copied to the destination field.
Editor	If you chose Yes in the Custom column, a button appears here to allow you open the Python Expression editor and configure your Python code. You can open the Python Expression editor only if Custom is set to Yes.

Related Information

Designer Guide: Match, Best record [page 562]

3.5.4.5.3.1.2 Best record options: Destination Protection tab

Protect data from being changed by enabling and defining destination protection.

Option	Description
Best record name	Enter a name for your Best Record operation. Make sure that this name is unique within this Match transform.
Enable destination protection	Select to protect records from best record operations that may modify the contents.
Default destination protection	Select the default destination protection setting. This is useful because the default setting will account for records that are protected (or not protected) through the use of sources or fields.
Specify destination protection by field	Select to enable destination protection through a value in a field.
Destination protection field	Choose the field that holds the destination protection value. The field must contain a value of Y or N. Any other value (including blank) will cause the default destination protection specification to occur, if you specified a default destination protection.
Specify destination protection by source	Select this option to control destination protection through membership in a particular source. Fill in the table with source names and whether they are protected.
Source Name	Choose the name of the source from the drop-down list. The list here is populated with defined sources and source groups from the *Input Sources Editor* window of the Match Editor.
Destination protected	Select a value to assign to the source. Select Yes to enable destination for that source. Select No, if you do not wish to protect records from that source.

3.5.4.5.3.1.3 Group statistics options

The Group Statistics option group includes the following options:

Option	Description
Group statistics name	Choose a name for this group statistics operation. If you are including more than one group statistics operation in this Match transform, make sure that the name is unique.
Generate only basic statistics	Select if you want to generate match group statistics. These will not include any statistics about input sources.
Generate source statistics from input sources	Select to generate statistic counts about your input sources. You must have input sources defined in the Match editor for this option to be active. If you do not check this, the Match transform will still generate statistics about your match groups.
Generate source statistics from source values	Select to generate source statistics based on source values in a field. If you have a source value field, using this option, you can choose to count all sources or specific ones based on a particular value.

Option	Description
Logical source field	Specifies the field that holds the value for your logical sources.
Default logical source value	Specifies a value to use if the field in the Logical source field option is blank. For example, if a record has a blank value in the field, this default value is used.
Count all sources	Select to count all sources, no matter what the value in the Logical source field is.
Choose sources to count	Select to specify particular sources to count, based on values in the Logical source field.
Default count flag value	Specifies the value to use when the Predefined count flag field is invalid (for example, if the field has data other than Y or N) or it is empty. *Yes:* Counts all of the records in the source. *No:* Does not count any of the records in the source.
Auto generate sources	Select to generate sources based on the value in a field.
Predefined count flag field	Specifies the field name that contains the indicator value (Y or N) to determine whether a source is counted.

Manually define logical source count flags

Be sure to fill in both columns for this to work.

Option	Description
Source value	Specifies the value in the field to find. This value is case sensitive.
Count	Specifies whether you want to use the value you entered in the Logical source value option in the count. *Yes:* Includes the logical source value in the count. *No:* Does not include the value in the logical source value option in the count.

3.5.4.5.3.1.4 Group prioritization options: Priority Order tab

Group forming prioritization

Use the Group prioritization operation to order records within each break group, which controls which records are used as the drivers during the comparison process.

Post-match prioritization

Add a Group prioritization operation before a Group Statistics operation to order records within a match group to control which record is flagged as the master record of each group of matching records. Add a Group prioritization operation before a Best Record operation to order records within a match group to control the destination of data that is being propagated from other records to form a best record.

Option	Description
Prioritization name	Specifies the name for this Group prioritization operation. If you have multiple operations in this Match transform, be sure to make this name unique.

Priority fields

Use the Priority fields table to order your break groups based on the content of a field (for example, dollar amount or date). Use the buttons to add, remove, and order rows. Place the primary sort field at the top of the list. The rest of the fields, in the order that they are positioned, determine the sub-sort that occurs.

Option	Description
Input field	Choose a field to sort your records on.
Field order	Specifies in which order records should be sorted.

3.5.4.5.3.1.5 Group prioritization options: Record Completeness tab

Option	Description
Prioritization name	Specifies the name for this Group prioritization operation. If you have multiple operations in this Match transform, be sure to make this name unique.
Order records based on completeness of data	Select this option to apply priority and blank penalty points to records to help control the order of your records.
Define only field penalties	Select this option when penalties need to be assessed based on blank fields.
Define priority and penalty fields	Select this option when you have specific fields that contain the actual integer values for priority and blank penalty.
Record priority field	Choose the field that contains priority values. This field must contain an integer.
Apply blank penalty field	Choose the field that contains the indicator (Y or N) for applying blank penalty points to a record.

Option	Description
Define priority and penalty based on input source	Select to have your record priority and blank penalty indicator (Y or N) determined by membership in a given source.
Source Name	Choose an input source from the drop-down list in the Source Name column. The sources listed here are defined in the Input Source operation.
Priority	Type a priority value (an integer) in the Priority column. Remember that the lower the priority score, the higher the priority.
Apply Blank Penalty	Choose Yes or No to determine whether a blank penalty is applied to a record based on membership to this source.
Default record priority	Specifies the default value for the record priority if the record does not contain a field with this value, this field is blank for a record, or if a record does not belong to any of the sources specified. Remember that the lower the priority score, the higher the priority.
Default apply blank penalty	Specifies the default indicator as to whether to add blank penalty points to records with blank fields. This indicator is used if a record does not have a field that carries this indicator, if that field is blank or has invalid data, or ifa record does not belong to any of the sources specified. *Yes:* Each record's blank penalty is added to the record's record priority to generate an adjusted record priority score. The lower the score, the higher the priority. *No:* No penalty is applied when the fields are blank.
Input field	Displays the input fields available to assign a blank penalty score to.
Blank penalty	Assign a penalty value (an integer) to apply when the specified field is blank in a record.

3.5.4.5.3.1.6 Unique ID options: Unique ID tab

Use the Unique ID options to assign sequential identification numbers to each new record when adding records to a data warehouse. For example, the largest number assigned in a particular project can be carried over as the beginning identification number (plus 1) to be used in the assignment of new sequential IDs. This occurs when the software processes the next source against the data warehouse file.

Note

Also see the Unique ID section for information about working with unique ID in a multi-server environment. Depending on the processing operation and starting value source you use, there could be limitations for using unique ID.

The Unique ID option group includes the following options:

Option	Description
Unique ID name	Enter a name for this Unique ID operation. If you are using other Unique ID operations in this Match transform, you may want to specify the name of the match transform and match level in this name to distinguish it from others.
Processing operation	Specifies the type of processing operation you want the application to perform. Valid values include: *Assign:* Assigns a new ID to unique records that need one, or assigns a new ID to all members of a group that don't have an ID. In addition, the assign operation copies an existing ID when a member of a match group already has an ID. For assign operations to work, all match group members must appear consecutively in one collection and must be in priority order (high to low). *AssignCombine:* Performs both an assign operation and a combine operation. All match group members must appear consecutively in one collection and must be in priority order (high to low). *Combine:* Combines the IDs of a match group when more than one ID is represented. All match group members must appear consecutively in one collection and must be in priority order (high to low). *Delete:* Removes unique IDs from records that have one, unless they are protected. *Split:* Splits the IDs of an ID group when more than one match group is represented. All ID group members must appear consecutively in one collection and must be in priority order (high to low).
Recycle unique IDs	Specifies whether unique IDs that were freed up during the delete operation should be used again in different records. You may want to recycle unique IDs if you have a limited amount available. Valid values include: *Yes:* Recycle freed-up unique IDs. *No:* Do not recycle freed-up unique IDs.
ID field	A field that holds a previously assigned unique ID. If this field is omitted, then it is assumed that no records have a unique ID.
Field	The starting unique ID is obtained from an input field. Be sure to map in a field from an upstream transform before you add this option.
Starting unique ID field	Choose the field that passes in the starting unique ID. If no Unique ID is received, the starting number will default to 1.
Constant value	The starting ID is specified as a positive whole number in the Starting value option.
Starting value	Indicates the starting unique ID value. Valid values range from 1 to UINT_MAX (unsigned integer max). The default value is 1.
Value from file	The starting Unique ID is read from the file specified in the File option.

Option	Description
File	Specifies the path and name of the file that manages unique IDs. A value is required here only when the Starting unique ID source option is set to File.
GUID	Uses the Globally Unique Identifier (GUID) as the unique ID. This is also known as the Universal Unique Identifier (UUID). The UUID variation used for unique ID is a time-based 36-character string with the format: `TimeLow-TimeMid-TimeHighAndVersion-ClockSeqAndReservedClockSeqLow-Node`. For more information about UUID, see the RFC document in the Related Topics section.
Save ending ID to file and reclaim recycled IDs	Specifies whether to save the last ID that was assigned to a file. Additionally, specifies whether to reclaim recycled IDs.
File	Specifies the file to write the last assigned ID to.
Allow multiple Match transforms to access unique ID file	Allows multiple Match transforms to access a shared unique ID file. When enabled, multiple data flows can access the same unique ID file, and single Match transforms can run in more than one process when the DOP setting is greater than 1. In addition, this allows multiple Match transforms within a single data flow to share a single unique ID file.
Number of IDs to get when accessing file	Specifies the number of IDs to retrieve from the unique ID file during each access. For example, with a setting of 100, the first process will access the file and retrieve IDs numbered 1-100. The next process with retrieve IDs numbered 101-200. If a process uses less than the number of retrieved IDs, the remaining IDs are written back to the unique ID file as recycled IDs. ℹ Note A setting greater than 1 improves performance when sharing a unique ID file between multiple processes by reducing the number of times the file must be accessed. However, integer numbers may not be assigned in sequential order.
Group number field	Specifies the field that holds a group number. The group number is used to assign the same unique ID to more than one record. If this field is omitted, then it is assumed that each record is unique and should have its own number.

Related Information

Designer Guide: Match, Assign unique IDs using a file [page 570]
Designer Guide: Match, Unique ID [page 570]

3.5.4.5.3.1.7 Unique ID options: Destination Protection tab

Use the Destination Protection tab to control whether a record's unique ID is protected based on the source that the record belongs to. This can help prevent IDs from being assigned to a suppression or rented source.

Option	Description
Unique ID name	Enter a name for this Unique ID operation. If you are using other Unique ID operations in this Match transform, you may want to specify the name of the match transform and match level in this name to distinguish it from others.
Enable destination protection	Select if you want to protect a destination source from having its unique IDs overwritten with the IDs from matching records.
Default destination protection	Select the default destination protection setting. This is useful because the default setting will account for records that are protected (or not protected) through the use of sources or fields.
Specify destination protection by field	Select to enable destination protection through a value in a field.
Unique ID protected field	Choose an input field from the drop-down list that holds the value for specifying whether this ID is protected. The field must contain a value of Y or N. Any other value (including blank) will cause the default destination protection specification to occur, if you specified one.
Specify destination protection by source	Select this option to control destination protection through membership in a particular source. Fill in the table with source names and whether they are protected.
Source name	Choose the name of the source from the drop-down list. The list here is populated with defined sources and source groups from the *Input Sources Editor* window of the Match Editor.
Unique ID protected	*Yes:* This source is protected. *No:* This source is not protected.

3.5.4.5.4 Output fields

The Associate transform requires that you map one field on output: Group_Number.

Field	Default content type	Description
Group_Number	Group_Number	The group number resulting from the association process. Records that belong to the same match group share the same group number. The group numbers start with the number one. Unique records have a blank group number.

Group prioritization output fields

The following output fields are available when you add a Group Prioritization operation to an Associate transform

Field	Description
Priority_Value	Record priority value assigned to record. If you did not include a priority value, this field outputs 0.

3.5.4.6 Country ID

The Country ID transform parses your input data and then identifies the country of destination for each record. After identifying the country, the transform can output the country name, any of three different ISO country codes, an ISO script code, and a percentage of confidence in the assignment.

Though you can use the Country ID transform before any transform in a data flow, you will probably find it most useful during a transactional address cleanse job. Place the Country ID transform before the Global Suggestion List transform. The Global Suggestion List transform needs the ISO_Country_Code_2Char field that the Country ID transform can output.

It is not necessary to use the Country ID transform before the Global Address Cleanse transform in a data flow because the Global Address Cleanse transform contains its own Country ID processing. It is also not necessary to use the Country ID transform before the USA Regulatory Address Cleanse transform because your input data should contain U.S. addresses only.

Country ID transform configuration

Data Quality provides you with a sample transform that can help you get started creating a Country ID transform useful to you.

Related Information

Input Fields [page 1147]
Output fields [page 1147]
Transform configurations [page 1123]

3.5.4.6.1 Input Fields

Use the Input_Fields option group to map the input field that you want to use in this transform.

Here is a list of the Country ID input fields and their descriptions.

Field	Description
Country	The country's name or code.
Lastline	The locality, region, and postal code on one line.
Locality1-3	City, town, or suburb information.
Multiline1-12	Lines that may contain any data. The type of data in these lines may vary from record to record.
Postcode	The postal code for the address.
Region1	The state, province, territory, or region of the address.

3.5.4.6.2 Output fields

The following are Data Service output fields that can be defined in the Output tab of the transform.

Field	Description
Confidence_Score	The percentage of certainty that the identified country is accurate. For example, a value of 100 is 100% certainty.
Country_ID_Info_Code	The Country ID info code when the Country ID transform cannot determine a country. *1010*: Indicates a tie in identifying the country. *1005*: Indicates that no country was identified.
Country_Name	The identified country name.
ISO_Country_Code_2Char	The 2-character ISO code for the identified country.
ISO_Country_Code_3Char	The 3-character ISO code for the identified country.
ISO_Country_Code_3Digit	The 3-digit ISO code for the identified country.
ISO_Script_Code	The 4-character script code to use for the identified country, such as LATN or KANA.

Related Information

Input Fields [page 1147]

3.5.4.7 Data Cleanse

Use the Data Cleanse transform to parse and format custom or person and firm data as well as phone numbers, dates, e-mail addresses, and Social Security numbers. Custom data includes operational or product data specific to your business.

> Note
>
> The Social Security number algorithm is no longer updated by the Social Security Administration. The SSN validation performed in Data Cleanse is based on data through July, 2011. The Social Security data is built into the cleansing package.

The cleansing package you specify defines how your data should be parsed and standardized.

Within a data flow, the Data Cleanse transform is typically placed after the address cleansing process and before the matching process.

3.5.4.7.1 Content objects

Transform configurations

A transform configuration is a transform with preconfigured input fields, output fields, and options that can be used in multiple data flows. These are useful if you repeatedly use a transform with specific options and input and output fields.

When Data Services is installed, read-only transform configurations are provided for the Data Quality transforms.

You can use transform configurations in your data flows or as an example of a typical transform. After you place an instance of the transform configuration in a data flow, you can override these preset defaults. You can also create your own transform configuration, either by replicating an existing transform configuration or creating a new one.

Sample blueprints and other objects

We have created Data Quality blueprints and other content objects to help you set up Data Services jobs. We've identified a number of common scenarios that you are likely to perform with Data Services. For each scenario, we've included a blueprint that is already set up to solve the business problem in that scenario.

Transform configurations [page 1123]

3.5.4.7.2 Data Cleanse options

The Data Cleanse transform includes options that control how person, firm, and custom data are parsed and standardized.

3.5.4.7.2.1 Common options

Option	Description
Run As Separate Process	*Yes:* Splits the transform into a separate process. *No:* Keeps the transform in the same process as the rest of the data flow.

3.5.4.7.2.2 Report and analysis

Use this option to generate report data for the Data Cleanse transform.

Option	Description
Generate Report Data	Specifies whether to generate report data for this transform. *Yes*: Generates report data for this transform. *No*: Turns off report data generation. If you do not need to generate reports (during testing, for example), you should set this option to *No* to improve performance.

3.5.4.7.2.3 Cleansing Package options

Controls the cleansing package options the Data Cleanse transform uses.

Option	Description
Cleansing Package Name	Selects the cleansing package that the Data Cleanse transform will use to parse data.

Option	Description
Content Domain Sequence	A content domain specifies which domain's properties should be assigned to a variation. You can specify more than one content domain. The Global domain is a special content domain which contains all variations and their associated properties. If a variation is not associated with domain-specific information the Global domain serves as the default domain. The Global domain is required for every content domain sequence. Be sure to add GLOBAL as the last domain in the sequence. ℹ Note You can set this option as a dynamic input field. Select the content domains you want to include. The arrows allow you to change the order of the content domains. GLOBAL - Global AR - Arabic ZH - Chinese CS - Czech DA - Danish NL - Dutch EN_US - English (United States & Canada) EN_GB - English (United Kingdom & Ireland) EN_AU - English (Australia & New Zealand) EN_IN - English (India) FR - French DE - German HU - Hungarian ID - Indonesian IT - Italian JA - Japanese MS - Malay NO - Norwegian PL - Polish PT_BR - Portuguese (Brazil) PT_PT - Portuguese (Portugal) RO - Romanian

Option	Description
	RU - Russian SK - Slovak ES_MX -Spanish (Latin America) ES_ES - Spanish (Spain) SV - Swedish
Output Format	Selects the format for output. Based on the specified domain in the output format, Data Cleanse uses certain output fields and formats the data in those fields according to the regional standards. Note You can set this option as a dynamic input field. Valid values for this option are: *AR* Arabic *ZH* Chinese *CS* Czech *DA* Danish *NL* Dutch *EN_US* English (United States & Canada) *EN_GB* English (United Kingdom & Ireland) *EN_AU* English (Australia & New Zealand) *EN_IN* English (India) *FR* French *DE* German *HU* Hungarian *ID* Indonesian *IT* Italian *JA* Japanese *MS* Malay *NO* Norwegian *PL* Polish *PT_BR* Portuguese (Brazil) *PT_PT* Portuguese (Portugal)

Option	Description
	RO Romanian *RU* Russian *SK* Slovak *ES_MX* Spanish (Latin America) *ES_ES* Spanish (Spain) *SV* Swedish

For more information, see the topics “About domains” and “About output format” in the *Information Steward User's Guide*.

3.5.4.7.2.4 Options

The Options group includes settings that control how the Data Cleanse transform parses and outputs data.

Option	Description
Filter Output Fields	Specifies which output fields are displayed in the Output tab. *Show_Relevant_Fields:* The fields available in the Output tab are based on the mapped input fields and the selected parser sequence multiline options. Includes all output fields that could possibly contain parsed data. The **`<Extra>`** fields are always available. *Show_All_Fields:* All Data Cleanse transform fields are available.

3.5.4.7.2.5 Input word breaker

Controls how the parser breaks input data.

Option	Description
Break on Whitespace Only	Specifies whether the Data Cleanse transform breaks input data only on white space or on white space, punctuation, alphanumeric transitions, and script transitions. *Yes:* Input data breaks only on white space. *No:* Input data breaks on white space, punctuation, alphanumeric transitions, and script transitions. For data in the CJK and Kana scripts, input data breaks on each character.

Option	Description
	This option allows the Data Cleanse transform to recognize alphanumeric product codes as entries in a custom cleansing package. For example, if *Break on Whitespace only* is set to no, the parser breaks a product code such as AF302 into two tokens, AF and 302. If *Break on Whitespace only* is set to yes, the parser recognizes AF302 as a single entry. Note This option typically applies to custom cleansing packages. The out of the box person and firm cleansing packages are designed to use the parsing strategy that breaks data on white space, punctuation, alphanumeric transitions, and script transitions.

3.5.4.7.2.6 Person standardization options

Controls how the Data Cleanse transform standardizes person-related output.

> Note
>
> The options in this group apply only to person and firm cleansing packages.

Option	Description
Assign Prenames	Specifies whether the transform should include assigned prenames (for example, Mr. or Mrs.) in the Prename output field. The Prename output field always includes prenames that are part of the name input data. Additionally, the Data Cleanse transform can assign prenames based on the gender of the name (strong_male or strong_female) in the Given_Name1 field. When the gender of Given_Name1 is not strong, prenames are assigned based on the settings for the *Gender Options* > *Use Given Name2 To Assign Gender* and *Gender Options* > *Use Family Name to Assign Gender* options. *Yes:* Turns on prename assignment. *No:* Turns off prename assignment. The Prename output field contains only prenames included in the input data
Associate Name Title	Defines how name and occupational title data found in separate input fields are associated. *Yes:* Data Cleanse assumes that the name and title data describe the same person and is associated. *No:* Data Cleanse assumes that the name and title data is not associated.

Option	Description
	For example, the diagram below shows the difference in the output based on the *Associate Name Title* setting.  Name_Line1: Thomas Jones Name_Line2: Manager Person1_Person:Thomas Jones Person1_Title: Manager Person2_Person: <Null> Person2_Title: <Null> Person1_Person: Thomas Jones Person1_Title: <Null> Person2_Person: <Null> Person2_Title: Manager
Combine Compound Names	Specifies how compound family names are standardized when the family name includes a Pre_Family_Name that is also a Pre_Family_Name_Combine. *Yes:* Combines compound family names. For example, the family name Mc Donald would combine to McDonald. *No:* Retains a space between the Pre_Family_Name and the family name. For example, the family name Mc Donald remains Mc Donald. Note This option has no impact on a Pre_Family_name that is not classified as a Pre_Family_Name_Combine. For example, the name Van Helsing will not be combined because "Van" is not classified with both PRE_FAMILY_NAME and PRE_FAMILY_NAME_COMBINE.
Enable Presumptive Name Parsing	Specifies whether you want to use presumptive name parsing on Name_Line input fields. *Yes:* Turns on presumptive name parsing. Data in the Name_Line input field is treated as a name. *No:* Turns off presumptive name parsing. Data in the Name_Line input field that does not parse as a name remains unparsed and is output to the Extra field. For example, if the data contains an automobile brand and model in a Name_Line input field, the Data Cleanse transform tries to parse the information as a name based on rules in the cleansing package. If the option is set to No and Data Cleanse is not able to assign the data, the unparsed data is output to the Extra field. If the option is set to Yes, Data Cleanse will assign the data as a name.
Name Order	Defines how Data Cleanse applies parsing rules to determine the content of the Given_Name and Family_Name output fields.

<table>
<tr><th>Option</th><th>Description</th></tr>
<tr><td></td><td><p><em>Given_Family_Name_Strict</em> and <em>Family_Given_Name_Strict</em>: These values specify the respective order of given and family names in the input file. Parsing rules that do not follow the strictly-defined name order are not considered when Data Cleanse determines which rule to apply to the input string.</p>
<p>These settings are useful when the order of the family and given names in the input data is consistent.</p>
<p><em>Given_Family_Name_Suggest</em> and <em>Family_Given_Name_Suggest</em>: These values specify which rule to choose in order to break a tie when two rules have the same confidence score. Data Cleanse chooses the rule that follows the suggested name order.</p>
<p><em>Unknown</em>: Data Cleanse chooses the rule with the highest confidence score based on information in the cleansing package. In the case of a tie, Data Cleanse chooses the first rule in the rule order.</p></td></tr>
<tr><td>Parse Discrete Input</td><td><p>Defines how to parse person data.</p>
<p><em>No</em>: discrete input fields are mapped directly to the corresponding output fields without being parsed.</p>
<p><em>Yes</em>: Discrete input fields are combined to one input field so the data can be parsed and output to discrete fields.</p>
<p>Example:</p>
<p>Table 156: Input data</p>
<table>
<tr><th>Column</th><th>Field</th></tr>
<tr><td>Person1_Given_Name1</td><td>Mr John T</td></tr>
<tr><td>Person1_Family_Name1</td><td>Smith Iii</td></tr>
</table>
<p>Table 157: Output data</p>
<table>
<tr><th>Column</th><th>Option=No</th><th>Option=Yes</th></tr>
<tr><td>Person1.Prename</td><td>&lt;blank&gt;</td><td>Mr</td></tr>
<tr><td>Person1.Given_Name1</td><td>Mr John T</td><td>John</td></tr>
<tr><td>Person1.Given_Name2</td><td>&lt;blank&gt;</td><td>T</td></tr>
<tr><td>Person1.Family_Name1</td><td>Smith Iii</td><td>Smith</td></tr>
<tr><td>Person1.Maturity_Postname</td><td>&lt;blank</td><td>III</td></tr>
</table></td></tr>
</table>

3.5.4.7.2.7 Gender standardization options

The gender standardization options control which input fields Data Cleanse uses to assign gender. These options are found in the *Gender Options* group under ▶ *Options* ▸ *Standardization Options* ▸ *Person* ◢.

ℹ Note

The options in this group apply only to person and firm cleansing packages.

Option	Description
Use Given Name2 To Assign Gender (Gender Options)	When the gender of the prename and Given_Name1 are unassigned or ambiguous, assigns gender based on the gender of the parsed Given_Name2. *Yes:* Turns on the option. *No:* Turns off the option. For example, if the option is set to No, the gender of the name Pat Robert Smith is ambiguous because the Given_Name1, Pat, is ambiguous. However, if the option is set to Yes, the gender is Strong_Male because the Given_Name2, Robert, is Strong_Male. The same logic applies if the name were P. Robert Smith; the Given_Name1, P, is ambiguous.
Use Family Name To Assign Gender (Gender Options)	When the gender of the prename, Given_Name1, and Given_Name2 are unassigned or ambiguous, assigns gender based on the gender of the family name. Uses Family_Name1 if gender is assigned and is not ambiguous. Uses Family_Name2 if unable to use Family_Name1. *Yes:* Turns on the option. *No:* Turns off the option. For example, if the option is set to No, the gender of the name N. Albiantsev is ambiguous because the Given_Name1, N., is ambiguous. However, if the option is set to Yes, the gender is Strong_Male because the Family_Name1, Albiantsev is Strong_Male.

3.5.4.7.2.8 Firm standardization options

The firm standardization options control how the Data Cleanse transform standardizes firm-related output.

ℹ Note

The options in this group apply only to person and firm cleansing packages.

Option	Description
Enable Presumptive Firm Parsing	Specifies whether you want to use presumptive firm parsing on Firm_Line input fields. *Yes*: Turns on presumptive firm parsing. Data in the Firm_Line input field is treated as a firm name. *No*: Turns off presumptive firm parsing. Data in the Firm_Line input field that does not parse as a firm remains unparsed and is output to the Extra field.

Option	Description
	For example, if the data has a given name and family name in a Firm_Line input field, the Data Cleanse transform tries to parse the information as a firm based on rules in the cleansing package. If the option is set to No and Data Cleanse is not able to assign the data, the unparsed data is output to the Extra field. If the option is set to Yes, Data Cleanse will assign the data as a firm.

3.5.4.7.2.9 Other standardization options

Standardization options control how the Data Cleanse transform standardizes many types of output.

Option	Description
Capitalization	Specifies the casing of your output. *Lower*: Converts the output to lowercase. For example, john mckay. *Mixed*: Preserves the casing for the standard form as defined within the cleansing package. If a standard form is not defined, the output is converted to mixed case. For example, if the standard form is defined as John Mckay, that would be preserved. If a standard form is not defined, the output is converted to mixed case, John McKay. *Preserve*: Preserves the input casing. *Upper*: Converts the output to uppercase. For example, JOHN MCKAY.
Character Width Style	Specifies the character width used in output fields. Useful when processing Japanese or mixed language data. *Normal_Width*: Output field width reflects the normalized character width based on the script type. Thus some output columns contain half-width characters and other columns contain full-width characters. For example, all full-width Latin characters are standardized to their half-width forms and all half-width katakana characters are standardized to their full-width forms. Normal_Width does not require special processing and therefore is the most efficient setting. *Full-width*: Characters are converted from their half-width forms to full-width forms for all output fields. For characters that do not have full-width forms, the half-width forms are used. *Half-width*: Characters are converted from their full-width forms to half-width forms for all output fields. For characters that do not have half-width forms, the full-width forms are used.

Option	Description
	ℹ Note Since the output width is based on the normalized width for the character type, the output data may be larger than the input data. You may need to increase the column width in the target table. For template tables, selecting the *Use NVARCHAR for VARCHAR columns in supported databases* box changes the VARCHAR column type to NVARCHAR and allows for increased data size.
North American Phone Delimiter	Specifies a character to use as a delimiter for phone output following the North American Numbering Plan (NANP). *Backslash (\)*: Uses backward slashes as the delimiter in the phone number. For example, 123\656\5000. *Dash (-)*: Uses dashes as the delimiter in the phone number. For example, 123-656-5000. *Slash (/)*: Uses forward slashes as the delimiter in the phone number. For example, 123/656/5000. *None*: Does not add a delimiter to the phone number. For example, 1236565000. *Period (.)*: Uses periods as the delimiter in the phone number. For example, 123.656.5000. *Space*: Uses spaces as the delimiter in the phone number. For example, 123 656 5000.
North American Phone Delimiter After Area	Specifies placement of a delimiter between the area code and prefix phone output following the North American Numbering Plan (NANP). To use this option, you must also specify a delimiter in the North American Phone Delimiter option. *Yes*: Adds a delimiter. For example, 123-656-5000. *No*: Does not add a delimiter. For example, 123 656-5000.
North American Phone Parens Area	Controls placement of parentheses () around the area code of phone number output following the North American Numbering Plan (NANP). *Yes*: Includes the parentheses. For example, (123) 656-5000. *No*: Omits the parentheses. For example, 123 656-5000.
One-to-one mapping	Specifies whether to place the input data into the corresponding output field for the following parsers: Phone, Email, Date. *Yes*: Places the parsed data into the corresponding output field. For example, if on input Date1 and Date2 are blank and Date3 contains data, then on output, Date1 and Date2 are blank and the data is placed in Date3.

Option	Description
	No: Places the parsed data into the first available output field in the category. For example, if on input Date1 and Date2 are blank and Date3 contains data, then on output, Date1 contains the parsed data that was input in the Date3 field.
Phone Extension Text	Specifies the standard text for a phone extension. For example, Ext.
Remove Diacritical Characters	Removes diacritical characters and replaces it with the ASCII equivalent. *Yes*: Replaces diacritical characters such as accent marks, umlauts, and so on with the ASCII equivalent. *No*: Retains the standardized diacritical characters. For example, when the option is set to *No*, the data is output with accent marks such as `María Hernández` or `Geschäftsführer`. When the option is set to *Yes*, the data is output without accent marks such as `Maria Hernandez` or `Geschaeftsfuehrer`.
Remove Punctuation	Removes all punctuation from standardized data (with the exception of hyphens between names). *Yes*: Removes punctuation. *No*: Leaves the punctuation as is on input. For example, if the standard form for extra large is X.L. and the option is set to Yes, the standardized output becomes XL.
SSN Delimiter	Specifies which character to use for standard U.S. Social Security number (SSN) output delimiters. *Backslash (\)*: Uses backward slashes as the delimiter in the SSN. For example, 799\45\6789. *Dash (-)*: Uses dashes as the delimiter in the SSN. For example, 799-45-6789. *Slash (/)*: Uses forward slashes as the delimiter in the SSN. For example, 799/45/6789. *None*: Does not add a delimiter to the SSN. For example, 799456789. *Period (.)*: Uses periods as the delimiter in the SSN. For example, 799.45.6789. *Space*: Uses spaces as the delimiter in the SSN. For example, 799 45 6789.

3.5.4.7.2.10 Date options

Configures standards for date-related data.

Option group	Description
Century Threshold	Indicates whether a two-digit date is considered part of the 20th or 21st century. The default value is 25. Specify a two-digit integer that represents the first year that a parsed two-digit year is considered part of the 21st century (20xx). All two-digit years greater than the specified integer are considered part of the 20th century (19xx). For example, if you enter 11, all two-digit years 11 or lower are considered part of the 21st century. 08 is considered 2008. 11 is considered 2011. All two-digit years higher than 11 are considered part of the 20th century. 12 is considered 1912.
Date Delimiter	Specifies what character to use for standard date output delimiters. *Backslash (\)*: Uses backward slashes as the delimiter for the date. For example, 04\01\2010. *Dash (-)*: Uses dashes as the delimiter for the date. For example, 04-01-2010. *Slash (/)*: Uses forward slashes as the delimiter for the date. For example, 04/01/2010. *None*: Does not add a delimiter to the date. For example, 04012010 *Period (.)*: Uses periods as the delimiter for the date. For example, 04.01.2010. *Space*: Uses spaces as the delimiter for the date. For example, 04 01 2010. *Chinese_Japanese*: Uses the following Chinese/Japanese characters as delimiters: ● 月 always follows the month ● 日 always follows the day ● 年 always follows the year An example of Arabic numbers with Chinese/Japanese delimiters is: 04 月 01 日 2010 年 An example of Chinese/Japanese Numbers with Chinese/Japanese delimiters is: 四 月 一 日 二千零一 十 年
Date Format	Specifies how to standardize date output. YEAR_MONTH_DAY: For Example, 2012-08-16 YEAR_DAY_MONTH: For Example, 2012-16-08 MONTH_DAY_YEAR: For Example, 08-16-2012 DAY_MONTH_YEAR: For Example, 16-08-2012
Enable Zero Pad	Specifies placement of a zero on the front of one-digit days and months. For example, July 4 could be 04-07 (or 07-04) with a zero pad, and 4-7 (or 7-4) without a zero pad. *Yes*: Turns on the option. *No*: Turns off the option.

Option group	Description
Input Month Before Day	Specifies whether the date follows the pattern of having the month first or the day first in the input. *Yes:* The month is first. For example, 11/12/2004 would be November 12, 2004. *No:* The day is first. For example, 11/12/2004 would be December 11, 2004.
Input Year First	Specifies whether the date follows the pattern of having the year first in the input. *Yes*: The year is first. For example, if your input is 03/02/04, the transform will convert it to 2003 February 4. *No*: The month is first. For example, 03/02/04 would be March 2, 2004.
Month Format	Specifies how to standardize date and month components. *Full_Text*: Standardizes output with spelled-out months. The language of the month is based on the domain selected in the Output Format option. For example, if one of the English domains is selected, the full-text month would be January, February, March, and so on. *Numeric*: Standardizes output with numeric months (for example, 03). *Short_Text*: Standardizes output with abbreviated months. The language of the month is based on the domain selected in the Output Format option. For example, if one of the English domains is selected, the short-text month would be Jan., Feb., Mar., and so on.
Numeric Format	Specifies the format of numeric date values *Arabic_Numbers*: Returns numeric date values in Arabic *Chinese_Japanese_Numbers*: Returns numeric date values in Chinese or Japanese.
Year Format	Specifies how to standardize date and year components. *Full:* Standardizes output with four-digit years (for example, 2004). *Short:* Standardizes output with two-digit years (for example, 04).

3.5.4.7.2.11 Parser configuration

Controls which parsing engines Data Cleanse uses for parsing multiline fields and the order in which they are applied. If a particular parser is not included, Data Cleanse does not look for that type of data in the input field.

Option	Description
Parser Sequence Multiline1-12	*Custom Parser:* Parses custom operational or product data for the category in the specified custom cleansing package. *Date:* Parses data as a date. *Email:* Parses data as an e-mail address.

Option	Description
	Firm: Parses data as firm name. *Person:* Parses data as a personal name *Person or Firm:* Parses data as a personal or firm name. *Phone:* Parses data as phone numbers. Any non-North American numbers are parsed first and can be output to the Phone and International_Phone fields. North American numbers are parsed later using thing North American Numbering Plan (NANP). The data can be output to Phone and North_American_Phone output fields. Phone number patterns that do not follow the NANP must be defined in Cleansing Package Builder. *SSN:* Parses data as a U.S. Social Security number. *UDPM:* Parses data using user-defined patterns created in Cleansing Package Builder.

3.5.4.7.2.12 Memory cache

To improve performance, you can set the cache in kilobytes (KB) to allocate a certain amount of memory for use in the Data Cleanse transform. For example, if you have a 39 MB cleansing package, you can set the cache size to 40000 KB and use the rest of available memory for processing other transforms. Likewise, if your cleansing package is larger, you can increase the value.

Option	Description
Memory in KB for Cache	(Optional) Enter a value of memory to allocate per thread for processing the Data Cleanse transform. Setting this option to `0` indicates that the internal default value (65536) should be used.

3.5.4.7.3 Input fields

The following are recognized input fields that you can use in the input mapping for the Data Cleanse transform. The fields are listed alphabetically.

Name	Description
Date1-6	Date. For example, 08/16/2004.
Email1-6	E-mail address.
Firm_Line1-2	Firm name, firm location, or both.
Firm_Location1-2	Location within a company or organization, such as a department, mail stop, room, or building.
Firm_Name1-2	Name of a company or organization.

Name	Description
Multiline1-12	Multiline data. Item types from this input are parsed in the order set in the Parser Sequence Multiline option, including parsers from custom cleansing packages.
Name_Line1-6	Whole name or names. May include job title.
Name_Or_Firm_Line1-6	Name of a person or organization.
Option_Country Option_Language Option_Region	The content domain sequence and output format usually can be automatically generated based on the Option_Country data. However, there are a few countries where Option_Language and Option_Region data is helpful to make the assignment, for example, Switzerland, Belgium, and Canada. Using Option_Language and Option_Region is optional, and is only used to determine the most appropriate content domain and output format. These input fields should be mapped from the following Global Address Cleanse output fields in this order: ● ISO_Country_Code_2Char ● Language ● Region1 These three input fields work together to determine the Option_Content_Domain_Sequence and/or Option_Output_Format.
Option_Content_Domain_Sequence (Dynamic input field)	The content domain sequence. The valid predefined values are: AR, CS, DA, DE, EN_AU, EN_GB, EN_IN, EN_US, ES_MX, ES_ES, FR, HU, ID, IT, JA, MS, NL, NO, PL, PT_BR, PT_PT, RO, RU, SK, SV, ZH, and GLOBAL.
Option_Output_Format (Dynamic input field)	The format for output specified as an abbreviation of the domain. The valid predefined values are: AR, CS, DA, DE, EN_AU, EN_GB, EN_IN, EN_US, ES_MX, ES_ES, FR, HU, ID, IT, JA, MS, NL, NO, PL, PT_BR, PT_PT, RO, RU, SK, SV, and ZH.
Person1_Family_Name1 Person2_Family_Name1	Discrete family name (for example, Smith).
Person1_Family_Name2 Person2_Family_Name2	Second discrete family name. May be useful for cultures where people are known by both paternal and maternal family names. If your input data contains two family name fields, map the first to Person1_Family_Name1 and the second to Person1_Family_Name2.
Person1_Given_Name1-2	Discrete given names (for example, John or B.).

Name	Description
Person2_Given_Name1-2	
Person1_Honorary_Postname Person2_Honorary_Postname	Honorary postname indicating certification, academic degree, or affiliation, such as CPA.
Person1_Maturity_Postname Person2_Maturity_Postname	Maturity postname indicating heritage, such as Jr., Sr., III.
Person1_Prename Person2_Prename	Discrete prename, such as Mr., Mrs., Dr., or Lt. Col.
Person1_Title Person2_Title	Discrete job title, such as Software Engineer.
Phone1-6	Phone number. Data Cleanse will first try to parse the number as an international phone number. If that fails, it will try to parse it as a North American phone number.
SSN1-6	U.S. Social Security number.
Title_Line1-6	Job title (for example, Accountant).
UDPM1-4	Input field associated with patterns and rules defined in the User-defined type of Reference Data in Cleansing Package Builder. For example, CN244-56.

Related Information

Dynamic transform settings [page 1129]

3.5.4.7.4 Output fields

The following are recognized output fields that you can use in the output mapping for the Data Cleanse transform. By default, the Extra, Info_Code, and Status_Code fields are always available, additional output fields are displayed based on the mapped input fields and the selected parser sequence multiline options. Additionally, the Ignore field may be available.

You can use the *Filter Output Fields* option to display a complete list of output fields. The fields are listed alphabetically.

Generated field name	Content type	Description
Date	Date	A date that is parsed.
Date_Day	Date	The day that is parsed from the date.

Generated field name	Content type	Description
Date_Month	Date	The month that is parsed from the date.
Date_Year	Date	The year that is parsed from the date.
Dual_Name	None	Set of components resulting from one input field that contains two names separated by a connecting word such as "and" or "or." Example 1: Input: Terry and Kris Johnson Output: Terry Johnson and Kris Johnson Example 2: Input: Terry Johnson or Kris Adams Output: Terry Johnson or Kris Adams
Email	Email	An entire e-mail address.
Email_Domain_All	Email	The domain of the e-mail address. For example, sap.com.
Email_Domain_Fifth	Email	In an e-mail address with more than one domain listed, this field parses the fifth to last domain.
Email_Domain_Fourth	Email	In an e-mail address with more than one domain listed, this field parses the fourth to last domain.
Email_Domain_Host	Email	The host of the e-mail address (the first item listed after the @ symbol). For example, in "joex@sap.com", "sap" is returned.
Email_Domain_Second	Email	In an e-mail address with more than one domain listed, this field parses the second to last domain.
Email_Domain_Third	Email	In an e-mail address with more than one domain listed, this field parses the third to last domain.
Email_Domain_Top	Email	The last listed domain of the e-mail address. For example, .com.
Email_Is_ISP	Email	The email address is a known ISP (internet service provider) or email domain name listed in the email data type of Reference Data in Cleansing Package Builder.
Email_User	Email	The user name of the e-mail address. For example, in "joex@sap.com", "joex" is returned.

Generated field name	Content type	Description
Extra	None	Any data that is not parsed by any of the active parsers and thus Data Cleanse does not recognize the data as fitting one of the other output fields.
Family_Name1	Family_Name	Family name (for example, Smith).
Family_Name1_Match _Std1-6	Family_Name1_ Match_Std	The match standard for family names. This field is only used with cleansing packages that include name data in more than one script. The match standards include the name as it is written in alternate script types. For example, for a family name included in the Japanese dictionary in Kanji script, the match standards include Kana renditions of the name. If the dictionary does not have an alias entry, the output field is empty. Compare with Match_Family_Name.
Family_Name2	Family_Name 2	Second family name. May be used to output the paternal and maternal family names to separate fields.
Family_Name2_ Match_Std1-6	Family_Name2_ Match_Std	The match standard for second family names. This field is only used with cleansing packages that include name data in more than one script. The match standards include the name as it is written in alternate script types. For example, for a family name included in the Japanese dictionary in Kanji script, the match standards include Kana renditions of the name. If the dictionary does not have an alias entry, the output field is empty. Compare with Match_Family_Name.
Firm	Firm	The name of a company or organization.
Firm_Location	Firm_Location	A location within a company or organization, such as a department. For example, Mailstop.
Firm_Match_Std1-6	Firm_Match_Std	The match standard for firms. For example, HP is the match standard or alias for Hewlett Packard. If the cleansing package does not have an alias entry, the output field is empty.

Generated field name	Content type	Description
		Compare with Match_Firm.
Firm_Location_ Match_Std1-6	Firm_Location_ Match_Std	The match standard for firm locations. For example, MS is the match standard or alias for mailstop. If the dictionary does not have an alias entry, the output field is empty.
Gender	None	The gender description. The following output is available: *Ambiguous:* The name does not reliably indicate a gender. The name could be either male or female. For example, Pat. *Male_Strong:* High confidence that the person is male. That is, the name belongs to someone who is almost certainly a male. For example, John. *Male_Weak:* Some confidence that the person is male. That is, the name belongs to someone who is probably male. For example, Terry. *Female_Strong:* High confidence that the person is female. That is, the name belongs to someone who is almost certainly a female. For example, Mary. *Female_Weak:* Some confidence that the person is female. That is, the name belongs to someone who is probably a female. For example, Lynn. For dual names, the following output is also available: *Multi_Names_Ambiguous:* At least one of the names does not reliably indicate a gender. For example, Pat and John. *Multi_Names_Female:* Some or high confidence that both of the names belong to people who are female. For example, Mary and Lynn. *Multi_Names_Male:* Some or high confidence that both of the names belong to people who are male. For example, John and Terry. *Multi_Names_Mixed:* Some or high confidence that one of the names belongs to a person who is female, and the other name belongs to a

Generated field name	Content type	Description
		person who is male. For example, Lynn and John.
Gender_ID	None	A numeric value that corresponds to the gender description: *0:* Unassigned *1:* Male_Strong *2:* Male_Weak *3:* Ambiguous *4:* Female_Weak *5:* Female_Strong *6:* Multi_Names_Mixed *7:* Multi_Names_Male *8:* Multi_Names_Female *9:* Multi_Names_Ambiguous
Given_Name1	Given_Name	Given name (for example, Robert).
Given_Name1_ Match_Std1-6	Given_Name1_ Match_Std	The match standard for given names. For example, the application can tell you that Patrick and Patricia are potential matches for the given name Pat. Match standards can help you overcome two types of matching problems: alternate spellings (Catherine and Katherine) and nicknames (Pat and Patty). Compare with Match_Given_Name1.
Given_Name2	Given_Name2	Second given name.
Given_Name2_ Match_Std1-6	Given_Name2_ Match_Std	The match standard for second given names. For example, the application can tell you that Patrick and Patricia are potential matches for the given name Pat. Compare with Match_Given_Name2.
Honorary_Postname	Postname	Honorary postname indicating certification, academic degree, or affiliation. For example, CPA.
Honorary_Postname_Match_Std1-6	Postname_Match_Std	The match standard for an honorary postname. For example, M.B.A. is the match standard or alias for MBA.

Generated field name	Content type	Description
		If the dictionary does not have an alias entry, the output field is empty.
Info_Code	None	The code that identifies the rows that may require manual review because the data is suspect.
International_Phone	Phone	The entire international phone number, including extra items such as the country code.
International_Phone_ Country_Code	Phone	The country code of an international phone number.
International_Phone_ Country_Name	Phone	The name of the country of origin of an international phone number.
International_Phone_ Line	Phone	The portion of the international phone number that is not the country code or the city code.
International_Phone_ Locality_Code	Phone	The locality code of an international phone number.
Match_Family_Name	Family_Name1	The combined standardized form of Family-Name1 and FamilyName2 with a space between used in the Match transform during the comparison process. Data is output in uppercase, apostrophes are removed, and other punctuation is replaced with a single space. PreFamilyName data is removed. Compare with Family_Name1_Match_Std1-6 and Family_Name2_Match_Std1-6.
Match_Firm	Firm	A form of Firm that may be used in the Match transform during the comparison process. Data is output in uppercase, apostrophes are removed, other punctuation is replaced with a single space, and data that is extraneous for matching purposes is removed. This extraneous data includes business types such as Ltd. and GambH, and noise words such as The, And, and Of. Note Some words are classified to be removed from all domains, while others are language-specific and are classified to be removed in specific cultural domains. Compare with Firm_Match_Std1-6.

Generated field name	Content type	Description
Match_Given_Name1	Given_Name1	The standardized form of GivenName1 used in the Match transform during the comparison process. Data is output in uppercase, apostrophes are removed, and other punctuation is replaced with a single space. PreGivenName data is removed. Compare with Given_Name1_Match_Std1-6.
Match_Given_Name2	Given_Name2	The standardized form of GivenName2 used in the Match transform during the comparison process. Data is output in uppercase, apostrophes are removed, and other punctuation is replaced with a single space. PreGivenName data is removed. Compare with Given_Name2_Match_Std1-6.
Match_Maturity_Postname	Postname	The standardized form of MaturityPostname used in the Match transform during the comparison process. Data is output in uppercase, apostrophes are removed, and other punctuation is replaced with a single space. Compare with Maturity_Postname_Match_Std1-6.
Match_Phone	Phone	The form of Phone used in the Match transform during the comparison process. Data is output as a string of digits. Spaces, punctuation, alphabetical characters, and leading zeros are removed.
Match_Prename	Prename	The standardized form of Prename used in the Match transform during the comparison process. Data is output in uppercase, apostrophes are removed, and other punctuation is replaced with a single space. Compare with Prename_Match_Std1-6.
Maturity_Postname	Postname	Maturity postname indicating heritage, such as Jr., Sr., III.
Maturity_Postname_Match_Std1-	Postname_Match_Std	The match standard for a maturity postname. For example, Sr. is a match standard or alias for Senior. If the cleansing package does not have an alias entry, the output field is empty.
Name_Connector	None	The connector component of a dual name. For example, and.

Generated field name	Content type	Description
Name_Designator	None	Name designator such as Attn: or c/o.
Name_Special	None	Term that generically describes a person. For example, occupant or current resident.
North_American _Phone	Phone	An entire North American Numbering Plan (NANP) phone number.
North_American _Phone_Area_Code	Phone	The area code parsed from the phone number.
North_American _Phone_Extension	Phone	An extension parsed from the phone number.
North_American _Phone_Line	Phone	The last four numbers (excluding an extension) parsed from a phone number. In (123) 456-7890, 7890 is returned.
North_American _Phone_Prefix	Phone	The middle three numbers parsed from a phone number. In (123) 456-7890, 456 is returned.
North_American _Phone_Type	Phone	The type of phone number that was parsed, if it is included with the input. For example, Home or Work.
Person	None	Set of components that define a single person. For example, Thomas Williams-Doyle Sr., M.D.
Phone	Phone	Shows the phone number that was identified as either North American or International.
Prename	Prename	Prename (for example, Mr.).
Prename_Match_Std1-6	Prename_Match_Std	The match standard for a prename. For example, Mr. is the match standard or alias for Mister. If the cleansing package does not have an alias entry, the output field is empty. Compare with Match_Prename.
Rule_Label	None	Retrieves the rule that parsed the indicated item.
Score	None	Retrieves the confidence score for a parsed item.
SSN	SSN	The entire Social Security number.
SSN_Area	SSN	The first three numbers of the Social Security number.
SSN_Group	SSN	The fourth and fifth numbers within a Social Security number.

Generated field name	Content type	Description
SSN_Serial	SSN	The last four numbers in a Social Security number.
Status_Code	None	The code describing how the data was standardized when the job is set for standardization, or how the data could be standardized when the job settings are not set for standardization.
Title	Title	Job or occupational title of a person. For example, Manager.
Title_Match_Std1-6	Title_Match_Std	The match standard for title. For example, CFO is the match standard or alias for Chief Financial Officer. If the dictionary does not have an alias entry, the output field is empty.
UDPM	None	Attribute field defined in User-defined pattern rules in Cleansing Package Builder Reference Data.
UDPM_ Subcomponent1-5	None	Subcomponents of the UDPM attribute field defined in a User-defined pattern rule.

3.5.4.8 DSF2® Walk Sequencer

To add walk sequence information to your data, include the DSF2 Walk Sequencer transform in your data flow. You can then send your data through presorting software to qualify for the following walk-sequence discounts:

- Carrier Route
- Walk Sequence
- 90% Residential Saturation
- 75% Total Active Saturation

DSF2 walk sequencing is often called "pseudo" sequencing because it mimics USPS walk sequencing. Where USPS walk-sequence numbers cover every address, DSF2 walk sequence processing provides "pseudo" sequence numbers for the addresses only in that particular file.

The software uses DSF2 data to assign sequence numbers for all addresses that are DPV-confirmed delivery points (DPV_Status contains “Y”, “S”, or “D”).

Other addresses present in your output file that are not valid DPV-confirmed delivery points will be blank or contain "0000" in the Walk_Sequence_Number output field. For example, if addresses have a DPV_Status of “N”, the walk sequence number is “0000”. If DPV_Status is blank, the walk sequence number field is blank.

i Note

Before processing your data with the DSF2 Walk Sequencer transform, you must first process it through CASS-certified software. This can be accomplished by processing data first with the USA Regulatory Address Cleanse transform with CASS certification enabled. The output from that processing can then be used as input for the DSF2 Walk Sequencer transform.

To help set up Data Services jobs, you can use Data Quality blueprints and other content objects, including several blueprints to run DSF2 certifications. These blueprints are located in **<LINK_DIR>**`\DataQuality\Certifications`.

3.5.4.8.1 Common

Option	Description
Run as Separate Process	*Yes*: Splits the transform into a separate process. *No*: Keeps the transform in the same process as the rest of the data flow.

3.5.4.8.2 Reference Files

Enter the path to the Delivery Statistics directory file (Delstats). It is best to use the substitution variable $ $RefFilesAddressCleanse for the Option Value. The substitution parameter represents the path, and you can change it dynamically.

ption	Description
Delstats Directory	`dsf.dir` Type the path and file name of the delivery statistics directory, or use the substitution variable $ $RefFilesAddressCleanse. SAP provides this file with the U.S. National Directory delivery. The Delivery Statistics directory file provides counts of business and residential addresses per Postcode1(ZIP Code), per Sortcode route (carrier route).

3.5.4.8.3 Processing Options

Option	Description
Site Location	Indicates at which site the current job was processed (if your company has multiple locations that provide DSF2 walk sequence processing). Enter the name of your company's location where the DSF2 walk sequence processing is performed for this job. Use the substitution variable $$DSF2SiteLocation if the site location doesn't change often.
USPS Certification Testing Mode	Specifies the type of certification you are performing for DSF2 walk sequence if applicable: *None:* Not performing any DSF2 walk sequence certifications (this is the default setting). Choose this option if you are processing a job that will not be submitted to the USPS for DSF2 certification. *Invoice:* Performing certification for DSF2 walk sequence invoice certification. For invoice certification, you are certifying that the software assigns walk sequence numbers correctly, and creates the Delivery Sequence Invoice report. *Sequence:* Performing certification for DSF2 sequence certification. For sequence certification, you are certifying that the software assigns walk sequence numbers correctly, creates the Delivery Sequence Invoice report, and creates the SEQ log file.

3.5.4.8.4 USPS License Information

The USPS License Information options in the DSF2 Walk Sequencer transform are required:

Option	Description
DSF2 License ID	Enter your DSF2 identification number, as the USPS assigned it to you. You can use the substitution variable $ $DSF2LicenseeID.
Licensee Name	Enter the name of the DSF2 licensed service provider. You can use the substitution variable $$USPSLicenseeName.
List ID	Enter the unique 6-digit identification code that you (the DSF2 licensee) assigned to the customer who owns the list.

3.5.4.8.5 Data Collection Config

The settings in this group of options control the break key formation. The break key optimizes your data flow by sorting your data to form collections of input records that have the same Postcode1 and Sortcode_Route field values.

Option	Description
Replace Null With Space	Specifies whether to convert NULL values to blank spaces in the break key fields. Eliminating NULL values helps to standardize data in the field so that break groups are formed properly and are consistent in size. *Yes*: Convert NULL to blank spaces. *No*: Do not convert NULL to blank spaces.
Right Pad With Spaces	Specifies whether to right pad the break key field with spaces. Because the break key is used for sorting and aggregating, it is sensitive to the position in which data is placed. By right-padding the break key fields you can help ensure that break groups are formed properly and are consistent in size. *Yes*: Right-pad fields with blank spaces. *No*: Do not right-pad fields with blank spaces. ➜ Tip If the *Replace NULL with space* option is set to *Yes* and the *Right pad with spaces* option is set to *Yes*, then fields with NULL values will be replaced with all spaces on the right (to the length of the field).
Presorted Data	Specifies whether the input data has been presorted or not. To make your input data more consistent, it is best to have the software sort data by the break key fields (Postcode1 and Sortcode_Route). *Yes*: The input data has already been presorted by Postcode1 and Sortcode_Route. *No*: The input data has not been sorted yet. ➜ Tip Choosing *No* allows the software to sort your data by Postcode1 and Sortcode_Route. This is the preferred setting for this option.

3.5.4.8.6 Input fields

Field	Description
Delivery_Point	The two-digit DPBC code.
DPV_Status	The DPV status component that is generated for this record. *D:* The primary range is a confirmed delivery point, but the secondary range was not available on input. *L:* The address triggered DPV locking. *N:* The address is not a valid delivery point. The Walk_Sequence_Number output field is 0000. *S:* The primary range is a valid delivery point, but the parsed secondary range is not valid in the DPV directory. *Y:* The address is a confirmed delivery point. The primary range and secondary range (if present) are valid. **`<blank>`**: A blank output value indicates that Enable DPV is set to No, DPV processing is currently locked, or the transform cannot assign the input address. The Walk_Sequence_Number output field is blank.
DSF2_Business_Indicator (optional)	Residential/business indicator. You may use this information to lower your parcel-shipping costs. (Some parcel delivery services charge more for delivery to residential addresses.) *Y:* Business address. *N:* Not a business address. **`<blank>`**: Address was not looked up.
LOT	The Line-of-Travel number.
LOT_Order	The Line-of-Travel sortation: *A:* Ascending *D:* Descending LOT codes are required for non-automated, CART presorting in Standard Mail, Enhanced Carrier Route Subclass.
Postcode1	The five-digit primary ZIP Code. It does not include the four digit ZIP4 Code.
Postcode2	The four-digit ZIP4 code. On a mail piece, this code follows the primary postal code with a hyphen placed between, for example, 54601-1234.
Sortcode_Route	The four-digit carrier route number.

3.5.4.8.7 Output fields

The software outputs walk-sequence number information to the fields listed in the table below.

Field	Description
Active_Del_Discount	Indicates whether the postcode1/sortcode route combination qualifies for the 75% total active deliveries discount. *Y:* The postcode1/sortcode route combination qualifies for the 75% total active deliveries discount. *N:* The postcode1/sortcode route combination does not qualify for the 75% total active deliveries discount. `<blank>`: The record was not sequenced. Tip Active deliveries include residential, business, and PO Box addresses.
Residential_Sat_Discount	Indicates whether the postcode1/sortcode route combination qualifies for the 90% residential saturation discount. *Y:* The postcode1/sortcode route combination qualifies for the 90% residential saturation discount. *N:* The postcode1/sortcode route combination does not qualify for the 90% residential saturation discount. `<blank>`: The record was not sequenced.
Sortcode_Route_Discount	Indicates whether the postcode1/sortcode route combination qualifies for the Sortcode (Carrier Route) discount. *Y:* The postcode1/sortcode route combination qualifies for the Sortcode discount. *N:* The postcode1/sortcode route combination does not qualify for the Sortcode discount. `<blank>`: The record was not sequenced. Tip Mailers must have 10 or more deliveries to the same postcode1/ sortcode combination to qualify for the discount.
Walk_Sequence_Discount	Indicates whether the postcode1/sortcode route combination qualifies for the walk sequence discount.

Field	Description
	Y: The postcode1/sortcode route combination qualifies for the walk sequence discount *N:* The postcode1/sortcode route combination does not qualify for the walk sequence discount. `<blank>`: The record was not sequenced. ➜ Tip Mailers must have 125 or more sequenced delivery points for each postcode1/sortcode route combination to qualify for the discount.
Walk_Sequence_Number	Indicates the sequence number from 0000 to 9999. i Note If Postcode2 field is blank, this field is blank. i Note If Postcode2 field is not blank and *DPV_Status* is *N*, then the field contains 0000.

3.5.4.9 Geocoder

How the Geocoder transform works

The Geocoder transform uses geographic coordinates expressed as latitude and longitude, addresses, and point-of-interest (POI) data. Using the transform, you can append addresses, latitude and longitude, census data (US only), and other information to your data.

Based on mapped input fields, the Geocoder transform has three modes of geocode processing:

- *Address geocoding*: The Geocoder transform assigns geographic data. Based on the completeness of the input address data, the Geocoder transform can return multiple levels of latitude and longitude data. Appending different levels of latitude and longitude information to your data may help your organization to target certain population sizes and other regional geographical data.
- *Reverse geocoding*: The Geocoder transform identifies the closest address or point of interest based on an input reference location

- *POI textual search*: The Geocoder transform uses address fields and POI name or type fields as search criteria to match with points of interest. The results are output in the Result_List XML output field.

Typically, the Geocoder transform is used in conjunction with the Global Address Cleanse or USA Regulatory Address Cleanse transform.

3.5.4.9.1 Content objects

Transform configurations

A transform configuration is a transform with preconfigured input fields, output fields, and options that can be used in multiple data flows. These are useful if you repeatedly use a transform with specific options and input and output fields.

When Data Services is installed, read-only transform configurations are provided for the Data Quality transforms.

You can use transform configurations in your data flows or as an example of a typical transform. After you place an instance of the transform configuration in a data flow, you can override these preset defaults. You can also create your own transform configuration, either by replicating an existing transform configuration or creating a new one.

Sample blueprints and other objects

We have created Data Quality blueprints and other content objects to help you set up Data Services jobs. We've identified a number of common scenarios that you are likely to perform with Data Services. For each scenario, we've included a blueprint that is already set up to solve the business problem in that scenario.

Related Information

Transform configurations [page 1123]

3.5.4.9.2 Geocoder options

The Geocoder transform includes options that control how geocoding data is appended to your data.

3.5.4.9.2.1 Common options

Option	Description
Run As Separate Process	*Yes:* Splits the transform into a separate process. *No:* Keeps the transform in the same process as the rest of the data flow.

3.5.4.9.2.2 Report and analysis

Use this option to generate report data for the Geocoder transform.

Option	Description
Generate Report Data	Specifies whether to generate report data for this transform. *Yes:* Generates report data for this transform. *No:* Turns off report data generation. If you do not need to generate reports (during testing, for example), you should set this option to *No* to improve performance. i Note This option is only available for the address geocoding mode. In the reverse geocoding and POI textual search modes, if you set the value to Yes, you will get a warning and no report is generated.

Related Information

Management Console Guide: Geocoder Summary report [page 2021]

3.5.4.9.2.3 Geocoder options

Specifies the assignment levels and other options. This option group is required.

All countries are supported.

Supported directory formats:

- *Basic*: Supports the address geocoding mode. It returns centroid-level and address-level latitude and longitude information.
- *Advanced*: Supports the address geocoding, reverse geocoding, and POI textual search modes. It returns range-based and centroid-level latitude and longitude information and point-of-interest information.

Option	Description	Supported directory format
Best Assignment Level	Specifies the depth of assignment for the latitude and longitude output fields. This option is used for address geocoding mode, and also for reverse geocoding with address mode. *Preferred:* Assigns to the finest depth. By default, this assigns to the primary number level. *Primary Number:* Assigns to the primary number level. *Postcode:* Assigns to the postcode level. *Locality:* Assigns to the locality, city, or suburb level. *Smallest Area:* The software first attempts to assign to the primary number. If the primary number is not returned, then it assigns based on postcode or locality, depending on which level is the smaller area. The Geocoder transforms compares the locality data to the postcode data, and then assigns to the level based on the smallest area. For example, the French postcode 75014 is a smaller area than the locality of Paris. Note For the Preferred, Primary Number, and Smallest Area values, if the Locality Assignment Threshold or Postcode Assignment Threshold option is not set to None, it will do locality or postcode centroid assignment.	Basic, Advanced
Distance Unit	Specifies the unit of distance used for the radius. *Kilometers* *Miles* The value of the Option_Distance_Unit input field takes precedence over the value of the Distance Unit option. The value of the Distance Unit option is only used if the Option_Distance_Unit input field is not mapped or is invalid, blank, or NULL.	Advanced
Locality Assignment Threshold	Limits the level of locality centroid assignment. For example, setting the option to Locality1 excludes Locality2–4 during assignment, even though the software may return values at those levels. However, if you set the option to Locality4 and there is no Locality4 data, the finest available data is returned, even if that is a Locality2 level.	Basic, Advanced

<table>
<tr><th>Option</th><th>Description</th><th>Supported directory format</th></tr>
<tr><td></td><td>This option is used for address geocoding mode, and also for reverse geocoding with address mode.

Locality1–4: Returns the locality level that you choose. Locality1 is the most general and Locality4 is the most specific.

<table><tr><th>Address</th><th>Locality level</th></tr><tr><td>Church Cottage</td><td>Locality3</td></tr><tr><td>Pemborough</td><td>Locality2</td></tr><tr><td>Bristol</td><td>Locality1</td></tr></table>
In this example, there is no Locality4. If you choose Locality4, the finest depth, Locality3, is returned.

None: Skips the specific assignment level. Use this setting if you do not want to return an assignment threshold on locality.

Preferred: Assigns to the finest depth at the locality level.</td><td></td></tr>
<tr><td>Max Records</td><td>Specifies the maximum number of records that can be returned. You can enter a number up to 100.

The value of the Option_Max_Records input field takes precedence over the value of the Max Records option. The value of the Max Records option is only used if the Option_Max_Records input field is not mapped or is blank.</td><td>Advanced</td></tr>
<tr><td>Offset Coordinates</td><td>Specifies whether the offset values of latitude and longitude are returned when the side of the street is known. This option is used for address geocoding mode, and also for reverse geocoding with address mode.

Yes: Returns the offset values.

No: Returns the center value regardless of whether the side of the street is known.</td><td>Advanced</td></tr>
<tr><td>Postcode Assignment Threshold</td><td>Limits the level of postcode centroid assignment. For example, setting the option to Postcode1 excludes the other levels during assignment, even though the application may return values at those levels.

This option is used for address geocoding mode, and also for reverse geocoding with address mode.

Postcode Full: Assigns to the entire extended postcode. For example, in the USA, it assigns to the 5-digit postcode and all four digits of the ZIP+4.

Postcode1: Assigns to the city or postcode area. For example, in the USA, it assigns to the 5-digit ZIP Code.</td><td>Basic, Advanced</td></tr>
</table>

Option	Description	Supported directory format
	Postcode2 Partial: Assigns to the first few characters of the extended postcode. For example, in the USA, it assigns the 5-digit postcode and the first two digits of the ZIP+4. *Preferred:* Assigns to the finest depth at the postcode level. *None:* Skips the specific assignment level. Use this setting if you do not want to return an assignment threshold on postcode.	
Radius	The distance from a specified reference point used to identify an area in which matching records are located. The value of the Option_Radius input field takes precedence over the value of the Radius option. The value of the Radius option is only used if the Option_Radius input field is not mapped or is blank. If a radius is not specified, a default radius of one kilometer is used. In reverse geocoding mode, the maximum radius distance is 111 kilometers or 68.97 miles.	Advanced

3.5.4.9.3 Reference files

Reference files are directory paths required by the Geocoder transform to process your data.

You can use a substitution variable for the directory location. The substitution variable for reference files is $ $RefFilesGeocoder. Use this substitution variable if you installed the directories in the path relative to where Data Services is installed; for example, **<INSTALL_DIR>**`\Data Services\DataQuality\reference_data`. If you installed to a different location, you can change the substitution variable while designing the work flow. For more information about variables, see the Variables and Parameters section in the *Data Services Designer Guide.*

You can duplicate this path by right-clicking and selecting *Duplicate option* to point to additional directory paths. However, you cannot have the same directory file located in both directories. In the *Directory Path* option, only specify the path. Do not specify the directory file names.

For information about downloading directories, see the latest directories update.

3.5.4.9.4 Geocoder fields

The Geocoder transform requires that you map fields on input and output. These mappings inform the transform how to process the data in the field.

Related Information

Input fields [page 1184]

Output fields [page 1186]
Result_List XML output fields [page 1192]
Information codes [page 1194]

3.5.4.9.4.1 Input fields

The following are recognized input fields that you can use in the input mapping for the Geocoder transform. The fields are listed alphabetically.

All countries are supported.

The table also shows the input field availability based on currently supported directory formats. Supported directory formats:

- *Basic*: Supports the address geocoding mode. It returns centroid-level and address-level latitude and longitude information.
- *Advanced*: Supports the address geocoding, reverse geocoding, and POI textual search modes. It returns range-based and centroid-level latitude and longitude information and point-of-interest information.

Input field name	Category	Description	Supported directory format
Country	Address	The two-character ISO country code.	Basic, Advanced
Latitude	Latitude/ Longitude	A relative distance north or south of the equator, measured in 0-90 degrees.	Advanced
Locality1–4	Address	The city, town, or suburb and any additional related information.	Basic, Advanced
Longitude	Latitude/ Longitude	A relative distance east or west of the Greenwich meridian, measured in 0-180 degrees.	Advanced
Option_Distance_Unit	Search Filter	The unit of distance used for the radius. Valid values are: *Kilometers* *Miles* The value of the Option_Distance_Unit input field takes precedence over the value of the Distance Unit option. The value of the Distance Unit option is only used if the Option_Distance_Unit input field is not mapped or is invalid, blank, or NULL. This setting is dynamic. If you change this setting, you do not have to terminate and reinitialize the transform in order for the new configuration to be recognized.	Advanced
Option_Max_Records	Max Records	The maximum number of records that can be returned. You can enter a number up to 100.	Advanced

Input field name	Category	Description	Supported directory format
		A value greater than 0 outputs multiple results as XML to the Result_List output field rather than to individual output fields. The value of the Option_Max_Records input field takes precedence over the value of the Max Records option. The value of the Max Records option is only used if the Option_Max_Records input field is not mapped or is blank or NULL. This setting is dynamic. If you change this setting, you do not have to terminate and reinitialize the transform in order for the new configuration to be recognized.	
Option_Radius	Search Filter	The distance from a specified reference point used to identify an area in which matching records are located. The value of the Option_Radius input field takes precedence over the value of the Radius option. The value of the Radius option is used only when the Option_Radius input field is not mapped or is blank or NULL. This setting is dynamic. If you change this setting, you do not have to terminate and reinitialize the transform in order for the new configuration to be recognized. In reverse geocoding mode, the maximum radius distance is 111 kilometers or 68.97 miles.	Advanced
POI_Name	Address POI	The name of a point of interest, such as the Washington Monument.	Advanced
POI_Type	Address POI	The point-of-interest type expressed as a number; for example, for one vendor 5999 is historical monument. In POI textual search mode, to return multiple point-of-interest types, concatenate POI type codes using a colon as a delimiter. For example, to return all schools (type 8211) and libraries (type 8231) within a defined area, you would enter: `8211:8231` The POI types and their corresponding codes differ depending on the data vendor that you use. For a detailed list of available POI types, see the vendor-specific directory update.	Advanced

Input field name	Category	Description	Supported directory format
Postcode1–2	Address	The postal code and a secondary postal code, if available.	Basic, Advanced
Primary_Name1–4	Address	The street name.	Basic, Advanced
Primary_Number	Address	The premise number.	Basic, Advanced
Primary_Postfix1	Address	Abbreviated directional (N, S, NW, SE) that follows a street name.	Basic, Advanced
Primary_Prefix1	Address	Abbreviated directional (N, S, NW, SE) that precedes a street name.	Basic, Advanced
Primary_Type1–4	Address	Abbreviated type of primary name (St., Ave., or Pl.).	Basic, Advanced
Region1–2	Address	The region symbol of the state, province, or territory.	Basic, Advanced
Search_Filter_Name	Search Filter	Search criteria for a point-of-interest name.	Advanced

Search_Filter_Type	Search Filter	Search criteria for a point-of-interest type, expressed as a four-digit number; for example, for one vendor 5999 is historical monument.
		If you want to return an address only, enter ADDR.
		To return multiple point-of-interest types, concatenate POI type codes using a colon as a delimiter. For example, to return all schools (type 8211) and libraries (type 8231) within a defined area, you would enter:
		`8211:8231`
		To return a point-of-interest type and its address, enter:
		`5999:ADDR`
		The POI types and their corresponding codes differ depending on the data vendor that you use. For a detailed list of available POI types, see the vendor-specific directory update.
			Advanced

3.5.4.9.4.2 Output fields

The following are recognized output fields that you can use in the output mapping for the Geocoder transform. The fields are listed alphabetically. The table also shows the output field availability based on currently supported countries and directory formats.

Supported countries:

- *All*: All countries
- *USA*

Supported directory formats:

- *Basic*: Supports the address geocoding mode. It returns centroid-level and address-level latitude and longitude information.
- *Advanced*: Supports the address geocoding, reverse geocoding, and POI textual search modes. It returns range-based and centroid-level latitude and longitude information and point-of-interest information.

Output field name	Category	Description	Supported countries	Supported directory format
Address_Line	Address	A line of data in an address that contains the primary address. The primary address can contain components such as the primary range, primary name, directionals (post- and pre-), and suffix.	All	Basic, Advanced
Assignment_Level	Assignment Level	The level to which the transform matches the address to the data in the reference fields (directories). *PRE:* Primary Range Exact assigns to the exact location of the address; for example, 123 Main St. This is the most precise level of assignment. To obtain the PRE, you must map either the POI_Type input field or the Primary_Name and Primary_Number input fields. *PRI:* Primary Range Interpolated assigns to the level of the address range; for example, 100-500 Main St. *L1–4:* Locality1–4 assigns to the level of city, town, or suburb. *P1:* Postcode1 assigns to the level of Postcode1. *P2P:* Postcode2 Partial assigns the full Postcode1 and the first few characters of Postcode2. *PF:* Postcode Full assigns to the level of Postcode1 and Postcode2, when available.	All	Basic, Advanced
Assignment_Level_Locality	Assignment Level	The level to which the transform assigns the locality.	All	Basic, Advanced

Output field name	Category	Description	Supported countries	Supported directory format
		L1–4: Returns up to four locality levels. L1 is the most general and L4 is the most specific.		
Assignment_Level_Postcode	Assignment Level	The level to which the transform assigns the postcode. *P1:* Postcode1 assigns to the level of Postcode1. *P2P:* Postcode2 Partial assigns the full Postcode1 and the first few characters of Postcode2. *PF:* Postcode Full assigns to the level of Postcode1 and Postcode2, when available.	All	Basic, Advanced
Census_Tract_Block	Census	The census tract code as defined by the government for reporting census information. Census tracts are small, relatively permanent statistical subdivisions of a county.	USA	Basic, Advanced
Census_Tract_Block_Prev	Census	The census tract code in the previous version of census data.	n/a	n/a
Census_Tract_Block_Group	Census	The census tract block group code as defined by the government for reporting census information. These codes are used for matching with demographic-coding databases. In the USA, the first six digits contain the tract number (for example, 002689); the next digit contains the block group (BG) number within the tract, and the last three digits contain the block code. The BG is a cluster of census blocks that have the same first digit within a census tract. For example, BG 6 includes all blocks numbered from 6000 to 6999.	USA	Basic, Advanced
Census_Tract_Block_Group_Prev	Census	The census tract block group code in the previous version of census data.	n/a	n/a
Country_Code	Address	The two-character ISO country code.	All	Basic, Advanced
Distance	Distance	The distance from the input address, geographical coordinates, or point of	All	Advanced

Output field name	Category	Description	Supported countries	Supported directory format
		interest to the closest address or point of interest.		
Gov_County_Code	Census	A unique county code as defined by the government for reporting census information. For example, in the USA, this is a Federal Information Processing Standard (FIPS) three-digit county code.	USA	Basic, Advanced
Gov_Locality1_Code	Census	A unique code for an incorporated municipality such as a city, town, or locality as defined by the government for reporting census information.	USA	Basic
Gov_Region1_Code	Census	A unique region code as defined by the government for reporting census information. For example, in the USA, this is a Federal Information Processing Standard (FIPS) two-digit state code.	USA	Basic, Advanced
Info_Code	Info Code	A three-character code that provides information about the geocoding results. The status for address and point-of-interest geocoding assignment is indicated in the third character. The status for reverse geocoding assignment is indicated in the second and third characters. If assigned to the best level, the Info_Code field is blank. The first character is not used at this time. For more information, see *Information codes* [page 1194].	All	Basic, Advanced
Latitude	Latitude/ Longitude	The latitude at the best assigned level (0–90 degrees north or south of the equator) in the format 45.32861.	All	Basic, Advanced
Latitude_Locality	Latitude/ Longitude	The latitude at the locality level centroid of the city, town, locality, or suburb in the format 45.32861.	All	Basic, Advanced
Latitude_Postcode	Latitude/ Longitude	The latitude at the postcode level centroid of the postcode in the format 45.32861.	All	Basic, Advanced

Output field name	Category	Description	Supported countries	Supported directory format
Latitude_Primary_Number	Latitude/ Longitude	The latitude at the primary number level centroid of the primary number in the format 45.32861.	All	Basic, Advanced
Locality1–4	Address	The city, town, or suburb and any additional related information.	All	Basic, Advanced
Longitude	Latitude/ Longitude	The longitude at the best assigned level (0–180 degrees east or west of Greenwich meridian) in the format 123.45833.	All	Basic, Advanced
Longitude_Locality	Latitude/ Longitude	The longitude at the locality level centroid of the city, town, locality, or suburb in the format 123.45833.	All	Basic, Advanced
Longitude_Postcode	Latitude/ Longitude	The longitude at the postcode level centroid of the postcode in the format 123.45833.	All	Basic, Advanced
Longitude_Primary_Number	Latitude/ Longitude	The longitude at the primary number level centroid of the primary number in the format 123.45833.	All	Basic, Advanced
Metro_ Stat_Area_Code	Census	The metropolitan statistical area. For example, in the USA, the 0000 code indicates the address does not lie in a metropolitan statistical area; usually a rural area. A metropolitan statistical area has a large population that has a high degree of social and economic integration with the core of the area. The area is defined by the government for reporting census information.	USA	Basic
Metro_ Stat_Area_Code_Prev	Census	The metropolitan statistical area in the previous version of census data.	n/a	n/a
Minor_Div_Code	Census	The minor civil division or census county division code when the minor civil division is not available. The minor civil division designates the primary government and/or administrative divisions of a county such as a civil township or precinct. Census county division are defined in a state or province that does not have a well-defined minor civil division. The area	USA	Basic, Advanced

Output field name	Category	Description	Supported countries	Supported directory format
		is defined by the government for reporting census information.		
Minor_Div_Code_Prev	Census	The minor civil division or census county division code in the previous version of census data.	n/a	n/a
POI_Name	Address POI	The point of interest name, such as the Washington Monument.	All	Advanced
POI_Type	Address POI	The point of interest type expressed as a four-digit number; for example, 5999 (historical monument).	All	Advanced
Population_Class_Locality1	Population	Indicates that the population falls within a certain size. *0:* Undefined. The population may be too large or small to provide accurate data. *1:* Over 1 million. *2:* 500,000 to 999,9999. *3:* 100,000 to 499,999. *4:* 50,000 to 99,999. *5:* 10,000 to 49,999. *6:* Less than 10,000.	All	Advanced
Postcode	Address	The postal code.	All	Basic, Advanced
Postcode1–2	Address	The postal code and a secondary postal code, if available.	All	Basic, Advanced
Primary_Name1–4	Address	The street name.	All	Basic, Advanced
Primary_Number	Address	The premise number.	All	Basic, Advanced
Primary_Postfix1	Address	Abbreviated directional (N, S, NW, SE) that follows a street name.	All	Basic, Advanced
Primary_Prefix1	Address	Abbreviated directional (N, S, NW, SE) that precedes a street name.	All	Basic, Advanced
Primary_Range_High	Address	The high value of a primary number range.	All	Basic, Advanced
Primary_Range_Low	Address	The low value of a primary number range.	All	Basic, Advanced

Output field name	Category	Description	Supported countries	Supported directory format
Primary_Type1–4	Address	Abbreviated type of primary name (St., Ave., or Pl.).	All	Basic, Advanced
Region1–2	Address	The region symbol of the state, province, or territory.	All	Basic, Advanced
Result_List	Results	The XML output when multiple records are returned for a search.	All	Advanced
Result_List_Count	Results	The number of results in the Result_List output field.	All	Advanced
Side_Of_Primary_Address	Side of Street	Indicates that the location is on the L (left) or R (right) side of the street when moving north, northeast, northwest, or east.	All	Advanced
Stat_Area_Code	Census	A core-based statistical area code where an area has a high degree of social and economic integration within the core that the area surrounds. The area is defined by the government for reporting census information.	USA	Basic
Stat_Area_Code_Prev	Census	The statistical area code in the previous version of census data.	n/a	n/a

Information codes [page 1194]

3.5.4.9.4.3 Result_List XML output fields

The following are recognized output fields that you can use in the Result_List XML output field in the Geocoder transform. The fields are listed alphabetically.

Output field name	Category	Description
Address_Line	Address	A line of data in an address that contains the primary address. The primary address can contain components such as the primary range, primary name, directionals (post- and pre-), and suffix.
Assignment_Level	Assignment Level	The level to which this transform matched the address to the data in the reference fields (directories).

Output field name	Category	Description
		PRE: Primary Range Exact assigns to the exact location of the address; for example, 123 Main St. This is the most precise level of assignment. To obtain the PRE, you must map either the POI_Type input field or the Primary_Name and Primary_Number input fields. *PRI:* Primary Range Interpolated assigns to the level of the address range; for example, 100-500 Main St. *L1–4:* Locality1-4 assigns to the level of city, town, or suburb. *P1:* Postcode1 assigns to the level of Postcode1. *P2P:* Postcode2 Partial assigns the full Postcode1 and the first few characters of Postcode2. *PF:* Postcode Full assigns to the level of Postcode1 and Postcode2, when available.
Country_Code	Address	The two-character ISO country code.
Distance	Distance	The distance from the input address, geographical coordinates, or point of interest to the closest address or point of interest.
Latitude	Latitude/Longitude	The latitude at the best assigned level (0–90 degrees north or south of the equator) in the format 45.32861.
Locality1–4	Address	The city, town, or suburb and any additional related information.
Longitude	Latitude/Longitude	The longitude at the best assigned level (0–180 degrees east or west of Greenwich meridian) in the format 123.45833.
POI_Name	Address POI	The point of interest name, such as the Washington Monument.
POI_Type	Address POI	The point of interest type expressed as a four-digit number; for example, 5999 (historical monument).
Postcode	Address	The postal code.
Postcode1–2	Address	The postal code and a secondary postal code, if available.
Primary_Name1–4	Address	The street name.
Primary_Number	Address	The premise number.
Primary_Postfix1	Address	Abbreviated directional (N, S, NW, SE) that follows a street name.
Primary_Prefix1	Address	Abbreviated directional (N, S, NW, SE) that precedes a street name.

Output field name	Category	Description
Primary_Range_High	Address	The high value of a primary number range.
Primary_Range_Low	Address	The low value of a primary number range.
Primary_Type1–4	Address	Abbreviated type of primary name (St., Ave., or Pl.).
Ranking	Ranking	A numeric value that indicates how well the returned records match the input field based on the match score. A record with a ranking of 1 has the highest match score.
Region1–2	Address	The region symbol of the state, province, or territory.

The following is an example for a result list that has one record:

```
<RESULT_LIST>
  <RECORD>
    <ADDRESS_LINE>332 FRONT ST</ADDRESS_LINE>
    <ASSIGNMENT_LEVEL>PRE</ASSIGNMENT_LEVEL>
    <COUNTRY_CODE>US</COUNTRY_CODE>
    <DISTANCE>0.3340</DISTANCE>
    <LATITUDE>43.811616</LATITUDE>
    <LOCALITY1>LA CROSSE</LOCALITY1>
    <LONGITUDE>-91.256695</LONGITUDE>
    <POI_NAME>ABC COMPANY</POI_NAME>
    <POI_TYPE>5800</POI_TYPE>
    <POSTCODE>56001-4023</POSTCODE>
    <POSTCODE1>56001</POSTCODE1>
    <POSTCODE2>4023</POSTCODE2>
    <PRIMARY_NAME1>FRONT</PRIMARY_NAME1>
    <PRIMARY_NUMBER>332</PRIMARY_NUMBER>
    <PRIMARY_TYPE1>ST</PRIMARY_TYPE1>
    <RANKING>1</RANKING>
    <REGION1>WI</REGION1>
  </RECORD>
</RESULT_LIST>
```

3.5.4.9.4.4 Information codes

The Info_Code output field is a three-character code that provides information about geocoding results.

The status for the address geocoding and POI textual search modes is indicated in the third character. The status for reverse geocoding is indicated in the second and third characters. If assigned to the best level, the Info_Code field is blank. The first character is not used at this time.

Use the following table to determine the code assigned to the Info_Code output field.

Information code	Description
1	Reference data is not available for the input country. Verify that the directory is installed and the reference path to the directory is valid.
2	Address-level reference data is not available for the input data. When Best Assignment Level is set to Primary Number and the address directory is unavailable or doesn't exist, this code is output.

Information code	Description
	Verify that the directory is installed and the reference path to the directory is valid.
3	Centroid-level reference data is not available for the input data. When the Best Assignment Level is set to Locality or Postcode, and the address directory is unavailable or doesn't exist, this code is output. Verify that the directory is installed and the reference path to the directory is valid.
4	Assignment is limited. The input data is insufficient or incorrect to match the reference data. When the Best Assignment Level fails, this code is output. The assignment may be made to a lower assignment level than the one specified. For example, if you set Best Assignment Level to Primary Number and the Primary Number field is blank, the assignment may be at the postcode or locality level, if the data is available. Verify your input data and input field mapping and make sure that the fields required for best assignment exist and are correctly mapped.
5	The input data does not match anything in the reference data. When the input record does not match the directory data for the Best Assignment Level or a lower assignment level, this code is output. Verify your input data and input field mapping and make sure that the fields required for best assignment exist and are correctly mapped.
6	The input data assigns ambiguously in the reference data. There is a tie for the Best Assignment Level. The input record matches several records in the directory data and the software cannot decide which one is the best. For example, if the reference data has two records: Record 1: 100 Main St La Crosse WI 54650 Record 2: 100 Main St Bt Micts WI 54650 When input with 100 Main ST WI 54650 without a locality name, the 006 information code for ambiguous assignment is output. Verify your input data and input field mapping and make sure that the fields required for best assignment exist and are correctly mapped.
7	The input data is blank or invalid. For example, if the US Postcode1 is a five-digit string and your input data is a six-digit string, the 007 information code is output. Verify your input data and input field mapping and make sure that the fields required for best assignment exist and are correctly mapped.
8	The input data is insufficient. When the input data for the selected Best Assignment Level is blank, this code is output. For example, this code is output when you set the Best Assignment Level to Primary Number and the input data is blank for Primary Number.
9	The POI type provided on input is invalid. The point-of-interest type is not correct.

Information code	Description
	Verify your input POI type with the POI types described in the appropriate directory update letter.
A	The POI input data was not used. The POI name or type does not match the directory data. A PRI or PRE level assignment was made; however, the input POI name and POI type were not used for the assignment.
B	The input data was not found. This code only occurs when an address is input during reverse geocoding assignment. The input address doesn't match the directory data and reverse geocoding cannot be performed based on the address.
C	Not all results returned for the input data, because the number of results exceeds the specified Max_Record. This code only occurs during reverse geocoding assignment. Increase the Max_Record value.
D	Not all results were returned for the input data, because the results exceed the field length available in the Result_List XML output field. This code only occurs during reverse geocoding assignment. The Geocoder transform allows a 60000 field length in the Result_List field.
E	The closest latitude and longitude to the input address is returned because the input house number does not exist in the geocoder directories. For example: Input address: 100 Main St La Crosse WI 54650 Directory data: 1-88 Main St La Crosse WI 54650 The software returns the latitude and longitude values for 88 Main St with the 00E information code to indicate that the house number does not match the directory data.

Related Information

Output fields [page 1186]

3.5.4.9.5 Directories

The Geocoder transform is flexible enough to accept new country directory data immediately after the directory data is released. There is no need to wait for the next SAP Data Services release to begin using new country directory data.

The Geocoder directories are designed specifically for use with the Geocoder transform. You must install the directories and point to them in the Reference Path. Your system administrator should have already installed these files to the appropriate locations.

If you start with the sample transform configuration, the reference path is completed with a substitution variable called $$RefFilesGeocoder. By default, this variable points to the reference data folder of the Data Services directory. You can change the location by editing the substitution variable. For more information about variables, see the “Variables and Parameters” section in the *Data Services Designer Guide.*

SAP offers two directory formats:

- *Basic*: Supports the address geocoding mode. It returns centroid-level and address-level latitude and longitude information.
- *Advanced*: Supports the address geocoding, reverse geocoding, and POI textual search modes. It returns a range-based and centroid-level latitude and longitude information and point-of-interest information

Directory updates

A quarterly vendor-specific directory update is available on the SAP Help Portal and is also included in each directory package. The directory update provides instructions for installing the directories and information about the directory contents. It describes the package names, files names, and the supported countries, directory format, geocoding mode, centroid level, and census information. It also lists the available POI types supported by the vendor.

3.5.4.10 Global Address Cleanse

The Global Address Cleanse transform identifies, parses, validates, and corrects global address data, such as primary number, primary name, primary type, directional, secondary identifier, secondary number, locality, region and postcode.

> Note
>
> The Global Address Cleanse transform does not support CASS certification or produce a USPS Form 3553. If you want to certify your U.S. address data, you must use the USA Regulatory Address Cleanse transform, which supports CASS.

If you perform both address cleansing and data cleansing, the Global Address Cleanse transform typically comes before the Data Cleanse transform in the data flow.

Sample transform configurations

The Global Address Cleanse transform has sample transform configurations that will help you to set up your data flow. The transforms include all of the required options except input fields.

Related Information

3.5.4.10.1 Global Address Cleanse transform options

3.5.4.10.1.1 Report And Analysis options

Choose to generate report data for the Global Address Cleanse transform.

Option	Description
Generate Report Data	Specifies whether to generate report data for this transform. *Yes*: Generates report data for this transform. *No*: Turns off report data generation. If you do not need to generate reports (during testing, for example), you should set this option to No to improve performance.

Related Information

Global Address Cleanse [page 1197]

3.5.4.10.1.2 Reference files

Reference files are directories required by the Global Address Cleanse transform to process your data.

You can use a substitution variable for the directory location. The substitution variable for reference files is $ $RefFilesAddressCleanse. Use this substitution variable if you accepted the default installation directory when you installed Data Services. If you installed to a location that wasn't the default location, you can change the substitution variable dynamically.

For information about downloading international directories, see the latest directories update.

Also, see the “Directory data” topic in the *Installation Guide*.

3.5.4.10.1.3 Country ID options (Global Address Cleanse)

Specifies whether or not to use Country ID processing. This option group is required.

Option	Description
Country ID Mode	Specifies whether to always use the specified Country Name or to run Country ID processing. *Constant*: Assumes all of your input data is for the specified Country Name and does not run Country ID processing. Choose this option only if all of your data is from one country, such as Australia. This option may save processing time. *Assigned*: Runs Country ID processing. Choose this option if the input data contains addresses from more than one country.
Country Name	Specifies the country of destination. *None*: Select when the *Country ID Mode* is set to Assigned and you don't want a default country to be set when the country cannot be identified. Special considerations: ● If the *Country ID Mode* is set to Constant, choose the country of destination from the Country Name list. The transform assumes that all of your data is for this country. i Note You cannot choose None if the *Country ID Mode* option is set to Constant. ● If the *Country ID Mode* is set to Assigned, choose a country name to be used when the Country ID could not identify a country. ● If Country Name is set to None, then the address will be sent to the default engine, Global Address.
Script Code	Specifies the ISO four-character script code for your data. *CJKK*: Chinese, Japanese, and Korean *GREK*: Greek *LATN*: Latin *None*: If this option is selected, transform will attempt to identify the overall script of the input data as CJKK, GREK, LATN, or other.

3.5.4.10.1.4 Standardization options

These options are found under ▶ *Standardization Options* › *Country* › *Options* ◀.

The Options group includes all the options that you need to standardize your address data. These settings apply to the country that you specify for ▶ *Standardization Options* › *Country* › *Country Name* ◀. This option group is required.

> i Note
>
> You can set these options for all countries or by individual country. To add another Country options group, Right click ▶ *Standardization Options* › *Country* ◀ and select *Duplicate Option*.

Option	Description
Address Line Alias	Specifies how to standardize the address line. (Engines supported: Canada, Global Address, and USA) *Convert*: Converts address lines based on Official address line components instead of Delivery address line components. *Preserve*: Retains non-preferred data in address lines unless the data is incorrect.
Assign Locality	Specifies how to standardize the locality name. *Convert*: Converts the locality name to the locality name preferred by the country's postal authority. *Preserve*: Preserves the input locality name unless it is incorrect. *Valid*: Retains the input locality name unless it is not valid for mailing. If it is not valid for mailing, replaces it with the preferred locality name.
Capitalization	Specifies the casing of your address data. *Mixed*: Converts data to initial capitals. For example, "MAIN STREET SOUTH" becomes "Main Street South." *Upper*: Converts data to full capitals. For example, "Main Street South" becomes "MAIN STREET SOUTH." i Note If you want consistent casing for your data, make sure that this option and the Capitalization setting in the Data Cleanse transform are the same.
Character Width Style	Specifies whether to standardize half-width and full-width characters. This option only applies to Chinese and Japanese data. *Normal Width*: Converts full-width Latin characters to half-width and converts half-width Chinese and Japanese characters to full width. *Half Width*: Convert all characters to half width. *Full Width*: Convert all characters to full width.
Convert_Latin_Output_To_US_ASCII	For Latin script records, converts any extended ASCII characters in the Best component to US ASCII characters, if a character conversion is available. For example, with the input street name “Østerbrogade”, you can preserve the local character or convert it to the international data format “Osterbrogade” in the cleansed output. Any extended ASCII characters for which there is no conversion (such as the degree symbol or inverted exclamation and question marks), are left as is. By default, the option is set to No. *Yes*: Converts extended ASCII characters. *No*: Does not convert extended ASCII characters.

Option	Description
Correct Assigned Data	Specifies whether to use the parsed or corrected data for the assigned output fields of type Best. *Yes*: Populates the Best components with corrected data. *No*: Populates the Best components with parsed data. ℹ Note If you choose No for this option, the Capitalization option is the only available Standardization option for your assigned data.
Correct Unassigned Data	Specifies whether the Global Address Cleanse transform standardizes your unassigned data. *Yes*: Populates the Best components with corrected data. *No*: Populates the Best components with parsed data. ℹ Note If you choose No for this option, the Capitalization option is the only available Standardization option for your unassigned data.
Country Style	Specifies how to standardize the country data. *ISO_2CHAR*: Standardizes country data to the two-character ISO code, such as AU, CA, or US. *ISO_3CHAR*: Standardizes country data to the three-character ISO code, such as AUS, CAN, or USA *ISO_3DIGIT*: Standardizes country data to the three-digit ISO code, such as 038, 124, or 840. *Name*: Standardizes country data to the full country name, such as Australia, Canada, or United States. *Preserve*: Attempts to retain the country data in the input record, otherwise uses the corrected country value.
Directional Punctuation	Specifies whether to use punctuation in the abbreviated directional data. *Yes*: Outputs directionals with punctuation (for example, N. or S.W.) *No*: Outputs directionals without punctuation (for example, N, SW). *Preserve*: If there is punctuation in the input parsed component, returns the corrected punctuation if the input is not found in the dictionary (for example, N/W on input would be updated to N.W.).
Directional Style	Specifies whether to abbreviate directional data. *Long*: Uses fully-spelled directionals such as "North," "South," "East," "West." *Preserve*: Preserves the style used in the input record.

Option	Description
	Short: Uses abbreviated directionals such as "N," "S," "E," "W."
European Postcode Prefix	Adds the one- to three-character European Postcode prefix, followed by a dash, for mail generated and distributed inside Europe. *Yes*: Adds the European Postcode prefix. *No*: Does not add the European Postcode prefix. *Preserve*: Retains the European Postcode prefix, if one is found on input. In the following address, for example, the D- is the European Postcode extension. Hallesches Ufer 32-38 D-10963 Berlin Germany ℹ Note The European Postcode prefix is for mail distributed from one European country to another European country.
Extra Lines	Specifies what to do with extra lines of non-address data. *Preserve*: Attempts to retain the extra line of non-address data in the general location in which it was input. *Remove*: Does not include any extra line of non-address data in the standardized lines or multiline fields. *Preferred*: All populated Extra fields are placed above or below the multiline fields and standardized input lines based on the country data being processed. For example, Extra fields for Japan will be located below the standardized lines.

Format Assigned Data	Specifies whether to format your assigned data based on the country's preferred address format. For example, the format for Germany is:
	{Primary_Name1} {Primary_Number}
	{Postcode1} {Locality}
	{Country}
	Yes: Formats the assigned data.
	No: Does not format the assigned data and leaves it in the location in which it was input. If data is added to the record, this data will be placed based on the format string.

Format Unassigned Data	Specifies whether to format your unassigned data based on the country's preferred address format. For example, the format for Germany is:
	{Primary_Name1} {Primary_Number}
	{Postcode1} {Locality}

Option	Description
	{Country} *Yes*: Formats the unassigned data. *No*: Does not format the unassigned data and leaves it in the line in which it was input.
Include Country	Specifies whether to include country names in standardized lines or multiline fields. *Yes*: Includes country name. *No*: Does not include country name. *Preserve*: Retains the country name if found on input.
Include Locality Addition	Specifies whether the Locality1_Full output field contains both the Locality1_Name and the Locality1_Addition information. *Yes*: Includes both the locality and the locality addition information. *No*: Does not include the locality addition. *Preserve*: Includes locality addition if found on input. This is the default setting. Note The Locality Name Style option in the Global Address Cleanse transform overrides this option. If the Locality Name Style option is set to Short, the Locality1_Full field will not contain the locality addition information.
Include Unused Address Line Data	Specifies whether to output the unused address line data (for standardized lines and multiline fields). This option affects unused address data classified as remainder, but not unused address data classified as extra. *Yes*: Outputs the unused address line data in the remainder fields Address_Line_Remainder1 through Address_Line_Remainder4 (for example, 100 Main St Red House). *No*: Does not output the unused address line data (for example, 100 Main St).
Include Unused Lastline Data	Specifies whether to output the unused last line data (for standardized lines and multiline fields): *Yes*: Outputs the unused last line data. *No*: Does not output the unused last line data.
Locality Name Style	Specifies the format for locality data in the Locality1_Name output field for addresses. This option applies to German addresses. *Preserve*: Preserves the locality data format as it was input. This is the default setting. *Short*: Outputs locality data in the abbreviated version, if available in the reference data.

Option	Description
	Note To use the short locality name style, the *Address Line Alias* option must be set to *Convert*. **Note** This option overrides the Include Locality Addition option.
Move Multiline Data	Determines the position of blank lines in output addresses. *Bottom*: If there are any blank lines, the transform moves them to the top and shifts the data to the bottom of the address block. *No*: Does not rearrange any lines, blank or otherwise. *Top*: If there are any blank lines, the transform moves them to the bottom of the address block and shifts the data to the top of the block. Example of Top:  Input data: Result of moving: Line1 Line2 Line3 Line4 Line5 100 Market Street Suite 202 Sycamore Building Boston MA 02109 Sycamore Building Suite 202 100 Market St Boston MA 02109
Output Country Language	Specify which language and script to use on output for the country name (not the entire record). *Preserve*: Preserves country name as it was on input. *Catalan - Latin* *Chinese - Hani* *Danish - Latin* *Dutch - Latin* *English - Latin* *Finnish - Latin* *French - Latin* *Greek - Greek* *German - Latin*

Option	Description
	Hungarian - Latin *Italian - Latin* *Japanese - Hani* *Japanese - Kana* *Korean - Hang* *Norwegian - Latin* *Polish - Latin* *Portuguese - Latin* *Spanish - Latin* *Swedish - Latin*
Postal Phrase Punctuation	If you choose *Short* for the Postal Phrase Style option, this option specifies whether to use punctuation in the postal abbreviation. *Yes*: Includes punctuation in postal abbreviations (for example P.O. Box). *No*: Does not insert any punctuation for postal abbreviations (for example, PO Box). *Preserve*: If there is punctuation in the input parsed component, returns the corrected punctuation if the input is not found in the dictionary.
Postal Phrase Style	Specifies whether to abbreviate postal phrases. *Long*: Outputs the fully-spelled postal phrase (for example Post Office Box). *Preserve*: Retains the style of the postal phrase if found in the input record. *Short*: Outputs the abbreviated postal phrase (for example, PO Box). The punctuation for this option is determined by the Postal Phrase Punctuation option.
Primary Type Punctuation	If you choose *Short* for the Primary Type Style option, this option specifies whether to use punctuation in primary type abbreviations. *Yes*: Includes a period at the end of primary type abbreviations (for example, St.). *No*: Does not insert any punctuation at the end of primary type abbreviations (for example, St). *Preserve*: If there is punctuation in the input parsed component, returns the corrected punctuation if the input is not found in the dictionary.
Primary Type Style	Specifies the style for primary type address elements. *Long*: Uses fully spelled primary types such as Street, Avenue, Road, or Strasse. *Preserve*: Retains the style used in the input record *Short*: Uses abbreviated primary type such as St, Ave, Rd, or Str. The punctuation for this option is determined by the Primary Type Punctuation option.

Option	Description
Region Style	Specifies whether to abbreviate the region name (for example, state or province). *Long*: Uses the fully spelled region name (for example, California or Ontario). *Preserve*: Retains the style used in the input record. *Short*: Abbreviates the region name (for example, CA or ON).
Remove Address Apostrophes	Specifies whether to include apostrophes in certain street names that include a DE L' or D'. *Yes*: Retains apostrophes in street names if it was present on input, for example, Rue D'Abbeville. *No*: Removes apostrophes in street names, for example, Rue D Abbeville.
Secondary Description Punctuation	If you choose *Short* for the Secondary Description Style, this option specifies whether to use punctuation in the abbreviation. *Yes*: Uses punctuation in the abbreviation (for example, Apt.). *No*: Does not use punctuation (for example, Apt). *Preserve*: If there is punctuation in the input parsed component, returns the corrected punctuation if the input is not found in the dictionary.
Secondary Description Style	Specifies whether to abbreviate the secondary description (for example, a unit or an apartment). *Long*: Uses the fully spelled secondary description (for example, Apartment). *Preserve*: Retains the style used in the input record. *Short*: Abbreviates the secondary description (for example, Apt). The punctuation for this option is determined by the Secondary Description Punctuation option.
Secondary Number Style	Specifies the format of the secondary number (for example, a suite or apartment number). This option applies to Canada and New Zealand addresses. *Attached*: Converts all secondary ranges to the attached format, so that the secondary number is prepended to the primary number and separated with a delimiter. For example, for Canada addresses, it places a dash between the secondary and primary range: 5-100 Main St. *Preserve*: Preserves the style of the address as it was input. *Unattached*: Converts all secondary ranges to the unattached format. For example, for Canada, it places the unit designator at the end of the primary address: 100 Main St Suite 5.
Street Name Style	Specifies the format for street data for addresses. This option applies to addresses in Germany and the Netherlands. *Preserve*: Preserves the street data format as it was input. For example: Annelien Kappeyne Van de Coppellostr 2

Option	Description
	Herten Limburg 6049 HD *Short*: Outputs street data in the format preferred by the postal authority. For the Netherlands, this returns a street address with a maximum of 24 characters in mixed case. For example: A K vd Coppellostr 2 Herten Limburg 6049 HD Note To use the short street name style, the *Address Line Alias* option must be set to *Convert*. Note The *Capitalization* option in the Global Address Cleanse transform overrides the *Street Name Style* option.
Use Local Primary Type Style	Specifies whether to use the type style for primary address components that is present in the address data. Setting this option to *Yes* ignores the *Primary Type Style* option. This option applies to Austria, Germany, and Switzerland. *Yes*: Uses the Primary Type Style that is present in the address data. *No*: Uses the Primary Type Style specified in the Primary Type Style option.
Use Postal Country Name	Specifies which country data is output for countries that receive their postal service from another country. For example, if you are using the USA engine and have addresses from the U.S. territories, the Country field is populated with the postal country (United States) rather than the territory name (such as American Samoa, Puerto Rico, and so on). The style of the Country field is still based on the Country Style option. If the country does not have a postal country, this option does not change the output. *Yes*: Uses the postal country name. *No*: Uses the territory country name.

3.5.4.10.1.5 Engines

Assigns the engines that you want to use with the Global Address Cleanse transform.

The Global Address Cleanse transform must always have one or more of the Global Address Cleanse engines enabled in order to process your data.

This option group is required.

Option	Description
Canada	Specify whether the Canada engine is used for the Global Address Cleanse transform. *Yes*: Activates the Canada engine. *No*: De-activates the Canada engine.
Dynamic Engine Init	Specify whether engines that are used for the Global Address Cleanse transform are limited to the engines that can be initialized. *Yes*: Uses only the engines that can successfully be initialized. If an engine fails to initialize, a warning is issued and the job continues. *No*: Uses all enabled engines. If an engine fails to initialize, the job fails. This is the default value.
Global Address	Specify whether the Global Address engine is used for the Global Address Cleanse transform. *Yes*: Activates the Global Address engine. *No*: De-activates the Global Address engine.
USA	Specify whether the USA engine is used for the Global Address Cleanse transform. *Yes*: Activates the USA engine. *No*: De-activates the USA engine.

3.5.4.10.1.5.1 Canada engine

Use the Canada engine to process your Canada address data with the Global Address Cleanse transform. The engine includes specific options that you can set for processing Canada address data and suggestion lists.

Related Information

Reference files [page 1198]
Canada engine options [page 1209]
Canada engine Suggestion List options [page 1212]
Canada engine Report options [page 1212]

3.5.4.10.1.5.2 Canada engine options

The Options group contains all of the specific settings that you must define when processing with Canada address data.

Option	Description
Disable Certification	*Yes*: Enables non-certified processing of Canada addresses and allows processing with non-POC (Point-of-Call) directories for non-mailing purposes. When you select *Yes*, you cannot print the SERP Report. Any list created with certification disabled cannot be used for mailing. *No*: Enables certified processing for Canada using POC (Point-of-Call) directories and enables printing of the SERP report. Note If this option is set to *Yes*, the following options should also be set to *Yes*: ● Enable LVR Rule ● Enable Rural Rule ● Postcode Only Search ● Postcode No Match Search
Dual Address	Specifies the action to take when the Canada engine encounters a dual address. *Position:* Selects an address based on the arrangement of the input data. The Canada engine tries to validate the address that is closest to the lower left corner of the address block. That might be the postal or the street address, depending on how the data was entered. (This value is required for SERP certification.) *Postal:* Tries to validate based on the postal address. If that fails, tries again based on the street address.

Option	Description
	Street: Tries to validate based on the street address. If that fails, tries again based on the postal address (rural route or PO box).
Enable LVR Rule	Canada Post requires that any address with a valid Large Volume Receiver (LVR) postal code be considered valid. The postal code cannot be changed to match other address components. Canada Post recommends that you don't correct LVR addresses; however, correction is permitted when a unique address can be determined without changing the postal code. *Yes:* Regards any LVR address as assigned, even when the address line is so flawed that a match to the postal directory is impossible. (This value is required for SERP certification.) *No:* Disables this rule. The transform reports an LVR address as unassigned when the address line is flawed.
Enable Rural Rule	Canada Post requires that any address with a valid rural postal code must be considered valid. (Rural postal codes have a zero in the second position.) This rule applies even if the address line is empty or contains bad data. Canada Post recommends that you don't correct rural addresses; however, the Canada engine will always attempt to correct the rest of the address. The valid rural postal code will always be left intact, according to CPC rules. This also applies if an address is entered without a postal code or with an incorrect postal code, and the locality (city) entered has just one postal code associated with it that is a rural postal code. *Yes:* Regards any rural address as valid, even if the address line is so flawed that a match to the postal directory is impossible. (This value is necessary for SERP certification). *No:* Reports a rural address as invalid if the address line is bad.
Output Address Language	*Convert:* Uses French for records in Quebec, and English for records in other regions (provinces). *English:* Converts records to English. *French:* Converts records to French. *Preserve:* Detects the input language and preserves that language upon output, no matter the region (province).
Parse Only	*Yes:* Parses records into discrete components, but does not perform a lookup in the postal directories. Parse Only is fast, but parsing results are unverified. *No:* Parses records into discrete components and performs a lookup in the postal directories. Setting this option to No may slow down processing, but parsing results are verified when the appropriate reference dat is available.
Postcode No Match Search	This option is important when the Canada engine has determined that the address line can be assigned, but doesn't match the incoming postal code. SERP rules specify that if this occurs, the transform must search the postal directories to ensure the following:

Option	Description
	- If the incoming address line is a PO Box address, the postal code must not be a valid postal code for an LVR (Large Volume Receiver), firm, or a civic (street) address, such as 100 Main St. - If the incoming address line is a civic (street) address, the postal code must not be a valid postal code for an LVR PO Box address. If either one of these conditions exist, Data Services cannot assign the address, according to SERP rules. Because doing a postal-code-only search is very time consuming, disabling this search should speed up your processing time. *Yes:* Turns on this option. (This value is necessary for SERP certification.) *No:* Turns off this option.
Postcode Only Search	This option affects assignment when the input address line is badly incomplete (for example, when the address includes a range but no street name). In this case, SERP rules specify that the transform must search based on postal code only, and attempt to find a street record containing that range. If the Canada engine can find only one street record that contains the range, then (the SERP rules state) the address line is assigned from the postal code. *Yes:* Turns on the option. (This value is necessary for SERP certification.) *No:* Turns off the option. In some cases, the result is a better address line. In other cases, the Canada engine more reliably detects that it cannot assign an address line.
Postcode Priority Over Street	Specifies whether postcode and street are equally weighted or whether street has priority over postcode. This option is important when the Canada engine is trying to break a tie between two possible assignments: - A near match on address line. - An exact match on postal code. *Yes:* When breaking a tie between a near match on street address line and an exact match on postal code, validates by placing more weight on the address line. Where possible, the transform changes the postal code to agree with the address line, because data-entry errors are common in postal codes. *No:* When breaking a tie between a near match for the address line and an exact match for the postal code, places an equal weight on the address line and the postal code. (This value is necessary for SERP certification.)
Unit Description	Specifies the unit description in English: *Apartment*: Uses Apartment as the default unit designator. *Default*: Uses the default unit designator. *Unit*: Uses Unit as the default unit designator.

Related Information

Standardization options [page 1199]

3.5.4.10.1.5.3 Canada engine Report options

Set these options to add the necessary Statement of Address Accuracy report information.

This is an optional group, however this option group must be completed so that Data Services produces a SERP Report (Software Evaluation and Recognition Program).

Option	Description
Customer Company Name	Specifies the company name of the organization for whom you are preparing the mailing (up to 40 characters).
Mailer Address1 Mailer Address2 Mailer Address3 Mailer Address4	Specifies the name and address of the person or organization for whom you are preparing the mailing (up to 40 characters per line).
Customer CPC Number	Specifies the customer's CPC number that is located on the Canada Post Contract (up to 15 characters).

3.5.4.10.1.5.4 Canada engine Suggestion List options

Set these options when you want to generate suggestion lists for your Canada address data.

Option	Description
Address Lines Match Minimum	Specifies the similarity score required for address-line suggestions. This score then determines which suggestions will be returned in the list. A higher number indicates that the suggestion must be more similar to the input in order to be returned as a possible suggestion. Type a value from 0 to 80.
Address Range	Specifies a span around the input primary address range for which to return suggestions. By using this option, you can limit the suggestions returned to be within a few blocks of your input. For example, assume you entered 500 for this value. Then, you submit the following street address: 1000 Pine St. Suggestions would be returned in a range from 750 to 1250 Pine Street.

Option	Description
	If you don't want to limit the ranges returned in suggestions, type 0.
Combine Overlapping Ranges	Specifies whether individual suggestions with overlapping ranges are combined. *Yes:* Ignores gaps and overlaps in ranges. Set this option to Yes if you want to limit the number of total suggestions presented to your user. However, you might not see gaps of invalid ranges that would be apparent if this option was set to No. For example, the following suggestions would be presented if this option is set to No: 1000-1099 Maple Ave 1100-1199 Maple Ave But this suggestion would only show if set to Yes: 1000-1199 Maple Ave *No:* Does not combine overlapping ranges.
Enable Suggestion Lists	Specifies whether suggestion lists are generated. *No:* Does not generate suggestion lists. *Yes:* Generates suggestion lists when assignment candidates are present.
Lastlines Match Minimum	Specifies the similarity score required for lastline suggestions. This score then determines which suggestions will be returned in the list. A higher number indicates that the suggestion must be more similar to the input in order to be returned as a possible suggestion. Type a value from 0 to 80.
Max Number Address Lines	Specifies the maximum number of address line suggestions that can be generated. You might set this option in order to limit the size of the SOAP documents being sent by the web service, or to limit the maximum number of suggestions that your users would have to choose from. However, by setting a maximum, you may occasionally eliminate a suggestion from the list that could be the correct one. The minimum number you can enter is 2. The maximum number you can enter is 50.
Max Number Lastlines	Specifies the maximum number of lastline suggestions that can be generated. You might set this option in order to limit the size of the SOAP documents being sent by the web service, or to limit the maximum number of suggestions that your users would have to choose from. However, by setting a maximum, you may occasionally eliminate a suggestion from the list that could be the correct one. The minimum number you can enter is 2. The maximum number you can enter is 15.

3.5.4.10.1.5.5 Global Address engine options

The Global Address engine includes specific options that you can set for processing global address data and suggestion lists.

Option	Description
Country Name	Choose a specific country for the Assignment option settings or choose Global (Apply to All Countries) to make global settings.
Disable Certification	Specifies whether to perform non-certified or certified processing of addresses for Australia, France, or New Zealand. **Note** If the reference data is missing or older than the certification requirements for any country (Australia, France, or New Zealand), a warning message will be issued. If the message is issued for data that is not required for the country you are processing, you can ignore the message. To avoid receiving this message, replicate the country options group for each country (Australia, France, and New Zealand) and only set the *Disable Certification* option to *No* for the country data you are processing. When you set the options for each country, all other options in the country-specific group will be used in place of the options selected in the global group. *Australia*: ● *Yes*: Enables non-certified features and extends the directory expiration for non-mailing purposes. You may extend the directory expiration period up to 14 months from the date the directories were created. Processing with expired directory data is allowed when you are not planning to use the records for AMAS mailing purposes. This is ideal for data warehousing industries, for example. However, when you select Yes, you cannot print the AMAS report. Any lists created with expired directories cannot be used for postage discounts. Data directories expire after 15 months when certification is disabled. ● *No*: Uses the most current directory information, disables non-certified features, and enables printing of the AMAS report. *France*: ● *Yes*: Enables non-certified processing of France addresses for non-mailing purposes. ● *No*: Enables certified processing of France addresses for mailing purposes. All punctuation will be removed except for firm data. Accented characters will have their accents removed (only A-Z and 0-9 are allowed). The returned address will be in 6 lines. **Note** To return the address in all upper case, set the Capitalization option under ▸ *Standardization Options* ▸ *Country* ▸ *Options* ◢ to *Upper*. *New Zealand*:

Option	Description
	• *Yes*: Enables non-certified processing of New Zealand addresses and allows processing with expired directories for non-mailing purposes. When you select Yes, you cannot print the SOA Report. Any list created with certification disabled cannot be used for mailing. • *No*: Enables certified processing for New Zealand and enables printing of the SOA report.
Dual Address	Specifies the action to take when the Global Address engine encounters a dual address. *Position*: Selects an address based on the arrangement of the input data. The transform attempts to assign the first address found in the input data. If it cannot assign the first address, it will attempt to assign the next address found. *Postal*: Attempts to validate based on the postal address. If that fails, attempts again based on the street address. *Street*: Attempts to validate based on the street address. If that fails, attempts again based on the postal address.
Output Address Script	Specifies how a native script is output. Supports Chinese (if the input character script is CJKK) and Russian (if the input character script is CYRL). *Latin*: Transliterates the native script and outputs the data as Latin. *Preserve*: Outputs the data in the native script.
Retain Postcode if Valid Format	Set this option for processing valid or invalid input postcodes. *Yes*: Retains input postcode unless it is an invalid format for the country and there is a single answer or intelligent matching is possible. *No*: Updates output postcode if there is a single answer or intelligent matching is possible. Otherwise retain input postcode. Note If the postcode is blank, the transform will add one if there is a single answer.

3.5.4.10.1.5.6 Global Address engine Suggestion List options

Set these options when you want to generate suggestion lists for your global address data.

Option	Description
Address Range	Specifies a span around the input primary address range for which to return suggestions. By using this option, you can limit the suggestions returned to be within a few blocks of your input. For example, assume you entered 500 for this value. Then, you submit the following street address: 1000 Pine St.

Option	Description
	Suggestions would be returned in a range from 750 to 1250 Pine Street. If you don't want to limit the ranges returned in suggestions, type 0. The maximum value is 5000.
Combine Overlapping Ranges	Specifies whether individual suggestions with overlapping ranges are combined. *Yes:* Ignores gaps and overlaps in ranges. You might set this option to Yes if you want to limit the number of total suggestions presented to your user. However, you might not see gaps of invalid ranges that would be apparent if this option was set to No. For example, a suggestion list might show the following suggestions if this option is set to No: 1000-1099 Maple Ave 1100-1199 Maple Ave But would only show this suggestion if set to Yes: 1000-1199 Maple Ave *No:* Does not combine overlapping ranges. ℹ Note It is recommended that if the option is set to *No*, you should consider increasing the size of the Suggestion_List output field so that it can contain all of the suggestions.
Enable Suggestion Lists	Specifies whether suggestion lists are generated. *No*: Does not generate suggestion lists. *Yes*: Generates suggestion lists when assignment candidates are present.
Max Number Address Lines	Specifies the maximum number of address-line suggestions that can be generated. You might set this option in order to limit the size of the SOAP documents being sent by the web service, or to limit the maximum number of suggestions that your users would have to choose from. The minimum number you can enter is 2. The maximum number you can enter is 10,000. The default setting is 100.
Max Number Lastlines	Specifies the maximum number of lastline suggestions that can be generated. You might set this option in order to limit the size of the SOAP documents being sent by the web service, or to limit the maximum number of suggestions that your users would have to choose from.

Option	Description
	The minimum number you can enter is 2. The maximum number you can enter is 10,000. The default setting is 60.

3.5.4.10.1.5.7 Global Address engine Report options

With the Report Options group, you can add the required information for the following reports:

- *Report options for New Zealand* [page 1217]
- *Report options for Australia* [page 1217]

3.5.4.10.1.5.8 Report options for New Zealand

With the Report Options group, you can add the required Statement of Accuracy (SOA) report information.

Option	Description
Customer Company Name	Specifies the name of the customer company name for whom you are preparing this list (up to 40 characters).
Customer Number	New Zealand Post customer number. If you want to submit your file for mailing and qualify for postage discounts, you must include your customer number on the report.
File Name	Name of the input data associated with the report.
Mailer Address 1 Mailer Address 2 Mailer Address 3 Mailer Address 4 Mailer Address 5 Mailer Address 6	Specifies the name and address of the person or organization for whom you are preparing the mailing (up to 29 characters per line).
SOA Issuer Name	Specifies the name of the company that prepared this list (up to 40 characters).

3.5.4.10.1.5.9 Report options for Australia

With this option group, you can add the required Australia AMAS - Address Matching Processing Summary information.

This is an optional group, however this option group must be completed so that Data Services produces an AMAS Report (Address Matching Processing Summary Report).

Option	Description
Customer Company Name	Specifies the name of the customer company name for whom you are preparing this list (up to 40 characters).
List Name	Specifies the name of your database or mailing list (up to 40 characters). This might be the file name, your title, or formal name for the list.
File Name	Specifies the actual input file name, such as australia.dbf (up to 40 characters).
Mailer Address1 Mailer Address2 Mailer Address3 Mailer Address4	Specifies the name and address of the person or organization for whom you are preparing the mailing (up to 29 characters per line).

3.5.4.10.1.5.10 USA engine

Use the USA engine with the Global Address Cleanse transform to address cleanse your data for the United States of America and its territories. The engine includes specific options that you can set for processing USA data.

Related Information

USA engine Suggestion List options [page 1219]
Standardization options [page 1336]

3.5.4.10.1.5.11 USA engine options

The Options group contains all of the specific settings that you must define when processing with USA address data.

Option	Description
Dual Address	Specifies the action to take when the transform encounters a dual address. *Position*: Selects an address based on the arrangement of the input data.

Option	Description
	The transform attempts to validate the address that is closest to the lower left corner of the address block. That might be the postal or the street address; it depends on how the data was entered. *Postal*: Attempts to validate based on the postal address. If that fails, attempts again based on the street address. *Street*: Attempts to validate based on the street address. If that fails, attempts again based on the postal address (rural route or PO Box).
Parse Only	*Yes*: Parses records into discrete components, but does not perform a lookup in the postal directories. Parse Only is fast, but parsing results are unverified. *No*: Parses records into discrete components and performs a lookup in the postal directories. Setting this option to No may slow down processing, but parsing results are verified.
Unit Description	Specifies how to standardize the unit description. *Convert*: Uses the unit description found in the postal directory (such as an apartment, suite, room, or floor). *Preserve*: Preserves the unit description from the input record, correcting any spelling errors.

Related Information

Standardization options [page 1199]

3.5.4.10.1.5.12 USA engine Suggestion List options

Set these options to generate suggestion lists for the USA and its territories.

Option	Description
Address Lines Match Minimum	Specifies the similarity score required for address-line suggestions. This value then determines which suggestions will be returned in the list. A higher number indicates that the suggestion must be more similar to the input in order to be returned as a possible suggestion. Type a value from 0 to 80.
Address Range	Specifies a span around the input primary address range for which to return suggestions. By using this option, you can limit the suggestions returned to be within a few blocks of your input. For example, assume you entered 500 for this value. Then, you submit the following street address:

Option	Description
	1000 Pine St. Suggestions would only be returned in a range from 750 to 1250 Pine Street. If you don't want to limit the ranges returned in suggestions, type 0.
Combine Overlapping Ranges	Specifies whether individual suggestions with overlapping ranges are combined. *Yes:* Ignores gaps and overlaps in ranges. You might set this option to Yes if you want to limit the number of total suggestions presented to your user. However, you might not see gaps of invalid ranges that would be apparent if this option was set to No. For example, a suggestion list might show the following suggestions if this option is set to No: 1000-1099 Maple Ave 1100-1199 Maple Ave But would only show this suggestion if set to Yes: 1000-1199 Maple Ave *No:* Does not combine overlapping ranges.
Enable Suggestion Lists	Specifies whether suggestion lists are generated. *Yes:* Generates suggestion lists when assignment candidates are present. *No:* Does not generate suggestion lists.
Lastlines Match Minimum	Specifies the similarity score required for lastline suggestions. This score then determines which suggestions will be returned in the list. A higher number indicates that the suggestion must be more similar to the input in order to be returned as a possible suggestion. Type a value from 0 to 80.
Max Number Address Lines	Specifies the maximum number of address line suggestions that can be generated. Limits the size of the SOAP documents being sent by the web service, or limits the maximum number of suggestions that your users would have to choose from. However, by setting a maximum, you may occasionally eliminate a suggestion from the list that could be the correct one. The minimum number you can enter is 2. The maximum number you can enter is 100.
Max Number Lastlines	Specifies the maximum number of lastline suggestions that can be generated. Limits the size of the SOAP documents being sent by the web service, or limits the maximum number of suggestions that your users would have to choose from. However, by setting a maximum, you may occasionally eliminate a suggestion from the list that could be the correct one. The minimum number you can enter is 2. The maximum number you can enter is 100.

3.5.4.10.1.6 Suggestion List (Global Address Cleanse transform)

The Suggestion List option group contains three options for constructing the suggestion list string. The string contains components based on the suggestion type that you generate. Each suggestion list option group contains fields associated with the suggestion type. The first table lists the Suggestion List group, and the second table lists the Suggestion Type fields.

Table 158: Suggestion List group

Option	Description
Suggestion List Components	Choose the address component fields that you want to include in the address suggestions.
Delimiter	Specifies a character to use to separate each suggestion list selection. This value is only considered if the Output Style option is set to Delimited. This value can be any character or string. Common delimiters include a pipe symbol (|), or a string of multiple asterisks (***). This value should differ from the Field Delimiter value.
Field Delimiter	Specifies a character to use to separate each field in a single suggestion list. Each selection can be made up of one or more fields. If you choose to retrieve multiple fields per selection, those fields are separated with the character you specify here. This value can be any character string. The default value is a pipe symbol (|). This value should differ from the Delimiter value.
Output Style	Specifies the format for how the suggestion list data should be output. *Delimited:* Outputs the suggestion list data in a delimited text format, with the delimiters specified in the Delimiter and Field Delimiter options. *XML:* Outputs the suggestion list data as hierarchical XML. This option is likely the preferred one for users who integrate suggestion lists via the web service. You can then use the XML tools you own to parse the suggestion list data.

Table 159: Suggestion List components

Field	Description
Building_Name	The building name for the address, which in some countries is used in place of the primary number. For example, in the U.K. an address may be

Field	Description
	“White House, High Street,” where “White House” is the building name instead of a primary number in an address such as “100 High Street.” In some cases, an address will include the bulding name and primary number.
Delivery_Installation_Name	The delivery installation city name, which is usually the same as the city name and (if it is the same) omitted from the address line.
Delivery_Installation_Qualifier	Delivery Installation qualifier (for example, “Main” in “RR 2 Vancouver Stn Main”).
Delivery_Installation_Type	The delivery installation type. *English*: *PO*: Post Office. *RPO*: Retail Post Outlet. *STN*: Station. *LCD*: Letter Carrier Depot. *CMC*: Community Mail Center. *CDO*: Commercial Dealership Outlet. *French*: *BDP*: Bureau de Poste. *CSP*: Comptoir Service Postal. *SUCC*: Succursale. *PDF*: Poste de Facteurs. *CPC*: Centre Postal Communautaire. *CC*: Concession Commerciale.
Firm	Returns the firm, company, or organization name.
Floor_Description	The level description, such as “Floor.”
Floor_Number_High Floor_Number_Low	If the floor number is a range such as 20-22, LOW contains “20” and HIGH contains “22.” If the floor number is not a range, both fields contain the floor number (for example, “20” and “20”).
Locality1 Locality2 Locality3 Locality4	Returns the city, town, or suburb. Additional locality information goes in Locality4.
Locality1_Official Locality2_Official	The locality name preferred by the postal authority.

Field	Description
Locality3_Official Locality4_Official	
Postcode	Returns the postal code.
Postcode1	*Australia*: Four-digit postcode. *Canada*: First three characters (FSA) of the postal code. *Global*: Postal code. *USA*: Five-digit primary postal code (ZIP Code). Does not include the four-digit secondary postal code (ZIP4).
Postcode2	The secondary postal code. *Canada*: The last three characters (LDU) of the postal code. *USA*: The four-digit ZIP Code, which on a mail piece, this code follows the primary postal code with a hyphen placed between (for example, 54601-1234).
Primary_Name1 Primary_Name2 Primary_Name3 Primary_Name4	Returns the street description. For example, Primary Name1 may return "Marina" and Primary Name2 may return "The Slipway." Suggestion List group: Available in the Primary Name Components option.
Primary_Name_Full1 Primary_Name_Full2	The primary name, primary type, primary prefix, and primary postfix.
Primary_Name_Full3 Primary_Name_Full4	The primary name and primary type.
Primary_Number_Description	A description preceding the primary number. For example, LOT (Australia).
Primary_Number_Extra	Data found near the parsed primary number, which in most cases cannot be identified or does not belong in a standardized address.
Primary_Number_Full	The primary number, primary number description, and primary number extra.
Primary_Number_High Primary_Number_Low	If the house number is a range such as 100-102, LOW contains “100” and HIGH contains “102.” If the house number is not a range, both fields contain the house number (for example, “100” and “100”).
Primary_Postfix1 Primary_Postfix2	Abbreviated or non abbreviated directional (for example, N, South, NW, SE) that follows a street name.

Field	Description
Primary_Prefix1 Primary_Prefix2	Abbreviated or non abbreviated directional (N, South, NW, SE) that precedes a street name.
Primary_Side_Indicator	Indicates if even, odd, or both values are valid. This applies to Street and PO box. *E*: The record is even-numbered. *O*: The record is odd-numbered. *B*: The record covers both the even- and odd-numbered sides of the street and PO Boxes.
Primary_Type1 Primary_Type2 Primary_Type3 Primary_Type4	The type of primary name (Some examples are rue, strasse, street, Ave, or Pl).
Region1–2	Returns the state, province, or region.
Secondary_Side_Indicator	Indicates if even, odd, or both values are valid. This applies to floors and units. *E*: The secondary record is even-numbered. *O*: The secondary record is odd-numbered. *B*: The secondary record covers both the even and odd-numbered values.
Selection	Returns a unique index number that identifies this suggestion from the others in the returned list. The suggestion “selection” number ranges from 1 to the number of suggestion selections in the suggestion list.
Stairwell_Description	Entrance or stairwell identifier for a building, such as, Stiege.
Stairwell_Name	The name or number of an entrance or stairwell for a building, such as, Stiege "1."
Unit_Description	Identifies a unit within a building, such as Room, Unit, Apt, Suite, and so on.
Unit_Number_High Unit_Number_Low	If the unit number is a range such as 1-20, Unit Number Low contains 1 and Unit Number High contains 20.

3.5.4.10.2 Global Address Cleanse fields

The Global Address Cleanse transform requires that you map fields on input and output.

3.5.4.10.2.1 Field category columns in Output tab

The Output tab lists output fields that hold the data that the transform cleanses or creates. You can choose to view the Best Practice, In Use, or All output fields by selecting the corresponding option at the top of the tab.

Best Practice: Lists all available output fields that have a field class of Best.

In Use: Lists only the output fields that you have chosen to output (listed in Schema Out).

All: Lists all output fields that are available for this transform.

> Note
>
> For details about mapping input and output fields, see the *Designer Guide*.

The output field attributes in the table below are listed in groups based on the field category column. Each field has categories that describe the type of content that is output. The field category displays "None" when it does not apply to the field.

Category	Description
Content Type	Identifies the type of data in the field. Setting the content type helps you map your fields when you set downstream transforms.
Field Addrclass	Specifies the address class for the generated field. *Delivery:* When used with the applicable Field Name, this value generates fields that reflect the address that is used in an attempt to assign an address. *Dual:* When used with the applicable Field Name, this value generates fields that reflect the address that is not used in an attempt to assign an address for input records that may contain both a street and postal address on input. *Official:* When used with the applicable Field Name, this value generates fields in the form of the data preferred by the Postal Authority. For example, in Winona, Minnesota USA, Broadway and 6th Street are alternate names for the same street. A letter addressed to Broadway is delivered, but the USPS prefers 6th Street.
Field Category	*Component:* Individual address components and postal codes that are related to the processed record. *Standardized:* Standardized input lines based on the settings in the Standardization Options group in the transform. *Suggestion:* Suggestion list output data based on the settings in the Suggestion List Options group.
Field Class (USA Regulatory Address Cleanse)	Specifies the field class that you want to assign to your output fields.

Category	Description
	Best: Outputs data based on various factors, such as whether an address was assigned, the Field AddrClass, and any settings that you defined in the Standardization Options group in the Options tab. Note When NCOALink is enabled and a valid move is available, Best fields contain the move-updated address data if it exists and if it matches in the U.S. National Directories. Or, the field contains the original address data if a move does not exist or if the move does not match in the U.S. National Directories. *Correct:* Outputs the complete and correct value found in the directories, and is standardized according to any settings that you defined in the Standardization Options group in the Options tab. *Parsed:* Outputs the parsed value. *Pre_LACSLink*: Retained address components that were replaced with LACSLink address information. *Move_Updated*: Outputs the address components that have been updated with move-updated address data. Note The transform looks for the move-updated address information in the U.S. National Directories. When the move-updated address is not found in the U.S. National Directories, the software populates the Move Updated fields with information found in the Move Update Directories only. The Move Updated fields that are populated as a result of standardizing against the U.S. National Directories is not updated.
Field Class (Global Address Cleanse)	Specifies the field class that you want to assign to your output fields. *Best:* Outputs data based on various factors, such as whether an address was assigned, the Field AddrClass, and any settings that you defined in the Standardization Options group in the Options tab. *Parsed:* Outputs the parsed value.
Field Name	Specifies a field name where the data is populated based on the options that you specify within this transform.
Type	Specifies the type and default length of data the output field contains; for example, varchar, date, and time.

Content types [page 1131]
Designer Guide: How address cleanse works [page 586]

3.5.4.10.2.2 Input fields

The following are recognized Data Services input fields that you can use in the Global Address Cleanse transform. The table also shows that each input field is available based on the engine(s) that you enable:

- Canada (C)
- Global Address (G)
- USA (U)

See the fields listed in the transform's Input tab to view each field's properties.

Field	Description	Engine(s)
Address_Line	The delivery address line, for example, "123 Main Street, Unit 4." *China*: Address_Line may represent the following address components: ● Street and street number ● Building, floor, unit ● Residential community For example, 晨晖路 123 号中华大厦 12 楼 1201 室 宝山新村 100 号 201 室 *Japan*: Address_Line may represent the following address components: ● Block (chome, kumi, Hokkaido go), sub-block (banchi, gaiku, tochi kukaku), and house number (go) parts of the Japanese address. ● The building name, building floor, building room parts of the Japanese address. ● The P.O. Box portion of the address, if applicable.	All engines
Country	The identified country name of the address.	All engines
Data_Source_ID	Specifies the input source. This field is used in reports to identify the record.	All engines

Field	Description	Engine(s)
Firm	The name of a company or organization. In some countries, large firms have their own postal code. If you include a Firm field in your input, this transform may assign more specific postal codes. *China*: China does not support Firm assignment. There is no Firm data for China. If the Firm is available on input, place it in this field. *Japan*: All Firm data for addresses in Japan should be placed in this field.	All engines
Lastline	The locality, region (when it is included in the data), and postal code on one line.	All engines
Locality1	The city, town, or suburb. *China*: The Prefecture level localities. Prefectures (地区 diqu), Autonomous prefectures (自治州 zizhizhou), Prefecture-level cities (地级市 dijishi), Leagues (盟 meng), or Provincial countries (省直辖县 shengzhixiaxian). *Japan*: The city (shi), island (shima), ward (ku), county (gun) district (machi) or village (mura).	All engines
Locality2	Any additional city, town, or suburb information. *China*: County level localities, counties (县 xian), autonomous counties (自治县 zizhixian), county-level cities (县级市 xianjishi), districts (市辖区 shixiaqu), banners (旗 qi), autonomous banners (自治旗 zizhiqi), forestry areas (林区 linqu), or special districts (特区 tequ). *Japan*: Any additional ward, district, village or sub-district (aza, bu, chiwari, sen). *USA*: The Puerto Rican urbanization.	G, U
Locality3	Any additional city, town, or suburb information. *China*: Township level localities, townships (乡 xiang), ethnic townships (民族乡 minzuxiang), towns (镇 zhen), subdistricts (街道办事处 jiedaobanshichu), district public offices (区公所 qugongsuo), sumu (苏木 sumu), or ethnic sumu (民族苏木 minzusumu). *Japan*: Any additional district, village, sub-district (aza, bu, chiwari, sen, donchi, and tori), or super block (joh).	G
Multiline1-12	A line that may contain any data. The type of data in this line may vary from record to record.	All engines

Field	Description	Engine(s)
	Japan: Represents the lines that may contain any data with the following restrictions. The address in total has to be in the traditional order of a Japanese address. In addition, the block (chome, kumi, Hokkaido go), sub-block (banchi, gaiku, tochi kukaku), and house number (go) should be within one line on input.	
NetWeaver_Building	A specialized input field that contains the building information. If you map this input field, you must also map NetWeaver_Street. ⚠ Caution Use this field properly to avoid unexpected results in your data. For more information, see *Mapping NetWeaver input fields* [page 1232].	All engines
NetWeaver_Floor	A specialized input field that contains the floor number. If you map this input field, you must also map NetWeaver_Street. ⚠ Caution Use this field properly to avoid unexpected results in your data. For more information, see *Mapping NetWeaver input fields* [page 1232].	All engines
NetWeaver_House_Num1	A specialized input field that contains the house number. If you map this input field, you must also map NetWeaver_Street. ⚠ Caution Use this field properly to avoid unexpected results in your data. For more information, see *Mapping NetWeaver input fields* [page 1232].	All engines
NetWeaver_House_Num2	A specialized input field that contains additional house number information. If you map this input field, you must also map NetWeaver_Street.	All engines

Field	Description	Engine(s)
	⚠ Caution Use this field properly to avoid unexpected results in your data. For more information, see *Mapping NetWeaver input fields* [page 1232].	
NetWeaver_Location	A specialized input field that contains additional street information. If you map this input field, you must also map NetWeaver_Street. ⚠ Caution Use this field properly to avoid unexpected results in your data. For more information, see *Mapping NetWeaver input fields* [page 1232].	All engines
NetWeaver_PO_Box	A specialized input field that contains the PO Box number. ⚠ Caution Use this field properly to avoid unexpected results in your data. For more information, see *Mapping NetWeaver input fields* [page 1232].	All engines
NetWeaver_RoomNumber	A specialized input field that contains the room number. If you map this input field, you must also map NetWeaver_Street. ⚠ Caution Use this field properly to avoid unexpected results in your data. For more information, see *Mapping NetWeaver input fields* [page 1232].	All engines
NetWeaver_Str_Suppl1	A specialized input field that contains additional street information. If you map this input field, you must also map NetWeaver_Street.	All engines

Field	Description	Engine(s)
	⚠ Caution Use this field properly to avoid unexpected results in your data. For more information, see *Mapping NetWeaver input fields* [page 1232].	
NetWeaver_Str_Suppl2	A specialized input field that contains additional street information. If you map this input field, you must also map NetWeaver_Street. ⚠ Caution Use this field properly to avoid unexpected results in your data. For more information, see *Mapping NetWeaver input fields* [page 1232].	All engines
NetWeaver_Str_Suppl3	A specialized input field that contains additional street information. If you map this input field, you must also map NetWeaver_Street. ⚠ Caution Use this field properly to avoid unexpected results in your data. For more information, see *Mapping NetWeaver input fields* [page 1232].	All engines
NetWeaver_Street	A specialized input field that contains the primary street name. ⚠ Caution Use this field properly to avoid unexpected results in your data. For more information, see *Mapping NetWeaver input fields* [page 1232].	All engines
Postcode	The postal code. *USA*: The five-digit ZIP Code and ZIP+4.	All engines
Region1	The state, province, or region. *China*: Province-level regions, provinces (省 sheng), autonomous regions (自治区 zizhiqu), municipalities (直辖市 zhixia-	All engines

Field	Description	Engine(s)
	shi), or special administrative regions (特别行政区 tebie xingzhengqu). *Japan*: Represents the prefecture (to, do, fu, ken). A prefecture is similar to a state in the U.S.	
Region2	The state, province, or region.	All engines
Suggestion_Reply1-6	Used to input the index number that corresponds to a specific last line suggestion, an address line suggestion, or secondary list suggestion. These fields can also be used to input a street primary range or a street secondary range. *Suggestion_Reply1*: If you do not want to use a suggestion list, make the value of this field 0 and the suggestion list will be ignored.	All engines

3.5.4.10.2.3 Mapping NetWeaver input fields

The NetWeaver input fields are designed to be used in conjunction with other NetWeaver input fields in SAP software. Use the fields properly to avoid unexpected results in your data.

You cannot map multiline or Address_Line input fields when you use the NetWeaver input fields. Although the NetWeaver input fields appear discrete, they behave and are processed as multiline fields. They are mapped internally to Multiline1-12 before normal Global Address Cleanse processing is performed. If a NetWeaver input field is not mapped, the multiline that would have been mapped to it is mapped to the next available NetWeaver input field.

CJK script

For CJK script input, several NetWeaver input fields are concatenated into the last multiline field.

If a descriptor is found on NetWeaver_House_Num2, the multiline is processed as follows (+ indicates that the fields are concatenated with no space between them):

```
NetWeaver_Street
+NetWeaver_House_Num1+NetWeaver_House_Num2+<Descriptor>NetWeaver_RoomNumber
+<Descriptor>NetWeaver_Floor+NetWeaver_Building
```

If no descriptor is found on NetWeaver_House_Num2, the multiline is processed as follows:

```
NetWeaver_Street+NetWeaver_House_Num1+NetWeaver_RoomNumber<Descriptor>
+NetWeaver_Floor<Descriptor>+NetWeaver_Building NetWeaver_House_Num2
```

Input fields [page 1227]

3.5.4.10.2.4 Output fields

The following are Data Services output fields that can be used for the Global Address Cleanse transform. The Field_AddrClass and Field_Class values are available in the Global Address Cleanse transform's Transform Configuration Editor on the Output Best Practices tab for each field.

The table also shows that each field is available based on the engine(s) that you enable:

- Canada (C)
- Global Address (G)
- USA (U)

Output field name	Description	Engine
Additional_Info1	*Austria*: Includes the PAC code of the currently valid address when you choose to preserve the alias address on output. *Belgium*: Includes the NIS code. *Canada*: The official 13-character abbreviation of the city name, or the full spelling if the city name is less than 13 characters (including spaces). *France*: Includes the INSEE code. *Germany*: Includes a portion of the German freightcode (Frachtleitcode). *Liechtenstein*: Includes the postal service district (Botenbezirke) when it is available in the data. *Poland*: Includes the district name (powiat). *Spain*: Includes the INE 91 section code. *Switzerland*: Includes the postal service district (Botenbezirke) when it is available in the data.	C, G
Additional_Info2	*Austria*: Includes the City ID (OKZ). *Canada*: The official 18-character abbreviation of the city name, or the full spelling if the city name is less than 18 characters (including spaces). *Germany*: Includes the District Code. *Liechtenstein*: Additional postcode. *Poland*: Includes the community name (gmina).	C, G

Output field name	Description	Engine
	Spain: Includes the INE Street code. *Switzerland*: Additional postcode.	
Additional_Info3	*Austria*: Includes the Pusher-Leitcode (parcel). *Germany*: Includes the German City ID (ALORT). *Spain*: Includes the INE Town code.	G
Additional_Info4	*Austria*: Includes the Pusher-Leitcode (letter). *Germany*: Includes the German street name ID (StrSchl).	G
Additional_Info5	*Austria*: Includes the SKZ Street Code (7-digit). *Germany*: Includes the discount code for the freight-code.	G
Additional_Info6	*Austria*: Includes the corner-house identification (1-digit). The value for a corner house is *1*.	G
Additional_Info7-8	Reserved for future use.	All engines
Address_Line_Remainder1-4	Extraneous data found in the address line, which either cannot be identified or does not belong in a standardized address. USA 1-2: Complete secondary non-postal address (for example, Apt. 10, Ste 500, Box 34, Rm 7, 5th Flr).	All engines
Address_Type	A one-character code that represents the type of address identified: *P*: Postal *S*: Street *X*: Unknown	All engines
Area_Name1	An industrial area such as RIICO INDUSTRIAL AREA.	G
Assignment_Info	Indicates whether a record is valid, invalid, or corrected, based on the status and information codes. *C*: Corrected *I*: Invalid *V*: Valid	All engines
Assignment_Level	The level to which this transform matched the address to the data in the reference files (directories):	All engines

Output field name	Description	Engine
	C: Country *L1*: Locality1 *L2*: Locality2 *L3*: Locality3 *L4*: Locality4 *PN*: Primary name *PR*: Primary range *R*: Region *S*: Secondary *X*: Unknown, or the address was unassigned	
Assignment_Type	A one- or two-character code that represents the type of address. Engine support varies; see each code listing for supported engines. *BN*: Building name (Canada, Global Address) *F*: Firm (Canada, Global Address, USA) *G*: General delivery (Canada, Global Address, USA) *H*: High-rise building (Canada, USA) *HB*: House Boat (Global Address) *L*: LOT (Global Address) *M*: Military (Canada, USA) *R*: Rural (Canada, USA) *P*: Postal (Canada, Global Address, USA) *PI*: Point of reference (Global Address) *PR*: Poste Restante (Global Address) *PS*: Packstation or Paketbox (Global Address) *RP*: Postal Served by Route (Global Address) *S*: Street (Canada, Global Address, USA) *SR*: Street served by route (Canada, Global Address) *U*: Uninhabited (Global Address) *W*: Caravan (Global Address)	All engines

Output field name	Description	Engine
	X: Unknown or the address was unassigned (Canada, Global Address, USA)	
Block_Description	Block description such as "Block."	G
Block_Number	Block number.	G
Building_Name1	The building name for the address, which in some countries is used in place of the primary number. For example, in the U.K. an address may be “White House, High Street,” where “White House” is the building name instead of a primary number in an address such as “100 High Street.”	G
Building_Name2	The building name for the address, which in some countries is used in place of the primary number.	G
Cert_Valid	Indicates a valid certification.	All engines
Country	The ISO country code or the country name of the input record. The parsed value of this component is the country data found in the input record.	All engines
Country_Name	Fully-spelled country name in the languages specified in the Output_Country_Language option.	All engines
County_Name	Fully spelled county name. *USA*: County information is not included on mail pieces.	U
Delivery_Installation_Name	The delivery installation city name, which is usually the same as the city name and (if it is the same) omitted from the address line. *Canada*: If the delivery installation name is different than the locality name, the delivery installation name is output to the secondary address fields. *Japan*: Returns the post office name.	C, G
Delivery_Installation_Qualifier	Delivery Installation qualifier (for example, “Main” in “RR 2 Vancouver Stn Main”).	C
Delivery_Installation_Type	The delivery installation type. *English*: *PO*: Post Office *RPO*: Retail Post Outlet *STN*: Station	C

Output field name	Description	Engine
	LCD: Letter Carrier Depot *CMC*: Community Mail Center *CDO*: Commercial Dealership Outlet *French*: *BDP*: Bureau de Poste *CSP*: Comptoir Service Postal *SUCC*: Succursale. *PDF*: Poste de Facteurs *CPC*: Centre Postal Communautaire *CC*: Concession Commerciale	
Delivery_Point	*Australia*: Eight-digit delivery point identifier. This is the primary component needed to generate a barcode. This component is not printed on mail pieces. *Austria*: Includes the PAC code, which is a unique identifier assigned by the Austrian postal authority. *New Zealand*: A seven-character code that represents the delivery-point identifier. *United Kingdom*: A two-character code that represents the delivery-point suffix.	G
Engine_Name	The name of the engine that was selected to process the record.	All engines
Error	Specifies the error status generated as the result of looking up the current record and performing suggestion processing. Possible output values are 0- 5. *0* No suggestion selection error. *1* Blank suggestion selection/entry. *2* Invalid suggestion selection. *3* Invalid primary range. *4* Invalid floor range. *5* Invalid unit range.	All engines
Extra1-12	Any non-address data found in the address block. Available only if the input data was presented through multiline fields.	All engines

Output field name	Description	Engine
Firm	The firm name for the address. Identification of firm name data in a multiline format may be inconsistent depending upon the level of firm data available in the postal directories for each engine. To avoid inconsistent identification of firm data, use the discrete Firm field when you process multiline data. *Canada and USA*: The firm name is taken from the postal directory if found; otherwise, it's taken from the input record. Be aware that the postal directory might contain some unusual or shortened spellings that you may or may not find suitable for printing on mail pieces. If you prefer to retain your own firm data, retrieve the parsed component. *Global Address*: If the firm name is available on input, the Global Address engine returns the firm name.	All engines
Floor_Description	The level description, such as "Floor." *Japan*: The level description, such as kai.	G
Floor_Number	The level number or information.	G
Floor_Qualifier	Additional word that precedes or follows the floor information.	G
Full_Address	The complete address line, including secondary address, and dual address (street and postal).	All engines
Info_Code	If the address is not fully assigned, displays a four-character code that describes why the address could not be assigned. If the address is fully assigned, the field is blank. For more information, see *Information codes (Global Address Cleanse)* [page 1409].	All engines
ISO_Country_Code_2Char	The two-character ISO code that identifies a country, for example, DE is Germany.	All engines
ISO_Country_Code_3Char	The ISO-3166 three-character code that identifies a country, for example, DEU is Germany.	All engines
ISO_Country_Code_3Digit	The three-digit ISO code that identifies a country, for example, 276 is Germany.	All engines
ISO_Script_Code	The four-character script code to use for an identified country, such as LATN or KANA.	All engines

Output field name	Description	Engine
Language	The two-character ISO language code that represents the language of the address.	All engines
Lastline	The locality (Locality1–Locality4 if available), region, and postal code together in one component. The region is only included when it is required for select countries.	All engines
Lastline_Remainder1-4	Unused lastline remainder data.	G
Locality1_Addition	Additional locality information.	G
Locality1_Alternate	Preserves the input locality if it is recognized by the postal authority as a locality name for this address. Misspellings are corrected.	C, U
Locality_Code	Used in some countries to distinguish sections of a large locality. For example, in France they are called arrondissements.	G
Locality1_Description	Locality1 descriptor. *Japan*: Locality1 descriptor. For example, shi, shima, and so on. *China*: Locality1 descriptor. For example, 市(Shi).	G
Locality2_Description	Description of a subdivision of Locality1.	G
Locality3_Description	Description of a subdivision of Locality2.	G
Locality4_Description	Description of a subdivision of Locality3.	G
Locality1_Full	Includes Locality1_Name, Locality_Code, Locality1_Description, and Locality1_Qualifier. It may include Locality1_Addition, depending on the standardization option settings of Locality Name Style and Include Locality Addition.	All engines
Locality2_Full	Includes Locality2_Name and Locality2_Description.	G, U
Locality3_Full	Includes Locality3_Name and Locality3_Description.	G
Locality4_Full	Includes Locality4_Name and Locality4_Description.	G
Locality1_Name	The city, town, locality, or suburb that is either the Locality1_Alternate or Locality1_Official, depending on the standardization option setting for Assign Locality.	All engines

Output field name	Description	Engine
	Japan: The city (shi), island (shima), ward (ku), county (gun), district (machi), or village (mura).	
Locality2_Name	Additional locality information. *USA*: Urbanization (Puerto Rican addresses only).	G, U
Locality3_Name	Additional locality information.	G
Locality4_Name	Additional locality information.	G
Locality1_Official	The locality name preferred by the postal authority.	All engines
Locality2_Official	The locality name preferred by the postal authority.	G
Locality3_Official	The locality name preferred by the postal authority.	G
Locality4_Official	The locality name preferred by the postal authority.	G
Locality1_Qualifier	Used by France for Cedex.	G
Locality2_Qualifier	Locality qualifier.	G
Locality3_Qualifier	Locality qualifier.	G
Locality4_Qualifier	Locality qualifier.	G
Match_Block_Number	The standardized form of Block_Number used in the Match transform during the comparison process. Block descriptions are not output. Data is output in uppercase, diacritical characters and apostrophes are removed, and other punctuation and multiple spaces are replaced with a single space. The field is available only as a Best component. Non-Latin scripts are transliterated for supported scripts if the Output Address Script option is selected. For CJK scripts, the field uses normal width standardization for consistency.	All engines
Match_Building_Name	The standardized form of Building_Name1 used in the Match transform during the comparison process. Builiding descriptions are output. Data is output in uppercase, diacritical characters and apostrophes are removed, and other punctuation and multiple spaces are replaced with a single space. The field is available only as a Best component. Non-Latin scripts are transliterated for supported scripts if the Output Address Script option is se-	All engines

Output field name	Description	Engine
	lected. For CJK scripts, the field uses normal width standardization for consistency. ℹ Note For China, building indicators will be removed.	
Match_Floor_Number	The standardized form of Floor_Number used in the Match transform during the comparison process. Floor descriptions and qualifiers are not output. Data is output in uppercase, diacritical characters and apostrophes are removed, and other punctuation and multiple spaces are replaced with a single space. The field is available only as a Best component. Non-Latin scripts are transliterated for supported scripts if the Output Address Script option is selected. For CJK scripts, the field uses normal width standardization for consistency.	All engines
Match_Locality	The standardized form of locality used in the Match transform during the comparison process. The output is not affected by standardization settings. Locality1_Official is output when a locality or better level assignment is made; otherwise, the Locality1_Name is output. Locality codes, qualifiers, or descriptions are not output. Data is output in uppercase, diacritical characters and apostrophes are removed, and other punctuation and multiple spaces are replaced with a single space. The field is available only as a Best component. Non-Latin scripts are transliterated for supported scripts if the Output Address Script option is selected. For CJK scripts, the field uses normal width standardization for consistency. ℹ Note For China and Japan, Locality1–4_Official or Locality1–4_Name are output, if present. For all other countries, only Locality1_Official or Locality1_Name is output.	All engines
Match_Primary_Directional	The standardized form of Primary_Prefix1 and Primary_Postfix1 used in the Match transform during the comparison process. The output is not affected by standardization settings. The abbreviated form is	All engines

Output field name	Description	Engine
	output, if available. If a prefix and postfix are both present, they are separated by a space. Data is output in uppercase, diacritical characters and apostrophes are removed, and other punctuation and multiple spaces are replaced with a single space. The field is available only as a Best component. Non-Latin scripts are transliterated for supported scripts if the Output Address Script option is selected. For CJK scripts, the field uses normal width standardization for consistency.	
Match_Primary_Name	The standardized form of Primary_Name1 used in the Match transform during the comparison process. The output is not affected by standardization settings. Data is output in uppercase, diacritical characters and apostrophes are removed, and other punctuation and multiple spaces are replaced with a single space. Prefix, postfix, suffix, and type data is removed. The field is available only as a Best component. Non-Latin scripts are transliterated for supported scripts if the Output Address Script option is selected. For CJK scripts, the field uses normal width standardization for consistency. Note For Brazil, China, and Japan, Primary_Name1–4 are output, if present. For all other countries, only Primary_Name1 is output.	All engines
Match_Primary_Number	The standardized form of Primary_Number used in the Match transform during the comparison process. Only the Primary_Number and Primary_Number_Extra are output, not the Primary_Number_Description. Data is output in uppercase, diacritical characters and apostrophes are removed, and other punctuation and multiple spaces are replaced with a single space. The field is available only as a Best component. Non-Latin scripts are transliterated for supported scripts if the Output Address Script option is selected. For CJK scripts, the field uses normal width standardization for consistency.	All engines
Match_Primary_Type	The standardized form of Primary_Type1–4 used in the Match transform during the comparison process. The output is not affected by standardization set-	All engines

Output field name	Description	Engine
	tings. The abbreviated primary type is output, if available. Data is output in uppercase, diacritical characters and apostrophes are removed, and other punctuation and multiple spaces are replaced with a single space. The field is available only as a Best component. Non-Latin scripts are transliterated for supported scripts if the Output Address Script option is selected. For CJK scripts, the field uses normal width standardization for consistency. Note For Brazil, China, and Japan, Primary_Type1–4 are output, if present. For all other countries, only Primary_Type1 is output.	
Match_Stairwell_Name	The standardized form of Stairwell_Name used in the Match transform during the comparison process. Stairwell descriptions are not output. Data is output in uppercase, diacritical characters and apostrophes are removed, and other punctuation and multiple spaces are replaced with a single space. The field is available only as a Best component. Non-Latin scripts are transliterated for supported scripts if the Output Address Script option is selected. For CJK scripts, the field uses normal width standardization for consistency.	All engines
Match_Unit_Number	The standardized form of Unit_Number used in the Match transform during the comparison process. Unit descriptions and qualifiers are not output. Data is output in uppercase, diacritical characters and apostrophes are removed, and other punctuation and multiple spaces are replaced with a single space. The field is available only as a Best component. Non-Latin scripts are transliterated for supported scripts if the Output Address Script option is selected. For CJK scripts, the field uses normal width standardization for consistency.	All engines
Match_Wing_Name	The standardized form of Wing_Name used in the Match transform during the comparison process. Wing descriptions are not output. Data is output in uppercase, diacritical characters and apostrophes are removed, and other punctuation and multiple	All engines

Output field name	Description	Engine
	spaces are replaced with a single space. The field is available only as a Best component. Non-Latin scripts are transliterated for supported scripts if the Output Address Script option is selected. For CJK scripts, the field uses normal width standardization for consistency.	
Multiline1-12	A line that may contain any data. The type of data in this line may vary from record to record.	All engines
NetWeaver_Formatted_Postcode	The postcode in a format that SAP software requires.	All engines
PMB_Full	Contains private mailbox information.	All engines
PName_Secondary_Addr	Contains the full primary name (with no associated primary number) and the full secondary address.	All engines
Point_Of_Reference1-2	A well known place or easily visible location to help locate an address. For example, Opposite to Citibank ATM.	G
Post_Office_Name	The name or numeric representation for a post office, such as, "01" BP 1012.	G
Postcode_Description	A word that indicates a postal code, when available on input. For example: *Brazil*: CEP, which stands for Código de Endereçamento Postal, and is output as CEP 52041-970. *China*: 邮编 *Japan*: 〒	G
Postcode_Full	*Australia*: Complete four-digit postal code. *Canada*: Complete six-character postal code (FSA + LDU). *Global Address*: Complete postal code. *USA*: The full ZIP Code with a hyphen (10 characters). *Japan*: The seven-digit postal code.	All engines
Postcode_In_NetWeaver_Supported_Format	Indicates whether the NetWeaver_Formatted_Postcode output field is populated.	All engines
Postcode_Prefix	The postcode prefix that is used by some European countries. For example, many countries use the same postal code format of four or five digits. You can prefix the numeric postal code with a country code to	G

Output field name	Description	Engine
	avoid confusion when sending mail to or from the European country. The codes used are generally based on License plate codes (D for Germany or F for France) rather than ISO codes.	
Postcode1	*Australia*: Four-digit postcode. *Canada*: First three characters (FSA) of the postal code. *Global Address*: Postal code. *USA*: Five-digit primary postal code (ZIP Code). Does not include the four-digit secondary postal code (ZIP4). *Japan*: The first three digits of the postal code.	All engines
Postcode2	The secondary postal code. *Canada*: The last three characters (LDU) of the postal code. *USA*: The four-digit ZIP Code, which on a mail piece, this code follows the primary postal code with a hyphen placed between (for example, 54601-1234). *Japan*: Contains the last four digits of the postal code.	All engines
Primary_Address	Primary address line, such as the street address or post office box. Does not include secondary address information such as apartment. *Japan*: The full block data.	All engines
Primary_Delivery_Mode	The delivery mode for a street served by route type address (Rural Route).	C
Primary_Delivery_Number	The delivery number for a street served by route type address (Rural Route).	C
Primary_Name1	The street name description (typically a street name or box description). *Japan*: Block (chome, kumi, Hokkaido go), sub-block (banchi, gaiku, tochi kukaku). The Post office name description (yuubinnkyoku or siten).	All engines
Primary_Name2	Second street and name description, typically a street name or box description. *Japan*: Additional block and sub-block information.	G

Output field name	Description	Engine
Primary_Name3	The street name, delivery mode, and so on. *Japan*: Additional block and sub-block information.	G
Primary_Name4	The street name, delivery mode, and so on. *Japan*: Additional block and sub-block information.	G
Primary_Name_Full1	The primary name, primary type, primary prefix, and primary postfix.	All engines
Primary_Name_Full2	The primary name2, primary type2, primary prefix2, and primary postfix2.	G
Primary_Name_Full3-4	The primary name and primary type.	G
Primary_Number_Description	A description preceding the primary number. For example, KM (Kilometer) or Blk. *Japan*: The postal number identifier 号 (go) or house number description 号 (go). *China*: The description after street number. For example, 号(hao).	G
Primary_Number	The premise number, rural route number, or PO Box number. In some cases it may include a range.	All engines
Primary_Number_Extra	Data found near the parsed primary number, which in most cases cannot be identified or does not belong in a standardized address. *Japan*: The postal box identifier.	G
Primary_Number_Full	The primary number, primary number description, and primary number extra.	All engines
Primary_Postfix1	Abbreviated or non abbreviated directional (for example, N, South, NW, SE) that follows a street name. Abbreviated or non abbreviated is based on the standardization setting for Directional Style. *Japan*: Directional that follows block or sub-block.	All engines
Primary_Postfix2	Abbreviated or non abbreviated directional (for example, N, South, NW, SE) that follows a street name. Abbreviated or non abbreviated is based on the standardization setting for Directional Style. *Japan*: Directional that follows block or sub-block.	G
Primary_Prefix1	Abbreviated or non abbreviated directional (N, South, NW, SE) that precedes a street name. Abbreviated or	G, U

Output field name	Description	Engine
	non abbreviated is based on the standardization setting for Directional Style. *Japan*: Directional that precedes block or sub-block.	
Primary_Prefix2	Abbreviated or non abbreviated directional (N, South, NW, SE) that precedes a street name. Abbreviated or non abbreviated is based on the standardization setting for Directional Style. *Japan*: Directional that precedes block or sub-block.	G
Primary_Secondary_Address	The primary address and secondary address in one component.	All engines
Primary_Type1	The type of primary name (some examples are rue, strasse, street, Ave, or Pl).	All engines
Primary_Type2-4	The type of primary name (some examples are rue, strasse, street, Ave, or Pl).	G
Quality_Code	Displays a two-character code that provides additional information about the quality of the address. The quality of the address depends on the input data, the processing engine, country, information code, and status code (if an information code is not generated). For more information, see *Quality codes (Global Address Cleanse)* [page 1416].	All engines
Region1	Either the Region1_Name or Region1_Symbol based on the standardization option Region Style.	All engines
Region1_Code	The region code, which may be the ISO region code.	All engines
Region1_Description	The Region1 description.	G
Region1_Full	Includes Region1 and Region1_Description.	All engines
Region1_Name	The fully spelled out Region1 name.	All engines
Region1_Symbol	An abbreviation of the Region1 name.	All engines
Region2	Either the Region2_Name or Region2_Symbol based on the standardization option Region Style.	G
Region2_Code	The region code, which may be the ISO region code.	All engines
Region2_Description	The Region2 description.	G

Output field name	Description	Engine
Region2_Full	Includes Region2 and Region2_Description.	G
Region2_Name	The fully spelled out Region2 name.	G
Region2_Symbol	An abbreviation of the Region2 name.	G
Remainder_Full	Contains all remainder information, including Address_Line_Remainder1-4 and Lastline_Remainder1-4.	All engines
Secondary_Address	The floor, unit, stairwell, or wing data on one line.	All engines
Single_Address	The full address and last line in one component.	All engines
Stairwell_Description	Entrance or stairwell identifier for a building, such as, Entrada "1."	G
Stairwell_Name	The name or number of an entrance or stairwell for a building, such as, Entrada "1."	G
Status	Specifies the suggestion status generated as the result of looking up the current record and performing suggestion processing. *A*: Primary address-line suggestions available. *AM*: Follow up primary address-line suggestions available. *F*: Floor range is invalid. *L*: Lastline suggestions available. *N*: No suggestions available. *R*: Primary range is invalid. *S*: Unit range is invalid. *U*: Secondary address-line suggestions available. *UM*: Follow up secondary address-line suggestions available.	All engines
Status_Code	Displays a six-character code that always starts with an S. This code explains what parts of the address changed during processing. For more information, see *Status codes (Global Address Cleanse)* [page 1412].	All engines
Unit_Description	The unit description, such as “Apartment” or “Flat.” *Japan*: The unit description, such as gousitsu.	All engines

Output field name	Description	Engine
Unit_Number	The unit number, such as 100 in “Apartment 100.”	All engines
Unit_Qualifier	Additional word that precedes or follows the unit information.	G
Wing_Description	Identifies a wing within a building, such as, West "Wing."	G
Wing_Name	The name or number of a wing within a building, such as "West" Wing.	G

3.5.4.10.2.5 Global Address Cleanse Suggestion List fields

The Global Address Cleanse transform's Suggestion List option requires that you map fields on input and output.

- *Suggestion List Input Fields* [page 1249]
- *Suggestion List Output Fields* [page 1250]

3.5.4.10.2.5.1 Suggestion List Input Fields

The Global Address Cleanse transform's Suggestion List option supports all Global Address Cleanse input fields in addition to the suggestion reply fields.

Field	Description
Suggestion_Reply1–6	Contains the reply when more information is needed to complete the query. Each of these fields also contain the reply if a selection from a list needs to be made. Possible types of generated suggestion lists are: ● Lastline ● Primary Address ● Follow-up Primary Address ● Secondary Address ● Follow-up Secondary Address

3.5.4.10.2.5.2 Suggestion List Output Fields

The following are fields that you can use for the Global Address Cleanse transform's Suggestion List option. The fields are listed alphabetically.

Field	Description
Building_Name	The building name for the address, which in some countries is used in place of the primary number. For example, in the U.K. an address may be “White House, High Street,” where “White House” is the building name instead of a primary number in an address such as “100 High Street.”
Delivery_Installation_Name	The delivery installation city name, which in some cases is the same as the city name and (if it is the same) omitted from the address line.
Delivery_Installation_Qualifier	Delivery Installation qualifier (for example, “Main” in “RR 2 Vancouver Stn Main”).
Delivery_Installation_Type	The delivery installation type. *English*: • *PO*: Post Office. • *RPO*: Retail Post Outlet. • *STN*: Station. • *LCD*: Letter Carrier Depot. • *CMC*: Community Mail Center. • *CDO*: Commercial Dealership Outlet. *French*: • *BDP*: Bureau de Poste. • *CSP*: Comptoir Service Postal. • *SUCC*: Succursale. • *PDF*: Poste de Facteurs. • *CPC*: Centre Postal Communautaire. • *CC*: Concession Commerciale.
Firm	The firm name for the address.
Floor_Description	The level description, such as “Floor.”
Floor_Number_High Floor_Number_Low	If the floor number is a range such as 20-22, LOW contains “20” and HIGH contains “22.” If the floor number is not a range, both fields contain the floor number (for example, “20” and “20”).
Locality1 Locality2 Locality3 Locality4	The city, town or suburb and any additional related information.

Field	Description
Locality1_Official Locality2_Official Locality3_Official Locality4_Official	The locality name preferred by the postal authority.
Postcode	The postal code. *USA*: The five-digit ZIP Code and ZIP+4.
Postcode1	*Australia*: Four-digit postcode. *Canada*: First three characters (FSA) of the postal code. *Global*: Postal code. *USA*: Five-digit primary postal code (ZIP Code). Does not include the four-digit secondary postal code (ZIP4).
Postcode2	The secondary postal code. *Canada*: The last three characters (LDU) of the postal code. *USA*: The four-digit ZIP Code, which on a mail piece, this code follows the primary postal code with a hyphen placed between (for example, 54601-1234).
Primary_Name1	The street name description (typically a street name or box description).
Primary_Name2	Second street name and description, typically a street name or box description.
Primary_Name3 Primary_Name4	The street name, delivery mode, and so on.
Primary_Name_Full1 Primary_Name_Full2	The primary name, primary type, primary prefix, and primary postfix.
Primary_Name_Full3 Primary_Name_Full4	The primary name and primary type.
Primary_Number_Description	A description preceding the primary number. For example, KM (Kilometer) or Blk.
Primary_Number_Extra	Data found near the parsed primary number, which in most cases cannot be identified or does not belong in a standardized address.
Primary_Number_Full	The primary number, primary number description, and primary number extra.
Primary_Number_High Primary_Number_Low	If the house number is a range such as 100-102, LOW contains “100” and HIGH contains “102.” If the house

Field	Description
	number is not a range, both fields contain the house number (for example, “100” and “100”).
Primary_Postfix1 Primary_Postfix2	Abbreviated or non-abbreviated directional (for example, N, South, NW, SE) that follows a street name.
Primary_Prefix1 Primary_Prefix2	Abbreviated or non-abbreviated directional (N, South, NW, SE) that precedes a street name.
Primary_Side_Indicator	Indicates if even, odd, or both values are valid. This applies to streets and PO Boxes. *E*: The record covers the even-numbered value. *O*: The record covers the odd-numbered value. *B*: The record covers both the even- and odd-numbered values.
Primary_Type1 Primary_Type2 Primary_Type3 Primary_Type4	The type of primary name (rue, strasse, street, Ave, or Pl).
Region1	Returns the state, province, or region.
Secondary_Side_Indicator	Indicates if even, odd, or both values are valid. This applies to floors and units. *E*: The secondary record covers the even-numbered value. *O*: The secondary record covers the odd-numbered value. *B*: The secondary record covers both the even- and odd-numbered values.
Selection	A unique index number that identifies this suggestion from the others in the returned list. The suggestion “selection” number ranges from 1 to the number of suggestion selections in the suggestion list.
Stairwell_Description	Entrance or stairwell identifier for a building, such as, "Entrada" 1.
Stairwell_Name	The name or number of an entrance or stairwell for a building, such as Entrada "1."
Unit_Description	The unit description, such as “Apartment” or “Flat.”
Unit_Number_High Unit_Number_Low	If the unit number is a range such as 20-22, LOW contains “20” and HIGH contains “22.” If the unit number is not a range, both fields contain the unit number (for example, “20” and “20”).

3.5.4.10.3 Global Address Cleanse sample configurations

For specialized processes like cleansing address data in Australia or Brazil, Data Services has Global Address Cleanse sample transform configurations that you can include in your data flows. Find the sample transform configurations in Data Services Object Library under Global_Address_Cleanse.

> Note
>
> Sample configurations include all required options except input fields. All sample configurations display in the designer as Global_Address_Cleanse.

Sample transform name	Description
Australia_AddressCleanse	A sample Global Address Cleanse transform configured to cleanse address data in Australia.
Brazil_ AddressCleanse	A sample Global Address Cleanse transform configured to cleanse address data in Brazil.
Canada_AddressCleanse	A sample Global Address Cleanse transform configured to cleanse address data in Canada.
China_AddressCleanse	A sample Global Address Cleanse transform configured to cleanse address data in China.
Europe_AddressCleanse	A sample Global Address Cleanse transform configured to cleanse address data in multiple European countries.
France_AddressCleanse	A sample Global Address Cleanse transform configured to cleanse address data in France.
Germany_AddressCleanse	A sample Global Address Cleanse transform configured to cleanse address data in Germany.
Global_AddressCleanse	A sample Global Address Cleanse transform configured to cleanse Latin script address data in any supported country.
GlobalSuggestions_AddressCleanse	A sample Global Address Cleanse transform configured to cleanse Latin-1 address data in any supported country using the Suggestion List feature.
Greece_AddressCleanse	A sample Global Address Cleanse transform configured to cleanse address data in Greece when the address data consists of Greek Data
Italy_AddressCleanse	A sample Global Address Cleanse transform configured to cleanse address data in Italy.
Japan_AddressCleanse	A sample Global Address Cleanse transform configured to cleanse address data in Japan when the address data consists of Japanese Kanji, Katakana, and Hiragana.

Sample transform name	Description
Portugal_AddressCleanse	A sample Global Address Cleanse transform configured to cleanse address data in Portugal.
Spain_AddressCleanse	A sample Global Address Cleanse transform configured to cleanse address data in Spain.
UK_AddressCleanse	A sample Global Address Cleanse transform configured to cleanse address data in the United Kingdom.
USA_AddressCleanse	A sample Global Address Cleanse transform configured to cleanse address data in the United States.
USASuggestions_AddressCleanse	A sample Global Address Cleanse transform configured to cleanse address data in the United States using the Suggestion List feature.

3.5.4.11 Global Suggestion List

The Global Suggestion List transform query addresses with minimal data, and it can offer suggestions for possible matches. It is a beneficial research tool for managing unassigned addresses from a batch process.

Global Suggestion List functionality is designed to be integrated into your own custom applications via the Web Service. If you are a programmer looking for details about how to integrate Global Suggestion List functionality, see "Integrate Global Suggestion List functionality" in the "Detailed concepts for integrators" section of your *Data Services Integrator Guide*.

The Global Suggestion List transform requires the two character ISO country code on input. Therefore, you may want to place a transform, such as the Country ID transform, that will output the ISO_Country_Code_2Char field before the Global Suggestion List transform.

The Global Suggestion List transform is available for use with the Canada, Global Address, and USA engines.

> Note
>
> No certification with Global Suggestion List: If you use the Canada engine, USA engine, or Global Address engine for Australia and New Zealand, you cannot certify your mailing for SERP, CASS, AMAS, or New Zealand certification.

> Note
>
> This option does not support processing of Japanese or Chinese address data.

3.5.4.11.1 Content objects

Transform configurations

A transform configuration is a transform with preconfigured input fields, output fields, and options that can be used in multiple data flows. These are useful if you repeatedly use a transform with specific options and input and output fields.

When Data Services is installed, read-only transform configurations are provided for the Data Quality transforms.

You can use transform configurations in your data flows or as an example of a typical transform. After you place an instance of the transform configuration in a data flow, you can override these preset defaults. You can also create your own transform configuration, either by replicating an existing transform configuration or creating a new one.

Sample blueprints and other objects

We have created Data Quality blueprints and other content objects to help you set up Data Services jobs. We've identified a number of common scenarios that you are likely to perform with Data Services. For each scenario, we've included a blueprint that is already set up to solve the business problem in that scenario.

3.5.4.11.2 Global Suggestion List option groups

The Global Suggestion List transform includes the following option groups.

> Note
>
> The Global Suggestion List transform does not support Chinese and Japanese addresses.

Option group	Description
Common: Run as Separate Process	Splits the transform into a separate process.
Engines	Sets the engines for processing. The default value for each country engine is *Yes*. Select *No* to disable the country engine. Countries include: ● Canada ● Global Address ● USA
Canada	Sets the directory path for your address cleanse reference files.
Global Address	Sets the directory path for your address cleanse reference files.
USA	Sets the directory path for your address cleanse reference files.
Reference Files	Specifies the location of your reference files. You can use a substitution variable.
Options	See *Options (Global Suggestion List)* [page 1257]
Suggestion List	See *Suggestion List (Global Suggestion List)* [page 1257].

3.5.4.11.3 Engines (Global Suggestion List)

The Engines option group allows you to enable or disable individual engines of the Global Suggestion List transform.

> Note
>
> The Suggestion List option does not support Chinese and Japanese addresses.

Option	Description
Canada	Specifies if the engine is enabled or disabled for suggestion List processing. Choose one of the following: *Yes:* Enables the engine. *No:* Disables the engine.
Global Address	Specifies if the engine is enabled or disabled for suggestion List processing. Choose one of the following: *Yes:* Enables the engine. *No:* Disables the engine.
USA	Specifies if the engine is enabled or disabled for suggestion List processing. Choose one of the following: *Yes:* Enables the engine.

Option	Description
	No: Disables the engine.

3.5.4.11.4 Options (Global Suggestion List)

This option group contains all of the settings that you need to define when you process data with the Global Suggestion List transform.

> Note
>
> The Global Suggestion List transform does not support Chinese and Japanese addresses.

Option	Description
Default Country	Specifies a country to use if the input field is not defined or if the Country input field is blank. Enter a valid two-character country code, or enter *None* if you do not want to use a default country.
Enter Firm Data	Specifies whether to request firm data when the selected suggestion does not have data available. *Yes:* Requests firm data. *No:* Does not request firm data.
Return Single Item Lists	Specifies whether the transform should return suggestion lists that have only one item. *Yes:* Returns suggestion lists that only have one item. *No:* If a suggestion list has only one item, then the single item is automatically selected from the suggestion list and processing continues.

3.5.4.11.5 Suggestion List (Global Suggestion List)

Use this option group to configure options for how suggestion lists are output, as well as set up the fields where the suggestion information is posted.

Yes: Outputs the component.

No: Does not output the component.

Table 160: Suggestion List options

Option/Option group	Description
Output Style	Specifies the format for the output suggestion list data. *Delimited:* Outputs the suggestion list data in a delimited text format, with the delimiters specified in the Delimiter and Field Delimiter options. *XML:* Outputs the suggestion list data as hierarchical XML. If you integrate suggestion lists via the web service, you are likely to use this option. You can then use the XML tools you own to parse through the suggestion list data.
Delimiter	Specifies a character to use to separate each suggestion in a suggestion list. This value is considered only if the Style option is set to Delimited. This value can be any character or string. Common delimiters include a pipe symbol (|), or a string of multiple asterisks (***). This value should differ from the Field Delimiter value.
Field Delimiter	Specifies a character to use to separate each field in a single suggestion. This value is considered only if the Style option is set to Delimited. Each suggestion can be made up of one or more fields. If you choose to retrieve multiple fields per suggestion, those fields are separated with the character specified here. This value can be any character or string. The default value is a pipe symbol (|). This value should differ from the Delimiter value.

Table 161: Lastline Components

Option/Option group	Description
Selection	Returns a unique index number that identifies this suggestion from the others in the returned list.
Locality1-3	Returns the city, town, or suburb. Additional locality information goes in Locality2.
City Addition	Returns unofficial city information that is associated with the locality. For example, there are two German cities named Frankfurt. The larger city of Frankfurt is called Frankfurt am Main and the smaller city is called Frankfurt (Oder). Locality1 would have Frankfurt for these two records, and City Addition would list (Oder) and am Main.
Region1	Returns the state, province, territory, or region of the address.
Postcode1	Returns the postal code or five-digit ZIP Code (USA).
Primary Names Available	Indicates whether or not street data is available for a locality: *Y*: Yes, there are streets. *N*: No, there are not streets.

Table 162: Primary Name Components

Option/Option group	Description
Selection	Returns a unique index number that identifies this suggestion from the others in the returned list.
Primary Name1 Primary Name2	Returns the street description. For example, Primary Name1 may return "Marina" and Primary Name2 may return "The Slipway."
Locality1-3	Returns the city, town, or suburb. Additional locality information goes in Locality2.
City Addition	Returns unofficial city information that is associated with the locality. For example, there are two German cities named Frankfurt. The larger city of Frankfurt is called Frankfurt am Main and the smaller city is called Frankfurt (Oder). Locality1 would have Frankfurt for these two records, and City Addition would list (Oder) and am Main.
Postcode1	Returns the postal code.

Table 163: Address Components

Option/Option group	Description
Selection	Returns a unique index number that identifies this suggestion from the others in the returned list.
Primary Side Indicator	Indicates if even, odd, or both values are valid. This applies to Street and PO box. *E*: The record covers the even-numbered values. *O*: The record covers the odd-numbered values. *B*: The record covers both the even- and odd-numbered values.
Firm	Returns the name of a firm, company, or organization.
Multiline1-6	Returns individual formatted address lines. This will not include country information, as it will be output in a separate field.
Postcode1	Returns the postal code.

3.5.4.11.6 Input fields

The following are input fields that you can use in the input mapping for the Global Suggestion List transform. The fields are listed alphabetically.

Note

The Global Suggestion List transform uses all fields provided on input to select a match and will return an error stating "no results" if the fields you include do not exist in the data. If you do not own address-level data for a country, do not include address-level fields in the input mapping. Also try removing address-level fields when address-level data is available, but Address Lists states there are no results. This allows you to view Locality-level data for the address.

ℹ Note

Global Suggestion List does not support Chinese and Japanese addresses.

Field	Description
Country	Specifies the country to look up in the query. This field must be the two-character country ISO code, not a country name. If your data does not contain the country code, place a transform that generates the country code field, such as the Country ID transform or Global Address Cleanse transform before the Global Suggestion List transform. If this field is blank, the transform uses the country found in the Default Country option.
Locality1	Specifies the city, town, or suburb.
Postcode	Specifies the postal code to look up.
Primary_Name1	Specifies the primary street name to look up. For example, in "255 Main St" the primary name is "Main."
Primary_Number	Specifies the primary number to look up. For example, in "255 Main St." the primary number is "255."
Reply1-5	Contains the reply when more information is needed to complete the query. Each of these fields also contain the reply if a selection from a list needs to be made. Possible types of generated suggestion lists are lastline, primary name, and address. ➜ Remember These fields must be added in ascending order; that is, you should populate Reply1 first, Reply2 second, and so on.
Start_Selection	Specifies the starting list number. If left blank, the default value is 1.
Script_Default	Sets the output script. This option is valid for Greece. If the input data is non-numeric, then the script type is determined by the script of the input data. For example, when the input data contains only numeric data for Greece and the option is set to 2, then the generated suggestion lists are output in Greek script, respectively. In the same situation except where the option is set to 1, then the generated suggestion lists are output in Latin script.

3.5.4.11.7 Output fields

The following are fields that you can use in the output mapping for the Global Suggestion List transform. The fields are listed alphabetically.

Note

Global Suggestion List does not support Chinese and Japanese addresses.

Field	Description
Country_Name	Returns the fully-spelled country name, in English.
Data_Type	Returns a single-character code that indicates what type of additional data is needed to complete processing. Possible output values are: *N:* No additional data is needed. *A:* Primary address data is needed. *F:* Firm data is needed. *R:* Primary range data is needed. *S:* Secondary range data is needed.
Error	Posts the error status generated as the result of looking up the current record and performing query processing. Possible output values are: *0:* There were no query errors. *1:* There was a system error while performing the query. *2:* The suggestion selection was invalid. For example, a selection of 8 is made and there are only 5 entries.
Firm	Specifies the firm name for the address.
Multiline1-6	Returns a line that may contain any data. The type of data in this line may vary from record to record. If you want to output the postal code, you cannot use one of these Multiline output fields. You must use the Postcode1 field.
Postcode1	Returns the postcode. *Canada and Global Address:* Postal code. *USA:* Five-digit primary postal code (ZIP Code). Does not include the four-digit secondary postal code (ZIP4).
Status	Returns a code indicating query status generated as the result of processing the input record and performing Global Suggestion List processing. Possible output values are: *C:* Querying is complete. *D:* More data is needed. *E:* There was an error. *P:* A suggestion list was generated.

Field	Description
Suggestion_Count	Returns the number of individual suggestion selections generated as the result of querying the current record. A nonnegative value is output. If the input record did not generate a suggestion list, this field contains a value of 0. Your application developer uses this field to know how many suggestion selections must be displayed to users of your custom application.
Suggestion_List	Contains the list of suggestions based on the Suggestion List Option settings that you set in the Global Suggestion List transform.
Suggestion_Type	Returns a code indicating what type of suggestion list was generated. Possible output values are: *N:* No suggestion list was generated. *A:* An address suggestion list was generated. *L:* A lastline suggestion list was generated. *S:* A secondary suggestion list was generated.
System_Error_ Description	Posts the current Global Suggestion List system error as a descriptive string.
System_Error_ Number	Posts the current system error as a number. The values are: *0:* No error. *1:* Invalid postcode. *2:* Invalid street. *3:* Invalid town. *4:* More information needed. *5:* Street information needed. *6:* No input given. *7:* Postcode numeric. *8:* Town needed. *9:* Town or postcode needed. *10:* No street information available. *11:* Country blank. *12:* Invalid country. *13*: No results. *14:* Address needed. *15:* Premise needed. *16:* Firm needed.

Field	Description
Warning	Posts the warning status generated as the result of looking up the current record and performing query processing. The values are: *0:* There were no query warnings. *1:* An incomplete suggestion list was generated. Generally, the maximum number of elements that can be placed in a suggestion list is 200. *2:* An invalid premise was entered. *3:* An invalid unit was entered.

3.5.4.12 Match

The Match transform is responsible for performing matching based on the business rules you define. The transform then sends matching and unique records on to the next transform in the data flow.

For best results, the data in which you are attempting to find matches should be cleansed. Therefore, you may need to include other Data Quality transforms before the Match transform.

Match concepts

This section describes the Match transform, how it fits into a data flow, and the options you can set to conform to your business rules. The Match transform is only one tool, albeit the most important one, for you to use in your matching strategy. For more information about matching concepts and other transforms you can use to achieve the results you are looking for, see the Match section of the *Designer Guide*.

3.5.4.12.1 Content objects

Transform configurations

A transform configuration is a transform with preconfigured input fields, output fields, and options that can be used in multiple data flows. These are useful if you repeatedly use a transform with specific options and input and output fields.

When Data Services is installed, read-only transform configurations are provided for the Data Quality transforms.

You can use transform configurations in your data flows or as an example of a typical transform. After you place an instance of the transform configuration in a data flow, you can override these preset defaults. You can also create your own transform configuration, either by replicating an existing transform configuration or creating a new one.

Sample blueprints and other objects

We have created Data Quality blueprints and other content objects to help you set up Data Services jobs. We've identified a number of common scenarios that you are likely to perform with Data Services. For each scenario, we've included a blueprint that is already set up to solve the business problem in that scenario.

Transform configurations [page 1123]

3.5.4.12.2 Match transform options

3.5.4.12.2.1 Match transform tab

These options control the Match transform itself. Here you control whether to generate report data, which match engine will be processing data, and so on.

Option	Description
Perform matching	Select to add the ability to compare records and other match-related operations. This option is not selected only in the Base_Match transform configuration. For all other configurations, this option is selected.

Option	Description
Match set name	Enter a name for this match set. Each Match transform in your data flow represents a match set. This option is already populated with name you chose if you used the Match wizard to generated this transform. Be sure that this name is unique within the data flow (it does not match the name of another match set). This name is used in the match reports to differentiate data processed by one match set versus another.
Match engine	Specifies the match engine to use, based on the type of data you will be processing. If you use the Multinational strategy in the Match wizard, this option is set to Latin1 for all match sets. *Chinese:* Specifies that the Match transform will be processing Chinese data in Chinese script. *Japanese:* Specifies that the Match transform will be processing Japanese data in Japanese script. *Korean:* Specifies that the Match transform will be processing Korean data in Korean script. *Latin1:* Specifies that the Match transform will be processing Latin1 data. In general, this is the data used throughout the Americas, Western Europe, Oceania, and much of Africa. *Other_Non_Latin1:* Specifies that the Match transform will be processing non-Latin1 data, other than Chinese, Japanese, Korean, and Taiwanese, such as Russian, Greek, Hebrew, Arabic, and others. *Taiwanese:* Specifies that the Match transform will be processing Taiwanese data in Taiwanese script. For optimum accuracy and performance, be sure that you have filtered your multinational data to separate match transforms with the appropriate match engine selected. The Match wizard can do this for you easily, if you select the Multinational strategy. By default, the Latin1 match engine is used. If you attempt to process non-latin1 data with the Latin1 engine, the results are unpredictable.
Generate report data	Specifies whether to generate report data for this transform. This option is available in every transform that generates report data. *Yes:* Generates report data for this transform. *No:* Turns off report data generation. If you do not need to generate reports (during testing of data flows, for example), you should set this option to No. This will improve match performance.
Logical source field	Specifies the field that contains the ID for the logical source.
Physical source field	Specifies the field that contains the ID for the physical source (Reader).

Option	Description
Run as a separate process	*Yes:* Splits the transform into a separate process. *No:* Keeps the transform in same process as the rest of the data flow.

Related Information

Performance Optimization Guide: Run as a separate process option [page 2153]

3.5.4.12.2.2 Match transform options: Data Salvage tab

Option	Description
Match set name	Enter a name for this match set. Each Match transform in your data flow represents a match set. This option is already populated with name you chose if you used the Match wizard to generated this transform. Be sure that this name is unique within the data flow (it does not match the name of another match set). This name is used in the match reports to differentiate data processed by one match set versus another.
Enable data salvage	Select to perform data salvaging. If two records match, data salvaging temporarily copies data from a passenger record to the driver record after comparing the two records. The copied data is data that is found in the passenger record but is missing or incomplete in the driver record. Data salvaging prevents blank matching or initials matching from matching records that you may not want to match.
Perform data salvage default	Specifies the default value that indicates whether to perform data salvage if the data record does not contain a field with this value. *Yes:* Performs the data salvage on the driver record after it matches a passenger record. *No:* Does not perform the data salvage on the driver record after it matches a passenger record.
Specify data salvage by field	Select to control data salvaging by means of a value in a field.
Perform data salvage field	Specifies the field that contains the indicator for performing the data salvage operation. Use this to override the default value.

Option	Description
Specify data salvage by source	Select to control data salvaging per source.
Source	Select a source from the drop-down menu. You must populate the Logical Input Source window with sources to have any appear in this drop-down list.
Perform data salvage	Select Yes or No to signify you want data salvaging performed on a source.

Related Information

Designer Guide: Match, Data Salvage [page 543]

3.5.4.12.2.3 Input Source options

Use the Input Sources options to define input sources for which you want to track statistics and to provide additional functionality throughout the Match transform. Before you define your input sources, you will need to map a field that contains the value that identifies the input source.

Option	Description
Value field	Choose an input field from the drop-down list that contains the value for your sources.
Source name	Enter a name for your input source.
Source value	Enter the value from the input data that identifies records belonging to this source. Sources are created by matching this case-sensitive value to that contained in the value field specified.
Source type	Choose a source type from the drop-down list. *Normal:* A Normal source contains good or eligible records. *Suppress:* A suppression source contains records that would often disqualify a record from use. For example, if you're using the software to refine a mailing list, a Suppress source removes records from the mailing. Examples: ● DMA Mail Preference File ● American Correctional Association prisons/jails lists ● No pandering or non-responder lists ● Credit card or bad-check suppression lists *Special:* A Special source is treated like a Normal source, with one exception. A Special source is not counted in when determining whether a match group is single-source or or multi-source. A Special source can contribute records, but it's not counted toward multi-source status.

Option	Description
	For example, some companies use a source of seed names. These are names of people who report when they receive advertising mail, so that the mailer can measure mail delivery. Appearance on the seed source should not be counted toward multi-source status.
Default source name	Specifies the name of a source to assign records to that do not belong to a predefined source. This name must match the name of a predefined source, so you must define input sources first to see any items in this list. The default source name will also be used if the Source value is blank or if the maximum number of sources is reached (maximum of 10,000).
Auto generate sources	Select to create sources for each unique entry in the Value field. This can save you time because you won't have to manually define your input sources. The name of an automatically generated source will be the same as the value in the Value field. As each record is processed, Match will first check to see if the record belongs to a predefined source. If it does, Match will assign that record to that source. If the record does not belong to a predefined source, then Match will check to see if the record belongs to an auto-defined source. If the record belongs to an auto-defined source, Match will use the auto-defined source. If the input source is not defined, Match will add the definition to the list of defined sources. If the maximum number of source definitions has been reached, then instead of adding a new source definition, Match will use the default source. ℹ Note When using auto generate sources, the Source ID is case sensitive but, the Type field is not case sensitive. Auto generate sources will accept Type field values of N, n, P, p, S, or s.
Default type	See the description of the Source type option in this table for information about source types. This type will be used for any source that does not already have a type defined in the Type field.
Type field	Choose an input field from the drop-down list that contains the input source type. The type field must have a value of: *N:* Normal *P:* Suppress (or Purge) *S:* Special If the field is not defined or if the field value is not N, n, P, p, S, or s, the default type is used.

Option	Description
	ℹ Note This option is not case sensitive.

3.5.4.12.2.4 Source Group options

Adding a Source Group operation can provide you with additional statistics in certain Match reports.

Option	Description
Source groups	Create your source groups here. To get started, double-click the checkbox in the first row, and type in a name for your source group.
Sources	This list contains all of the sources defined in the Input Sources operation.
Undefined action	Specifies the action to take if an input source does not appear in a source group. *Ignore:* The input source does not belong to any source group. *Default:* The input source belongs to the default source group specified in the *Default source group* option. *Auto:* ● If the *Source group field* option is not defined, then the input source will belong to a source group of the same name as the input source. The source group is created if necessary. ● If the *Source group field* option is defined, then the input source belongs to the source group named in the *Source group field* option. The source group is created if necessary. ● If the source group field's content is blank, then that input source will not belong to a source group (equivalent of Ignore).
Default source group	Select a default source group name from the drop-down list. You can choose from your defined source groups. This option is required if you chose Default as the value for the *Undefined action* option.
Source group field	Specifies the field that contains the value for your source groups.

3.5.4.12.3 Group forming

Group forming allows you to group and prioritize records for better match accuracy and efficiency.

Break groups

Break groups allow you to group records based on common field values (for example, postal code). Only records that share the same break group value will be compared with one another.

Use break groups to lower the number of comparisons needed and to increase the speed of the matching process.

Candidate selection

The process of candidate selection appends records from a relational database to an existing break group for processing.

For real-time jobs, candidate selection pulls a candidate set of records based on a single record or many records.

> i Note
>
> Candidate selection works with relational databases only; it does not work with flat files.

Group prioritization

Use group prioritization to ensure that your most complete and accurate records drive the comparison process.

Related Information

Break group options [page 1270]
Candidate selection options [page 1272]
Group prioritization options: Priority Order tab [page 1140]

3.5.4.12.3.1 Break group options

Use the break group options to group records based on common field values.

Options	Description
Split records into break groups	Select this option if you want to form break groups to reduce the total number of comparisons made. The most common case for deselecting this option is when have a real-time job and your data comes in as one break group. This scenario also often makes use of candidate selection (selecting a limited number of records from a relational database) for optimal real-time matching.

Options	Description
	⚠ Caution Deselect this option with caution within a batch data flow. The size of a break group may not exceed 2 GB. If you use this option in a batch data flow, also set the *Maximum allowable break group size (in records)* option so that the collection does not exceed the size limit. If it does exceed the limit, the data flow will abort. i Note Break group size is calculated by multiplying the record length by the number of records in the break group.
Field	Choose a mapped input field name from the drop-down menu that you want to include in the break key. Click the Add Row button to add another field. If you require a more complex break key, you could define that field using an upstream Query transform and select the field here.
Start Position	Enter the start position of the field. Valid values for a field of n are 1 to n and -1 to -n. Negative start values signify that the start position is counted from the right. For example, a field with a length of 7 contains JOHNSON. A start position of 2 would mean start with "O." A start position of -4 means start with the "N" (This would also be the case if the field has a length of 20, because the negative start value starts from the actual length of the string, not of the field).
Length	Enter the number of characters in the field you want included in the break key.
Break key case sensitive	Specifies whether to treat the break key as case sensitive. *Yes:* Treat the break key as case sensitive. *No:* Do not treat the break key as case sensitive. For example, if you create a break key using the primary name (street), separate break groups would be formed with values of “Main” and “main” when you specify that the break key is case sensitive.
Replace NULL with empty string	Specifies whether to convert NULL values with an empty string in the break key. *Yes:* Convert NULL to an empty string. *No:* Do not convert to an empty string.
Right pad fields with blanks	Because the break key is used for sorting and aggregating, it is sensitive to the position in which data is placed. By right-padding the break key fields you can help ensure that break groups are formed properly.

Options	Description
	If the *Replace NULL with empty string* option is set to YES and this option is set to YES, then fields with NULL values will be replaced with all spaces (to the length of the field). *Yes:* Right-pad fields with blank spaces. *No:* Do not right-pad fields.
Input already sorted	Specifies that the input data has already been sorted, and you do not want it sorted again. For example, if you require a more complex break key, you could use a Query transform to create it, and use the ORDER BY operation to order your data. *Yes:* The transform will not re-sort the input data. *No:* The transform will sort the break keys at runtime before forming break groups.
Maximum allowable break group size (in records)	Specifies the maximum number of records allowed in a break group. An empty value or zero means that there is no limit on the break group size. With this option, you can control the amount of memory used during processing by specifying the number of records processed at one time. If more records make it into a single break group than specified, then the data flow throws an error and stops.

Designer Guide: Match, Break keys and candidate selection [page 533]

3.5.4.12.3.2 Candidate selection options

The candidate selection option group includes the following options:

Option	Description
Datastore	Select a valid datastore. This list is populated with all valid SQL and persistent cache datastores. If you choose a persistent cache datastore, you will not be able to enter custom SQL.
Cache type	This option can be used to improve performance, with a trade-off of more memory consumption. *No_Cache:* Specifies that each query will be sent to the database.

Option	Description
	Pre_Load_Cache: Specifies that the entire secondary table is cached to a local disk or memory.
Auto-generate SQL	Select to have your SQL generated by the transform. This option allows you to query a simple single table. If you need to join tables or create a complex WHERE clause, you should select the *Create custom SQL* option.
Table	Enter a valid table name from the datastore.
Use break column from database	Select this option if your database already contains a column that corresponds to the break key field.
Break key field	Select the column from the secondary table that contains the break key field.
Create custom SQL	Select to create custom SQL.
Launch SQL Editor	Opens the SQL editor. This button is only enabled if you select the *Create custom SQL* option.
Use constant source value	Select to assign records to a physical source for generating appropriate statistics.
Physical source value	Type a value for your physical source. This value will be placed in the physical source field you select.
Physical source field	Select the mapped field that contains the physical source name.
Add DB columns to mapping table	If you are using the *Create custom SQL* option, clicking this button will add only the database columns that appear in the SELECT statement and in the order that they appear in the SELECT statement. If you are using the *Auto-generate SQL* option, clicking this button will add ALL database columns, in the order that they appear in the table schema. Note If you do not associate an input field to any of these columns in the column mapping table, they will be removed when you close the window.

Column mapping table

This table allows you to specify which mapped field in the data flow each database selected field is assigned to.

Column	Description
Break key	Specifies whether this field is used as part of your break key.
Field	Each cell contains a list of the mapped names from the input fields in the transform.

Column	Description
DB column	Each cell contains a list of the column names in your database table or the selected columns from a custom query. Match the data of a column in your database to the data of a mapped field.

Related Information

Designer Guide: Match, Break keys and candidate selection [page 533]

3.5.4.12.3.3 Group prioritization options: Priority Order tab

Group forming prioritization

Use the Group prioritization operation to order records within each break group, which controls which records are used as the drivers during the comparison process.

Post-match prioritization

Add a Group prioritization operation before a Group Statistics operation to order records within a match group to control which record is flagged as the master record of each group of matching records. Add a Group prioritization operation before a Best Record operation to order records within a match group to control the destination of data that is being propagated from other records to form a best record.

Option	Description
Prioritization name	Specifies the name for this Group prioritization operation. If you have multiple operations in this Match transform, be sure to make this name unique.

Priority fields

Use the Priority fields table to order your break groups based on the content of a field (for example, dollar amount or date). Use the buttons to add, remove, and order rows. Place the primary sort field at the top of the list. The rest of the fields, in the order that they are positioned, determine the sub-sort that occurs.

Option	Description
Input field	Choose a field to sort your records on.
Field order	Specifies in which order records should be sorted.

3.5.4.12.3.4 Group prioritization options: Record Completeness tab

Option	Description
Prioritization name	Specifies the name for this Group prioritization operation. If you have multiple operations in this Match transform, be sure to make this name unique.
Order records based on completeness of data	Select this option to apply priority and blank penalty points to records to help control the order of your records.
Define only field penalties	Select this option when penalties need to be assessed based on blank fields.
Define priority and penalty fields	Select this option when you have specific fields that contain the actual integer values for priority and blank penalty.
Record priority field	Choose the field that contains priority values. This field must contain an integer.
Apply blank penalty field	Choose the field that contains the indicator (Y or N) for applying blank penalty points to a record.
Define priority and penalty based on input source	Select to have your record priority and blank penalty indicator (Y or N) determined by membership in a given source.
Source Name	Choose an input source from the drop-down list in the Source Name column. The sources listed here are defined in the Input Source operation.
Priority	Type a priority value (an integer) in the Priority column. Remember that the lower the priority score, the higher the priority.
Apply Blank Penalty	Choose Yes or No to determine whether a blank penalty is applied to a record based on membership to this source.
Default record priority	Specifies the default value for the record priority if the record does not contain a field with this value, this field is blank for a record, or if a record does not belong to any of the sources specified. Remember that the lower the priority score, the higher the priority.
Default apply blank penalty	Specifies the default indicator as to whether to add blank penalty points to records with blank fields. This indicator is used if a record does not have a field that carries this indicator, if that field is blank or has invalid data, or ifa record does not belong to any of the sources specified. *Yes:* Each record's blank penalty is added to the record's record priority to generate an adjusted record priority score. The lower the score, the higher the priority. *No:* No penalty is applied when the fields are blank.
Input field	Displays the input fields available to assign a blank penalty score to.
Blank penalty	Assign a penalty value (an integer) to apply when the specified field is blank in a record.

3.5.4.12.4 Matching

3.5.4.12.4.1 Match level options

These options affect processing at the match level only.

Table 164: Person Options

<table>
<tr><th>Option</th><th>Description</th></tr>
<tr><td>*Match level name*</td><td>Enter a name for this match level. Be sure that this name is unique within the Match transform.</td></tr>
<tr><td>*Weighted match score*</td><td>Specifies the weighted match score for this level.
When your matching method includes weighted scoring, records are considered matches when the total contribution score is greater than or equal to this value.</td></tr>
<tr><td>*Number of names that must match*</td><td>Specifies the number of names that must match. This option requires that you have criteria of Person1_Given_Name1, Person1_Family_Name1, and so on.
One: Specifies that records are a match when at least one of the names meet the criteria.
All: Specifies that records are a match only when all of the names meet the criteria.</td></tr>
<tr><td>*Match on hyphenated family name*</td><td>Specifies whether a single family (last) name in one record matches a hyphenated family name in another record. For example, this option considers whether the two records shown below are matches.
This comparison is performed only if one field has a hyphen and the other does not.
<table>
<tr><th>Given</th><th>Family</th></tr>
<tr><td>Laura</td><td>Smith</td></tr>
<tr><td>Laura</td><td>Albers-Smith</td></tr>
</table>
This option works on a criteria named Family_Name1, Family_Name2, or Family_Name3.
Yes: The family names match as long as the single family name in one record matches one of the hyphenated family names in another record.
No: The hyphenated family name is considered a single family name and the comparison results in a low similarity, usually not meeting your family name criteria, resulting in a no-match.</td></tr>
<tr><td>*Compare Given Name1 to Given Name2*</td><td>Specifies whether the given name1 (first name) of one record is compared to the given name2 (middle name of another record).
For example, the two records shown below could be considered duplicate records if this option is set to Yes.</td></tr>
</table>

<table>
<tr><th>Option</th><th>Description</th></tr>
<tr><td></td><td><table>
<tr><th>Given name1</th><th>Given name2</th><th>Family name1</th></tr>
<tr><td>John</td><td></td><td>Smith</td></tr>
<tr><td>R</td><td>John</td><td>Smith</td></tr>
</table>
To use this option, you must have criteria named Person1_Given_Name1 and Person1_Given_Name2, Person2_Given_Name1 and Person2_Given_Name2, and/or Person3_Given_Name1 and Person3_Given_Name2.
<i>Yes</i>: The Given_Name1 field of one record is compared to the Given_Name2 field of another record.
<i>No</i>: The Given_Name1 field of one record is not compared to the Given_Name2 field of another record.</td></tr>
<tr><td><i>Ignore family name when female</i></td><td>Specifies whether an adjustment occurs for family names when the given name is a female. To use this option, you must have at least these three criteria: Given_Name1, Family_Name1, and Gender.
<i>Yes</i>: The Family_Name1 criteria is ignored when the given name gender is a female (Gender=5). For example, Laura Smith may match Laura Albers.
<i>No</i>: The gender is not used and the matching process is performed as usual.</td></tr>
</table>

Table 165: Address Options

<table>
<tr><th>Option</th><th>Description</th></tr>
<tr><td><i>Match on Street and RR, or on Box</i></td><td>Specifies whether to match on PO Box only or on street, rural route, and PO Box. This option affects business and household records matching on address.
<i>Yes</i>: Records are considered a match if the Boxes match. If the Boxes do not match, then the address and rural route address must pass the match criteria settings.
<table>
<tr><th>firm</th><th>number</th><th>street</th><th>suffix</th><th>postal number</th><th>postcode</th></tr>
<tr><td>Acme Hardware</td><td>100</td><td>Elm</td><td>Ave</td><td>200</td><td>02961</td></tr>
<tr><td>Acme Hardware</td><td>123</td><td>Main</td><td>St</td><td>200</td><td>02961</td></tr>
</table>
<i>No</i>: All forms of the address (street, rural route, and PO Box) must match.</td></tr>
<tr><td><i>Address matches blank if Firms match</i></td><td>Specifies whether to match on firm data when other address data does not match. This only affects records when one has street information and the other has PO Box information. If both records have Street information that do not match, or if both have PO Box information that do not match, the records will not be found as duplicates.</td></tr>
</table>

<table>
<tr><th>Option</th><th>Description</th></tr>
<tr><td></td><td><table>
<tr><th>firm</th><th>number</th><th>street</th><th>suffix</th><th>postal number</th><th>postcode</th></tr>
<tr><td>Acme Hardware</td><td>100</td><td>Elm</td><td>Ave</td><td></td><td>02961</td></tr>
<tr><td>Acme Hardware</td><td></td><td></td><td></td><td>300</td><td></td></tr>
</table>
<p><em>Yes</em>: If firm data matches and neither firm field is blank, blank matching is allowed for all address components.</p>
<p><em>No</em>: If firm data matches, but address data in one of the records is blank, the records will not be considered a match (unless blank matching is turned on for those address components).</p></td></tr>
<tr><td><em>Unique on resident if RR, but no Box</em></td><td><p>Specifies whether to match on Rural Route when an input record's Family Name field contains a resident-type name of Current Resident, Occupant, blank, or name not defined and a rural route address, with no box number.</p>
<p><em>Yes</em>: Places all records with this type of name data into the same match group.</p>
<p><em>No</em>: Does not place records with this type of name data into the same match group.</p></td></tr>
<tr><td><em>Ignore Firm if Name matches</em></td><td><p>This option works with odd abbreviations or spellings of firm names. This assumes that you are matching on two Family Names.</p>
<p><em>Yes</em>: Indicates matching names at the same address are matches, even if the firms don’t match. This lets you catch the following match, which might otherwise have been missed.</p>
<p>Rita Terranova Greenco 100 Bren Rd 55343</p>
<p>Rita Terranova Eco Technologies 100 Bren Rd 55343</p>
<p><em>No</em>: Both the firm criteria and the address criteria must meet the minimum similarity threshold in order to match.</p></td></tr>
</table>

Related Information

Designer Guide: Match, Weighted scoring method [page 550]

3.5.4.12.4.2 Match criteria table

Use the match criteria table to navigate to a particular criteria by double-clicking a row in the table.

Use the Add, Remove, and Move buttons to adjust the quantity and order of your match criteria.

3.5.4.12.4.2.1 Match criteria options: Criteria Fields tab

Available criteria

Choose a criteria that best reflects the data in the field you want to compare.

Category	Description
Geographic	*Address_Data1-5:* Use for address data that is not accounted for in other address-based criteria in the Geographic category. You can also use this criteria for fields that you know contain address data, but you're not sure which type it contains, or you can use it for international data that has not been parsed.
	Address_Post_Office_Box: Post Office box number.
	Address_Primary_Name: Street name data.
	Address_Primary_Number: Street number data.
	Address_Primary_Postfix: Address data that comes at the end of a street name, such as a directional.
	Address_Primary_Prefix: Address data that comes at the beginning of a street name, such as a directional.
	Address_Primary_Type: Data that tells what type of street it is (street, boulevard, lane, and so on).
	Address_Private_Mail_Box: A private mail box (PMB) number. These are mail boxes that are not run by a postal authority.
	Address_Rural_Route_Box: Rural-route box number (number only, without “Box” prefix).
	Address_Rural_Route_Number: Rural route number.
	Address_Secondary_Number: The number of a unit, building, floor, or room.
	Country: Country name.
	Locality: City, town, locality, or suburb.
	Latitude_Longitude: Latitude and longitude.
	Postcode1: Primary postal code.
	Postcode2: Secondary postal code.
	Region: Region data, such as state or province.
Firm	*Firm:* Firm name.

Category	Description
	Firm_Data1-3: Use for firm data that is not accounted for in other firm-based criteria. You can also use this criteria for fields that you know contain firm data, but you're not sure which type it contains. You can also use this for international data.
	Firm_Match_Std1-6: Firm match standards. The data in these fields is generated by the Data Cleanse transform or other pre-Match transforms.
	Firm_Location: A location within a company or organization.
	Firm_Location_Match_Std1-6 Match standards for a location within a company or organization.
Person	*Name_Data1-3:* Use for name data that is not accounted for in other name-based criteria. You can also use this criteria for fields that you know contain name data, but you're not sure which type.
	Person1-3_Given_Name1: The given name1 (first name) of the persons.
	Person1_Given_Name1_Match_Std1-6: Given_Name1 (first name) match standards for the first person.
	Person2_Given_Name1_Match_Std1-6: Given_Name1 (first name) match standards for the second person.
	Person3_Given_Name1_Match_Std1-6: Given _Name1 (first name) match standards for the third person.
	Person1-3_Gender: Gender.
	Person1-3_Family_Name1: Family (last) name.
	Person1-3_Family_Name1_Match_Std1-6: Family_Name1 match standards for the persons in your data record.
	*Person1-3_Family_Name2:*Family (last) name. Use this field when family name data is split into two fields, for example, for cultures where they store the paternal family name and the maternal family name in different fields.
	Person1-3_Family_Name2_Match_Std1-6: Family_Name2 match standards for the persons in your data record.
	Person1-3_Maturity_Postname: Maturity postname.. For example, Sr. or Jr. (one standard per person).
	Person1-3_Maturity_Postname_Match_Std1-6: Maturity postname match standards for the persons in your data record.
	Person1-3_Given_Name2: Given name2 (middle name).

Category	Description
	Person1_Given_Name2_Match_Std1-6: Given_Name2 (middle name) match standards for the first person.
	Person2_Given_Name2_Match_Std1-6: Given_Name2 (middle name) match standards for the second person.
	Person3_Given_Name2_Match_Std1-6: Given_Name2 (middle name) match standards for the third person.
	Person1-3_Honorary_Postname: Honorary postname for up to three persons indicating certification, academic degree, or affiliation. For example, CPA.
	Person1-3_Honorary_Postname_Match_Std1-6: Honorary postname match standards.
	Person1-3_Prename: Prename (for example, Mr. or Mrs.) for up to three persons.
	Person1-3_Prename_Match_Std1-6: Prename match standards.
	Person1-3_Title: Job or occupational title of each person. For example, Manager.
	Person1-3_Title_Match_Std1-6: Title match standards for each person.
	Social_Security_Number1-3: Social Security numbers for up to three people in a record.
Other	*Date1-3:* Date data. For example, birthdate data.
	Phone: Phone number.
Custom	Use custom fields to match data that does not qualify for any of the specifically named criteria. If you prepared fields for matching through a custom Universal Data Cleanse solution, the Data Cleanse dictionary names appear in the Custom category.

Criteria field mapping

Option	Description
Criteria field	The criteria field that contains the data you want to compare.
Input field mapped name	Choose the mapped name for your criteria field. If you choose any of the following input fields, the Match transform automatically adds the appropriate match standard fields. The fields displayed will vary depending on the value chosen for *Compare data using* on the Options tab. ● Firm ● Firm_Location

Option	Description
	- Person*_Given_Name1 - Person*_Given_Name2 - Person*_Honorary_Postname - Person*_Maturity_Postname - Person*_Prename - Person*_Title You can then choose to include or exclude any of these from mapping. Note If you enable multiple field matching, any appropriate match standard fields are removed. If you want to include them in the match process, add them in the *Additional fields to match* table in the *Multiple field matching* section.

3.5.4.12.4.2.2 Match criteria options: Options tab

Option	Description
Compare data using	Specifies how to handle fields where more than one word commonly exists. Only those options appropriate for the chosen value appear in the Comparison Rules table. *Field Similarity:* If you choose Field Similarity, the transform compares the entire field's data as a single string. This algorithm is more efficient and should be used in fields that typically have just one word. *Geo Proximity*: If you choose Geo proximity, the transform compares latitude and longitude information from different records for geographic proximity to determine if they are close enough to be considered duplicates. *Numeric Difference*: If you choose Numeric Difference, the transform compares numeric information from different records based on numerical difference to see if they are close enough to be considered duplicates. *Numeric Percent Difference*: If you choose Numeric percent difference, the transform compares numeric information from different records based on percentage of numerical difference to see if they are close enough to be considered duplicates. *Word Similarity:* If you choose Word Similarity, the transform first parses the data into words and then compares the words. This algorithm is less efficient than the Field algorithm, but will do a better job comparing data that typically has more than one word in it. Many criteria options require this option to be set to Word Similarity.

Pre-comparison options

Use these options to alter the data used for the comparison process. These options do not alter the data that is output from the Match transform.

Option	Description
Field compare length	Specifies the number of characters in the field to compare. Note This option will be disabled (grayed out) if the input field mapped to the main criteria (not a match standard) is not of type varchar.
Remove punctuation	Specifies whether to remove punctuation from your data to help provide more accurate matches. Be aware of the following: - This option is valid for Latin1 data only. - Match will not remove a dash from a Family_Name* field. *Yes:* Removes punctuation. *No:* Keeps punctuation in your data. Note This option works on the mapped input field used in this and other criteria. If you set this option to something different than how it is set in another criteria using this same field, it will override that setting. Before setting this option, be sure that there are no other criteria using this same field. ⚠ Caution Setting this option and the *Convert text to numbers* option to *Yes* may produce undesirable results. For example: Suppose you have `1.23` as data in a criteria field. Setting *Remove punctuation* to *Yes* would convert this number to `123`. This number would then match another value of `123`, or, in the case of converting text to numbers, match a value of "one hundred twenty-three".
Convert to uppercase	Specifies whether to convert all data to uppercase for matching purposes only. This option is valid for Latin1 data only. *Yes:* Converts the data to uppercase for the comparison process. *No:* Preserves the case of the data for the comparison process, treating A and a as different characters.

Option	Description
	Note This option works on the mapped input field used in this and other criteria. If you set this option to something different than how it is set in another criteria using this same field, it will override that setting. Before setting this option, be sure that there are no other criteria using this same field.
Convert diacritical characters	Specifies whether to include diacritical characters in the matching process. Be aware of the following: • This option is valid for all match engine options. • This option works only on upper-Latin1 characters (values between 128 and 255). If you are processing Japanese data, for example, you may have some Latin1 data mixed in. In these cases you will be able to convert diacritical characters. *Yes:* Converts diacritical characters to the closest English ASCII equivalent for matching purposes. For example, ä converts to a. *No:* Preserves diacritical characters in the matching process, treating ä and a as not identical characters. Note This option works on the mapped input field used in this and other criteria. If you set this option to something different than how it is set in another criteria using this same field, it will override that setting. Before setting this option, be sure that there are no other criteria using this same field.
Convert text to numbers	Specifies whether numbers represented as text (one, two, three) should be converted to numbers. If you choose Yes, they will be in cardinal (one = 1) or ordinal (first = 1st) format. *Yes:* Converts numbers represented as text to numbers. *No:* Leaves any numerical text intact. Note This option works on the mapped input field used in this and other criteria. If you set this option to something different than how it is set in another criteria using this same field, it will override that setting. Before setting this option, be sure that there are no other criteria using this same field. Caution Setting this option and the *Remove punctuation* option to *Yes* may produce undesirable results. For example:

Option	Description
	Suppose you have `1.23` as data in a criteria field. Setting *Remove punctuation* to *Yes* would convert this number to `123`. This number would then match another value of `123`, or, in the case of converting text to numbers, match a value of "one hundred twenty-three".
Locale	Specifies the locale setting for this criteria field. If nothing is specified, or you specify *DEFAULT*, the default system locale in the software will be used. Setting this option is recommended if you plan to use the *Convert text to numbers* option.

Comparison rules

<table>
<tr><th>Option</th><th>Description</th></tr>
<tr><td><i>Approx substring adjustment score</i></td><td>Specifies what score to give to words that were not matched to the other words in the compared string. This option is commonly used to compare family names that have varying representations in which the <i>Substring adjustment score</i> option is too strict to compare, such as "Cruz Rodríguez" and "C. de Rodríguez".
Enter a value from 0 (default) to 100. Enter a value of 0 to disable the option.</td></tr>
<tr><td><i>Abbreviation adjustment score</i></td><td>This option controls matching whole words to abbreviations. For example, long firm names are often abbreviated by removing letters. International Health Providers might be abbreviated to Intl Health Providers.
For example:
<table>
<tr><th>Full word</th><th>Possible abbreviations</th></tr>
<tr><td>Business</td><td>Bus, Bsnss, Bss</td></tr>
<tr><td>Database</td><td>Dat, Db, Dse</td></tr>
</table>
As shown in the examples, abbreviation means that the first letter of the shorter word matches the first letter of the longer word, and all remaining letters of the shorter word appear in the longer word in the same order as in the shorter word. The value you enter is the score given to the letters that are in the longer word but not the shorter word.
● Enter a value of 0 (zero) to disable abbreviation checking.
● Enter a value greater than 0 to enable this option.
● Enter a value of 100 if you want abbreviations and longer words to be considered a perfect match.</td></tr>
</table>

Option	Description
	ℹ Note For this option to work, you must set the *Compare data using* option to *Word Similarity*.
Both fields blank operation	Specifies whether to use this criteria when both of the records' fields for this criteria are blank. *Eval:* The value entered in the Both fields blank score option is used as the similarity score for this criteria. *Ignore:* This criteria is ignored in the comparison process, and its contribution to the weighted score is proportionally distributed among the remaining criteria, therefore negating any impact the contribution score may have had.
Both fields blank score	Specifies the similarity score if both of the fields are blank and Both fields blank operation is set to *Eval*. Enter a value from 0 to 100.
Check for transposed letters	Specifies whether the match score should be adjusted for any transposed characters encountered. *Yes:* The transform deducts half as many points for transposed characters as it deducts for other non-matching characters. For example: Comparison: Smith—Simth Finding: Words differ by one transposition (penalty of 1 correction) Percentage alike: 90% *No:* The transform handles transposed characters the same way it handles any non-matching characters. For example: Comparison: Smith—Simth Finding: Words differ by one transposition (penalty of 1 correction) Percentage alike: 80%
Contribution to weighted score	Specifies the contribution value, when you use the weighted or the combination scoring method. If no single criteria decides a match or no-match, the contribution score is calculated by summing the products of each criteria's score by each criteria's weight. Type a value between 0 and 100.

Option	Description
Distance Unit	Specifies the type of distance unit used to calculate the distance between two Latitude, Longitude pairs. This option is only available when the Geo Proximity option is selected. Select one of the following: ● *Feet* ● *Kilometers* ● *Meters* ● *Miles*
Enable inter-script matching	Enable this option if you have the same data in different scripts (writing systems). For example one record has Latin1 and other has Katakana, or one has Latin and other has Cyrillic .
Ext abbreviation adjustment score	This option handles a variation of the *Abbreviation adjustment score* option. Enter a number that adjusts the similarity score for these types of abbreviations. For example: ● Enter a value of 0 (default) to disable abbreviation checking. ● Enter a value greater than 0 to enable abbreviation checking. Remember the following when using this option: ● The first letter of the short word must match the first letter of the first word in the multiple-word string, and the remaining letters of the short word must be found in order in the multiple-word string. ● Letters that match are given a score of 100. The remaining letters are given the score that you specify. ● The two scores are proportionally combined to render the overall score. Note For this option to work, you must set the *Compare data using* option to *Word Similarity*.
Initials adjustment score	Specifies whether you want initials or acronyms to match whole words. For example, the firm name International Health Providers could match IHP. Enter a value from 0 to 100. Enter a value of 0 (default) to disable initial checking. Remember the following when using this option: ● The initial must match the first letter of the word. ● The letters that match are given a score of 100. The remaining letters are given the score that you specify (from 1-100). ● The two scores are proportionally combined to render the overall score. If there are other words in the field that are not shortened, they are scored the usual way. For example, New York Police Department may be shortened to New York PD and still match.

Option	Description
	ℹ Note For this option to work for multiple-word abbreviations (such as International Health Providers = IHP) you must set the *Compare data using* option to Word Similarity. For this option to work for single-word abbreviations (such as Maria = M) you may set the *Compare data using* option to either Word Similarity or Field Similarity..
Match score	Specifies the minimum similarity score needed for the records to be considered a match based on this criteria. Type a value from 0 to 101. A value of 101 ensures that this criteria alone is not enough to consider two records a match and that you want to consider other criteria in the comparison process. For example, a value of 90 means that you consider this data to be important enough that if the data in two records is 90% similar or higher, the records are considered a match.
No match score	Specifies the maximum similarity score needed for the records to be considered a no-match based on this criteria. Type a value from -1 to 100. A value of -1 ensures that this criteria is not enough to consider two records a no-match and that you want to consider other criteria in the comparison process. For example, a value of 49 means that if the similarity between the data in two records is less than 50%, the records do not match.
Max Difference	Specifies the maximum difference allowed in a numeric range. Type a value from 0 - 2147483647.
Max Difference Score	Specifies what score to generate when the difference is the same as the Max Difference. Valid values for this required attribute range from 0 to 100. Any difference larger than the Max Difference will receive a score of 0. A difference equal to Max Difference will receive a score of Max Difference Score. Any difference less than Max Difference will receive a proportional score between Max Difference Score and 100.
Max Distance	Specifies the maximum distance allowed when calculating the distance between two Latitude, Longitude pairs. Type a value from 0 to 4294967295.0.
Max Distance Score	Specifies what score to generate when the distance is the same as Max Distance. Type a value from 0 to 100. Any distance larger than the Max Distance will receive a score of 0. A distance equal to Max Distance will receive a score of Max Distance Score.

Option	Description
	Any distance less than Max Distance will receive a proportional score between Max Distance Score and 100.
Max Percent Difference	Specifies the maximum difference allowed as a percent of the absolute value. Type a value from 0 to 100.
Max Percent Difference Score	Specifies what score to generate when the difference is the same as Max Percent Difference. Valid values for this required attribute range from 0 to 100. Any difference larger than the Max Percent Difference will receive a score of 0. A difference equal to Max Percent Difference will receive a score of Max Percent Difference Score. Any difference less than Max Percent Difference will receive a proportional score between Max Percent Difference Score and 100.
Numeric words match exactly	Specifies how to match data that contains both numbers and letters. *None:* Numeric words don't need to match exactly to be considered a match. *Any_Position:* Numeric words don't need to be in the same position in two different strings to be considered a match. *Any_Position_Consider_Punctuation:* This value behaves the same as the Any_Position value. However, the Match transform takes the position of a decimal separator (comma or period) within the numeric words into consideration. *Any_Position_Ignore_Punctuation:* Same as Any_Position, except that decimal separators (comma or period) are completely ignored. *Same_Position:* Numeric words must match exactly and be in the same position in the string to be considered a match. Note For this option to work, you must set the *Compare data using* option to *Word Similarity*.
One field blank operation	Specifies whether to use this criteria if one record's field is populated and the other record's field is blank. *Eval:* The value entered in the One field blank score is used as the similarity score for this criteria. *Ignore:* This criteria is ignored in the comparison process, and its contribution to the weighted score is proportionally distributed among the remaining criteria.
One field blank score	Specifies the similarity score to use if one of the fields is blank and the *One field blank operation* option is set to *Eval*. Type a value from 0 to 100.

Option	Description
Substring adjustment score	Allows matching longer strings of words to shorter strings. For example, long firm names are often shortened to the first few words of the name. A fictitious company such as Mayfield Painting and Sand Blasting might be shortened to Mayfield Painting. Remember the following rules about values to enter: - Enter a value from 0 to 100. Enter a value of 0 (default) to disable substring checking. - Enter a value of 100 if you want substrings and longer strings to be considered a match. Here is what happens after processing. - Letters that match are given a score of 100. The remaining letters are given the score you specify (from 1-100). - The two scores are proportionally combined to render the overall score. To qualify as a substring match, the shorter string must exactly match the first part of the longer string. Consider the following example: Matching substrings - Mayfield - Mayfield Painting - Mayfield Painting and Sand Substrings that do not match - Mayfield Sand Blasting - Painting and Sand Blasting Alternate spellings in any of the words also disqualify the substrings as a match. For example, “Murphy Painting and Sand Blasting” does not match. (This comparison would have a similarity score of 85% without this option set.) Note For this option to work, you must set the *Compare data using* option to *Word Similarity*.
Use in weighted score if greater than	Specifies the minimum similarity score needed to qualify this criteria to contribute to the Weighted Match Score. For example, if the value entered here is 59 for a given name criteria, and the given names between two records are less than 60% similar, then the given name criteria is ignored and the contribution value is proportionally distributed among the remaining criteria.
Zero weighted score if less or equal	Specifies the minimum similarity score needed for this criteria to qualify for contributing a value other than zero to the weighted match score.

Option	Description
	For example, if the value is 59 for the given name criteria, and the given names between two records are less than 60% similar, then the given name criteria contributes zero toward the weighted match score.

Reset Rules buttons

We provide you with default matching scores for every criteria (including options such as Match score, No match score, Contribution to weighted score, One field blank score, Both fields blank score, and so on). The Reset Rules buttons allow you to try different base levels of matching scores, as well as provide you a way to return to the default scores. These buttons primarily adjust the No match score and other options that are dependent on that score. The *Reset All to Default* button returns all options and scores to the original default values.

Loose matches mean that there will be more matches in a match group, but you may sacrifice in the quality of the matches.

Exact matches mean that the quality of the matches will be high, but they will be fewer in number.

3.5.4.12.4.2.3 Match criteria options: Multiple Field Comparisons tab

Multiple field mapping

Option	Description
Compare multiple fields	Enable multiple field matching.
All selected fields in other records	Match each field against all fields selected in the table in each record.
The same field in other records	Match each field only against the same field in each record.

Additional fields to compare

Option	Description
Criteria field	Choose the input field that contains the data you want to compare.
Custom name	Enter a name for your custom field.
Input field mapped name	Choose the mapped input field name for the criteria field. The fields displayed will vary depending on the value chosen for *Compare data using* on the Options tab.

Pre-comparison options

Use these options to optimize your data for faster comparison. These options do not alter your source data; they allow Match to change your data internally.

Option	Description
Field compare length	Specifies the number of characters in the field to compare.
Remove punctuation	Specifies whether to remove punctuation from your data to help provide more accurate matches. Be aware of the following: ● This option is valid for Latin1 data only. ● Match will not remove a dash from a Family_Name* field. *Yes*: Removes punctuation. *No*: Keeps punctuation in your data. Note This option works on the mapped input field used in this and other criteria. If you set this option to something different than how it is set in another criteria using this same field, it will override that setting. Before setting this option, be sure that there are no other criteria using this same field. Caution Setting this option and the *Convert text to numbers* option to *Yes* may produce undesirable results. For example: Suppose you have `1.23` as data in a criteria field. Setting *Remove punctuation* to *Yes* would convert this number to `123`. This number would then match another value of `123`, or, in the case of converting text to numbers, match a value of "one hundred twenty-three".
Convert to uppercase	Specifies whether to convert all data to uppercase for matching purposes only. Be aware of the following:

Option	Description
	- This option is valid for English language, Latin1 data only. - This option is ignored for all other Match engine option values. *Yes*: Converts the output data to uppercase where appropriate. *No*: Leaves the output data intact. ℹ Note This option works on the mapped input field used in this and other criteria. If you set this option to something different than how it is set in another criteria using this same field, it will override that setting. Before setting this option, be sure that there are no other criteria using this same field.
Convert diacritical characters	Specifies whether to include diacritical characters in the matching process. Be aware of the following: - This option is valid for all match engine options. - This option works best when using the Latin1 engine. If you are processing Japanese data, for example, you may have some Latin1 data mixed in. In these cases you will be able to convert diacritical characters. *Yes*: Converts diacritical characters to the closest English ASCII equivalent for matching purposes. For example, ä converts to a. *No*: Preserves diacritical characters in the matching process, treating ä and a as not identical characters. ℹ Note This option works on the mapped input field used in this and other criteria. If you set this option to something different than how it is set in another criteria using this same field, it will override that setting. Before setting this option, be sure that there are no other criteria using this same field.
Convert text to numbers	Specifies whether numbers represented as text (one, two, three) should be converted to numbers. If you choose Yes, they will be in cardinal (one = 1) or ordinal (first = 1st) format. *Yes*: Converts numbers represented as text to numbers. *No*: Leaves any numerical text intact. ℹ Note This option works on the mapped input field used in this and other criteria. If you set this option to something different than how it is set in another criteria using this same field, it will override that setting. Before setting this option, be sure that there are no other criteria using this same field.

Option	Description
	⚠ Caution Setting this option and the *Remove punctuation* option to *Yes* may produce undesirable results. For example: Suppose you have `1.23` as data in a criteria field. Setting *Remove punctuation* to *Yes* would convert this number to `123`. This number would then match another value of `123`, or, in the case of converting text to numbers, match a value of "one hundred twenty-three".
Locale	Specifies the locale setting for this criteria field. If nothing is specified, or you specify *DEFAULT*, the default system locale in SAP Data Services will be used. Setting this option is recommended if you plan to use the *Convert text to numbers* option.

3.5.4.12.4.3 Compare table

The compare table options create a table that is used to determine which record pairs qualify to be compared or which sources should be compared. If you do not include a Compare table to the Match transform, a driver record is compared with all remaining passenger records in the break group.

> 🠚 Tip
>
> If you are using many physical or logical sources in your project, it may be easier to specify what not to compare, as opposed to what to compare. For example, say you have 10 sources: A through J. You want to compare all but A and B. Set the Default action option to Compare. Then set up a table row for both source A and source B, and set the Action options for those sources to No_Match.

Option	Description
Default action	Specifies the action assigned to each cell of the compare table initially before any Compare actions table rows are applied. *Compare:* Compares all of the logical sources specified in the compare table. You can then specify a pair to not be compared in the Compare actions table. *No_Match:* Does not compare all logical sources in the compare table. You can then specify a pair to be compared in the Compare actions table.
Default source	Specifies the source that a record belongs to if that record has no field to identify it. If there are no pre-defined sources, you can type a name.
Define compare actions using field values	Select to use values in a field as the criteria for comparison, rather then membership in an input source. To use this option, you will need to enter field values in the *Compare Actions* table.

Option	Description
	This option is automatically selected if you do not have any input sources defined.
Logical source field	Specifies the field that contains the logical source value (name).
Default logical source value	If you are not passing in a field from another location that contains the logical source value, or there is no value in the field, then you must specify the default value here. This option specifies which value defined in the Compare actions table is the default value.

Compare actions

Use this table to set the action of driver records and the records they are compared with (passenger records). These entries can override your Default action option value.

Option	Description
Driver source	Specifies the source contained in the driver record. If it is omitted, then all drivers records are assumed to be the first in a break group.
Passenger source	Specifies the value contained in the passenger record. If it is omitted, then all passenger records are assumed to be any record not the first in the break group.
Action	Specifies the action to take when a record from the Driver source is to be compared with a record from the Passenger source. *Compare:* Compare the two records *No_Match:* Do not compare the two records. This option overrides the Default action option. For example, if you set the Default action option to No_Match, you can specify that you want this pair to be compared by setting this option to Compare.

3.5.4.12.4.4 Post-match processing

Use the Post-match processing table to navigate to your operations by double-clicking the desired row in the table.

Best record

The purpose of best record post-processing is to salvage data from matching records—that is, members of match groups—and consolidate, or post, that data to a best record, or to all matching records.

Group statistics

Use group statistics to generate statistical information about your group of matching records. Find out:

- the number of records within the match group
- the sequential group order number
- the group rank, which flags one record within each group of matching records as the Master record and all other records in the group as Subordinate records
- whether the records in a match group belong to more than one source

Group statistics are essential for generating data for match reports.

Prioritization

Use the prioritization operation to order records for processing by other post-match operations.

Unique ID

You can use the Unique ID options to assign sequential identification numbers to each new record when adding records to a data warehouse. For example, the largest number assigned in a particular project can be carried over as the beginning identification number (plus 1) to be used in the assignment of new sequential IDs. This occurs when the software processes the next source against the data warehouse file.

Output record

Use the Output record options to flag certain types of records for potential processing downstream.

Group forming [page 1269]

Output flag selection options [page 1306]
Designer Guide: Match, Best record [page 562]
Designer Guide: Match, Unique ID [page 570]

3.5.4.12.4.4.1 Best record options: Best Record tab

Use the best record post-match processing operation to update your records with information from other records in a match group, among other things.

Option	Description
Best record name	Enter a name for your Best Record operation. Make sure that this name is unique within this Match transform.
Best record strategy	Choose the strategy to determine whether any action is taken on records in a match group. This is the criteria for further action. After you choose the strategy, priority, and field that you want to work with, the Match transform automatically generates the Python code for you (except for Custom). *Custom:* Choose this strategy to base your strategy entirely on custom Python code. This allows you to open the Python Expression editor and create custom Python code. *Date:* Choose Date to base your strategy on a date field. *Length:* Choose Length to base your strategy on the length of data in a field. *Non_Blank:* Choose Non_Blank to base your strategy on the completeness of data in a field. *Priority_Number:* Choose Priority_Number to base your strategy on a number. *Priority_String:* Choose Priority_String to base your strategy on string data in a field.
Strategy priority	These are the choices for priorities for each of the best record strategies, other than Non_Blank and Custom. Date • *Newest:* The newest date in the field will cause an action to take place. • *Oldest:* The oldest date in a field will cause an action to take place. Length • *Longest:* The longest string in a field will cause an action to take place. • *Shortest:* The shortest string in a field will cause an action to take place. Priority_Number • *Highest:* The highest number in a field will cause an action to take place. • *Lowest:* The lowest number in a field will cause an action to take place. Priority_String

Option	Description
	- *Ascending:* The string with the most ascending string order will cause an action to take place. - *Descending:* The string with the most descending string order will cause an action to take place.
Strategy field	Choose a field that contains data that you need to execute your strategy.
Posting destination	Specifies the destination record. *Master:* Post only to a master record. *Subs:* Post only to subordinate records. *Master to Subs:* Push information from the master record and post it to each subordinate record. *All:* Post to both the master and subordinate records.
Post only once per destination	*Yes:* Post only once per destination record. After data is posted to the destination record, the operation stops. *No:* Post more than once per destination. After data is posted to the destination record, the operation continues and the destination record is populated again with the next value. This option should be used when accumulating values such as total sales. Set this option to Yes when you are using the NON_BLANK strategy. Set this option to No when you are using the Longest, Shortest, Newest, Oldest, Ascending, or Descending priorities. Note This option is ignored when using the *Master to Subs* posting destination. With this posting destination, information can be posted only once.
View/Edit Python	The View/Edit Python button opens the Python Expression editor. If you chose the Custom strategy, you can create your custom Python code. If you chose any other strategy, Python viewed in the editor is read-only.

Best record action fields

Use the best record action fields table to define the actions taken on the fields based on your strategy.

Option/Option group	Description
Source field	Specifies the name of the source field in the input record.
Destination field	Specifies the name of the destination field in the output record, or the destination of this best record action.

Option/Option group	Description
	You can have the action post to the same input field, or you can post to a different field.
Custom	*Yes:* Specifies that you want to create custom Python code to perform an action on the destination field. *No:* Specifies that you want to use the same source and destination fields. When this option is set to No, the contents of the source field are copied to the destination field.
Editor	If you chose Yes in the Custom column, a button appears here to allow you open the Python Expression editor and configure your Python code. You can open the Python Expression editor only if Custom is set to Yes.

Related Information

Designer Guide: Match, Best record [page 562]

3.5.4.12.4.4.2 Best record options: Destination Protection tab

Protect data from being changed by enabling and defining destination protection.

Option	Description
Best record name	Enter a name for your Best Record operation. Make sure that this name is unique within this Match transform.
Enable destination protection	Select to protect records from best record operations that may modify the contents.
Default destination protection	Select the default destination protection setting. This is useful because the default setting will account for records that are protected (or not protected) through the use of sources or fields.
Specify destination protection by field	Select to enable destination protection through a value in a field.
Destination protection field	Choose the field that holds the destination protection value. The field must contain a value of Y or N. Any other value (including blank) will cause the default destination protection specification to occur, if you specified a default destination protection.
Specify destination protection by source	Select this option to control destination protection through membership in a particular source. Fill in the table with source names and whether they are protected.

Option	Description
Source Name	Choose the name of the source from the drop-down list. The list here is populated with defined sources and source groups from the *Input Sources Editor* window of the Match Editor.
Destination protected	Select a value to assign to the source. Select Yes to enable destination for that source. Select No, if you do not wish to protect records from that source.

3.5.4.12.4.4.3 Group statistics options

The Group Statistics option group includes the following options:

Option	Description
Group statistics name	Choose a name for this group statistics operation. If you are including more than one group statistics operation in this Match transform, make sure that the name is unique.
Generate only basic statistics	Select if you want to generate match group statistics. These will not include any statistics about input sources.
Generate source statistics from input sources	Select to generate statistic counts about your input sources. You must have input sources defined in the Match editor for this option to be active. If you do not check this, the Match transform will still generate statistics about your match groups.
Generate source statistics from source values	Select to generate source statistics based on source values in a field. If you have a source value field, using this option, you can choose to count all sources or specific ones based on a particular value.
Logical source field	Specifies the field that holds the value for your logical sources.
Default logical source value	Specifies a value to use if the field in the Logical source field option is blank. For example, if a record has a blank value in the field, this default value is used.
Count all sources	Select to count all sources, no matter what the value in the Logical source field is.
Choose sources to count	Select to specify particular sources to count, based on values in the Logical source field.
Default count flag value	Specifies the value to use when the Predefined count flag field is invalid (for example, if the field has data other than Y or N) or it is empty. *Yes:* Counts all of the records in the source. *No:* Does not count any of the records in the source.
Auto generate sources	Select to generate sources based on the value in a field.

Option	Description
Predefined count flag field	Specifies the field name that contains the indicator value (Y or N) to determine whether a source is counted.

Manually define logical source count flags

Be sure to fill in both columns for this to work.

Option	Description
Source value	Specifies the value in the field to find. This value is case sensitive.
Count	Specifies whether you want to use the value you entered in the Logical source value option in the count. *Yes:* Includes the logical source value in the count. *No:* Does not include the value in the logical source value option in the count.

3.5.4.12.4.4.4 Group prioritization options: Priority Order tab

Group forming prioritization

Use the Group prioritization operation to order records within each break group, which controls which records are used as the drivers during the comparison process.

Post-match prioritization

Add a Group prioritization operation before a Group Statistics operation to order records within a match group to control which record is flagged as the master record of each group of matching records. Add a Group prioritization operation before a Best Record operation to order records within a match group to control the destination of data that is being propagated from other records to form a best record.

Option	Description
Prioritization name	Specifies the name for this Group prioritization operation. If you have multiple operations in this Match transform, be sure to make this name unique.

Priority fields

Use the Priority fields table to order your break groups based on the content of a field (for example, dollar amount or date). Use the buttons to add, remove, and order rows. Place the primary sort field at the top of the list. The rest of the fields, in the order that they are positioned, determine the sub-sort that occurs.

Option	Description
Input field	Choose a field to sort your records on.
Field order	Specifies in which order records should be sorted.

3.5.4.12.4.4.5 Group prioritization options: Record Completeness tab

Option	Description
Prioritization name	Specifies the name for this Group prioritization operation. If you have multiple operations in this Match transform, be sure to make this name unique.
Order records based on completeness of data	Select this option to apply priority and blank penalty points to records to help control the order of your records.
Define only field penalties	Select this option when penalties need to be assessed based on blank fields.
Define priority and penalty fields	Select this option when you have specific fields that contain the actual integer values for priority and blank penalty.
Record priority field	Choose the field that contains priority values. This field must contain an integer.
Apply blank penalty field	Choose the field that contains the indicator (Y or N) for applying blank penalty points to a record.
Define priority and penalty based on input source	Select to have your record priority and blank penalty indicator (Y or N) determined by membership in a given source.
Source Name	Choose an input source from the drop-down list in the Source Name column. The sources listed here are defined in the Input Source operation.
Priority	Type a priority value (an integer) in the Priority column. Remember that the lower the priority score, the higher the priority.
Apply Blank Penalty	Choose Yes or No to determine whether a blank penalty is applied to a record based on membership to this source.
Default record priority	Specifies the default value for the record priority if the record does not contain a field with this value, this field is blank for a record, or if a record does not belong to any of the sources specified. Remember that the lower the priority score, the higher the priority.

Option	Description
Default apply blank penalty	Specifies the default indicator as to whether to add blank penalty points to records with blank fields. This indicator is used if a record does not have a field that carries this indicator, if that field is blank or has invalid data, or ifa record does not belong to any of the sources specified. *Yes:* Each record's blank penalty is added to the record's record priority to generate an adjusted record priority score. The lower the score, the higher the priority. *No:* No penalty is applied when the fields are blank.
Input field	Displays the input fields available to assign a blank penalty score to.
Blank penalty	Assign a penalty value (an integer) to apply when the specified field is blank in a record.

3.5.4.12.4.4.6 Unique ID options: Unique ID tab

Use the Unique ID options to assign sequential identification numbers to each new record when adding records to a data warehouse. For example, the largest number assigned in a particular project can be carried over as the beginning identification number (plus 1) to be used in the assignment of new sequential IDs. This occurs when the software processes the next source against the data warehouse file.

Note

Also see the Unique ID section for information about working with unique ID in a multi-server environment. Depending on the processing operation and starting value source you use, there could be limitations for using unique ID.

The Unique ID option group includes the following options:

Option	Description
Unique ID name	Enter a name for this Unique ID operation. If you are using other Unique ID operations in this Match transform, you may want to specify the name of the match transform and match level in this name to distinguish it from others.
Processing operation	Specifies the type of processing operation you want the application to perform. Valid values include: *Assign:* Assigns a new ID to unique records that need one, or assigns a new ID to all members of a group that don't have an ID. In addition, the assign operation copies an existing ID when a member of a match group already has an ID. For assign operations to work, all match group members must appear consecutively in one collection and must be in priority order (high to low).

Option	Description
	AssignCombine: Performs both an assign operation and a combine operation. All match group members must appear consecutively in one collection and must be in priority order (high to low). *Combine:* Combines the IDs of a match group when more than one ID is represented. All match group members must appear consecutively in one collection and must be in priority order (high to low). *Delete:* Removes unique IDs from records that have one, unless they are protected. *Split:* Splits the IDs of an ID group when more than one match group is represented. All ID group members must appear consecutively in one collection and must be in priority order (high to low).
Recycle unique IDs	Specifies whether unique IDs that were freed up during the delete operation should be used again in different records. You may want to recycle unique IDs if you have a limited amount available. Valid values include: *Yes:* Recycle freed-up unique IDs. *No:* Do not recycle freed-up unique IDs.
ID field	A field that holds a previously assigned unique ID. If this field is omitted, then it is assumed that no records have a unique ID.
Field	The starting unique ID is obtained from an input field. Be sure to map in a field from an upstream transform before you add this option.
Starting unique ID field	Choose the field that passes in the starting unique ID. If no Unique ID is received, the starting number will default to 1.
Constant value	The starting ID is specified as a positive whole number in the Starting value option.
Starting value	Indicates the starting unique ID value. Valid values range from 1 to UINT_MAX (unsigned integer max). The default value is 1.
Value from file	The starting Unique ID is read from the file specified in the File option.
File	Specifies the path and name of the file that manages unique IDs. A value is required here only when the Starting unique ID source option is set to File.
GUID	Uses the Globally Unique Identifier (GUID) as the unique ID. This is also known as the Universal Unique Identifier (UUID). The UUID variation used for unique ID is a time-based 36-character string with the format: `TimeLow-TimeMid-TimeHighAndVersion-ClockSeqAndReservedClockSeqLow-Node`. For more information about UUID, see the RFC document in the Related Topics section.

Option	Description
Save ending ID to file and reclaim recycled IDs	Specifies whether to save the last ID that was assigned to a file. Additionally, specifies whether to reclaim recycled IDs.
File	Specifies the file to write the last assigned ID to.
Allow multiple Match transforms to access unique ID file	Allows multiple Match transforms to access a shared unique ID file. When enabled, multiple data flows can access the same unique ID file, and single Match transforms can run in more than one process when the DOP setting is greater than 1. In addition, this allows multiple Match transforms within a single data flow to share a single unique ID file.
Number of IDs to get when accessing file	Specifies the number of IDs to retrieve from the unique ID file during each access. For example, with a setting of 100, the first process will access the file and retrieve IDs numbered 1-100. The next process with retrieve IDs numbered 101-200. If a process uses less than the number of retrieved IDs, the remaining IDs are written back to the unique ID file as recycled IDs. Note A setting greater than 1 improves performance when sharing a unique ID file between multiple processes by reducing the number of times the file must be accessed. However, integer numbers may not be assigned in sequential order.
Group number field	Specifies the field that holds a group number. The group number is used to assign the same unique ID to more than one record. If this field is omitted, then it is assumed that each record is unique and should have its own number.

Related Information

Designer Guide: Match, Unique ID [page 570]

3.5.4.12.4.4.7 Unique ID options: Destination Protection tab

Use the Destination Protection tab to control whether a record's unique ID is protected based on the source that the record belongs to. This can help prevent IDs from being assigned to a suppression or rented source.

Option	Description
Unique ID name	Enter a name for this Unique ID operation. If you are using other Unique ID operations in this Match transform, you may want to spec-

Option	Description
	ify the name of the match transform and match level in this name to distinguish it from others.
Enable destination protection	Select if you want to protect a destination source from having its unique IDs overwritten with the IDs from matching records.
Default destination protection	Select the default destination protection setting. This is useful because the default setting will account for records that are protected (or not protected) through the use of sources or fields.
Specify destination protection by field	Select to enable destination protection through a value in a field.
Unique ID protected field	Choose an input field from the drop-down list that holds the value for specifying whether this ID is protected. The field must contain a value of Y or N. Any other value (including blank) will cause the default destination protection specification to occur, if you specified one.
Specify destination protection by source	Select this option to control destination protection through membership in a particular source. Fill in the table with source names and whether they are protected.
Source name	Choose the name of the source from the drop-down list. The list here is populated with defined sources and source groups from the *Input Sources Editor* window of the Match Editor.
Unique ID protected	*Yes:* This source is protected. *No:* This source is not protected.

3.5.4.12.4.4.8 Output flag selection options

Select types of records you want to flag on output based on each of the input sources. You may want to flag these records so that they will be available for writing to output. Downstream in a data flow, you can check the value of the Select_Record (Y/N) and decide whether you want to write it to output by using a Case transform, for example.

This is a repeatable operation.

Record type	Description
Output flag selection name	Enter a unique name for this operation that will allow you to identify it in a report and in your Select_Record output field. For example, suppose you have two two Output Flag Selection operations in this match level: DMA_Matches and Mail_List. Your output fields are then called: ● <match level name>_DMA_Matches_Select_Record ● <match level name>_Mail_List_Select_Record
Unique	Records that are not members of any match group. No matching records were found. These can be from sources with a normal- or special-type source.

Record type	Description
Single source masters	Highest ranking member of a match group whose members all came from the same source. Can be from normal- or special-type sources.
Single source subordinates	A record that came from a normal- or suppress-type source and is a subordinate member of a match group.
Multiple source masters	Highest ranking member of a match group whose members came from two or more sources. Can be from normal- or special-type sources.
Multiple source subordinates	A subordinate record of a match group that came from a normal- or suppress-type source whose members came from two or more sources.
Suppression matches	Subordinate member of a match group that includes a higher-priority record that came from a suppress -type source. Can be from normal- or special-type source.
Suppression uniques	Records that came from a suppress-type source, and for which no matching records were found.
Suppression masters	A record that came from a suppress-type source and is the highest ranking member of a match group.
Suppression subordinates	A record that came from a suppress-type source and is a subordinate member of a match group.

3.5.4.12.5 Input fields

The following are recognized input fields that you can use in the input mapping for the Match transform.

Name	Description
Option_Field_Algorithm_Geo_Proximity_**`<<logical_name>>`** _Max_Distance	The distance used in proximity matching. This setting is dynamic. If you change this setting, you do not have to terminate and reinitialize the transform in order for the new configuration to be recognized. **`<<logical-name>>`** is a name used to reference option groups. Some option groups can be repeated and the transform needs a way to uniquely identify each option group. In the Designer, this name is generated automatically by the Match editor. In order to understand which option is affected by this input field, look in the option tab of the Match transform and find the Field Algorithm Geo Proximity option group whose name is the same as appears in the input field.

Related Information

Designer Guide: Set up Geographic Proximity matching - Criteria options [page 560]

3.5.4.12.6 Output fields

The following Match fields are generated by the Match transform per match level. Use these fields when you map your output schema.

Field name	Default content type	Description
All_Match_Criteria	None	For internal use only
All_Match_Records	None	For internal use only
Break_Key	None	Specifies the break key generated for this record.
Conflict_Record	None	The sequence number of the record that has a conflict with this record. Conflict means that records that do not match directly are in the same match group. For example, records A and B match record C, but records A and B do not match directly, therefore the pair of records A and B are conflict records. For records that have no conflict, the value is blank. i Note Select this field for output only if your job was created by Information Steward Data Cleansing Advisor and you have the Match transform configured for pattern matching (which is not currently available). Using this field under other conditions will result in output that is either blank or provides no value.
First_Match_Record	None	Specifies the sequence number of the record that this record first matched. Unique records will have a value of Null. This output field is useful when *Match Mode* is set to “Multi-Driver” to determine to which record a record first matched. i Note Select this field for output only if your job was created by Information Steward Data Cleansing Advisor and you have the Match transform configured for pattern matching (which is not currently available). Using these fields under other conditions will result in blank output.

Field name	Default content type	Description
		Note Currently, the Match mode option is not available for edit in Data Services.
Group_Number	Group_Number	Specifies the records that belong to the same match group, which share the same group number. The group numbers start with the number 1. Unique records have a blank group number. If you are using association matching in your job, you need to map this on output, because the Associate transform uses it.
Match_Criterion	None	Specifies the name of the criteria or pattern that made the decision (if the Match_Type is *R*). Otherwise, the field is blank. Note Pattern matching is not currently available in Data Services
Match_Level	None	Specifies the name of the match level used.
Match_Pair_Count	None	Specifies how many records this record matched. A unique record will have a value of 0. A record that matched all the other records in a match group will have a value that is one less than the match group count. If Match Mode is set to “Single Driver”, then the driver record will have a match pair count equaling one less than the match group count, and the passengers will have a match pair count of 1. Note Select this field for output only if your job was created by Information Steward Data Cleansing Advisor and you have the Match transform configured for pattern matching (which is not currently available). Using this field under other conditions will result in output that is either blank or provides no value. Note Currently, the Match mode option is not available for edit in Data Services.
Match_Score	None	The Match_Score field outputs the following values: ● The criteria or pattern similarity score when the Match_Type is *R*. ● The total weighted score when the Match_Type is *W*. ● Blank if the record is a driver record (Match_Type of *D*) or if the records are unique.

Field name	Default content type	Description
		ℹ Note Pattern matching is not currently available in Data Services.
Match_Status	None	The values for the Match_Status field that appear in your output are: *D:* This record is a driver in a match group. *P:* This record is a passenger in a match group. *U:* This is a unique record. *B:* Signifies that the *Match mode* option is set to "Multi-Driver" and the record is both a driver and passenger. ℹ Note Currently, the Match mode option is not available for edit in Data Services.
Match_Type	None	Indicates what type of match was made to bring the record into a match group. Possible values are: *<blank>:* The record did not match any other record. It is a unique record. *D:* The record was the driver record in the comparison process. *R:* The decision was made by a rule (criteria) or pattern. *W:* The record was identified as matching the driver because the total weighted score met the Weighted match score. See "Matching methods" in the *Data Services Designer Guide* for more information on weighted scores. ℹ Note Pattern matching is not currently available in Data Services.
Review_Record	None	The sequence number of the record that matches with this record but something about the pair of matching records is identified as questionable. For records that do not need review, the value is blank. ℹ Note Select this field for output only if your job was created by Information Steward Data Cleansing Advisor and you have the Match transform configured for pattern matching (which is not currently available). Using this field under other conditions will result in output that is either blank or provides no value.

Field name	Default content type	Description
Sequence_Number	None	Each record input to the Match transform is assigned a sequence number. This number will be stored internally by a 64-bit integer. The first value assigned after the Match transform is initialized is 1, the second value is 2, and so on. The sequence number will allow Match to connect two records by having them reference each other's sequence number. The field data type is Decimal. Note Select this field for output only if your job was created by Information Steward Data Cleansing Advisor and you have the Match transform configured for pattern matching (which is not currently available). Using this field under other conditions will result in output that is either blank or provides no value.

Input Source operation output fields

These fields are available only when you use an Input Source operation in your Match transform.

Field name	Description
Source_Group_Name	Specifies the name of the Source Group that the current record belongs to. If a record does not belong to any Source Group, then an empty string is output.
Source_Name	Specifies the name of the input source that the current record belongs to.
Source_Type	Specifies the type of source that the current record belongs to. *N:* The record comes from a normal source. *P:* The record comes from a suppress source. *S:* The record comes from a special source.

If you also add a Group Statistics post-match operation, and select the *Generate source statistics from input sources* option, the following output fields are available (these are in addition to the fields generated by the Group statistics operation).

Field name	Description
Group_Count	Provides the total number of records in the match group. Unique records have a value of 1.
Group_Rank	Specifies whether the record is a master (M) or a subordinate (S). Unique records have an empty value.
Group_Source_Appearance	Specifies the order the input source appears in this match group. The first input source appearing in the match group receives a value of 1, the second Input

Field name	Description
	Source appearing will get 2, and so forth. Records that come from the same input source will receive the same Group_Source_Appearance value. Unique records have a value of 0.
Group_Source_Group_Order	Specifies the order of the records within the match group that have the same Group_Source_Group_Appearance value. The first occurrence receives a value of 1, the second occurrence receives a value of 2, and so on. Unique records receive a value of 0. Records in a match group not assigned to a source group will also get a value of 0.
Group_Source_Order	Specifies the order of the records within the match group that have the same Group_Source_Appearance value. The first occurrence receives a value of 1, the second occurrence receives a value of 2, and so on. Unique records have a value of 0.
Group_Source_Type	Specifies the type of source in the match group. This field will contain one of the following values: *M:* The records come from more than one input source (excluding records from Special sources). *P:* The records come from a Suppress source. (If the master record comes from a suppression source, then all records in the match group have a P. If the master record comes from a normal or special source, then the suppression record and all records after it have a P, but the records before the suppression record have an M or S.) *S:* The records come from a single input source . *<empty>:* The record is unique.
Multi_Source_Count	Specifies the number of sources represented in the match group (excluding the Special sources and Suppress sources and Normal sources that follow a Suppress source in the match group). The values of this field could range from 0 to the number of records in the match group. Unique records receive a value of 1, if from a Normal list, and 0, if from a Special source or a Suppress source.
Source_Count	Specifies the number of sources represented in the match group (regardless of the source types). The values of this output field could range from 1 to the number of records in the match group. Unique records will have a value of 1.
Source_Group_Count	Specifies the number of Source Groups represented in the match group. Records in the match group that do not belong to a Source Group are not counted. The value of this output field range from 0 to the maximum number of input sources (10,000). Unique records will have a value of 0 or 1.

If you also add a Group Statistics post-match operation, and select the *Generate source statistics from source values* option, the following output fields are available (these are in addition to the fields generated by the Group statistics operation).

Field name	Description
Group_Count	Provides the total number of records in the match group.

Field name	Description
	Unique records have a value of 1.
Group_Order	The master record receives a value of 1. Subordinate records receive a value of 2 through the number of records in the match group. You may control the order by including a Group Prioritization in the Post Match Operations. Unique records have a value of 0.
Group_Rank	Specifies whether the record is a master (M) or a subordinate (S). Unique records have an empty value.
Group_Type	Specifies whether a record contributed to the source count, and if so, whether there were other sources represented in the match group. *M:* Multiple sources. Records from multiple sources are represented in the match group (records from Special sources are not counted toward a multiple-source match group). *S:* Single source. All records in the match group come from a single source (records from Special sources are not counted toward a multiple-source match group). *P:* At least one record from a Suppression source is included in the match group. (If the master record comes from a suppression source, then all records in the match group have a P. If the master record comes from a normal or special source, then the suppression record and all records after it have a P, but the records before the suppression record have an M or S.)
Source_Count	Specifies the number of sources represented in the match group (regardless of the source types). The values of this output field could range from 1 to the number of records in the match group. Unique records will have a value of 1.
Source_ID	Specifies the logical source value. In most cases, this is the input source value. In other cases it is the default logical source value.
Source_ID_Count	Specifies the number of source IDs represented in the match group.
Source_Type_ID	Specifies the type of logical source. *N:* Normal source *P:* Suppress source *S:* Special source

Source group operation output fields

These fields are available only if you use a Source Group operation in your Match transform.

Field name	Description
Group_Source_Group_Appearance	Specifies the order the source group appears in this match group. The first source group appearing in the match group receives a value of 1, the second

Field name	Description
	source group appearing receives a value of 2, and so on. Records that come from the same source group will receive the same Group_Source_Group_Appearance value. Unique records receive a value of 0. Records in a match group not assigned to a source group will also get a value of 0.
Group_Source_Group_Order	Specifies the order of the records within the match group that have the same Group_Source_Group_Appearance value. The first occurrence receives a value of 1, the second occurrence receives a value of 2, and so on. Unique records receive a value of 0. Records in a match group not assigned to a source group will also get a value of 0.
Source_Group_Count	Specifies the number of source groups represented in the match group. Records in the match group that do not belong to a source group are not counted. The values of this output field could range from 0 to the number of records in the match group. Unique records receive a value of 0 or 1.
Source_Group_Name	Specifies the name of the source group that the current record belongs to. If a record does not belong to any source group, then an empty string is output.

Group statistics operation output fields

These fields are available only if you use a Group Statistics operation in your Match transform.

Field name	Description
Conflict_Group	Contains C if the record is part of a match group that includes a conflict. Conflict means that records that do not match directly are in the same match group. For example, records A and B match record C, but records A and B do not match directly, therefore the pair of records A and B are conflict records. For records that do not belong to a match group with any conflicts, the value is blank. Note Select this field for output only if your job was created by Information Steward Data Cleansing Advisor and you have the Match transform configured for pattern matching (which is not currently available). Using this field under other conditions will result in output that is either blank or provides no value.
Group_Count	Provides the total number of records in the match group. Unique records have a value of 1.
Group_Order	The master record receives a value of 1. Subordinate records receive a value of 2 through the number of records in the match group. You may control the order by including a Group Prioritization in the Post Match Operations. Unique records have a value of 0.

Field name	Description
Group_Rank	Specifies whether the record is a master (M) or a subordinate (S). Unique records have an empty value.
Group_Type	Specifies whether a record contributed to the source count, and if so, whether there were other sources represented in the match group. *M:* Multiple sources. Records from multiple sources are represented in the match group (records from Special sources are not counted toward a multiple-source match group). *S:* Single source. All records in the match group come from a single source (records from Special sources are not counted toward a multiple-source match group). *P:* At least one record from a Suppression source is included in the match group. (If the master record comes from a suppression source, then all records in the match group have a P. If the master record comes from a normal or special source, then the suppression record and all records after it have a P, but the records before the suppression record have an M or S.)
Review_Group	Contains R if the record is part of a match group for which review is recommended. Review is recommended because the pair of matching records is identified as questionable. For records that do not belong to a match group with any review records, the value is blank. Note Select this field for output only if your job was created by Information Steward Data Cleansing Advisor and you have the Match transform configured for pattern matching (which is not currently available). Using this field under other conditions will result in output that is either blank or provides no value.
Source_Count	Shows the number of logical sources in this match group. Unique records have a blank value
Source_ID	Specifies the logical source value. In most cases, this is the input source value. In other cases it is the default logical source value.
Source_ID_Count	Specifies the number of source IDs represented in the match group.
Source_Type_ID	Specifies the type of logical source. *N:* Normal source *P:* Suppress source *S:* Special source

Unique ID operation output fields

These fields are available only if you use a Unique ID operation in your Match transform.

Field name	Description
ID_Status	Specifies the status of the Unique_ID output field. This field generates the following values: *<blank>:* No change. The Unique_ID output field is the same as the Unique_ID input field. *D:* Indicates that the Unique_ID output field has a blank unique ID and that the old unique ID was deleted. *N:* Indicates that the Unique_ID output field has a new unique ID. *O:* Indicates that the Unique_ID output field is assigned an old (existing) ID. This happens when a record is combined.
Record_Operation	Specifies the operation that should be performed on the record, based on the input fields (except protected fields). This field generates the following values: *<blank>:* Does not call an operation. *A:* Assigns a unique ID to the record. *C:* Combines the record's unique ID. *D:* Deletes the record's unique ID. *S:* Splits the record's unique ID.
Unique_ID	Specifies the unique ID the Match transform generated for this record. If the record already has a valid unique ID, then the output field will output the same unique ID. If the Match transform does not assign a unique ID, the output field is blank.

Group prioritization output fields

The following output fields are available when you add a Group Prioritization operation to a Match transform

Field	Description
Priority_Value	The sum of all priority and blank penalty values defined in the Record Completeness tab of the Group Prioritization. If you do not order records using the Record Completeness tab, this field contains 0.

Output flag selection output fields

The following output fields are available when you add an Output flag election operation to a Match transform.

Field	Description
Select_Record	Specifies whether the current record should be selected or not, based on your selections in the Output Flag Selection Editor. Valid values of this output field are Y if the record should be selected and N if the record should not be selected.

3.5.4.13 USA Regulatory Address Cleanse

The USA Regulatory Address Cleanse transform identifies, parses, validates, and corrects U. S. address data according to the U.S. Coding Accuracy Support System (CASS). This transform can create the USPS Form 3553 and output many useful codes to your records. You can also run in a non-certification mode as well as produce suggestion lists.

> Note
>
> If an input record has characters not included in the Latin1 code page, the USA Regulatory Address Cleanse transform will not process that data. Instead, the software sends the mapped input record to the corresponding standardized output field (if applicable). No other output fields will be populated for that record. If your Unicode database has valid U.S. addresses from the Latin1 character set, the transform processes as normal.

If you perform both data cleansing and matching, the USA Regulatory Address Cleanse transform typically comes before the Data Cleanse transform and any of the Match transforms in the data flow. SAP recommends using a sample job or data flow that is set up according to best practices for a specific use case.

The USA Regulatory Address Cleanse transform has several sample transform configurations that can help you set up your data flow. The transforms include all of the required options except input fields.

3.5.4.13.1 Content objects

Transform configurations

A transform configuration is a transform with preconfigured input fields, output fields, and options that can be used in multiple data flows. These are useful if you repeatedly use a transform with specific options and input and output fields.

When Data Services is installed, read-only transform configurations are provided for the Data Quality transforms.

You can use transform configurations in your data flows or as an example of a typical transform. After you place an instance of the transform configuration in a data flow, you can override these preset defaults. You can also create your own transform configuration, either by replicating an existing transform configuration or creating a new one.

Sample blueprints and other objects

We have created Data Quality blueprints and other content objects to help you set up Data Services jobs. We've identified a number of common scenarios that you are likely to perform with Data Services. For each scenario, we've included a blueprint that is already set up to solve the business problem in that scenario.

3.5.4.13.3 Report and analysis

Use these options to generate USA Regulatory Address Cleanse report data.

Option	Description
Gather Statistics Per Data Source	Specifies whether to generate report data per Data_Source_ID field value.

Option	Description
	Yes: Generates report statistics (if the *Generate Report Data* option is set to Yes) per Data_Source_ID field value. *No*: Generates reports (if the *Generate Report Data* option is set to Yes) for the input database without generating statistics based on the Data_Source_ID field value. i Note If you select Yes, other setup requirements apply. Read about statistics based on logical groups in the *Designer Guide*.
Generate Report Data	Specifies whether to generate report data for this transform. *Yes:* Generates report data for this transform. *No:* Turns off report data generation. If you do not need to generate reports (during testing, for example), you should set this option to *No* to improve performance.

Related Information

Designer Guide: Data Quality, Multiple data source statistics reporting [page 679]

3.5.4.13.4 Reference files

Reference files are directories used by the USA Regulatory Address Cleanse transform to correct and standardize your data. It is best to use the applicable substitution variable for the Option Value. This substitution variable represents the path to the reference files, and if you change that location, you can change the substitution variable so that all of your jobs reflect the current location.

Option	Description
Address Directory 1	`zip4us.dir` This directory, also called the National Directory, is organized by ZIP Code. It lists street names, ranges of house numbers, and postal and other codes. Use the substitution variable `$$RefFilesAddressCleanse`.
Address Directory 2	`*.dir` This second address directory is optional, and can be used for a customized address directory. No directory is automatically provided for this option. Most users should leave the Address Directory 2 option blank.
Address Geo 1 Directory	`ageo1.dir`

Option	Description
Address Geo 2 Directory *Address Geo 3 Directory* *Address Geo 4 Directory* *Address Geo 5 Directory* *Address Geo 6 Directory* *Address Geo 7 Directory* *Address Geo 8 Directory* *Address Geo 9 Directory* *Address Geo 10 Directory*	The Address-level GeoCensus files, `ageo1.dir` through `ageo10.dir`, are required only if you use the Address-level GeoCensus option or if you use the Geocoder transform. Use the substitution variable `$$RefFilesAddressCleanse`.
Address SHS Directory	`zip4us.shs` This directory enhances normal primary name lookups and is required for processing. Use the substitution variable `$$RefFilesAddressCleanse`.
Centroid Geo Directory	`cgeo2.dir` This directory is required only if you use the centroid-level GeoCensus option or if you use the Geocoder transform. Use the substitution variable `$$RefFilesAddressCleanse`.
City Directory	`city##.dir` The City directory is a table of city names, states, and ZIP Codes. It is organized by state and city. Use the substitution variable `$$RefFilesAddressCleanse`.
DPV Path	Specify the path to the DPV (Delivery Point Validation) directory files. These directory files are required for CASS certification. Use the substitution variable `$$RefFilesAddressCleanse`.
DSF2 Augment Path	Specify the path to the directory that contains the DSF2 (Second Generation Delivery Sequence) files you received from the USPS. Use the substitution variable `$$RefFilesAddressCleanse`.
eLOT Directory	`elot.dir` The eLOT directory contains eLOT codes for the delivery point that represents the mail carrier's delivery route walk sequence. Include this directory only if the *Enable eLot* option in the Assignment Options group is set to *Yes*. Use the substitution variable `$$RefFilesAddressCleanse`.
EWS Directory	`ewsyymmdd.dir`

Option	Description
	The software lists *ew*.dir* in the Option Value column, so that the transform finds the most current directory. Use the substitution variable `$$RefFilesAddressCleanse`.
LACSLink Path	Specify the path to the LACSLink directory files. These directory files are required for CASS certification. Use the substitution variable `$$RefFilesAddressCleanse`.
NCOALink Path	The location for the NCOALink directory files. These directory files are required for NCOALink processing and certification. Use the substitution variable `$$RefFilesAddressCleanse`.
Postcode Directory	`zcf10.dir` This directory contains the same data as the City directory, but is organized by ZIP Code. Use the substitution variable `$$RefFilesAddressCleanse`.
Postcode Reverse Directory	`revzip4.dir` The Reverse ZIP+4 directory enables the software to assign more postal codes when the input data includes a unique ZIP Code and valid ZIP+4. Use the substitution variable `$$RefFilesAddressCleanse`.
RDI Path	The RDI directory indicates whether an address is residential. Use the substitution variable `$$RefFilesAddressCleanse`.
Reverse Soundex Address Directory	`zip4us.rev` This directory enhances primary name lookups. Use the substitution variable `$$RefFilesAddressCleanse`.
SuiteLink Path	The SuiteLink directories contain specially indexed address information such as secondary numbers and unit designators for locations identified as high-rise business default buildings. These directory files are required for CASS certification. Specify the path to the SuiteLink directory files. Use the substitution variable `$$RefFilesAddressCleanse`.
USPS Log Path	Specify the path to the directory for NCOALink, DPV, and LACSLink log files. The provided substitution parameter is `$$Certification-LogPath`. The software determines the file names during processing as the USPS requires. This directory must already exist and be writable.

Option	Description
	It is important to use the same path for all jobs. If you have multiple clients, use the same log file directory for all clients so that the log files are combined.
Z4 Change Directory	`z4change.dir` The Z4Change directory lists all the ZIP Codes and ZIP+4 Codes in the country. Use the substitution variable `$$RefFilesAddressCleanse`.

For information about downloading directories, see the latest directories update.

3.5.4.13.5 Transform performance

The Transform Performance option group for the USA Regulatory Address Cleanse transform contains options that could improve the performance of DPV, DSF2, LACSLink, NCOALink, RDI, and SuiteLink processing.

Option	Description
Cache DPV Directories	Specifies whether the DPV directories are cached into memory. If the directories are cached, the caching takes place only once and is shared among all DPV threads running in the data flow. *Yes*: Enables caching. *No*: Disables caching.
Cache DSF2 Augment Directories	Specifies whether the DSF2 Augment directories are cached into memory. *Yes*: Enables caching. *No*: Disables caching.
Cache LACSLink Directories	Specifies whether the LACSLink directories are cached into memory. *Yes*: Enables caching. *No*: Disables caching.
Cache RDI Directories	Specifies whether the RDI directories are cached into memory. *Yes*: Enables caching. *No*: Disables caching.
Cache SuiteLink Directories	Specifies whether the SuiteLink directories are cached into memory. *Yes*: Enables caching. *No*Disables caching.

Option	Description
Insufficient Cache Memory Action	Specifies the action to take if there is insufficient memory to cache the directories that you have set up for caching. *Continue*: Attempts to continue initialization without caching. *Error*: Issues an error and terminates the transform.
NCOALink Caching Mode	Specifies the method for caching NCOALink directories. *Auto*: Select to have Data Services use available memory for caching. *Manual*: Select if you have a limited amount of memory available and you want to allocate a set amount of memory for caching. Enter a value in the *NCOALink Memory Usage* option. *None*: Disables caching. This is the default setting. Consider this option for smaller jobs because the overhead of caching directories could take longer than the actual job execution duration.
NCOALink Memory Usage	If the *NCOALink Caching Mode* is set to Manual, enter a value here to allocate a set amount of memory for NCOALink directory caching. The transform uses this value as the maximum amount of memory that can be used for the caching of NCOALink directories. i Note If the *Degree of Parallelism* value is greater than one, the *NCOALink Memory Usage* value is the total to be allocated for all threads. The value is not per thread.

3.5.4.13.6 USPS license information options

This group of options is required for all users performing NCOALink, SuiteLink, LACSLink, DPV, and DSF2 processing. You must provide information about the company performing the processing (the licensee) and the company for whom they are performing the processing (the customer). If you are performing the processing for yourself, you are the licensee and the customer.

The following table describes the *USPS Licensee and Customer Information Options* for the USA Regulatory Address Cleanse transform.

Option	Description
Customer Company Name *Customer Company Address* *Customer Company Locality* *Customer Company Region*	The customer is the person or company for whom you are performing NCOALink processing. End users may leave these fields blank unless you have an alternate stop processing agreement and have entered the special keycode into License Manager. The customer information appears in the NCOALink Processing Summary report and log files. The provided substitution parameters for these fields are: `$$CompanyName`

Option	Description

Customer Company Postcode1
Customer Company Postcode2
	`$$CompanyAddress`
	`$$CompanyLocality`
	`$$CompanyRegion`
	`$$CompanyPostcode1`
	`$$CompanyPostcode2`

Customer Company Phone	This is an optional field. The provided substitution parameter for this field is `$$CompanyPhone`.
DSF2 Licensee ID	Enter your DSF2 identification number as the USPS assigned it to you. You can use the substitution variable `$$DSF2LicenseeID` in this option.
IMB Mailer ID	This is an optional field. Enter your unique Intelligent Mail barcode (IMB) mailer ID that you received from the USPS, if applicable. The provided substitution parameter for this field is `$$IMBMailerID`. The IMB Mailer ID is a unique 6-digit or 9-digit numeric code assigned to mailers by the USPS based on their annual mail volumes. This information is included in the NCOALink Processing Acknowledgement Form (PAF).
Licensee Name	This field is required for NCOALink. The name of the company, up to 30 characters, as mentioned in the license agreement with the USPS. The licensee performs the NCOALink processing. This information appears in the PAF log and NCOALink Processing Summary report.
List Owner NAICS Code	This is a required field. Enter the North American Industry Classification System (NAICS) code, which identifies the business in which the list owner engages. The provided substitution parameter for this option is `$$CompanyNAICSCode`. For more information, visit the NAICS Web site at *http://www.census.gov/epcd/www/naics.html* .
List ID	The Customer or List ID is required for NCOALink limited and full service providers. End users may leave it blank. A unique ID assigned by the licensee to identify the list owner (customer). If the licensee does not have a naming scheme in place for the customer or lists, the six digits could be made up of the following: ● First 3 digits: Customer name/identifier ● Last 3 digits: List name identifier
List Processing Frequency	This 2-digit number (from 1 to 52) indicates how many times per year the list is processed with NCOALink. If the list owner has other lists processed by the NCOALink licensee at different frequencies, enter 99.

Option	Description
List Received Date	Enter the date when the NCOALink licensee received the list. Use the `yyyy/mm/dd` format. If you are an end user, you may leave this blank.
List Return Date	Enter the date when the list will be returned to the customer. Use the `yyyy/mm/dd` format. If you are an NCOALink end user, you may leave this blank.
Provider Level	This option lists the provider levels for which you have a registered license keycode. It defaults to the substitution parameter `$$USPSProviderLevel`. Only provider levels supported in your registered keycodes display in the option list.

3.5.4.13.6.1 Required options for USPS License Information

If you are processing NCOALink, DSF2, DPV, SuiteLink, or LACSLink, the USPS License Information group contains options that must be completed.

Tip

These options have substitution variables that you can set up in *Tools* › *Substitution Parameter Configurations*.

Option	NCOALink Full Service Provider*	NCOALink Limited Service Provider[2]	NCOALink End User*	DSF2	DPV	LACSLink
Licensee Name	X	X	X	X		
List Owner NAICS Code	X	X	X	X		
List ID	X	X	X	X		
Customer Company Name	X	X	X	X	X	X
Customer Company Address	X	X	X	X	X	X
Customer Company Locality	X	X	X	X	X	X
Customer Company Region	X	X	X	X	X	X
Customer Company Postcode1	X	X	X	X	X	X
Customer Company Postcode2	X	X	X	X	X	X
Customer Company Phone						

[2] With NCOALink enabled

Option	NCOALink Full Service Provider*	NCOALink Limited Service Provider[2]	NCOALink End User*	DSF2	DPV	LACSLink
List Processing Frequency	X	X	X			
List Received Date	X	X		X		
List Return Date	X	X		X		
Provider Level	X	X	X			
IMB Mailer ID						
DSF2 Licensee ID				X		

3.5.4.13.7 NCOALink options

This section describes the options in the NCOALink group. The related links list the sub option groups.

Option	Description
Mailing List Name	Enter the name of this list, up to 30 characters. If this list is a master house list or your only mailing list, consider entering your company name here. This name appears in the log files.
Platform ID	The platform ID is the NCOALink licensee's identification number that is assigned by the USPS. It's exactly four characters long.

3.5.4.13.7.1 Processing options

The following table describes the *NCOALink Processing Options*.

[2] With NCOALink enabled

Option	Description
Consider Moves Within Months	Use this setting to ignore change-of-address data older than the specified number of months. For example, enter 12 to use change-of-address data that has a move-effective date within the last 12 months. If you are an end user or limited service provider, enter a value from 6 to 18. If you're a full service provider or using ANKLink, enter a value from 6 to 48. If the option is blank, the transform uses all available data based on your license. The default is blank.
External Processes Updating List	Indicate whether the list undergoes additional processing before or after the USA Regulatory Address Cleanse transform.
High Match Rate Expectancy	The USPS wants to distinguish between files that have a legitimate reason for a high percentage of NCOALink matches and files that are fraudulently used to create mover lists. Select *None* or leave blank if you don't expect a high match rate. This option provides legitimate reasons for a high match rate. *None:* Default. *ANKLink Processed List:* An ANKLink-processed file contains records for people who have moved but you don't yet have their new address. This option is available only to full service providers. *Stage File:* If you're performing Stage I or Stage II testing, ensure that the *List Processing Objective* is set to a Stage option. *Return Mail List:* A returned mail list file contains records for mail that was returned to sender.
List Processing Mode	*Change Of Address:* You're processing this job to update it with the latest address data. Default. *Statistics Only:* You're processing this job to analyze statistics such as the number of records in your list that have updated addresses and the number of moves of each type. When you choose this option, you do not receive move-updated addresses. *Return Codes Only:* You're processing this job for informational purposes. When you choose this option and post to the NCOALink_Return_Code or ANKLink_Return_Code output component, you can see the return codes, which further explain whether matching records were found in the NCOALink directories and why or why not. With this option, you do not receive move-updated addresses.
List Processing Objective	Specify your reason for using NCOALink: *Employee Training:* You're processing this file as part of employee training. *Internal Database Testing:* You're testing with a licensee-owned database. *Marketing:* You're testing with external customer lists.

Option	Description
	Normal: You're processing the mailing list to update it before a mailing. Default. *Stage I* and *Stage II:* You're testing the matching performance against a USPS test file. The USPS scores the Stage II test file. Choose Stage I or Stage II only if you are processing a USPS test file. *System Testing:* You're processing this file as part of system testing such as loading USPS file updates. Note When certifying for CASS and DSF2, you indicate the reason in the *Assignment Options* > *USPS Certification Testing Mode* option.
Processing First Class Mail *Processing Periodicals* *Processing Standard Mail* *Processing Package Service Mail*	Select the types of mail to process by selecting *Yes* or *No* for each option. *Processing First Class Mail* defaults to *Yes*; the others default to *No*.
Retrieve Move Types	Choose the types of moves to process: *Business:* Business moves only. *Individual:* Individual moves only. *Individual and Business* *Individual and Family* *Individual and Family and Business:* Default.

3.5.4.13.7.2 Report Options

There is one option in the *NCOALink Report Options* group.

Option	Description
Generate Return Code Descriptions	The NCOALink Processing Summary report always includes a brief summary of return codes, and you can include more detailed return code descriptions using this option. Return codes indicate whether a record was affected by a move, how the NCOALink match was made, or why a match could not be made. *Yes*: Includes the report codes in the NCOALink Processing Summary report.

Option	Description
	No: Default. Excludes report codes from the NCOALink Processing Summary report.

3.5.4.13.7.3 NCOALink Output Options

There is one option in the *NCOALink Output Options* group.

Option	Description
Apply Move to Standardized Fields	Component output fields are not affected by this option. *Yes*: Default. Data Services updates standardized fields to contain details about the address available through NCOALink. *No*: Standardized output fields have the standardized version of input rather than the moved address.

3.5.4.13.7.4 Processing Acknowledgment Form (PAF) Details

The following table describes the NCOALink PAF Details. PAF Details are not required for end users.

Option	Description
Company Website	Enter the company website address for the person signing the PAF. You can leave this parameter blank.
Customer Alternate Company Name	If the list owner's company is also known by another name, enter that alternate name here.
Customer Parent Company Name	If the list owner's company is owned by another company, enter the parent company's name here.
Date Signed By Licensee	Enter the date that the licensee (the NCOALink service provider) signed the PAF in yyyy/mm/dd format.
Date Signed By Customer	Enter the date the customer signed the PAF in yyyy/mm/dd format.
Email of Person Signing	Enter the email address for the person who is signing the PAF. You can leave this parameter blank.
Name Of Person Signing	Enter the name of the person signing this PAF, up to 50 characters.
Title Of Person Signing	Enter the job title of the person signing this PAF, up to 50 characters.

Option	Description
Type	*Initial*: This is the first PAF you're completing to become authorized to process addresses for this particular customer. *Modified*: You're completing a new PAF because some information on your old one changed. *Renewal*: You're completing a new PAF because your old one is expiring.
Using Alternative PAF	*Yes*: Select if you are using a PAF that is not the USPS form (you must have permission from the USPS). *No*: The default setting for this field. This field requires either a *Yes* or *No.*
Using Cooperative Database	Indicates whether the list is from a cooperative database. Applicable for Full and Limited Service Providers only. *Yes* *No:* (the default setting) Note A PAF must be on file for each participant in the cooperative database. Note When set to Yes, a "C" is included in the PAF log to indicate that the list processed was a cooperative database.

3.5.4.13.7.5 Service Provider Options

The following table describes the *NCOALink Service Provider Options*. These options are not required for end users.

Option	Description
Additional Notes	*None*: Default. *Customer Requested Extension*: Select if the customer submitted a written request for an extension.
Buyer Company Name	If the list was processed for rent, sale, or lease, enter the name of the company or individual who bought the list.
Concurrent Processed Data Modified	*No*: If you are processing this data in some other way while performing NCOALink processing, indicates that the concurrent processing does not include changes to the data. Default.

Option	Description
	From Postal Data: If you are processing this data in some other way while performing NCOALink processing, indicates whether the processing includes changes with postal data. *From Non Postal Data*: If you are processing this data in some other way while performing NCOALink processing, indicates whether the processing includes changes with non-postal data. *From Both*: If you are processing this data in some other way while performing NCOALink processing, indicates whether the processing includes changes with both postal and non-postal data.
Concurrent Processes Performed	Indicates whether you processed or will process this data in some other way while performing NCOALink processing. *Yes* *No*
In House List Processing	Indicates whether the list is an in-house (internal) list. Applicable for Full Service Providers only. *Yes* *No* Note When set to Yes, an “I” is included in the Customer Service log to indicate that the list was an in-house list.
Output Returned	Identifies the type of output returned to the client. *Standard*: All required NCOALink output was returned to the client. Default. *Modified*: One or more post processes modified the return information (updates were applied to the list). *Both*: One or more post processes modified the return information (updates were applied to the list); however, a separate file containing all of the required output was also returned.
Post Processed Data Modified	*No*: If you are processing this data after performing NCOALink processing, indicates that the postprocessing does not include changes to the data. Default. *From Postal Data*: If you are processing this data after performing NCOALink processing, indicates whether the postprocessing includes changes with postal data. *From Non Postal Data*: If you are processing this data after performing NCOALink processing, indicates whether the postprocessing includes changes with non-postal data.

Option	Description
	From Both: If you are processing this data after performing NCOALink processing, indicates that the postprocessing includes changes with both postal and non-postal data.
Post Processes Performed	Indicates whether you are processing this data after performing NCOALink processing. *Yes* *No*
Postcode For Mail Entry	Specifies the ZIP Code of the Business Mail Entry Unit (BMEU) or post office where the mail will be submitted for mailing.
Pre Processed Data Modified	*No*: If you are processing this data before performing NCOALink processing, indicates that the preprocessing does not include changes to the data. Default. *From Postal Data*: If you are processing this data before performing NCOALink processing, indicates whether the preprocessing includes changes with postal data. *From Non Postal Data*: If you are processing this data before performing NCOALink processing, indicates whether the preprocessing includes changes with non-postal data. *From Both*: If you are processing this data before performing NCOALink processing, indicates that the preprocessing includes changes with both postal and non-postal data.
Pre Processes Performed	Indicates whether you processed or will process this data before performing NCOALink processing. *Yes* *No*

3.5.4.13.7.6 Contact Detail List

The following table describes the *NCOALink Contact Details* options that are located in the Contact Detail List group. These options are not required for end users.

Option	Description
Address	Enter the broker's or list administrator's address.
Contact Level	Enter the degree of separation this contact is from you from 1 to 99. For example, enter 1 if you received the list from this contact. If your contact received the list from a different broker, then enter 2 for this contact.

Option	Description
	Note that the transform doesn't use this value in any logs.
Contact Company Website	Enter the website of the broker or list administrator. You can leave this parameter blank.
Locality	Enter the broker's or list administrator's locality (city).
Type	*Broker:* A broker directs business to the service provider. *List Administrator:* A list administrator stores and maintains address lists.
License Assigned ID	Enter a unique six-character ID number for the broker or list administrator. You assign the ID number.
NAICS Code	Enter the broker's or list administrator's numeric North American Industry Classification System code, which identifies the business in which they engage. For more information, see *http://www.census.gov/epcd/www/naics.html* .
Name	Enter the broker's or list administrator's name.
PAF Signing Date	Enter the date when the contact signed the PAF in the format yyyy/mm/dd.
Phone	Enter the broker's or list administrator's phone number.
Postcode1	Enter the broker's or list administrator's Postcode1 (ZIP Code).
Postcode2	Enter the broker's or list administrator's Postcode2 (ZIP+4 Code).
Region	Enter the broker's or list administrator's region (state).

3.5.4.13.8 Assignment options

With this option group, you can choose the add-on features that you want to use during processing.

Option	Description
Dual Address	Specifies the action to take when the transform encounters a dual address. *Position:* Selects an address based on the arrangement of the input data. The transform attempts to validate the address that is closest to the lower left corner of the address block. That might be the postal address (rural route or PO Box) or the street address; it depends on how the data was entered. *Postal:* The transform attempts to validate based on the postal address. If that fails, the transform attempts again based on the street address. *Street:* The transform attempts to validate based on the street address. If that fails, the transform attempts again based on the postal address.

Option	Description
Enable DPV	Specifies whether to perform DPV (Delivery Point Validation) processing. *Yes:* Enables DPV processing. *No:* Disables DPV processing.
Enable DSF2 Augment	Specifies whether to perform DSF2 (Delivery Sequence File Second Generation) augment processing. *Yes:* Enables DSF2 augment processing. *No:* Disables DSF2 augment processing.
Enable eLOT	Specifies whether to perform eLOT (Enhanced Line of Travel) processing. *Yes:* Enables eLOT processing. *No:* Disables eLOT processing.
Enable EWS	Specifies whether to perform EWS (Early Warning System) processing. If this transform cannot make an exact match within the `zip4us.dir` (Address Directory 1), it searches the EWS directory to see if the address is a new delivery point. If the address is located in the EWS directory, the transform marks the record as an EWS match and does not attempt further assignment. *Yes:* Enables EWS processing. *No:* Disables EWS processing.
Enable LACSLink	Specifies whether to perform LACSLink (Locatable Address Conversion System) processing. *Yes:* Enables LACSLink processing. *No:* Disables LACSLink processing.
Enable NCOALink	Specifies whether to perform NCOALink (National Change of Address) processing. *Yes:* Enables NCOALink processing. *No:* Disables NCOALink processing.
Enable RDI	Specifies whether to perform RDI (Residential Delivery Indicator) processing. *Yes:* Enables RDI processing. *No:* Disables RDI processing.
Enable Reverse Soundex Search	Specifies whether to use the `zip4us.rev` (Reverse Soundex) directory in an attempt to make address assignments. *Yes:* Enables Reverse Soundex. *No:* Disables Reverse Soundex.

Option	Description
Enable SuiteLink	Specifies whether to perform SuiteLink processing. *Yes:* Enables SuiteLink processing. *No:* Disables SuiteLink processing.
Geo Mode	Specifies which type of GeoCensus processing you want to perform. *Address:* The transform processes address-level GeoCensus only. *Both:* The transform makes an address-level GeoCensus assignment first if applicable. If no assignment is made, the transform makes a centroid-level GeoCensus assignment if applicable. *Centroid:* The transform processes centroid-level GeoCensus only. *None:* The transform turns off GeoCensus processing. Choose this option if you have not purchased the GeoCensus option or if you do not want to perform GeoCensus processing. i Note GeoCensus functionality in the USA Regulatory Address Cleanse transform will be deprecated in a future version. It is recommended that you upgrade any data flows that currently use the GeoCensus functionality to use the Geocoder transform. For instructions on upgrading from GeoCensus to the Geocoder transform, see the *Upgrade Guide*.
USPS Certification Testing Mode	Indicates the type of certification being processed so that the software checks for the appropriate settings and issues warnings and errors when applicable. *None:* The transform processes the job normally, without any special settings for certification. This is the default setting. *CASS:* The transform processes the job with the appropriate settings for CASS self-certification. *DSF2 Augment:* The transform processes the job with appropriate settings for DSF2 augment certification. i Note When certifying for NCOALink, you set the testing mode in the *NCOALink* > *Processing Options* > *List Processing Objective* option.

3.5.4.13.9 Standardization options

This option group contains all of the standardization settings that you need to define for processing USA data. (The options are listed alphabetically.)

Option	Description
Add Firm Match Secondary	*Yes*: Adds secondary address information obtained from SuiteLink directories to the address line. *No*: Does not add secondary address information obtained from SuiteLink directories to the address line, but includes SuiteLink-found information reflected in the lastline ZIP+4 Code and in other output fields. CASS users who do not want to update address lines in their data with SuiteLink secondary information should set this option to No. The software updates the last line to reflect the SuiteLink secondary information in the ZIP+4, and does not update the original address. The software also updates the address line based on your standardization settings in the job setup. Sometimes the option setting has no effect on the presence of the SuiteLink secondary address information. This can happen when the secondary address does not match the National directories, but exactly matches the SuiteLink secondary address information. In this situation, the software does not consider the SuiteLink secondary address as a change to the input secondary address, and does not remove the secondary address from the output address even when the Add Firm Match Secondary option is set to No. This applies to an exact match to the SuiteLink secondary unit and range, or, in cases where there is no unit designator on input, an exact match to the SuiteLink secondary range.
Address Line Alias	Specifies how to standardize the address line if the input primary address is an alias. *Convert*: Converts address lines to the preferred form found in the postal directory. *Preserve*: Retains address lines as they were input. Note To be compliant with CASS, set up your jobs to return the USPS preferred address. When the *Address Line Alias* option is set to *Convert*, the USPS preferred address is returned, even when the input record has a base address or an alias address. You can choose to set up your job to preserve the preferred address (*Address Line Alias* set to *Preserve*), but the software does not produce a USPS 3553 form.
Append Private Mailbox	Private mailboxes (PMB) are like post office boxes, except that they are hosted by private companies. *Yes*: Places the address and PMB in the same field. *No*: Places the PMB into a separate field. PMB information is output to the NON_POSTAL_SECONDARY_ADDRESS, NON_POSTAL_UNIT, and NON_POSTAL_UNIT_NUMBER fields.
Assign With Input Locality	Specifies whether to use the last-line index when assigning the locality (city) name.

Option	Description
	Yes: Assigns the Locality1 based on the locality name that is input if it is valid for the Postcode1. Does not change the Locality1 based on last line index. *No*: Assigns the Locality1 based on the locality that is input if it is valid for the Postcode1 and not a place name; otherwise, assigns Locality1 based on the last-line index of the address line. Produces a more geographically true Locality1. If you choose *No*, the value you choose for the *Preserve Place Names* option does not matter; place names are converted. Note When the *Use USPS Locality Abbreviation* option is set to *Yes*, *Preserve Place Names* is set to *Yes*, and *Assign with Input Locality* is set to *No*, the software may not preserve some place names over 13 characters and abbreviates them.
Capitalization	Specifies the casing of your address data. *Lower*: Converts data to all lowercase letters. For example, "Main Street South" becomes "main street south." *Mixed*: Converts data to initial capital letters. For example, "MAIN STREET SOUTH" becomes "Main Street South." *Upper*: Converts data to all capital letters. For example, "Main Street South" becomes "MAIN STREET SOUTH." Note If you want consistent casing for your data, make sure that this option and the *Capitalization* setting in the Data Cleanse transform are the same.
Combine Multilines	Specifies what to do with related fields input on separate lines. *Yes*: Looks for related fields that were input on separate lines, and tries to put them together on the same line. *No*: Does not try to combine fields.
Directional Style	Specifies whether to abbreviate directional data. *Long*: Uses fully-spelled directionals such as "North," "South," "East," and "West." *Preserve*: Preserves the style used in the input record. *Short*: Uses abbreviated directionals such as "N," "S," "E," and "W." Note When the *Use USPS Street Abbreviation* option is set to *Yes*, the software overrides a setting of *Long* and *Preserve* for the *Directional Style* option and outputs the short directional style.

<table>
<tr><th>Option</th><th>Description</th></tr>
<tr><td>*Include Unused Address Line Data*</td><td>
Specifies whether to output the unused address line data (for discrete and multiline fields).
Yes: Includes the unused address line data, including invalid secondary information, in the address line and in the ADDRESS_LINE_REMAINDER1 field.
No: Does not output the unused address line data in the address line but outputs the information to certain output fields.
Example:
<table>
<tr><th>Input</th><th colspan="2">Include Unused Address Line Data option</th></tr>
<tr><td></td><td>**Yes**</td><td>**No**</td></tr>
<tr><td>SAP
332 FRONT ST S FL 9
LA CROSSE WI 54601</td><td>SAP
332 FRONT ST S FL 3 FL 9
LA CROSSE WI 54601-4025</td><td>SAP
332 FRONT ST S FL 3
LA CROSSE WI 54601-4025</td></tr>
<tr><td colspan="3">*Output fields*</td></tr>
<tr><td>Primary_Secondary_Address</td><td>332 FRONT ST S FL 3</td><td>332 FRONT ST S FL 3</td></tr>
<tr><td>Full_Address</td><td>332 FRONT ST S FL 3 FL 9</td><td>332 FRONT ST S FL 3</td></tr>
<tr><td>Address_Line_Remainder1</td><td>FL 9</td><td>FL 9</td></tr>
<tr><td>Secondary_Address</td><td>FL 3</td><td>FL 3</td></tr>
<tr><td>Pre_SuiteLink_Unit_Description</td><td>FL</td><td>FL</td></tr>
<tr><td>Pre_SuiteLink_Unit_Number</td><td>9</td><td>9</td></tr>
</table>
</td></tr>
<tr><td>*Move Multiline Data*</td><td>
If you turn on this feature, the *USA Regulatory Address Cleanse* transform rearranges your multiline data to conform to USPS guidelines.
The transform moves the primary address into position above the locality-region-postal code line (or lastline).
Bottom: Rearranges the lines according to USPS guidelines. If there are any blank lines, the transform moves them to the top and shifts the data to the bottom of the block.
No: Does not rearrange any lines, blank or otherwise.
Top: Rearranges the lines according to USPS guidelines. If there are any blank lines, the transform moves them to the bottom and shifts the data to the top of the block.
Example:
</td></tr>
</table>

Option	Description
	 Input data: Result of moving: Line1 Line2 Line3 Line4 Line5 100 Market Street Suite 202 Sycamore Building Boston MA 02109 Sycamore Building Suite 202 100 Market St Boston MA 02109 This feature does not require that you standardize your data. *Note:* If you choose *Top* or *Bottom*, the input field lengths of all fields mapped to Multiline**<x>** must be the same. For example, if Multiline1 is set to a length of 60, all Multiline fields that you use must be set to 60.
Multiline Update Postcode 1	This option affects multiline data only (data passed in and retrieved through multiline fields). *Dont_Update*: Assigns Postcode1 fields, but does not write them to the Multiline output fields. In those fields, leaves the original Postcode1 intact and the assigned Postcode1 is available in other output fields. *Erase_Then_Update*: Replaces the original Postcode1 with the assigned Postcode1 in the Multiline output fields. If no Postcode1 is assigned, the original Postcode1 is not included in the Multiline output fields. *Update*: Replaces the input Postcode1 with the assigned Postcode1 in the Multiline output fields. If no Postcode1 is assigned, the original is retained.
Multiline Update Postcode 2	This option affects multiline data only (data passed in and retrieved through multiline fields). *Dont_Update*: Assigns Postcode2, but does not write them to the Multiline output fields. The transform leaves the original Postcode2 intact and the assigned Postcode2 is available in other output fields. *Erase_Then_Update*: In the Multiline output fields, replaces the original Postcode2 with the assigned Postcode2. If no Postcode2 is assigned, the original Postcode2 is not available in the Multiline output fields. *Update*: In the Multiline output fields, replaces the input Postcode2 with the assigned Postcode2. If no Postcode2 is assigned, it retains the original.
Preserve Dual Address Order	Specifies whether to preserve or change the dual address order. *Yes*: When an address contains both a street and mailing address, keeps the address order as it was input. *No*: When the input address contains both a locality and mailing address, moves the assigned address immediately above the locality and region.
Preserve Place Names	Specifies whether to preserve or change non-mailing city names (place names). *Yes*: Preserves the non-mailing city name. Given Hollywood as input, the transform outputs Hollywood.

Option	Description
	No: Changes non-mailing city names to city names preferred by the USPS. Given Hollywood as input, the transform outputs Los Angeles. ℹ Note When the *Use USPS Locality Abbreviation* option is set to *Yes*, *Preserve Place Names* is set to *Yes*, and *Assign with Input Locality* is set to *No*, the software may not preserve some place names over 13 characters and abbreviates them.
Primary Type Style	Specifies whether to abbreviate the street (primary) type. *Long:*: Uses fully-spelled primary types such as Street, Avenue, and Road. *Preserve*: Preserves the style used in the input record. *Short*: Uses abbreviated primary types such as St, Ave, and Rd. ℹ Note When *Use USPS Street Abbreviation* is set to *Yes*, the software overrides a setting of *Long* and *Preserve* for the *Primary Type Style* option and outputs the short primary type style.
Retain Pound Sign in Unit Description	Outputs "#" into either extraneous fields or to the UNIT_DESCRIPTION output field. *Yes*: Outputs the # unit designator to the UNIT_DESCRIPTION output field. *No*: Outputs the # unit designator to the EXTRANEOUS_SECONDARY_UNIT_NUMBER and/or the EXTRANEOUS_SECONDARY_ADDRESS_DATA output fields. The option does not affect the following address situations: ● Puerto Rican addresses ● Military addresses ● Rural Route addresses ● Addresses without "#" in the address line ● Addresses with remainder words
Standardize Assigned Address	Specifies whether to correct and standardize the assigned address line and lastline data. *Yes*: Corrects and standardizes your address line and lastline data. Use this value for CASS certification. *No*: Does not standardize your address line or lastline data.
Standardize Unassigned Address	Specifies whether to standardize unassigned data. *Yes*: Attempts to parse and standardize any unassigned addresses. *No*: Leaves unassigned addresses as entered on input.
Unit Description	Specifies how to standardize the unit description. *Convert*: Uses the unit description found in the postal directory (such as an apartment, suite, room, or floor).

Option	Description
	Preserve: Preserves the unit description from the input record and corrects any spelling errors.
Use USPS Locality Abbreviation	*Yes*: Enables this option (and affects only the multiline and standardized last line fields). *No*: Disables this option. Provides a USPS 13-character city name when one is available. If the city name is not valid (for example, it is a non mailing city name), the software relies on other settings in the job to determine what to output for city. If the city name is longer than 13 characters, the software returns an abbreviation that is 13 characters or less. If the city name is already 13 characters or less, the software does not abbreviate it. Note When the number of characters in the output is greater than the length specified for the output field, the software attempts to truncate the output data to fit in the output field without eliminating vital address data. Intelligent truncation abbreviates the output data first, and if it still doesn’t fit the output buffer, it truncates the data. There are no options to set this up in the USA Regulatory Address Cleanse transform. The transform does this automatically. If the *Use USPS Primary Name Abbreviation* and/or the *Use USPS Locality Abbreviation* options are enabled, the software uses those abbreviations first. If the values don't fit within the length of the output fields, then intelligent truncation occurs.
Use USPS Primary Name Abbreviation	*Yes*: Enables this option. *No*: Disables this option. Abbreviates the address line to 30 characters or less when the output address line exceeds 30 characters and when an abbreviated form of the address is available in the directory data supplied by the USPS. Abbreviated forms of an address are only provided for output addresses 30 characters or greater. If the output address line is already 30 characters or less, the output address line is not abbreviated. Note An address line may be output with more than 30 characters in situations where no abbreviated form of the address is available in the directory data. If your data must fit exactly into 30 characters, we recommend to set appropriate address output field lengths to 30. This option affects multiline and standardized last line fields when set to *Yes*. If the *Use USPS Street Abbreviation* option is set to *Yes*, it affects the following address components on output: ● *Suffix Style*: The style will be short.

Option	Description
	• *Directional Style*: The style will be short. • *Address Line Alias*: The setting of *Preserve* may be overridden. Note When the number of characters in the output is greater than the length specified for the output field, the software attempts to truncate the output data to fit in the output field without eliminating vital address data. Intelligent truncation abbreviates the output data first, and if it still doesn't fit the output buffer, it truncates the data. There are no options to set this up in the USA Regulatory Address Cleanse transform. The transform does this automatically. If the *Use USPS Primary Name Abbreviation* and/or the *Use USPS Locality Abbreviation* options are enabled, the software uses those abbreviations first. If the values don't fit within the length of the output fields, then intelligent truncation occurs.

3.5.4.13.10 Non Certified options

This option group includes options to process your data without following CASS certification rules.

Option	Description
Accept Inexact Postcode Move	When an input record has an obsolete postcode or a postcode move, specifies whether the transform should ignore some of the non-matching elements between the input record and the record in the national directory, and use built-in matching thresholds to determine if the records match. *Yes*: Ignores the non-matching elements and uses built-in matching thresholds. *No*: Disables this option (and does not ignore non-matching elements).
Assign With Input Postcode	Specifies whether the transform should use the last four digits of the 9-digit postcode (if present on input), which is usually the Postcode2 field (ZIP+4), during address assignment. *Yes*: Enables the transform to use the record's last four digits of the 9-digit postcode to try to make a finer level of assignment than it could make under CASS rules. Under CASS rules, the transform doesn't consider the last four digits of the 9-digit postcode. In order for this option to work, the last four digits of the 9-digit postcode must be unique to a valid firm or secondary address. *No*: Disables this option.

Option	Description
Assign Postcode2 Not DPV Validated	Specifies whether to output the Postcode2 when an assignment is made even when *Enable DPV* is set to *No* and *Disable Certification* is set to *Yes*. The output address is not validated by DPV. *Yes*: Assigns the Postcode2 when *Enable DPV* is set to *No*. *No*: Leaves the Postcode2 blank when an assignment is made and *Enable DPV* is set to *No*.
Disable Certification	Specifies whether to run address cleansing for CASS certification. *Yes*: Runs address cleansing without the restrictions of CASS certification rules. Choose this value if you want to use any of the other options in this option group. This value also enables non-mailers to process addresses for 14 months after the directory creation date rather than 3 to 4 months for postal discounts through the USPS. You will not receive any postal discounts with this value or be able to produce a USPS Form 3553. *No*: Runs address cleansing under CASS certification rules. The other options in this option group are ignored.
Enable Geo Only	ℹ Note GeoCensus functionality in the USA Regulatory Address Cleanse transform will be deprecated in a future version. It is recommended that you upgrade any data flows that currently use the GeoCensus functionality to use the Geocoder transform. For instructions on upgrading from GeoCensus to the Geocoder transform, see the *Upgrade Guide*. Specifies whether the transform should process only with the address-level GeoCensus or centroid GeoCensus directories. Choose the type of GeoCensus processing in the Assignment Options group. *Yes*: Runs address cleansing with the GeoCensus directories only. The transform does not process your data with the postal directories. Make sure that you have defined the location of the GeoCensus directories in the Reference Files option group. You must also include the appropriate GeoCensus output fields; data is not posted in any other output fields. *No*: Enables you to run address cleansing with the GeoCensus directories, as well as the postal directories.
Enable Parse Only	Specifies whether the transform should parse and validate your data or parse only. *Yes*: Parses records into their discrete components, but does not perform a lookup in the postal directories. This mode is fast, but parsing results are unverified. *No*: Parses records into their discrete components and performs a lookup in the postal directories. This mode may be slower, but parsing results are verified.
Enable Suggestion Lists	Specifies whether suggestion lists are generated for records that cannot be assigned. This option is for transactional projects.

Option	Description
	Yes: Generates suggestion lists. *No*: Does not generate suggestion lists.

3.5.4.13.11 CASS Report options

With this option group, you add the necessary USPS Form 3553 information as required by the USPS when certifying a mailing.

Option	Description
Company Name Certified	If you rely on SAP for vendor CASS certification, leave this parameter blank; the transform inserts "SAP" as the default value. If you have your own end-user CASS certification from the USPS, type your company name (up to 40 characters).
List Name	Specifies the name of the mailing list (up to 20 characters).
List Owner	Specifies the name of your company (up to 19 characters).
LOT Certification	Specifies whether you have LOT certification. *Yes:* You have LOT certification but you do not have CASS certification in your own name. *No:* You have CASS certification in your own name but you did not seek or obtain LOT certification. In this case, setting LOT Certified to No ensures that the LOT Certification lines on your USPS 3553 forms are blank, which is appropriate.
Mailer Address 1	Specifies the name and address of the person or organization for whom you are preparing the mailing (up to 29 characters per line).
Mailer Address 2	
Mailer Address 3	
Mailer Address 4	
Software Version	If you rely on SAP for vendor CASS certification, you may leave this parameter blank. The transform inserts the appropriate software name and version as the default value. If you have received end-user CASS certification in your own company's name, type the software name and version number that you use to receive CASS certification.

3.5.4.13.12 Suggestion List group

Set the options in this group to configure how suggestion lists are output.

Option/Option group	Description
Address Lines Match Minimum	Specifies the similarity score required for address-line suggestions. Valid values are 0 to 80. The similarity score determines which suggestions are returned in the list. A higher number indicates that the suggestion must be more similar to the input to be returned as a possible suggestion.
Address Range Window	Specifies a number that represents a span. The software uses the number to present a range of addresses around the input primary address range for which to return suggestions. By using this option, you can limit the suggestions returned to be within a few blocks of your input. For example, assume you entered 500 for this value. Then, you submit the following street address: 1000 Pine St. Suggestions would only be returned in a range from 750 to 1250 Pine Street. Type "0" if you don't want to limit the ranges returned in suggestions.
Combine Overlapping Ranges	Specifies how individual suggestions with overlapping ranges are consolidated. *Combine_Ignoring_Gaps:* Ignores gaps and overlaps in primary ranges, so consolidation is more aggressive. *Combine_Preserving_Gaps:* Preserves gaps in primary ranges, but overlapping ranges are consolidated. *None:* Suggestions are not consolidated.
Delimiter	Specifies the delimiter to use between each suggestion. This is applicable if you chose *Delimited* for the *Style* option. Choose any character or string to separate each suggestion. This value should differ from the *Field Delimiter* value.
Field Delimiter	Specifies the delimiter to use between each suggestion list. This is applicable if you chose *Delimited* for the *Style* option. This value should differ from the *Delimiter* value.
Lastlines Match Minimum	Specifies the similarity score required for lastline suggestions. Enter a value from 0 to 80.

Option/Option group	Description
	The similarity score determines which suggestions are returned in the list. A higher number indicates that the suggestion must be more similar to the input to be returned as a possible suggestion.
Match Range	Specifies whether to disregard an address-line suggestion when it does not match the primary range of the input address. *Yes:* Returns address-line suggestions only when they match the primary range of the input address. *No:* Returns a possible address-line suggestion when it doesn't have the same primary range as the input.
Max Number Addresslines	Specifies the maximum number of address-line suggestions that can be generated. The maximum number that you can enter is 100. For example, you could set this option to limit the size of the SOAP documents being sent by the web service, or to limit the maximum number of suggestions that your users would have to choose from. ℹ Note If you set a low maximum, a viable suggestion could be left out of the suggestion list.
Max Number Lastlines	Specifies the maximum number of lastline suggestions that can be generated. The maximum number that you can enter is 15. For example, you could set this option to limit the size of the SOAP documents being sent by the web service, or to limit the maximum number of suggestions that your users would have to choose from. ℹ Note If you set a low maximum, a viable suggestion could be left out of the suggestion list.
Style	Specifies the style of the output file. *Delimited:* Outputs the suggestion list data in a delimited text format, with the delimiters specified in the *Delimiter* and *Field Delimiter* options. *XML:* Outputs the suggestion list data as hierarchical XML. This option is likely the preferred one for users who integrate suggestion lists via the web service. You can then use the XML tools that you own to parse the suggestion list data.
Suggestion List Components	Specifies the address field components that you want to include in the Suggestion_List output field.

Option/Option group	Description
	ℹ Note Suggestion list field components that do not have a value are not output to the Suggestion_List output field if the selected *Style* is *XML*.

Designer Guide: Data Quality, Similarity score [page 548]
Designer Guide: Nested Data, Extracting data quality XML strings using extract_from_xml function [page 370]

3.5.4.13.13 Suggestion List Components

These options let you choose what information to output to the Suggestion_List output field.

> ℹ Note
>
> If XML is the selected Style in the Suggestion List option group, suggestion list fields that do not have a value are not output to the Suggestion_List output field.

Option/option group	Description
Firm	Select Yes to output the firm name for the secondary address.
Locality1	Select Yes to output the locality1 (city) preferred by the USPS. Applicable for primary, secondary, and lastline address levels.
Postcode	Select Yes to output the five-digit Postcode1 (not including the four-digit ZIP4). Applicable for primary, secondary, and lastline address levels.
Postcode2 Even	Select Yes to output the four-digit ZIP4 code, even numbers only. Applicable for primary and secondary address levels.
Postcode2 Odd	Select Yes to output the four-digit ZIP4 code, odd numbers only. Applicable for primary and secondary address levels.
Primary Name1	Select Yes to output the street name description. Applicable for primary and secondary address levels.

Option/option group	Description
	ℹ Note Primary numbers (high or low) are not output to this field.
Primary Name Full1	Select Yes to output the primary address line, such as the street address or post office box. The output includes the following information: Primary Prefix1, Primary Name1, Primary Type1, and Primary Postfix1. Applicable for primary and secondary address levels. ℹ Note Primary numbers (high or low) are not output to this field.
Primary Number High	Select Yes to output the high portion of the premise number range. Applicable for primary and secondary address levels.
Primary Number Low	Select Yes to output the low portion of the premise number range. Applicable for primary and secondary address levels.
Primary Postfix1	Select Yes to output the abbreviated directional (for example, N, S, NW, or SE) that follows a street name. Applicable for primary and secondary address levels.
Primary Prefix1	Select Yes to output the abbreviated directional (for example, N, S, NW, or SE) that precedes a street name. Applicable for primary and secondary address levels.
Primary Side Indicator	Select Yes to output Odd or Even for the primary side indicator. Applicable for primary and secondary address levels.
Primary Type1	Select Yes to output the abbreviated street type (for example, St, Ave, or Pl). Applicable for primary and secondary address levels.
Region1	Select Yes to output the state, province, territory, or region. Applicable for primary, secondary, and lastline address levels.
Secondary Side Indicator	Select Yes to output Odd or Even for the secondary side indicator. Applicable for secondary address level.
Selection	Select Yes to output the selection number for multiple suggestions.
Unit Description	Select Yes to output the unit description (for example, #, Apartment, or Flat). Applicable for secondary address level.
Unit Number High	Select Yes to output the high portion of the unit number range. Applicable for secondary address level.
Unit Number Low	Select Yes to output the low portion of the unit number range. Applicable for secondary address level.

3.5.4.13.14 Z4 Change options

With the Z4Change options you can turn on Z4Change processing and specify the last time the Postcode2 was updated.

Option	Description
Enable Z4 Change	Specifies whether to enable Z4Change processing. *Yes:* Turns on Z4Change processing. *No:* Turns off Z4Change processing.
Last ZIP4 Assign Date	Specifies the month and year that the input records were most recently ZIP+4 coded—either through a full address correction process or a previous Z4Change pass. Enter the date using the format MM/YYYY. For example, enter a date of January 2004 by typing **`01/2004`**. The USA Regulatory Address Cleanse transform verifies that your date is within the 12-month period covered by the Z4Change file. If there is a date problem, you will receive an error message when Data Quality runs your project.

3.5.4.13.15 USA Regulatory Address Cleanse fields

The USA Regulatory Address Cleanse transform requires that you map fields on input and output.

Related Information

Input fields [page 1351]
Output fields [page 1353]

3.5.4.13.15.1 Field category columns in Output tab

The Output tab lists output fields that hold the data that the transform cleanses or creates. You can choose to view the Best Practice, In Use, or All output fields by selecting the corresponding option at the top of the tab.

Best Practice: Lists all available output fields that have a field class of Best.

In Use: Lists only the output fields that you have chosen to output (listed in Schema Out).

All: Lists all output fields that are available for this transform.

> Note
>
> For details about mapping input and output fields, see the *Designer Guide*.

The output field attributes in the table below are listed in groups based on the field category column. Each field has categories that describe the type of content that is output. The field category displays “None” when it does not apply to the field.

Category	Description
Content Type	Identifies the type of data in the field. Setting the content type helps you map your fields when you set downstream transforms.
Field Addrclass	Specifies the address class for the generated field. *Delivery:* When used with the applicable Field Name, this value generates fields that reflect the address that is used in an attempt to assign an address. *Dual:* When used with the applicable Field Name, this value generates fields that reflect the address that is not used in an attempt to assign an address for input records that may contain both a street and postal address on input. *Official:* When used with the applicable Field Name, this value generates fields in the form of the data preferred by the Postal Authority. For example, in Winona, Minnesota USA, Broadway and 6th Street are alternate names for the same street. A letter addressed to Broadway is delivered, but the USPS prefers 6th Street.
Field Category	*Component:* Individual address components and postal codes that are related to the processed record. *Standardized:* Standardized input lines based on the settings in the Standardization Options group in the transform. *Suggestion:* Suggestion list output data based on the settings in the Suggestion List Options group.
Field Class (USA Regulatory Address Cleanse)	Specifies the field class that you want to assign to your output fields. *Best:* Outputs data based on various factors, such as whether an address was assigned, the Field AddrClass, and any settings that you defined in the Standardization Options group in the Options tab. Note When NCOALink is enabled and a valid move is available, Best fields contain the move-updated address data if it exists and if it matches in the U.S. National Directories. Or, the field contains the original address data if a move does not exist or if the move does not match in the U.S. National Directories. *Correct:* Outputs the complete and correct value found in the directories, and is standardized according to any settings that you defined in the Standardization Options group in the Options tab. *Parsed:* Outputs the parsed value.

Category	Description
	Pre_LACSLink: Retained address components that were replaced with LACSLink address information. *Move_Updated*: Outputs the address components that have been updated with move-updated address data. Note The transform looks for the move-updated address information in the U.S. National Directories. When the move-updated address is not found in the U.S. National Directories, the software populates the Move Updated fields with information found in the Move Update Directories only. The Move Updated fields that are populated as a result of standardizing against the U.S. National Directories is not updated.
Field Class (Global Address Cleanse)	Specifies the field class that you want to assign to your output fields. *Best:* Outputs data based on various factors, such as whether an address was assigned, the Field AddrClass, and any settings that you defined in the Standardization Options group in the Options tab. *Parsed:* Outputs the parsed value.
Field Name	Specifies a field name where the data is populated based on the options that you specify within this transform.
Type	Specifies the type and default length of data the output field contains; for example, varchar, date, and time.

Related Information

Content types [page 1131]

Designer Guide: How address cleanse works [page 586]

3.5.4.13.15.2 Input fields

The following are Data Services input fields that you can use to map the input data file fields for the USA Regulatory Address Cleanse transform.

Field	Description
Address_Line	The delivery address line (for example, "123 Main Street, Unit 4").

Field	Description
Check_Digit	The check-digit for 11-digit delivery-point bar code. Applicable only if the transform can make a full assignment. The transform provides the check digit for a five-digit bar code when a five-digit assignment is possible, or the address is undeliverable. When the address is unassigned, the check digit is based on the unverified input Postcode1 (ZIP Code).
Country	The country name. This transform does not attempt to make an assignment for addresses outside of the U.S. and its possessions, territories, and protectorates.
County_Code	The three-digit county code. Numbers start at 001 within each state.
Data_Source_ID	The input source or list identifier. Use this field to identify the source of an input set or to identify the list that an input record belongs to in the case that multiple lists are present in the input. Statistics are generated for each unique value in this field when you map the field in conjunction with enabling the *Gather Statistics Per Data Source* option in the Reports and Statistics group.
Delivery_Point	The two-digit DPBC code.
Family_Name1	The family name (for example, Smith).
Firm	The company name.
Given_Name1	The given name (for example, Robert).
Given_Name2	The second given name (for example, B.).
Lastline	The last line delivery information that can include all or some of the following fields: Locality1, Region1, Postcode1, or Postcode2.
Locality1	The city, town, or suburb.
Locality2	The Puerto Rican urbanization information.
LOT	The Line-of-Travel number.
LOT_Order	The Line-of-Travel sortation: *A*: Ascending *D*: Descending LOT codes are required for non-automated, CART presorting in Standard Mail, Enhanced Carrier Route Subclass.

Field	Description
Multiline1-12	A line from the input file which may contain data. The type of data in this line may vary from record to record.
Name	The name of the person associated with the address.
Postcode_Full	The complete postal code (ZIP10 with a hyphen; ZIP9 without a hyphen).
Postcode1	The five-digit primary ZIP Code. It does not include the four-digit ZIP4 Code.
Postcode2	The four-digit ZIP4 code. On a mail piece, this code follows the primary postal code with a hyphen placed between; for example, 54601-1234.
Postname	The honorary postname (indicating certification, academic degree, or affiliation such as CPA) or maturity postname (indicating heritage such as Jr.).
Prename	The prename (for example, Mr.).
Region1	The name of the state or province for this address.
SortCode_Route	The four-digit carrier route number.
Stage_Address_Flag Stage_Lastline_Flag Stage_Name_Flag Stage_Record_Key	The USA Regulatory Address Cleanse information required from the stage file. For NCOALink stage testing only.
Suggestion_Reply1-5	The index number that corresponds to a specific lastline suggestion or an address line suggestion. These fields can also be used to input a street primary range or a street secondary range. If you do not want to use a suggestion list, make the value of this field 0, and the suggestion list will be ignored.
Unit_Number	The secondary address information (for example, the unit description and/or secondary number).

3.5.4.13.15.3 Output fields

The following are Data Services output fields that can be used for the USA Regulatory Address Cleanse transform. See the fields listed in the transform's Output tab to view each field's properties.

Field	Description
Address_Line	Complete, standardized primary and secondary address line. The style of suffixes, directional, and unit designators depends on how you define your options.

Field	Description
	i Note If the output values don't fit within the length of the output field, then intelligent truncation occurs.
Address_Line_Remainder1	Extraneous data found on the address line that cannot be identified as address data or does not belong in the standardized address line. This may include invalid secondary address information.
Address_Type (DELIVERY, DUAL)	The record-type indicator for the assigned address. Applicable for DELIVERY and DUAL Generated Field Address Class. The first character indicates the type of record in the address directory to which the address matched: *F*: Firm *G*: General delivery *H*: High-rise apartment or office building *M*: Military *P*: Post office box *R*: Rural route or highway contract *S*: Street (usually, one side of one city block) **`<blank>`**: Unassigned The second character may be a *D* or blank. The D stands for default; it means that the transform detected, from the address directory, that a finer level of address assignment would be possible if further input information were available. *FD*: Firm default. The transform did not assign a firm-level Postcode2, but could do so if given more or better firm information. *GD*: General delivery default. Assigned when General Delivery is the only primary name listed for the Postcode1. *HD*: High-rise default. The transform assigned the Postcode2 for the entire building. Assignment at the unit, floor, or wing level is possible. Often caused by a suite or apartment number out of range. *RD*: Rural route or highway contract default. The transform assigned the Postcode2 for the entire route but could make a better assignment with the box number. *SD*: Street default. Usually means that there is no Postcode2 for the building, so the transform had to assign the Postcode2 for the block. *UD*: Unique default. Either the owner of the unique Postcode1 has not provided Postcode2 assignments, or the address could not be matched.

Field	Description
	When the transform cannot assign an address, it provides an address-type indication based on the way that the input data was parsed. This process is not foolproof. The transform may indicate that a street, rural route, highway contract, general delivery, or PO Box was parsed.
AGeo_Countycode	Federal Information Processing Standard (FIPS) county code (for example, 063).
AGeo_Latitude	Latitude (degrees north of the equator) in the format 12.123456.
AGeo_Longitude	Longitude (degrees west of the Greenwich Meridian) in the format -12.123456.
AGeo_MCDCode	U.S. Census Bureau Minor Civil Division (MCD) data or if MCD data is unavailable, Census County Division (CCD) data (for example, 40775).
AGeo_Placecode	Federal Information Processing Standard (FIPS) place code (for example, 40775).
AGeo_Sectioncode	U.S. census tract code in the format 1234567890 (for example, 0003001059).
AGeo_Statecode	Federal Information Processing Standard (FIPS) state code (for example, 55).
Alias_Type (OFFICIAL)	The alias-type indicator for the assigned address. Applicable for OFFICIAL Generated Field Address Class. It describes the input address, not the output address. *A*: The input address matches an abbreviated street name. *B*: The input address matches the high-rise alternate default base record. *C*: The input street name is out of date; to get new street name, convert your record to the preferred alias. *H*: The input address is an undesirable alternate, subject to conversion to a USPS preferred street address (high-rise alternate). *O*: The input address is a street nickname or other alias. *P*: The input address is a preferred alias. `<blank>`: The input address is not an alias or is unassigned.
ANKLink_Return_Code	ANKLink return code (Attempted Not Known). Valid values are: *77*: An ANKLink match was found. If NCOALink_Return_Code contains an A, 91, or 92, you may be able to obtain a new address from an NCOALink full service provider. `<blank>`: No NCOALink lookup or no ANKLink match. This is always blank for full service providers.
Audit_Dropped_Secondary	This field is used for audit testing. This field is also populated when an ANKLink match is made.

Field	Description
Audit _Prename Audit _Given_Name1 Audit _Given _Name2 Audit_Family_Name1 Audit _Postname	These fields contain the name data used to make an NCOALink match. In some cases, the name in these fields is not the same as the input name (for example, if a nickname, alternate spelling, or initial is used instead). In the case of a firm match, these name fields contain a split version of the firm data. These fields are also populated when an ANKLink match is made.
Audit _Gender	This field is used for audit testing. This field is also populated when an ANKLink match is made.
Audit _General	This field contains information for Stage I and Stage II tests, specifically query data, result data, and hint bytes, as the USPS requires. Use this field for audit purposes only. This field is required for audits. For more information about the content of this field, see the NCOALink User Technical Reference at *http://ribbs.usps.gov/* . This field can also contain ANKLink return codes.
Audit _Primary_Name	This is the primary name that is sent to NCOALink for matching. This field is required for audits.
Audit _Range	This is the range that is sent to NCOALink for matching. This field is required for audits.
Audit _Secondary_Range	This is the secondary range that is sent to NCOALink for matching. This field is required for audits.
Audit _Truncated_Given_Name1	This field is used for audit testing. This field is also populated when an ANKLink match is made.
Audit _Truncated_Given_Name2	This field contains the truncated middle name as stored in the NCOALink data. Use this field for audit purposes only. This field is required for audits.
Audit_Unit	This is the unit data that is sent to NCOALink for matching. This field is required for audits.
Carrier_Route_Sort_Zone	The carrier-route sort zone indicates eligibility for Standard Mail Automation Enhanced Carrier Route. *A*: Carrier route rates are available and merging is allowed. *B*: Carrier route rates are available and merging is not allowed. *C*: Carrier route rates are not available and merging is allowed. *D*: Carrier route rates are not available and merging is not allowed.
CASS_Assignment_Type	Indicates the option used in making the assignment:

Field	Description
	O: The non-CASS and DPV tie-break options are disabled or not used to make an assignment. *1*: Inexact Postcode1 move assignment. *2*: Input Postcode2 assignment. *3*: DPV tie-breaking was used to make this assignment. **`<blank>`**: The transform cannot assign an input address.
CASS_Record_Type	The record type necessary for posting on the CASS test. This field is populated for assigned records only. The valid record types include: *F*: Firm *G*: General delivery *H*: High-rise *P*: Post office box *R*: Rural route or highway contract *S*: Street
CGeo_BSACode	A Core-Based Statistical Area (CBSA) that consists of: ● A county with an incorporated place or a census-designated place that has a population of at least 10,000. ● Adjacent counties with at least 25 percent of employed residents of the county who work in the CBSA's core or central county. For example, 29100. CBSAs are either metropolitan (population of at least 50,000) or micropolitan (population between 10,000 and 50,000). With CBSAs, you can collect statistics for less urban areas of the country. CBSAs cover approximately 90 percent of the entire U.S. population.
CGeo_Latitude	Latitude (degrees north of the equator) in the format 12.123456.
CGeo_Longitude	Longitude (degrees west of the Greenwich Meridian) in the format -12.123456.
CGeo_Metrocode	Metropolitan Statistical Area (MSA) number (for example, 3870). The value 0000 indicates that the address does not lie in any MSA (usually a rural area).
CGeo_Sectioncode	U.S. census tract and block group code (for example, 0202001067). The first six digits are the tract number, and the first of the final four digits is the block group code within the tract. The Metropolitan Statistical Area (MSA) and block group codes are used for matching to demographic-coding databases. To uniquely specify a census block group within the entire country, combine the Sortcode_Postcode and CGeo_Sectioncode fields.

Field	Description
Check_Digit	Check digit for the delivery-point bar code, or for a five-digit bar code if a full postal code (ZIP+4) could not be assigned.
Count	Specifies the suggestion count generated as the result of looking up the current record. A nonnegative value is output. If the current record does not end processing with a suggestion list needing resolution, then the value in this field is 0.
Country	The country name.
County_Code	Federal Information Processing Standard (FIPS) three-digit county code. Numbers are unique within states. You might use county information if you are preparing a presorted periodicals mailing.
County_Name	The fully-spelled county name.
Delivery_Point	The two-digit DPBC code.
Delivery_Type	Type of postal facility: *A*: Airport Mail Facility (AMF) *B*: Branch Office *C*: Community Post Office (CPO) *D*: Area Distribution Center (ADC) *E*: Sectional Center Facility (SCF) *F*: Delivery Distribution *G*: General Mail Facility (GMF) *K*: Network Distribution Centers (NDC) *M*: Money Order Unit *N*: City/place name *P*: Post Office (main) *S*: Station *U*: Urbanization (Puerto Rico only)
District	District number for the U.S. House of Representatives.
DPV_CMRA	The DPV Commercial Mail Receiving Agencies (CMRA) component that is generated for this record. *L*: The address triggered DPV locking. *N*: The address is not a CMRA. *Y*: The address is a valid CMRA.

Field	Description
	<blank>: A blank output value indicates that Enable_DPV_Validation is set to No, DPV processing is currently locked, or the transform cannot assign the input address.
DPV_Footnote	DPV footnotes are required for end-user CASS certification. The footnotes contain the following information: *AA*: The input address matches to the ZIP+4 file. *A1*: The input address does not match to the ZIP+4 file. *BB*: All input address field values match to DPV. *CC*: The input address primary number matches to DPV, but the secondary number does not match (the secondary is present but invalid). *F1*: The input address matches to a military address. *G1*: The input address matches a general delivery address. *M1*: The input address primary number is missing. *M3*: The input address primary number is invalid. *N1*: The input address primary number matches to DPV but the address is missing the secondary number. *NL*: An NCOALink move address cannot be DPV confirmed. The NCOALink directory data does not exactly match the DPV directory data. This may happen because the NCOALink directories are updated more frequently than the DPV directories. Note The NL footnote is applicable only for the Move Updated generated field class. *P1*: The input address is missing the rural route or highway contract box number. *P3*: The input address is an invalid post office, rural route, or highway contract number. *RR*: The input address matches to CMRA. *R1*: The input address matches to CMRA, but the secondary number is not present. *U1*: The input address matches a unique address. Note The transform always posts the DPV footers in the same order and this field is not always 12 characters in length.

Field	Description
DPV_NoStats	No Stat indicator. No Stat means that the address is a vacant property, it receives mail as a part of a drop, or it does not have an established delivery yet. *Y*: The address is flagged as No Stat in DPV data. *N*: The address is not No Stat. **`<blank>`**: The address was not looked up. ℹ Note The US Addressing report contains DPV NoStats counts in the DPV Summary section.
DPV_Status	The DPV status component that is generated for this record. *D*: The primary range is a confirmed delivery point, but the secondary range is not available on input. *L*: The address triggered DPV locking. *N*: The address is not a valid delivery point. *S*: The primary range is a valid delivery point, but the parsed secondary range is not valid in the DPV directory. *Y*: The address is a confirmed delivery point. The primary range and secondary range (if present) are valid. **`<blank>`**: A blank output value indicates that Enable_DPV_Validation is set to No, DPV processing is currently locked, or the transform cannot assign the input address.
DPV_Vacant	Vacant address indicator. *Y*: The address is vacant. *N*: The address is not vacant. **`<blank>`**: The address was not looked up. ℹ Note The US Addressing report contains DPV Vacant counts in the DPV Summary section.
DSF2_Business_Indicator	Residential/business indicator. You may use this information to lower your parcel-shipping costs. (Some parcel delivery services charge more for delivery to residential addresses.) *Y*: Business address. *N*: Not a business address.

Field	Description
	`<blank>`: The address was not looked up.
DSF2_Delivery_Type	Delivery type. *1*: Curb-side delivery. *2*: NDCBU (Neighborhood Delivery Centralized Box Unit) delivery. *3*: Central delivery. *4*: Door-slot delivery. `<blank>`: The address was not looked up.
DSF2_Drop_Count	Drop count. If DSF2_Drop_Indicator contains Y or DPV_CMRA contains Y, then this field contains a value from 000 to 999, indicating the number of businesses or families served by this delivery point.
DSF2_Drop_Indicator	Drop indicator. *Y*: The delivery point serves multiple businesses or families. For example, delivery point may be a CMRA (Commercial Mail Receiving Agency). *N*: The delivery address is not a CMRA. `<blank>`: The address was not looked up.
DSF2_Educational_Ind	Educational indicator. *Y*: The address is an educational institution. *N*: The address is not an educational institution. `<blank>`: The address was not looked up.
DSF2_LACS_Conversion_Indicator	LACS (Locatable Address Conversion System) indicator. *Y*: The address is LACS convertible. *N*: The address is not LACS convertible. `<blank>`: The address was not looked up.
DSF2_Record_Type	Record type. *B*: Business address. *R*: Residential address. *U*: Unknown. AP.DSF_Deltype is blank. `<blank>`: No information available.
DSF2_Seasonal_Indicator	Seasonal address indicator.

Field	Description
	Y: The address is seasonally occupied. *N*: The address is not seasonal. **`<blank>`**: The address was not looked up.
DSF2_Throwback_Indicator	Throwback indicator. *Y*: Customer with street address wants delivery at PO Box instead. *N*: No throwback necessary. **`<blank>`**: The address was not looked up.
Error	Specifies the error status generated as the result of looking up the current record and performing a suggestion processing. Possible output values are 0–5. *0:* There are no suggestion selection errors. *1:* The necessary selection information is blank. For example, a lastline suggestion list is generated, but there is no lastline selection input field data to make a choice. *2:* The suggestion selection is invalid. For example, 8 was selected but there are only five suggestions. *3:* The suggestion entry in the input field is invalid. *4:* The suggestion range in the input field is invalid. *5:* The suggestion secondary range in the input field is invalid.
EWS_Match	Returns the results of the EWS (Early Warning System) match. *T*: True, the address is located in the EWS directory and is an EWS match. *F*: False, the address is not located in the EWS directory. **`<blank>`**: EWS is not enabled.
Extra1-10	Any non-address data found above or below the address data in the address block. Available only if the input data is presented through multiline fields.
Extraneous_Secondary_Address_Data	Consists of the data from Extraneous_Secondary_Unit_Number and Extraneous_Secondary_Non_Postal respectively. Any additional # data is placed in the remainder or extra components. This may include invalid secondary address data.
Extraneous_Secondary_Non_Postal	Extraneous data retained in this field is the best guess at Private Mail Box data, based on the position in the address line and other information contained in the address, such as a pound unit designator (#). This may include invalid secondary address data.

Field	Description
Extraneous_Secondary_Unit_Number	Extraneous data retained in this field is the best guess at secondary range data, based on the position in the address line and other information contained in the address. This may include invalid secondary address data.
Fault_Code	The fault code. This is blank if the address is assigned. For more information, see *Fault codes (USA Regulatory Address Cleanse)* [page 1417].
Fault_Or_Status_Code	The fault code if the address is unassigned; the status code if the address is assigned.
Finance_Area_Postcode	The Finance Area Postcode is the lowest Postcode1 within a Finance Number. (Finance Numbers are currently used to link data to a single post office or postmaster.)
Firm	Firm name. Do not use this field if the input was multiline, because if there is no firm name in the postal directory, the transform cannot reliably identify firm names from multilines. If you retrieve the corrected component, the firm name is taken from the postal directory if found; otherwise, it's taken from the input record. Be aware that the postal directory might contain some unusual or shortened spellings that you may or may not find suitable for printing on mail pieces. If you prefer to retain your own firm data, retrieve the original component.
Foreign_Code	Specifies whether the address is foreign or domestic. *F:* Foreign addresses **`<blank>`**: Domestic U.S.
Full_Address	The complete address line, including secondary address and dual address (street and postal) line data. i Note This field may contain invalid secondary address information when you set the *Include Unused Address Line Data* option in the Standardization Options group to *Yes*. i Note If the output values don't fit within the length of the output field, then intelligent truncation occurs.
Geo_Matchcode	Match code indicating the precision of the latitude and longitude assignment. *0:* Matches in address level.

Field	Description
	1: Nine-digit match. Usually indicates precision to a particular block face. *4:* Seven-digit match. Usually indicates precision within a few blocks. *5:* Five-digit match. Usually indicates precision to within a mile or two. *7:* No match in centroid-level. *8:* No match in address-level. *9:* No match in centroid-level or address-level. **<blank>**: No centroid-level or address-level directory lookup performed.
Intermediate_Codes	Intermediate codes provide information that the USPS requires when you perform NCOALink certification or audit testing.
LACSCode	LACS (Locatable Address Conversion System) indicator. *T:* The address needs 9-1-1 conversion (from box to street address) and should be submitted to a LACS vendor. *F:* The address does not need conversion. **<blank>**: The address was not assigned.
LACSLink_Indicator	Returns the conversion status of addresses processed by LACSLink. *Y:* The address was converted by LACSLink (the LACSLink_Return_Code value is A). *N:* The address was looked up with LACSLink but not converted. *F:* The address was a false-positive. *S:* A LACSLink conversion was made, but it was necessary to drop the secondary information. **<blank>**: No LACSLink lookup attempted.
LACSLink_Query	Returns the pre-conversion address, populated only when LACSLink is turned on and a LACSLink lookup was attempted. This address is in the standard Pub. 28 format. However, when an address has both a unit designator and secondary unit, the unit designator is replaced by the pound character (#). **<blank>**: No LACSLink lookup attempted.
LACSLink_Return_Code	Returns the match status for LACSLink processing. *A:* LACSLink record match. A converted address is provided in the address data fields. *00:* No match and no converted address. *09:* LACSLink matched an input address to an old address, which is a "high-rise default" address; no new address is provided.

Field	Description
	14: Found a LACSLink record, but couldn't convert the data to a deliverable address. *92:* LACSLink record matched after dropping the secondary number from input address. **`<blank>`**: No LACSLink lookup attempted.
Lastline	Locality, region, and postal code together on one line. Note If the output values don't fit within the length of the output field, then intelligent truncation occurs.
Locality1	*Canada and USA engines:* Locality preferred by the postal authority. *Other engines:* City, town, locality, or suburb. Note If the output values don't fit within the length of the output field, then intelligent truncation occurs.
Locality1_Alternate	Preserves the input Locality1 if it is not recognized by the postal authority as a valid Locality1 name for the input address line, and the original Locality1 was changed because of address assignment rules. Also outputs the default Locality 1 for the assigned finance area when there is no input Locality1, or the input Locality1 is not valid in the assigned finance area.
Locality1_LLIDX	Yields a city name (locality1 name) that is more geographically precise than Locality1_Official. LLIDX (last-line index) is a USPS number that ties a ZIP+4 record to a particular city, state, and ZIP. Note If the output values don't fit within the length of the output field, then intelligent truncation occurs.
Locality1_Name	The city, town, or suburb. Locality names that are marked as invalid for mailing by the USPS are always preserved, never converted, regardless of the values set for the *Preserve Place Name* and *Assign With Input Locality* options.

Field	Description
Locality1_Official	The standardized locality name. When the input city name is tagged by the USPS as invalid for mailing, this field always yields a converted city name, no matter how the *Preserve Place Name* option is set.
Locality1_Official_ABBR	The official USPS abbreviation of the city name, if one is available. This field is blank if the full city name is less than 13 characters or if the full name is longer, but the USPS has not provided an official abbreviation.
Locality2	*USA engine:* Urbanization (Puerto Rican addresses only). *Other engines:* Additional city, town, locality, or suburb information.
Locality2_Official	Urbanization name; produced only when the address is in Puerto Rico.
LOT	Line-of-travel number.
LOT_Order	Line-of-travel sortation. *A:* Ascending. *D:* Descending.
Matched_Addressline_Indicator	Match level indicator. *T:* The address line is matched to a ZIP+4 record. *F:* The address line is not matched to a ZIP+4 record.
Matched_Lastline_Indicator	Match level indicator. *T:* The last line is matched to a City/ZCF record. *F:* The last line is not matched to a City/ZCF record.
Move_Effective_Date	The date that the move is effective as indicated on the change of address card sent to the USPS in the format yyyymm. The yyyymm format is returned from the NCOALink directories and is required by the USPS for audit purposes. To use it in a function or post it to an output file, you'll probably have to convert the format to mm/dd/yyyy first. This field is also populated when an ANKLink match is made.
Move_Type	Type of move record. *B:* Business (matched by company name). *F:* Family (matched by last name). *I:* Individual (matched by first and last name). This field is also populated when an ANKLink match is made.
Multiline1-12	A line that may contain any data. The type of data in this line may vary from record to record.

Field	Description
	ℹ Note These fields may contain invalid secondary address information when you set the *Include Unused Address Line Data* option in the*Standardization Options* group to *Yes*. ℹ Note For address data, if the output values don't fit within the length of the output field, then intelligent truncation occurs.
Name	The name of a person associated with the address.
NCOALink_Hint_Byte	This field is used for audit testing.
NCOALink_Return_Code	This field shows NCOALink return codes. To populate this field, set the *List Processing Mode* to one of the three available options: *Change of Address*, *Statistics Only*, or *Return Codes Only*. A brief description of the return codes appears on the NCOALink Processing Summary report. To print more detailed return code descriptions on the report, enable the *Generate Return Code Descriptions* option in the NCOALink Report Options group. This field is also populated when an ANKLink match is made.
Stage_Test_Record	This field is for stage testing only. It applies to NCOALink, CASS, DSF2 Augment, DSF2 Sequence, and DSF2 Invoice self-certifications. The USA Regulatory Address Cleanse transform populates the values of this field automatically to match the format required for stage testing.
Non_CASS_Firm	The firm match that is made by using the input ZIP+4 for missing or invalid firm information.
Non_CASS_Secondary_Address	The secondary address match that is made using the input ZIP+4 for missing or invalid secondary address information. ℹ Note If the output values don't fit within the length of the output field, then intelligent truncation occurs.
Non_CASS_Unit	The unit designator match that is made using the input ZIP+4 for missing or invalid unit designator information.
Non_CASS_Unit_Number	The unit designator match that is made using the input ZIP+4 for missing or invalid unit designator information.

Field	Description
Non_Postal_Secondary_Address	The complete non-postal secondary address (for example, "PMB 10" or "# 10"). Non-postal means that the mail is delivered through a private mailbox company rather than the USPS.
Non_Postal_Unit	Non-postal unit designator (PMB or #). Non-postal means that the mail is delivered through a private mailbox company rather than the USPS.
Non_Postal_Unit_Number	Non-postal secondary range (PMB number only, does not include designator). Non-postal means that the mail is delivered through a private mailbox company rather than the USPS.
Parsed_Firm	If the change of address is made based on a firm (company) name, the firm name is posted in this field. This field is also populated when an ANKLink match is made.
Postal_Box_Number	Post office box number.
Postcode_Full	The complete ZIP10 with a hyphen.
Postcode_Full_No_Hyphen	The complete ZIP9 without a hyphen.
Postcode_Type	The type of ZIP Code that is assigned. *M:* Military. *U:* Unique (specific to a university, large firm, or other institution). **`<blank>`**: Ordinary ZIP Code or the ZIP Code was not assigned.
Postcode1	The five-digit ZIP Code. Does not include the four-digit ZIP4.
Postcode1_Change_Ind	Indicates whether the address is affected by postal code realignment. *T:* True, the transform corrected the postal code (and the locality, if applicable). *F:* False. **`<blank>`**: The address was not corrected.
Postcode2	Four-digit ZIP4 Code. On a mail piece, this code follows the primary postal code, with a hyphen placed between, for example, 54601-1234.
Pre_Suitelink_Delivery_Point	The numeric two-digit code for the delivery point bar code that was generated before SuiteLink processing.
Pre_Suitelink_Postcode1	The ZIP Code that was assigned by the transform before SuiteLink processing. *5-digit ZIP Code*: SuiteLink Retcode value is A. **`<blank>`**: No ZIP Code assigned.

Field	Description
Pre_Suitelink_Postcode2	The ZIP+4 that was assigned by the transform before SuiteLink processing. The ZIP+4 is either for a high-rise default or street default record.
Pre_Suitelink_Unit_Description	The unit designator that existed before SuiteLink processing. If this field is blank, the transform did not assign any secondary information.
Pre_Suitelink_Unit_Number	The secondary range information that existed before SuiteLink processing. If this field is blank, the transform did not assign any secondary information.
Primary_Address	Primary address line, such as the street address or post office box. Does not include secondary address information such as apartment. If the *Use USPS Primary Name Abbreviation* option is enabled, the software uses the USPS Primary Name abbreviation first. If the values don't fit within the length of the output fields, then intelligent truncation occurs.
Primary_Name1	Street name description. Note If the output values don't fit within the length of the output field, then intelligent truncation occurs.
Primary_Number	The premise number.
Primary_Postfix1	An abbreviated directional (such as N, S, NW, or SE) that follows a street name.
Primary_Postfix1_Long	A fully-spelled directional (such as North or South) that follows the street name.
Primary_Prefix1	An abbreviated directional (such as N, S, NW, or SE) that precedes a street name.
Primary_Prefix1_Long	A fully-spelled directional (such as North or South) that precedes the street name.
Primary_Secondary_Address	The primary address and secondary address on one line. Does not include remainder data. This line is always output as if the *Include Unused Address Line Data* option is set to *No*, which means that the output does not include invalid secondary address line information. Note If the output values don't fit within the length of the output field, then intelligent truncation occurs.
Primary_Type1	Abbreviated street type (for example, St, Ave, or Pl).
Primary_Type1_Long	Fully-spelled street type (for example, Street or Avenue).

Field	Description
QSS_Default	Specifies whether the record qualified as a default match instead of qualifying as a match at a higher level of assignment. Output values are: *T:* True *F:* False
RDI_Indicator	The residential delivery indicator (RDI) shows whether the address is residential or nonresidential. *Y:* Residential address *N:* Nonresidential address
Region1	State, province, territory, or region.
Rural_Route_Box_Number	The rural route box number.
Rural_Route_Number	The rural route number.
Secondary_Address	The building name, floor, and room number in one field.
Sortcode_Postcode	The federal code for state and county (FIPSCODE). Combines the two-digit state code with the three-digit county code. U.S. territories, possessions, or protectorates such as Puerto Rico, the U.S. Virgin Islands, or the Pacific Islands do not have FIPS state digits.
Sortcode_Route	The four-digit carrier route.
Status	Specifies the suggestion status generated as the result of looking up the current record and performing suggestion processing. *A:* Suggestion processing ended with an address suggestion list needing resolution. *L:* Suggestion processing ended with a lastline suggestion list needing resolution. *N:* No suggestion lists were generated and no suggestion processing was performed. *R:* The primary range is invalid for the selected address suggestion. *S:* The secondary range is invalid for the selected address suggestion. *U:* The secondary address is invalid for the selected address suggestion.
Status_Code	The status code. This field is blank if the address is unassigned. For more information, see *Status codes (USA Regulatory Address Cleanse)* [page 1418].
Suggestion_List	Contains all of the Suggestion List Component field values that you chose in the Suggestion List group of the USA Regulatory Address Cleanse transform.

Field	Description
SuiteLink_Retcode	*A:* SuiteLink match—Secondary information exists and was assigned to this record as a result of SuiteLink processing. *00:* No SuiteLink match—Lookup was attempted but no matching record was found. **<blank>**: A SuiteLink lookup was not attempted because one of the following is true: • The address is not a high-rise default according to CASS. • The address does not contain a firm.
Undeliverable_Indicator	Indicates whether the record is a deliverable address. *T:* The address is tagged by the USPS as unsuitable for mail delivery (for example, a cemetery). *F:* The address either was not matched to a ZIP+4 record or was matched to a record that indicates that the address is suitable for mail delivery.
Unit_Description	Unit description (for example, #, Apartment, or Flat).
Unit_Description_Directory	Unit designator from ZIP+4 directory, or blank if none was found.
Unit_Number	Unit number (for example, 100 in "APT 100").

3.5.4.14 User-Defined

The User-Defined transform provides you with custom processing in a data flow using full Python scripting language. The applications for the User-Defined transform are nearly limitless. It can do just about anything that you can write Python code to do. You can use the User-Defined transform to generate new records, populate a field with a specific value, create a file, connect to a website, or send an email, just to name a few possibilities.

You can place this transform anywhere in your data flow. If you have created your own transform, then the only restrictions about where it can be located in the data flow are those which you place on it.

Although the User-Defined transform is quite flexible and powerful, you will find that many of the tasks you want to perform can be accomplished with the Query transform. The Query transform is generally more scalable and faster, and uses less memory than User-Defined transforms.

Editors

Like all Data Quality transforms, the User-Defined transform has a transform editor which contains the Input, Options, and Output tabs.

Unlike most of the other Data Quality transforms, you cannot edit options in the User-Defined transform editor. To edit options, you must use the User-Defined editor, which is accessed from the Options tab in the User-Defined transform editor or from the Tools menu.

You may also notice some options displayed in the Options tab of the User-Defined transform editor that are not displayed in the User-Defined editor. These options are not editable.

⚠ Caution

Make sure that if you use an input field in a Python expression in your User-Defined transform, you first map it to a recognized field name in the Input tab. If it is not mapped, you will receive an error message similar to the following:

def GetField(*args): return apply(_flpythonmodulesu.FlDataRecord_GetField,args) RuntimeError: FlDataRecord::GetField() error: Invalid field name MAPPED_RECNO.

3.5.4.14.1 Content objects

Transform configurations

A transform configuration is a transform with preconfigured input fields, output fields, and options that can be used in multiple data flows. These are useful if you repeatedly use a transform with specific options and input and output fields.

When Data Services is installed, read-only transform configurations are provided for the Data Quality transforms.

You can use transform configurations in your data flows or as an example of a typical transform. After you place an instance of the transform configuration in a data flow, you can override these preset defaults. You can also create your own transform configuration, either by replicating an existing transform configuration or creating a new one.

Sample blueprints and other objects

We have created Data Quality blueprints and other content objects to help you set up Data Services jobs. We've identified a number of common scenarios that you are likely to perform with Data Services. For each scenario, we've included a blueprint that is already set up to solve the business problem in that scenario.

3.5.4.14.2 User-Defined options

The User-Defined transform contains options that determine how the transform processes data. Many User-Defined transform options are also found in the Match transform.

Option	Description
Mode	Specifies how the Python expression is applied to the transform. *Per collection:* Applies the expression to entire data collection. Use this option when adding new records, which did not exist before, into the data flow. Selecting this option displays the Group Forming option group, in which you set up break groups and candidate selection. *Per record:* Applies the expression to each record. You cannot add new records into the data flow with this option. This option is the default and what you will want to use most often.

Related Information

Group forming [page 1373]
User-Defined Transform options [page 1378]

3.5.4.14.2.1 Group forming

Group forming allows you to group and prioritize records for better match accuracy and efficiency, as well as performing custom Python processing.

Break groups

Break groups allow you to group records based on common field values.

Use break groups to lower the number of comparison the Match transform needs to make and to increase the speed of the matching process.

Candidate selection

The process of candidate selection appends records from a relational database to an existing data collection for processing.

For real-time jobs, candidate selection pulls a candidate set of records based on a single record or many records.

To display the Candidate Selection option group, right-click the Group Forming option group and select Add Candidate Selection.

> ℹ Note
>
> Candidate selection works with relational databases only; it does not work with flat files.

Candidate selection options [page 1272]

3.5.4.14.2.1.1 Break group options

Use the break group options to group records based on common field values.

Options	Description
Split records into break groups	Select this option if you want to form break groups to reduce the total number of comparisons made. The most common case for deselecting this option is when have a real-time job and your data comes in as one break group. This scenario also often makes use of candidate selection (selecting a limited number of records from a relational database) for optimal real-time matching. ⚠ Caution Deselect this option with caution within a batch data flow. The size of a break group may not exceed 2 GB. If you use this option in a batch data flow, also

Options	Description
	set the *Maximum allowable break group size (in records)* option so that the collection does not exceed the size limit. If it does exceed the limit, the data flow will abort. Note Break group size is calculated by multiplying the record length by the number of records in the break group.
Field	Choose a mapped input field name from the drop-down menu that you want to include in the break key. Click the Add Row button to add another field. If you require a more complex break key, you could define that field using an upstream Query transform and select the field here.
Start Position	Enter the start position of the field. Valid values for a field of n are 1 to n and -1 to -n. Negative start values signify that the start position is counted from the right. For example, a field with a length of 7 contains JOHNSON. A start position of 2 would mean start with "O." A start position of -4 means start with the "N" (This would also be the case if the field has a length of 20, because the negative start value starts from the actual length of the string, not of the field).
Length	Enter the number of characters in the field you want included in the break key.
Break key case sensitive	Specifies whether to treat the break key as case sensitive. *Yes:* Treat the break key as case sensitive. *No:* Do not treat the break key as case sensitive. For example, if you create a break key using the primary name (street), separate break groups would be formed with values of “Main” and “main” when you specify that the break key is case sensitive.
Replace NULL with empty string	Specifies whether to convert NULL values with an empty string in the break key. *Yes:* Convert NULL to an empty string. *No:* Do not convert to an empty string.
Right pad fields with blanks	Because the break key is used for sorting and aggregating, it is sensitive to the position in which data is placed. By right-padding the break key fields you can help ensure that break groups are formed properly. If the *Replace NULL with empty string* option is set to YES and this option is set to YES, then fields with NULL values will be replaced with all spaces (to the length of the field). *Yes:* Right-pad fields with blank spaces. *No:* Do not right-pad fields.

Options	Description
Input already sorted	Specifies that the input data has already been sorted, and you do not want it sorted again. For example, if you require a more complex break key, you could use a Query transform to create it, and use the ORDER BY operation to order your data. *Yes:* The transform will not re-sort the input data. *No:* The transform will sort the break keys at runtime before forming break groups.
Maximum allowable break group size (in records)	Specifies the maximum number of records allowed in a break group. An empty value or zero means that there is no limit on the break group size. With this option, you can control the amount of memory used during processing by specifying the number of records processed at one time. If more records make it into a single break group than specified, then the data flow throws an error and stops.

Related Information

Designer Guide: Match, Break keys and candidate selection [page 533]

3.5.4.14.2.1.2 Candidate selection options

The candidate selection option group includes the following options:

Option	Description
Datastore	Select a valid datastore. This list is populated with all valid SQL and persistent cache datastores. If you choose a persistent cache datastore, you will not be able to enter custom SQL.
Cache type	This option can be used to improve performance, with a trade-off of more memory consumption. *No_Cache:* Specifies that each query will be sent to the database. *Pre_Load_Cache:* Specifies that the entire secondary table is cached to a local disk or memory.
Auto-generate SQL	Select to have your SQL generated by the transform. This option allows you to query a simple single table. If you need to join tables or create a complex WHERE clause, you should select the *Create custom SQL* option.

Option	Description
Table	Enter a valid table name from the datastore.
Use break column from database	Select this option if your database already contains a column that corresponds to the break key field.
Break key field	Select the column from the secondary table that contains the break key field.
Create custom SQL	Select to create custom SQL.
Launch SQL Editor	Opens the SQL editor. This button is only enabled if you select the *Create custom SQL* option.
Use constant source value	Select to assign records to a physical source for generating appropriate statistics.
Physical source value	Type a value for your physical source. This value will be placed in the physical source field you select.
Physical source field	Select the mapped field that contains the physical source name.
Add DB columns to mapping table	If you are using the *Create custom SQL* option, clicking this button will add only the database columns that appear in the SELECT statement and in the order that they appear in the SELECT statement. If you are using the *Auto-generate SQL* option, clicking this button will add ALL database columns, in the order that they appear in the table schema. Note If you do not associate an input field to any of these columns in the column mapping table, they will be removed when you close the window.

Column mapping table

This table allows you to specify which mapped field in the data flow each database selected field is assigned to.

Column	Description
Break key	Specifies whether this field is used as part of your break key.
Field	Each cell contains a list of the mapped names from the input fields in the transform.
DB column	Each cell contains a list of the column names in your database table or the selected columns from a custom query. Match the data of a column in your database to the data of a mapped field.

Related Information

Designer Guide: Match, Break keys and candidate selection [page 533]

3.5.4.14.2.2 User-Defined Transform options

Custom options table

This table allows you to create custom options to be used as variables in your Python expression. The custom options are only available within the User-Defined transform. These options adjust the User-Defined transform's run-time behavior. Add or remove rows by using the buttons.

Option	Description
Custom option	Specifies variables for use in your Python expression.
Value	Specifies the value of the custom option.

The User-Defined Transform option group also contains the following option:

Option	Description
Run as separate process	This option creates a separate sub data flow process for the transform when Data Services executes the data flow. *Yes:* Splits transform into separate process. *No:* Keeps transform in same process as the rest of the data flow.

3.5.4.14.2.2.1 Python Expression Editor option

This option group contains the actual Python expression that the User-Defined transform will use. This option group is required.

Click the Launch Python Editor button to access the Python Expression editor.

Option	Description
Python	Displays the Python expression that will be applied to the transform. You can enter the Python code here or use the Python Expression editor.

⚠ Caution

Make sure to use a "u" to indicate Unicode every time you use a Unicode string to look up field names; for example, in a GetField, SetField, or SendToPipe method. If you do not, an error or crash may occur.

Related Information

Python [page 1813]
Create an expression with the Python Expression editor [page 1817]

3.5.4.15 Address Cleanse reference

This section describes reference information for use with the Address Cleanse transforms (Global Address Cleanse and USA Regulatory Address Cleanse). For the USA Regulatory Address Cleanse transform, it lists the available certifications and the steps to achieve those certifications.

This section also explains how to use the Show A and Show L utilities (for United States addresses only) that you can use to query the postal directories used by either of the Address Cleanse transforms.

For the Global Address Cleanse transform:

- Information codes
- Status codes
- Quality codes

For the USA Regulatory Address Cleanse transform:

- Status codes
- Fault codes

3.5.4.15.1 Beyond the basic address cleansing

The USA Regulatory Address Cleanse transform offers many additional address cleanse features for U.S. addresses. These features extend address cleansing beyond the basic parsing and standardizing. To read about the USA Regulatory Address Cleanse transform and its options, see the *Reference Guide*.

3.5.4.15.1.1 USPS certifications

The USA Regulatory Address Cleanse transform is CASS-certified. Therefore, when you process jobs with the USA Regulatory Address Cleanse transform (and it is set up correctly) you reap the benefits of that certification.

If you integrate Data Services into your own software and you want to obtain CASS certification, you must follow the steps for CASS self-certification using your own software.

You can also obtain licenses for DSF2 (Augment, Invoice, Sequence) and for NCOALink by using USA Regulatory Address Cleanse and DSF2 Walk Sequencer blueprints that are specifically set up for that purpose.

Note

In this section we direct you to the USPS website and include names of documents and procedures. The USPS may change the address, procedure, or names of documents (and information required) without our prior knowledge. Therefore some of the information may become outdated.

Related Information

CASS self-certification [page 1383]
DSF2 Certification [page 1392]
Designer Guide: Getting started with NCOALink [page 656]

3.5.4.15.1.1.1 Completing USPS certifications

The instructions below apply to USPS CASS self-certification, DSF2 license, and NCOALink license certification.

During certification you must process files from the USPS to prove that your software is compliant with the requirements of your license agreement.

The CASS, DSF2, and NCOALink certifications have two stages. Stage I is an optional test which includes answers that allow you to troubleshoot and prepare for the Stage II test. The Stage II test does not contain answers and is sent to the USPS for evaluation of the accuracy of your software configuration.

1. Complete the applicable USPS application (CASS, DSF2, NCOALink) and other required forms and return the information to the USPS.
   After you satisfy the initial application and other requirements, the USPS gives you an authorization code to purchase the CASS, DSF2, or NCOALink option.
2. Purchase the option from the USPS. Then submit the following information to SAP:
   - your USPS authorization code (see step 1)
   - your NCOALink provider level (full service provider, limited service provider, or end user) (applicable for NCOALink only)
   - your decision whether or not you want to purchase the ANKLink option (for NCOALink limited service provider or end user only)

   After you request and install the feature from SAP, you are ready to request the applicable certification test from the USPS. The software provides blueprints to help you set up and run the certification tests. Import them from **`<DS_COMMON_DIR>`**`\DataQuality\Certifications`, where **`<DS_COMMON_DIR>`** is the software's common configuration directory.
3. Submit the Software Product Information form to the USPS and request a certification test.
   The USPS sends you test files to use with the blueprint.
4. After you successfully complete the certification tests, the USPS sends you the applicable license agreement. At this point, you also purchase the applicable product from SAP.

Related Information

Designer Guide: About ANKLink [page 655]
To set up the NCOALink blueprints [page 1390]
To set up the DSF2 certification blueprints [page 1394]

3.5.4.15.1.1.2 Introduction to static directories

Users who are self-certifying for CASS must use static directories. Those obtaining DSF2 licenses also need to use static directories. Static directories do not change every month with the regular directory updates. Instead, they can be used for certification for the duration of the CASS cycle. Using static directories ensures consistent results between Stage I and Stage II tests, and allows you to use the same directory information if you are required to re-test. You obtain static directories from SAP.

> Note
>
> If you do not use static directories when required, the software issues a warning.

3.5.4.15.1.1.2.1 Static directories

The following directories are available in static format:

- `zip4us.dir`
- `zip4us.shs`
- `zip4us.rev`
- `revzip4.dir`
- `city10.dir`
- `zcf10.dir`
- `dpv*.dir`
- `elot.dir`
- `ew*.dir`
- SuiteLink directories
- LACSLink directories

3.5.4.15.1.1.2.2 Obtaining static directories

To request static directories, contact SAP Business User Support. Contact information (toll-free number and email address) is available at *http://service.sap.com*.

1. Click *SAP Support Portal*.

2. Click the *Help and Support* tab.
3. Click *Contact SAP*.
4. Complete the form and then click *Submit*.

3.5.4.15.1.1.2.3 Static directories location

It is important that you store your static directories separately from the production directories. If you store them in the same folder, the static directories will overwrite your production directories.

We suggest that you create a folder named “static” to store your static directories. For example, save your static directories under **<DS_COMMON_DIR>**`\DataQuality\reference\static`, where **<DS_COMMON_DIR>** is the software's common configuration directory.

3.5.4.15.1.1.2.4 Static directories safeguards

To prevent running a production job using static directories, the software issues a verification warning or error under the following circumstances:

- When the job has both static and non-static directories indicated.
- When the release version of the `zip4us.dir` does not match the current CASS cycle in the software.
- When the data versions in the static directories aren't all the same. For example, for CASS Cycle M the data versions in the static directories are M01.
- When the job is set for self-certification but is not set up to use the static directories.
- When the job is not set for self-certification but is set up to use the static directories.

3.5.4.15.1.1.3 To import certification blueprints

The software includes blueprints to help you with certification testing. Additionally, the blueprints can be used to process a test file provided by the USPS during an audit. You need to first import the blueprints to the repository before you can use them in Data Services.

To import the certification blueprints, follow these steps:

1. Open Data Services Designer.
2. Right-click in the Object Library area and select *Repository* > *Import from file*.
3. Go to **<DS_COMMON_DIR>**`\DataQuality\certifications`, where **<DS_COMMON_DIR>** is the software's common configuration directory.
4. Select the applicable blueprint and click *Open*.

> i Note
>
> A message appears asking for a pass phrase. The blueprints are not pass phrase protected, just click *Import* to advance to the next screen.

5. Click *OK* at the message warning that you are about to import the blueprints.

   Importing the blueprint files into the repository adds new projects, jobs, data flows, and flat file formats. The naming convention of the objects includes the certification type to indicate the associated certification test.

Related Information

CASS self-certification blueprint [page 1384]
NCOALink blueprints [page 1389]
DSF2 Certification blueprints [page 1393]

3.5.4.15.1.1.4 CASS self-certification

If you integrate Data Services into your own software, and you want to CASS-certify your software, you must obtain CASS certification on your own (self certification). You need to show the USPS that your software meets the CASS standards for accuracy of postal coding and address correction. You further need to show that your software can produce a facsimile of the USPS Form 3553 . You need a USPS Form 3553 to qualify mailings for postage discounts.

Obtaining CASS certification on your own software is completely optional. However there are many benefits when your software is CASS certified.

Visit the USPS RIBBS website at *http://ribbs.usps.gov/index.cfm?page=cassmass* for more information about CASS certification.

Related Information

Completing USPS certifications [page 1380]

3.5.4.15.1.1.4.1 CASS self-certification process overview

1. Familiarize yourself with the CASS certification documentation and procedures located at *http://ribbs.usps.gov/index.cfm?page=cassmass* .
2. (Optional.) Download the CASS Stage I test from the RIBBS website.
   This is an optional step. You do not submit the Stage I test results to the USPS. Taking the Stage I test helps you analyze and correct any inconsistencies with the USPS-expected results before taking the Stage II test.
3. Import and make modifications to the CASS self-certification blueprint (`us_cass_self_certification.atl`). The blueprint is located in **`<DS_COMMON_DIR>`**`\DataQuality\Certifications`, where **`<DS_COMMON_DIR>`** is the software's common configuration location.
   Edit the blueprint so it contains your static directories location, Stage I file location, your company name, and other settings that are required for CASS processing.

4. When you are satisfied that your Stage I test results compare favorably with the USPS-expected results, request the Stage II test from the USPS using the Stage II order form located on the RIBBS website.
   The USPS will place the Stage II test in your user area on the RIBBS website for you to download.
5. Download and unzip the Stage II test file to an output area.
6. After you run the Stage II file with the CASS self-certification blueprint, check that the totals on the USPS Form 3553 and the actual totals from the processed file match.
7. Compress the processed Stage II answer file (using WinZip for example) and name it using the same name as the downloaded Stage II file (step 5).
8. Upload the processed Stage II answer file to your user area on the RIBBS website.

The USPS takes about two weeks to grade your test.

3.5.4.15.1.1.4.2 CASS self-certification blueprint

SAP provides a CASS self-certification blueprint. The blueprint contains the corresponding project, job, data flow, and input/output formats. Additionally, the blueprint can be used to process a test file provided by the USPS during an audit.

Import the `us_cass_self_certification.atl` blueprint from **`<DS_COMMON_DIR>`**`\DataQuality\Certifications` where **`<DS_COMMON_DIR>`** is the software's common configuration location. The table below contains the file names for the CASS self-certification blueprint:

Object	Name
ATL file	us_cass_self_certification.atl
Project	DataQualityCertificationCASS
Job	Job_DqBatchUSAReg_CASSSelfCert
data flow	DF_DqBatchUSAReg_CASSSelfCert
Input file format	DqUsaCASSSelfCert_In
Output file format	DqUsaCASSSelfCert _Out

3.5.4.15.1.1.4.3 USPS Form 3553 required options for self certification

The following options in the CASS Report Options group are required for CASS self certification. This information is included in the USPS Form 3553.

Option	Description
Company Name Certified	Specify the name of the company that owns the CASS-certified software.
List Name	Specify the name of the mailing list.

Option	Description
List Owner	Specify the name of the list owner. ℹ Note Keep the CASS self-certification blueprints setting of "USPS".
Mailer Address(1-4)	Specify the name and address of the person or organization for whom you are preparing the mailing (up to 29 characters per line).
Software Version	Specify the software name and version number that you are using to receive CASS self certification.

3.5.4.15.1.1.4.4 Points to remember about CASS

Remember these important points about CASS certification:

- As an end user (you use Data Services to process your lists), you are not required to obtain CASS self certification because Data Services is already CASS certified.
- CASS certification is given to software programs. You obtain CASS self certification if you have incorporated Data Services into your software program.
- The CASS reports pertain to address lists.
- CASS certification proves that the software can assign and standardize addresses correctly.

3.5.4.15.1.1.5 NCOALink certification

NCOALink is a feature that must be purchased before testing.

The NCOALink certification consists of the following steps:

1. Application and Self-Certification Statement Approval
2. Software acquisition
3. Testing and certification
4. Execution of License Agreement

This entire procedure is documented in the USPS Certification Procedures documents posted on the RIBBS website at *http://ribbs.usps.gov/ncoalink/documents/tech_guides* . Select either NCOALink End User Documents, NCOALink Limited Service Provider Documents, or NCOALink Full Service Provider Documents as applicable.

You must complete the appropriate service provider certification procedure for NCOALink in order to purchase the NCOALink product from the USPS.

Related Information

Designer Guide: Getting started with NCOALink [page 656]

3.5.4.15.1.1.5.1 About NCOALink directories

After you have completed the certification requirements and purchased the NCOALink product from the USPS, the USPS sends you the latest NCOALink directories monthly (if you're an end user) or weekly (if you're a limited or full service provider). The NCOALink directories are not provided by SAP.

The USPS requires that you use the most recent NCOALink directories available for your NCOALink jobs.

> i Note
>
> The NCOALink directories expire within 45 days.

The software provides a DVD Verification (Installer) utility that installs (transfers and unpacks) the compressed files from the NCOALink DVD onto your system. The utility is available with a GUI (graphical user interface) or you can run it from a command line.

If you are a service provider, then each day you run an NCOALink job, you must also download the daily delete file and install it in the same folder where your NCOALink directories are located.

Related Information

Designer Guide: About the NCOALink daily delete file [page 659]
To install NCOALink directories with the GUI [page 1386]

3.5.4.15.1.1.5.1.1 To install NCOALink directories with the GUI

Prerequisites

Ensure your system meets the following minimum requirements:

- At least 60 GB of available disk space
- DVD drive
- Sufficient RAM.

1. Insert the USPS DVD containing the NCOALink directories into your DVD drive.
2. Run the DVD Installer, located at `$LINK_DIR\bin\ncoadvdver.exe` (Windows) or `$LINK_DIR/bin/ncoadvdver` (UNIX), where `$LINK_DIR` is the path to your software installation directory.

   For further installation details, see the online help available within the DVD Installer (choose *Help* > *Contents*).

For more information about required disk space for reference data, see the Product Availability Matrix at *https://service.sap.com/PAM*.

Related Information

SAP Business Objects information resources, Supported platforms (Product Availability Matrix) [page 169]

3.5.4.15.1.1.5.1.2 To install NCOALink directories from the command line

Prerequisites:

Ensure your system meets the following minimum requirements:

- At least 60 GB of available disk space
- DVD drive
- Sufficient RAM

1. Run the DVD Installer, located at `$LINK_DIR\bin\ncoadvdver.exe` (Windows) or `$LINK_DIR/bin/ncoadvdver` (UNIX), where `$LINK_DIR` is the path to your installation directory.
2. To automate the installation process, use the `ncoadvdver` command with the following command line options:

Option		Description
Windows	UNIX	
	-c	Run selected processes in console mode (do not use the GUI).
/p:t	-p:t	Perform transfer. When using this option you must also specify the following: ○ DVD location with /d or -d ○ transfer location with /t or -t
/p:u	-p:u	Perform unpack. When using this option, you must also specify the following: ○ DVD location with /d or -d ○ transfer location with /t or -t
/p:v	-p:v	Perform verification. When using this option, you must also specify the transfer location with /t or -t.
/d	-d	Specify DVD location.
/t	-t	Specify transfer location.
/nos	-nos	Do not stop on error (return failure code as exit status).

Option		Description
Windows	UNIX	
/a	-a	Answer all warning messages with Yes.

You can combine p options. For example, if you want to transfer, unpack, and verify all in the same process, enter /p:tuv or -p:tuv.

After performing the p option specified, the program closes.

Example

Your command line may look something like this:

Windows

```
ncoadvdver /p:tuv /d D:\ /t C:\pw\dirs\ncoa
```

UNIX

```
ncoadvdver [-c] [-a] [-nos] [-p:(t|u|v)] [-d<path>] [-t <filename>]
```

3.5.4.15.1.1.5.2 NCOALink software product information

Use the information below to complete the Compliance Testing Product Information Form. Find this form on the RIBBS website at http://ribbs.usps.gov/ncoalink/documents/tech_guides . Click the Compliance Testing Form.doc link.

Compliance Testing Product Information form	Description
Company Name & License Number	Your specific information. The license number is the authorization code provided in your USPS approval letter.
Company's NCOALink Product Name	Mover ID for NCOALink
Platform or Operating System	Your specific information
NCOALink Software Vendor	SAP Americas, Inc.
NCOALink Software Product Name	Mover ID
NCOALink Software Product Version	ACE
Address Matching ZIP+4 Product Name	Contact SAP Business User Support.
Address Matching ZIP+4 Product Version	Contact SAP Business User Support.
Address Matching ZIP+4 System	Closed
Is Software Hardware Dependent?	No
DPV® Product Name	ACE
DPV Product Version	Contact SAP Business User Support.

Compliance Testing Product Information form	Description
LACSLink® Product Name	ACE
LACSLink Product Version	Contact SAP Business User Support.
NCOALink Software options: Integrated or Standalone check boxes	Integrated
ANKLink Enhancement check box (applicable for Limited Service Providers and End Users)	Check the box if you purchased the ANKLink option from SAP.
HASH—FLAT—BOTH check boxes	Indicate your preference. The software provides access to both file formats.
NCOALink Level Option check boxes	Check the appropriate box.

3.5.4.15.1.1.5.3 Completing NCOALink certification

During certification you must process files from the USPS to prove that you adhere to the requirements of your license agreement. NCOALink certification has two stages. Stage I is an optional test which includes answers that allow you to troubleshoot and prepare for the Stage II test. The Stage II test does not contain answers and is sent to the USPS for evaluation of the accuracy of your software configuration.

Related Information

To run the NCOALink certification jobs [page 1391]

3.5.4.15.1.1.5.4 NCOALink blueprints

SAP provides NCOALink blueprints. The blueprints contain the corresponding projects, jobs, data flows, and input/output formats. Additionally, the blueprints can be used to process a test file provided by the USPS during an audit.

Import NCOALink blueprints from **`<DS_COMMON_DIR>`**`\DataQuality\Certifications` where **`<DS_COMMON_DIR>`** is the software's common configuration location.

The table below contains the file names for the Stage I NCOALink blueprints:

Object	Name
ATL file	us_ncoalink_stage_certification.atl
Project	DataQualityCertificationNCOALink
Job	Job_DqBatchUSAReg_NCOALinkStageI
data flow	DF_DqBatchUSAReg_NCOALinkStageI
Input file format	DqUsaNCOALinkStageI _in
Output file format	DqUsaNCOALinkStageI _out

The table below contains the file names for the Stage II NCOALink blueprints:

Object	Name
ATL file	us_ncoalink_stage_certification.atl
Project	DataQualityCertificationNCOALink
Job	Job_DqBatchUSAReg_NCOALinkStageII
data flow	DF_DqBatchUSAReg_NCOALinkStageII
Input file format	DqUsaNCOALinkStageII _in
Output file format	DqUsaNCOALinkStageII _out

3.5.4.15.1.1.5.5 To set up the NCOALink blueprints

Before performing the steps below you must import the NCOALink blueprints.

To set up the NCOALink Stage I and Stage II blueprints, follow the steps below.

1. In the Designer, select ▶ *Tools* ▶ *Substitution Parameter Configurations* ◀.
   The *Substitution Parameter Editor* opens.
2. Choose the applicable configuration from the *Default Configuration* drop list and enter values for your company's information and reference file locations. Click *OK* to close the Substitution Parameter Configurations tool.
3. Open the DataQualityCertificationsNCOALink project (which was imported with the blueprints).
4. Open the Job_DqBatchUSAReg_NCOALinkStageI job and then open the DF_DqBatchUSAReg_NCOALinkStageI data flow.
5. Click the DqUsaNCOALinkStageI_in file to open the *Source File Editor*. Find the *Data Files(s)* property group in the lower portion of the editor and make the following changes:
   a) In the *Root Directory* option, type the path or browse to the directory containing the input file.
      If you type the path, do not type a backslash (\) or forward slash (/) at the end of the file path.
   b) In the *File name(s)* option, change StageI.in to the name of the Stage file provided by the USPS.
   c) Exit the *Source File Editor*.
6. Click the DqUsaNCOALinkStageI_out file to open the *Target File Editor*. In the *Data Files(s)* property group make the following changes:

   a) In the *Root Directory* option, type the path or browse to the directory containing the output file.

      If you type the path, do not type a backslash (\) or forward slash (/) at the end of the file path.
   b) (Optional.) In the *File name(s)* option, change `StageI.out` to conform to your company's file naming convention.
   c) Exit the *Target File Editor*.
7. Double-click the USARegulatoryNCOALink_AddressCleanse transform to open the Transform Editor and click the *Options* tab.
8. Enter the correct path location to the reference files in the Reference Files group as necessary. Use the $ $RefFilesAddressCleanse substitution variable to save time.
9. In the USPS License Information group, do the following:
   a) Enter a meaningful number in the *List ID* option.
   b) Enter the current date in the *List Received Date* and *List Return Date* options.
   c) Ensure that the provider level specified in the substitution parameter configuration by the $ $USPSProviderLevel is accurate or specify the appropriate level (Full Service Provider, Limited Service Provider, or End User) in the *Provider Level* option.
   d) If you are a full service provider or limited service provider, complete the options in the *NCOALink* > *PAF Details* group and the *NCOALink* > *Service Provider Options* group.
10. When you are satisfied with the results of the Stage I test, repeat steps 4 through 9 to set up the Stage II objects found in the DF_DqBatchUSAReg_NCOALinkStage II data flow.

Related Information

DSF2 Certification blueprints [page 1393]

NCOALink blueprints [page 1389]

CASS self-certification blueprint [page 1384]

3.5.4.15.1.1.5.6 To run the NCOALink certification jobs

Before you run the NCOALink certification jobs, make sure that you have installed the DPV, LACSLink, and U.S. National directory files to the locations you specified during configuration and that the NCOALink DVD provided by the USPS is available.

Running the Stage I job is optional; the results do not need to be sent to the USPS. However, running the Stage I job can help you ensure that you have configured the software correctly and are prepared to execute the Stage II job.

1. Use the NCOALink DVD Verification utility to install the NCOALink directories provided by the USPS. (See the link below for information about the NCOALink DVD Verification utility.)
2. Download the current version of the USPS daily delete file from *https://epf.usps.gov/* .
3. Download the Stage I file from *http://ribbs.usps.gov/* and uncompress it to the location you specified when setting up the certification job.

Ensure the input file name in the source transform matches the name of the Stage I file from the USPS.

4. Execute the Stage I job and compare the test data with the expected results provided by the USPS in the Stage I input file.

   As necessary, make modifications to your configuration until you are satisfied with the results of your Stage I test.
5. Download the Stage II file from the location specified by the USPS and uncompress it to the location you specified when setting up the certification job.

   Ensure the input file name in the transform matches the name of the Stage II file from the USPS.
6. Execute the Stage II job. Follow the specific instructions in the *NCOALink Certification/Audit Instructions* document that the USPS should have provided to you.
7. Compress the following results (using WinZip for example) and name it using the same name as the downloaded Stage II file (step 5):
   - Stage II output file
   - NCOALink Processing Summary Report
   - CASS Form 3553
   - All log files generated in the `$$CertificationLog` path
     - Customer Service Log
     - PAF (Service Providers only)
     - Broker/Agent/List Administrator log (Service Providers only)
8. Send the results to the USPS for verification.

3.5.4.15.1.1.6 DSF2 Certification

DSF2 is a feature that must be purchased before testing.

The DSF2 certification consists of the following steps:

1. Application and Self-Certification Statement Approval
2. Documentation Requirements
3. Stage I Interface Development
4. DSF2 Testing and Certification
5. Execution of License

The entire process is detailed in the USPS *DSF2 Certification Package* document posted on the RIBBS website.

Select the DSF2 Certification Package link on *https://ribbs.usps.gov/dsf2/documents/tech_guides/* .

The *DSF2 Certification Package* contains processes and procedures and the necessary forms for you to complete the five steps listed above.

3.5.4.15.1.1.6.1 DSF2 Equipment Information for USPS certifications

In the DSF2 Certification Package document, there is an Equipment Information form. You are required to provide information about the software you are using to certify for DSF2. Use the information in the following table as you complete the form for the DSF2 certification process.

Equipment Information form	Description
Interface Software Vendor	SAP Americas, Inc.
Interface Software Product Name	ACE
Interface Software Product Version	Contact SAP Business User Support.
Address Matching ZIP+4 Product Name	ACE
Address Matching ZIP+4 Product Version	Contact SAP Business User Support.
Address Matching ZIP+4 System	Closed System
Interface Hardware Vendor/Model/Type	N/A The software is not hardware dependent
Interface Hardware Operating System	N/A The software is not hardware dependent
Interface Hardware Serial Number	N/A The software is not hardware dependent

Find the DSF2 Certification Package document on the RIBBS website at *https://ribbs.usps.gov/dsf2/documents/tech_guides/* .

3.5.4.15.1.1.6.2 DSF2 Certification blueprints

SAP BusinessObjects provides DSF2 certification blueprints for the three types of DSF2 certifications. The blueprints contain the corresponding projects, jobs, data flows, and input/output formats. Additionally, the blueprints can be used to process a test file provided by the USPS during an audit.

Import the DSF2 certification blueprints from **<DS_COMMON_DIR>**`\DataQuality\Certifications`, where **<DS_COMMON_DIR>** is the software's common configuration location.

The table below contains the file names for the USPS DSF2 Augment certification:

Object	Name
ATL file	us_dsf2_certification.atl
Project	DataQualityCertificationDSF2
Job	Job_DqBatchUSAReg_DSF2Augment
data flow	DF_DqBatchUSAReg_DSF2Augment
Input file format	DqUsaDSF2Augment_in
Output file format	DqUsaDSF2Augment_out

The table below contains the file names for the USPS DSF2 Invoice certification:

Project	Name
ATL file	us_dsf2_certification.atl
Project	DataQualityCertificationDSF2
Job	Job_DqBatchUSAReg_DSF2Invoice
data flow	DF_DqBatchUSAReg_DSF2Invoice
Input file format	DqUsaDSF2Invoice_in
Output file format	DqUsaDSF2Invoice_out

The table below contains the file names for the USPS DSF2 Sequence certification:

Project	Name
ATL file	us_dsf2_certification.atl
Project	DataQualityCertificationDSF2
Job	Job_DqBatchUSAReg_DSF2Sequence
data flow	DF_DqBatchUSAReg_DSF2Sequence
Input file format	DqUsaDSF2Sequence_in
Output file format	DqUsaDSF2Sequence_out

3.5.4.15.1.1.6.3 To set up the DSF2 certification blueprints

Before performing the steps below you must import the DSF2 blueprints.

Follow these steps to set up the DSF2 Augment, Invoice, and Sequence certification blueprints.

1. In the Designer, select *Tools* > *Substitution Parameter Configurations* .
   The *Substitution Parameter Editor* opens.
2. Choose the applicable configuration from the *Default Configuration* drop list and enter values for your company's information and reference file locations.

   > **Note**
   >
   > DSF2 Augment only. Remember to enter the static directories location for the $$RefFilesUSPSStatic substitution variable.

3. Open the DataQualityCertificationDSF2 project (downloaded with the blueprint).
4. Expand the desired certification job and data flow. For example, if you are setting up for DSF2 Augment, expand the Job_DqBatchUSAReg_DSF2Augment job and then the DF_DqBatchUSAReg_DSF2Augment data flow.
5. Double-click the applicable input file format (*.in) to open the *Source File Editor*. For example, for DSF2 Augment certification, double-click `DSF2_Augment.in`.
6. In the *Data Files(s)* property group make the following changes:
   a) In the *Root Directory* option, type the path or browse to the directory containing the input file.

If you type the path, do not type a backslash or forward slash at the end of the file path.

b) In the *File name(s)* option, change the input file name to the name of the file provided by the USPS.

7. Double-click the applicable output file format (*.out) to open the Target File Editor. For example, for DSF2 Augment certification, double-click `DSF2_Augment.out`.
8. In the Data Files(s) property group make the following changes:

   a) In the *Root Directory* option, type the path or browse to the directory containing the output file.

   If you type the path, do not type a backslash or forward slash at the end of the file path.

   b) (Optional) In the *File name(s)* option, change the output file name to conform to your company's file naming convention.
9. Click the USARegulatory_AddressCleanse transform to open the Transform Editor and click the *Options* tab.

> i Note
>
> For DSF2 Sequence and Invoice certifications, you will open the DSF2_Walk_Sequencer transform.

10. As necessary, in the Reference Files group, enter the correct path location to the reference files.

    For DSF2 Augment certification, use the $$RefFilesUSPSStatic substitution variable to save time.
11. In the CASS Report Options, update each option that is listed as “CHANGE_THIS” if applicable.

3.5.4.15.2 Country ISO codes and assignment engines

The table shows which engine (if any) provides address correction. Additionally, it lists the 2-character and 3-character ISO code, the 3-digit ISO code, European Postcode prefix, and the level of assignment. The assignment level is based on the reference data that you own.

Table 166: Table Key

Engine	Assignment Level

Canada = C
Global Address = G
USA = U
	Country = C
	Locality = L
	Primary Name = Pn
	Premise = Pr
	Secondary = S

3.5.4.15.3 Information codes (Global Address Cleanse)

Information codes are four characters that explain why an address is unassigned. Information codes have six levels of classification:

- The 1000 level represents input record discrepancies.
- The 2000 level represents inconsistent last line information.
- The 3000 level represents inconsistent address information.
- The 4000 level represents inconsistent secondary address information.
- The 5000 level represents all other types of information.
- The 6000 level represents an unclassified error.

The table also shows that each information code is available based on the engine(s) that you enable.

- Canada (C)
- Global Address (G)
- USA (U)
- All engines: Consists of C, G, and U.
- Transform Level (T): Information code does not come from a specific engine.

Use the following table to determine the code assigned to the Info_Code output field.

Information code	Description	Engine(s)
1020	Address validated in multiple countries.	T
1030	No country found by Country ID or no country set for the record.	T
1040	Address contains at least one character that is not part of the character set supported by the engine.	T
1060	The country identified is not supported by any of the active engines.	T
1080	The script identified is not supported by any of the active engines.	T
2000	Unable to identify locality, region, and/or postcode information on input.	All engines
2010	Unable to identify locality and invalid postcode found.	All engines
2020	Unable to identify postcode. Invalid locality is preventing a possible address correction.	All engines
2030	Invalid locality and postcode are preventing a possible address correction.	All engines
2040	Invalid postcode is preventing a locality selection.	G, U
2050	Lastline matches are too close to choose one.	G
3000	Locality, region, and postcode are valid. Unable to identify the primary address line.	All engines
3010	Locality, region, and postcode are valid. Unable to match primary name to directory.	All engines
3020	Possible primary name matches are too close to choose one.	All engines
3030	Primary range is missing on input or not in the directory.	All engines
3050	An invalid or missing primary type is preventing a possible address match.	All engines
3060	A missing primary type and prefix/postfix (directional) is preventing a possible address match.	G, U

Information code	Description	Engine(s)
3070	An invalid or missing prefix/postfix (directional) is preventing a possible address match.	All engines
3080	An invalid or missing postcode is preventing a possible address match.	All engines
3090	An invalid or missing locality is preventing a possible address match.	G, U
3100	Possible address-line matches are too close to choose one.	All engines
3110	Address conflicts with postcode and the same primary name has a different postcode.	C
3200	The building name is missing on input or not in the directory.	G
3210	The building's address is not in the directory.	G
3220	Possible building names are too close to choose one.	G
3250	The building name is missing on input or not in the directory, or the range is missing on input or invalid with the input building.	G
3300	The postcode only lookup returned multiple primary names.	G
4000	The secondary information is missing on input or not in the directory.	All engines
4010	Possible secondary address line matches are too close to choose one.	All engines
4500	The organization is missing on input or not in the directory.	G
4510	The organization's address is not in the directory.	G
4520	Possible organization names are too close to choose one.	G
5000	The address was valid, but the postal authority classified this address as undeliverable.	G, U
5010	The address does not reside in the specified country.	C, U

Information code	Description	Engine(s)
5020	The entire input record was blank.	T
5030	The country's postal authority will not permit assignment due to violation of an assignment rule.	G
5040	Assignment not made after lastline processing due to a violation of lastline assignment rules.	G
6000	Unclassified error.	All engines

3.5.4.15.4 Status codes (Global Address Cleanse)

Status codes (assigned to the Status_Code output field) are five or six characters that represent the corrections made to the address during processing. The number of characters depends on the engine used for processing.

- The first character is always an S (for Status).
- The second character is associated with any last line corrections.
- The third character is associated with any address line corrections.
- The fourth character is associated with any secondary address line corrections.
- The fifth character is associated with changes to components that are not considered basic address components (Other Primary Address and Other Secondary Address).
- The sixth component indicates additional information about a record that is not related to a change in the address.

Second character

The value of the second character depends on corrections to the country, postcode, region, or locality.

Value	Description
0	No significant difference between the input data and the corrected data.
1	Corrected country.
2	Corrected postal code.
3	Corrected country and postal code.
4	Corrected region.
5	Corrected country and region.

Value	Description
6	Corrected postal code and region.
7	Corrected country, postal code, and region.
8	Corrected locality.
9	Corrected country and locality.
A	Corrected postal code and locality.
B	Corrected country, postal code, and locality.
C	Corrected region and locality.
D	Corrected country, region, and locality.
E	Corrected postal code, region, and locality.
F	Corrected country, postal code, region, and locality.

Third character

The value of the third character depends on corrections to the pre/post directionals, primary type, primary name, and primary range.

Value	Description
0	No significant difference between the input data and the corrected data.
1	Corrected pre/post directional.
2	Corrected primary type.
3	Corrected pre/post directional and primary type.
4	Corrected primary name.
5	Corrected pre/post directional and primary name.
6	Corrected primary type and primary name.
7	Corrected pre/post directional, primary type, and primary name.
8	Corrected primary range.
9	Corrected pre/post directional and primary range.

Value	Description
A	Corrected primary type and primary range.
B	Corrected pre/post directional, primary type, and primary range.
C	Corrected primary name and primary range.
D	Corrected pre/post directional, primary name, and primary range.
E	Corrected primary type, primary name, and primary range.
F	Corrected pre/post directional, primary type, primary name, and primary range.

Fourth character

The value of the fourth character depends on corrections to the unit description, unit number, firm, building name, floor description, floor number, stairwell description, stairwell name, Wing description, and Wing name.

Value	Description
0	No significant difference between the input data and the corrected data.
1	Corrected one or more secondary address component (unit description, floor description, stairwell description, or wing description).
2	Corrected one or more secondary address component (unit number, floor number, stairwell name, or wing name).
3	Corrected one or more secondary address component (unit description, unit number, floor description, floor number, stairwell description, stairwell name, wing description, or wing name).
4	Corrected building name.
5	Corrected one or more secondary address component (unit description, floor description, stairwell description, or wing description), and building name.
6	Corrected the one or more secondary address component (unit number, floor number, stairwell name, or wing name), and building name.
7	Corrected one or more secondary address component (unit description, unit number, floor description, floor number, stairwell description, stairwell name, wing description, or wing name), and building name.
8	Corrected firm.

Value	Description
9	Corrected one or more secondary address component (unit description, floor description, stairwell description, or wing description), and firm.
A	Corrected one or more secondary address component (unit number, floor number, stairwell name, or wing name), and firm.
B	Corrected one or more secondary address component (unit description, unit number, floor description, floor number, stairwell description, stairwell name, wing description, or wing name), and firm.
C	Corrected building name and firm.
D	Corrected one or more secondary address component (unit description, floor description, stairwell description, or wing description), building name, and firm.
E	Corrected one or more secondary address component (unit number, floor number, stairwell name, or wing name), building name, and firm.
F	Corrected one or more secondary address component (unit description, unit number, floor description, floor number, stairwell description, stairwell name, wing description, or wing name), building name, and firm.

Fifth Character

The value of the fifth character depends on changes to components that are not considered basic address components (Other Primary Address and Other Secondary Address).

Other Primary Address components:

- Primary_Delivery_Mode
- Primary_Delivery_Number

Other Secondary Address components:

- Delivery_Installation_Name
- Delivery_Installation_Qualifier
- Delivery_Installation_Type

Value	Description
0	No significant change between the input data and the corrected data.
1	Changed the Other Primary Address components.
2	Changed the Other Secondary Address components.
3	Changed the Other Primary Address and Other Secondary Address components.

Value	Description
4	Changed the point of reference.
5	Changed the Other Primary Address components and the point of reference.
6	Changed the Other Secondary Address components and the point of reference.
7	Changed the Other Primary Address, Other Secondary Address components, and the point of reference.

Sixth Character

The value of the sixth character indicates additional information about a record that is not related to a change in the address.

Value	Description
A	Alias record used for assignment. Global Address engine.
B	Base record assignment. Global Address engine (New Zealand). A Bordering Locality. Global Address engine (Australia).
C	An Alias and a Bordering locality. Global Address engine (Australia).
D	Deleted record. Global Address engine (Austria and Germany).
I	Record ignored. Global Address engine (New Zealand).
L	Large Volume Receiver (LVR). Global Address engine (Brazil).
U	Unique address. Global Address engine (New Zealand).

3.5.4.15.5 Quality codes (Global Address Cleanse)

Quality codes relay additional information about the quality of the address. There are six levels of quality codes based on these factors:

- The country of the input data
- The engine used for processing
- The information code
- The status code if there is not an information code

Use the following table to determine the code assigned to the Quality_Code output field.

Quality code	Description
Q1	Perfect address on input. All address components were validated without corrections.
Q2	Corrected address. All address components were validated after corrections were made.
Q3	Not all components of the address could be fully validated. There was insufficient information to make a final correction. However, the assessment of the record leads to the assumption that there is a "high" likelihood that this address is deliverable.
Q4	Not all components of the address could be fully validated. There was insufficient information to make a final correction. However, the assessment of the record leads to the assumption that there is a "fair" likelihood that this address is deliverable.
Q5	Not all components of the address could be fully validated. There was insufficient information to make a final correction. However, the assessment of the record leads to the assumption that there is a "small" likelihood that this address is deliverable.
Q6	Not all components of the address could be fully validated. There was insufficient information to make a final correction. However, the assessment of the record leads to the assumption that it is "highly unlikely" that this address is deliverable.

3.5.4.15.6 Fault codes (USA Regulatory Address Cleanse)

When the transform cannot assign an address, it creates a fault code (Fault_Code output field). This code tells you why the address could not be assigned.

Fault Code	Description
E101	Last line is bad or missing.
E212	No locality and bad postal code.
E213	Bad locality, valid region, and no postal code.
E214	Bad locality and bad postal code.
E216	Bad postal code and can't determine which locality match to select.
E302	No primary address line parsed.
E412	Primary name not found in directory.
E413	Possible primary name matches are too close to choose one.
E420	Primary range is missing.
E421	Primary range is invalid for the street/route/building.
E422	Primary prefix needed, input is wrong or missing.
E423	Primary type needed, input is wrong or missing.
E425	Primary type and directional needed, input is wrong or missing.

Fault Code	Description
E427	Primary postfix needed, input is wrong or missing.
E428	Bad postal code, can't select an address match.
E429	Bad locality, can't select an address match.
E430	Possible address-line matches too close to choose one.
E431	Locality2 needed, input is wrong or missing.
E439	Exact match made in EWS directory.
E500	Other error.
E501	Foreign address.
E502	Input record entirely blank.
E503	Postal code not in area covered by partial USPS directory.
E504	Overlapping ranges in USPS directory.
E505	Address does not exist in the USPS directories. Undeliverable address.
E600	Marked by USPS as unsuitable for delivery of mail.
E601	The primary address number did not DPV confirm, and the Postcode2 was removed.

3.5.4.15.7 Status codes (USA Regulatory Address Cleanse)

When the transform assigns an address, it creates a status code (Status_Code output field). This code can tell you how the input address differs from the assigned address.

Digit	Description
1st	*A*: The transform truncated the address line to make it fit your field. *B*: The transform truncated both the address line and the Locality1_Name. *C*: The transform truncated the Locality1_Name to make it fit your field. *S*: No truncation occurred.
2nd	*0*: Regarding the Locality1_Name, Region1, Postcode1, and Postcode2, there is no significant difference between the input data and the data that the transform assigned. *1*: The transform assigned a different Postcode1. *2*: The transform assigned a different Locality1_Name. *3*: The transform assigned a different Locality1_Name and Postcode1. *4*: The transform assigned a different Region1. *5*: The transform assigned a different Region1 and Postcode1.

Digit	Description
	6: The transform assigned a different Locality1_Name and Region1. 7: The transform assigned a different Locality1_Name, Region1, and Postcode1. 8: The transform assigned a different Postcode2. 9: The transform assigned a different Postcode1 and Postcode2. A: The transform assigned a different Locality1_Name and Postcode2. B: The transform assigned a different Locality1_Name, Postcode1, and Postcode2. C: The transform assigned a different Region1 and Postcode2. D: The transform assigned a different Region1, Postcode1, and Postcode2. E: The transform assigned a different Locality1_Name, Region1, and Postcode2. F: The transform assigned a different Locality1_Name, Region1, Postcode1, and Postcode2.
3rd	0: Regarding the primary name, primary prefix/postfix, and primary type, there is no significant difference between the input and what the transform assigned. 1: The transform assigned a different primary type. 2: The transform assigned a different primary prefix. 3: The transform assigned a different primary prefix and primary type. 4: The transform assigned a different primary postfix. 5: The transform assigned a different primary type and primary postfix. 6: The transform assigned a different primary prefix and primary postfix. 7: The transform assigned a different primary prefix, primary type, and primary postfix. 8: The transform assigned a different primary name. 9: The transform assigned a different primary name and primary type. A: The transform assigned a different primary prefix and primary name. B: The transform assigned a different primary prefix, primary name, and primary type. C: The transform assigned a different primary name and primary postfix. D: The transform assigned a different primary name, primary type, and primary postfix. E: The transform assigned a different primary prefix, primary name, and primary postfix. F: The transform assigned a different primary prefix, primary name, primary postfix, and primary type.
4th	0: Regarding the county number, sort code route, delivery point, and unit description, there is no significant difference between the input data and the data that the transform assigned. 1: The transform assigned a different unit description. 2: The transform assigned a different delivery point.

Digit	Description
	3: The transform assigned a different delivery point and unit description. 4: The transform assigned a different sort code route. 5: The transform assigned a different sort code route and unit description. 6: The transform assigned a different sort code route and delivery point. 7: The transform assigned a different sort code route, delivery point, and unit description. 8: The transform assigned a different county number. 9: The transform assigned a different county number and unit description. A: The transform assigned a different county number and delivery point. B: The transform assigned a different county number, delivery point, and unit description. C: The transform assigned a different county number and sort code route. D: The transform assigned a different county number, sort code route, and unit description. E: The transform assigned a different county number, sort code route, and delivery point. F: The transform assigned a different county number, sort code route, delivery point, and unit description.
5th	0: Regarding the LOT, LOT_Order, and Locality2_Official, there is no significant difference between the input data and the data that the transform assigned. 1: The transform assigned a different LOT. 2: The transform assigned a different LOT_Order. 3: The transform assigned a different LOT and LOT_Order. 4: The transform assigned a different Locality2_Official. 5: The transform assigned a different Locality2_Official and LOT. 6: The transform assigned a different Locality2_Official and LOT_Order. 7: The transform assigned a different Locality2_Official, LOT, and LOT_Order.
6th	Always outputs a zero (0).

3.5.4.15.8 About ShowA and ShowL (USA)

The Show programs are used for looking inside the postal directories to find answers to questions like these:

- Why did the transform standardized the address in an unexpected way?
- Why didn't the transform assign the address?
- Why did the transform’s error code indicate a flaw in the directory?

Note

Run the ShowA/ShowL utilities from a DOS command line using specific command-line options. These options are listed when you enter the following command:

Windows: `showa /op`

UNIX: `showa -op`

Query the postal directories

You can use ShowA to display or output information from the Address_1_Directory, and you can use ShowL to query the City_Directory and the Post_Code_Directory.

Edit configuration files

Each Show utility has its own configuration file. These files contain parameters for controlling how the program behaves.

USA addresses:

Utility	Executable	File name	Location
ShowA	`showa.exe`	`showa.cfg`	**`<LINK_DIR>`** `\dataquality\urac`
ShowL	`showl.exe`	`showl.cfg`	**`<LINK_DIR>`** `\dataquality\urac`

Before you run the Show utilities, set both configuration files for the appropriate country directory. The configuration files contain instructions and detailed information about how to run the programs.

Note

Run the ShowA/ShowL utilities in the same directory as the ShowA/ShowL configuration files. You can change the location of the Show A/L executable files, however the utilities will not run if you did not accept the default location for the configuration files.

Related Information

USA ShowA command line options [page 1422]

3.5.4.15.8.1 ShowA/ShowL modes of operation

The ShowA and ShowL utilities have two modes for entering queries: prompts and command line options.

Prompts

If you type the ShowA/ShowL command without any options at all, then ShowA/ShowL prompts you to enter your query data. It takes all other information and options from the configuration file.

After your first query, ShowA/ShowL prompts you to enter the next one. You can exit by typing "quit" at any prompt.

Command line options

You may enter your query data on your ShowA/ShowL command line. ShowA/ShowL performs one query, displays and/or outputs the results, and then exits.

From the configuration file, ShowA/ShowL takes information about the auxiliary files, output file, display and search options. If you must override any value taken from the configuration file, you can do so. You can use command line options selectively to override where you need to, and depend on the configuration file for the rest. The only value you cannot specify through command- line options is the optional output fields.

> **Note**
>
> If any command option is present, then ShowA/ShowL detects that you are operating in command line mode. It will not prompt you to enter your query data. Use command line options to enter your query data.

3.5.4.15.8.2 USA ShowA command line options

To view a summary of command line options, use this command:

Windows: `showa /op`

UNIX: `showa -op`

The following table lists the command line options and the command descriptions.

UNIX	Windows	Description
-a	/a	Appends information to the output file (if it already exists).
-alias	/alias	Includes preferred alias address lines.
-d	/d	Displays your query data on screen.

UNIX	Windows	Description
-fin	/fin	Expands the query to cover USPS finance area.
-op	/op	Displays the list of options (in this table).
-p	/p	Pauses screen display every 22 lines.
-2:dpbc	/2:dpbc	Enter the DPBC code for `dpbc`.
-4:zip4	/4:zip4	Enter the postcode2 for`zip4`.
-ad:file	/ad:file	Enter the Address-line dictionary and path name (**addrln.dct**) for `file`.
-c:cart	/c:cart	Enter the carrier route number for `cart`.
-f:file	/f:file	Enter the file path and name of the output file (to hold the information from the query instead of just displaying it on screen) for `file`.
-nd:file	/nd:file	Enter the National ZIP+4 directory path and name (**zip4us.dir**) for `file`.
-pre:dir	/pre:dir	Enter the primary prefix (N, NE, E, SE, S, SW, W, NW) for `dir`.
-pos:dir	/pos:dir	Enter the primary postfix (N, NE, E, SE, S, SW, W, NW) for `dir`.
-s:street	/s:street	Enter the street primary name (in quotes if multiple words) for `street`.
-sfx:suffix	/sfx:suffix	Enter the primary type (Ave, Blvd, St, Rd, and so on) for `suffix`.
-sh:range	/sh:range	Enter the street (primary) range high for `range`.
-sl:range	/sl:range	Enter the street (primary) range low or exact for `range`.
-t:type	/t:type	Enter the file type (dBASE3, ASCII, or DELIMITED) for `type`.
-u:urb idx	/u:urb idx	Enter the urbanization Index for `urb idx`.
-z:lo-hi	/z:lo-hi	Enter the low and high range for postcode1 for `lo-hi`.
-z:zip	/z:zip	Enter the postcode1 for `zip`.

Related Information

ShowA/ShowL modes of operation [page 1422]

3.5.4.15.8.3 USA ShowL command line options

To view a summary of command line options, use this command:

Windows: `showl /op`

UNIX: `showl -op`

The following table lists the command line option and the command descriptions.

UNIX	Windows	Description
-a	/a	Appends query information to an output file (if it already exists).
-d	/d	Displays query data on screen.
-op	/op	Displays this list of options.
-p	/p	Pauses screen display every 22 lines.
-ab:query	/ab:query	Enter the abbreviated locality1 for `query`.
-cd:file	/cd:file	Enter the City directory path and name (**city04.dir**) for `file`.
-cn:city	/cn:city	Enter locality1 name (in quotes if multiple words) for `city`.
-dr:dir	/dr:dir	Enter which directory to search, City or ZCF for `dir.`
-f:file	/f:file	Enter the output file path and name for `file`.
-ml:query	/ml:query	Enter the military postcode1 for `query`.
-mz:query	/mz:query	Enter the multi-zone locality1 for `query.`
-pn:query	/pn:query	Enter a place name for `query.`
-st:state	/st:state	Enter region1 (for US use USPS abbreviations or full state names) for `state`.
-t:type	/t:type	Enter the output file type (dBASE3, ASCII, or DELIMITED) for `type`.
-un:query	/un:query	Enter the unique postcode1 for `query`.
-z:zip	/z:zip	Enter the postcode1 for `zip`.
-zd:file	/zd:file	Enter the ZCF directory path and name (**zcf04.dir**) for `file`.
-z:lo-hi	/z:lo-hi	Enter the postcode1 range for `lo-hi`.

Related Information

ShowA/ShowL modes of operation [page 1422]

3.5.4.16 Data Cleanse reference

This section describes the following reference information for use with the Data Cleanse transform:

- Status codes
- Information codes
- Diacritical character conversion chart

3.5.4.16.1 Status codes (Data Cleanse)

Status codes (assigned to the Status_Code output field) have the same format: **`<parser name>`**_**`<output field name>`**_STD or **`<parser name>`**_**`<output field name>`**_ADD. The **`<parser name>`** includes one of the following parsers: custom, date, firm, person, phone, and SSN.

Only the status codes that have standardized output are shown. The status codes show one of the following depending on whether the standardization options are chosen:

- how the data was standardized
- that a specific standard could be used on the data

i Note

When only minor changes occur, a status code may not be generated. See the exceptions at the bottom of this topic.

Person parser

Person parser status codes have the PERSON#_**`<output field>`**_STD or PERSON#**`<output field>`**_ADD format where the pound sign (#) is replaced with the person number, such as Person1 or Person2 through Person6.

Table 167: Person parser status codes

Status code	Description
Person#_Name_Designator_Std	Used a Name_Designator standard.
Person#_Prename_Add	Prename was assigned.
Person#_Prename _Std	Prename was provided and a prename standard was used.

Status code	Description
Person#_Given_Name1_Std	Used a Given_Name1 standard.
Person#_Given_Name2_Std	Used a Given_Name2 standard.
Person#_Family_Name1_Std	Used a Family_Name1 standard.
Person#_Family_Name2_Std	Used a Family_Name2 standard.
Person#_Honorary_Postname_Std	Used an Honorary_Postname standard.
Person#_Maturity_Postname_Std	Used a Maturity_Postname standard.
Person#_Title_Std	Used a Title standard.
Person#_Name_Special_Std	Used a Name_Special standard.

Example

Multiple status codes can be assigned per record and are separated by a comma. For example, the status code:

```
PERSON1_PRENAME_STD,PERSON1_GIVEN_NAME1_STD,PERSON1_FAMILY_NAME1_STD,PERSON2_GIVEN
_NAME2_STD,PERSON6_MATURITY_POSTNAME_STD
```

provides the following information:

- The Person1 parse used standards for Prename, Given_Name1, and Family_Name1 output fields.
- The Person2 parse used standards for the Given_Name2 output field.
- The Person6 parse used standards for the Maturity_Postname output field.

Firm parser

Firm parser status codes have the FIRM#_**`<output field>`**_STD format where the pound sign (#) is replaced with the Firm number, such as Firm1 or Firm2 through Firm6.

Table 168: Firm parser status codes

Status code	Description
Firm#_Firm_Std	Used a Firm standard.
Firm#_Firm_Location_Std	Used a Firm_Location standard.

Example

Multiple status codes can be assigned per record and are separated by a comma. For example, the status code:

```
FIRM1_FIRM_STD,FIRM2_FIRM_LOCATION_STD,FIRM3_FIRM_STD,FIRM3_FIRM_LOCATION_STD
```

provides the following information:

- The Firm1 parse used a Firm standard.
- The Firm2 parse used a Firm_Location standard.

- The Firm3 parse used both a Firm standard and a Firm_Location standard.

Date, Phone and Social Security number parsers

Date, Phone and Social Security number (SSN) parser status codes have the following status code formats:

Table 169: Date, Phone and Social Security number parser status codes

Status code	Description
Date#_Date_Std	Used a Date standard.
Phone#_Phone_Std	Used a Phone number standard.
SSN#_SSN_Std	Used a Social Security number standard.

Example

Multiple status codes can be assigned per record and are separated by a comma. For example, the Date status code, `DATE1_DATE_STD,DATE6_DATE_STD`, shows that both Date1 and Date6 were standardized.

`SSN1_SSN_STD,SSN5_SSN_STD` shows that both SSN1 and SSN5 were standardized.

`PHONE1_PHONE_STD,PHONE3_PHONE_STD` shows that both Phone1 and Phone3 were standardized.

Custom parser

Custom parser status codes have the **<parser name>**#_**<output field>**_STD format where the pound sign (#) is replaced with the parser number.

Table 170: Custom parser status code

Status code	Description
<parser name>#_**<output field>**_Std	Used the **<output field>**'s standard.

Example

Multiple status codes can be assigned per record and are separated by a comma. For example, the Automobile status code, `AUTOMOBILE1_COLOR_STD,AUTOMOBILE1_SIZE_STD,AUTOMOBILE2_COLOR_STD`, shows the following information:

- Automobile1 used a color and size standard.
- Automobile2 used a color standard.

Status code exceptions

When there are only minor changes, a status code may not be generated. There are several instances where a status code is not generated.

Exception	Description	Example
Trailing period	A status code is not generated when a period is added or removed after a piece of data.	J Smith has a standard of "J." No status code. J. Smith has a standard of "J" No status code. UK has a standard of "U.K." A status code is generated because there are more punctuation changes than the trailing period.
Capitalization option	A status code is not generated when the only difference between the standard and the original data is how the data is cased.	Mcdonald has a standard of "McDonald" but is output as "MCDONALD" because the *Capitalization* option is set to *Upper*. No status code.
Remove punctuation option	A status code is not generated when the only difference between the standard and the original data is removed punctuation when this option is set to *Yes*.	UK has a standard of "U.K." However, the *Remove punctuation* option is set to *Yes*. No status code.
Remove diacritical characters option	A status code is not generated when the only difference between the standard and the original data is the diacritical characters when this option is set to *Yes*.	Hernandez has a standard of "Hernández". However, the *Remove diacritical characters* option is set to *Yes*. No status code. Hernandez has a standard of "Hernández". However, the *Remove diacritical characters* option is set to *No*. A status code is generated to show that a standard was used.

3.5.4.16.2 Information codes (Data Cleanse)

Information codes (assigned to the Info_Code output field) provide information about the data that may be suspect and might require a manual review. The output field contains one or more codes separated by a comma. Each code begins with a letter followed by three numbers classified as follows:

- Date parse information

Information code format	Description
D1##	Date1 parse level information
D2##	Date2 parse level information
D3##	Date3 parse level information
D4##	Date4 parse level information
D5##	Date5 parse level information

Information code format	Description
D6##	Date6 parse level information

- Firm parse information

Information code format	Description
F1##	Firm1 parse level information
F2##	Firm2 parse level information
F3##	Firm3 parse level information
F4##	Firm4 parse level information
F5##	Firm5 parse level information
F6##	Firm6 parse level information

- Input field information

Information code format	Description
I###	Input field level information

- Person parse information

Information code format	Description
P1##	Person1 parse level information
P2##	Person2 parse level information
P3##	Person3 parse level information
P4##	Person4 parse level information
P5##	Person5 parse level information
P6##	Person6 parse level information

- Phone parse information

Information code format	Description
T1##	Phone1 parse level information
T2##	Phone2 parse level information
T3##	Phone3 parse level information
T4##	Phone4 parse level information
T5##	Phone5 parse level information
T6##	Phone6 parse level information

- Record level information

Information code format	Description
R###	Record level information

The following table shows more details about the information codes.

Information code	Description
R001	All input field data went to one or more Extra output fields; nothing was parsed for the record.
R002	Parsed some of the input fields. One or more other input fields went to the Extra output field.
R003	Parsed part of the input fields. Some of the record data went to the Extra output field.
R004	All of the record's input fields were parsed into appropriate output fields. None of the input data went to the Extra output field.
R400	The data in Option_Content_Domain_Sequence overrode the content domain sequence transform option.
R405	The data in Option_Content_Domain_Sequence was not recognized as a content domain sequence. The data in Option_Country or the data in content domain sequence transform option was used to determine the content domain sequence.
R410	The data in Option_Output_Format overrode the output format data cleanse transform option.
R415	The data in Option_Output_Format was not recognized as a valid output format. The data in Option_Country or the output format transform option was used to determine the output format.
R420	The data in Option_Country was recognized as an ISO2 country code and overrode the content domain sequence transform option.
R421	The data in Option_Country was recognized as an ISO2 country code and overrode the output format transform option.
R425	The data in Option_Country was not recognized as an ISO2 country code. One or more situations occurred where Option_Country data was used to override the content domain sequence and/or output format transform options, but failed: ● Attempted to use Option_Country to override the content domain sequence transform option. This occurs when the Option_Content_Domain_Sequence data is invalid (R405) or the data is not supplied (no status code is generated when this occurs). The data was parsed based using the content domain sequence transform option. ● Attempted to use Option_Country to override the output transform option. This occurs when the Option_Output_Format data is invalid (R415) or is not supplied (no status code is generated when this occurs). The data was parsed based using the output format transform option.
P#01	The person# parse contained some data that was not found in the cleansing package. This information code does not report on title information, which is different than information code P#51.
P#02	The person# parse had a close firm parse. This is only applicable for Person_Firm multiline parse when using the Person_Firm multiline parser or Name_Firm_Line when the data came from the input field Name_Firm_Line.
P#03	The person# parse was a presumptive name parse (based on reasonable evidence).
P#04	The person# parse has no given name, or has a questionable given name.

Information code	Description
P#05	The person# parse has no family name, or has a questionable family name.
P#51	The person# parse contained a title token that was not found in the cleansing package. This is different than information code P#01.
F#01	The firm# parse contained some data that was not found in the cleansing package.
F#02	The firm# parse had a close person parse. This is only applicable for Person_Firm multiline parse when using the Person_Firm multiline parser or Name_Firm_Line when the data came from the input field Name_Firm_Line.
F#03	The firm# parse was a presumptive firm parse (based on reasonable evidence).
D#01	Date# was not in the expected format.
D#02	Date# was converted from 2-digits to 4-digits. The century threshold transform option was applied.
D#03	Date# was in the Day_Month_Year format.
D#04	Date# was in the Month_Day_Year format.
D#05	Date# was in the Year_Month_Day format.
D#06	Date# was in the Year_Day_Month format.
D#07	Date# was in an ambiguous format. There is more than one possible format for the date. For example, 12/09/10 is valid for all of the formats, whereas 03/16/94 is valid only for the Month_Day_Year format.
T#01	The phone# parse did not have a North American area code.
I111-I116	All of the input data in Name_Line# went to one or more Extra output fields; nothing was parsed for this input field.
I131-I136	Parsed some of the input data in Name_Line#, the rest of the data is in the Extra output field.
I151-I156	All of the input data in Title_Line# went to one or more Extra output fields; nothing was parsed for this input field.
I171-I176	Parsed some of the input data in Title_Line#, the rest of the data is in the Extra output field.
I311-I316	All of the input data in Name_Or_Firm_Line# went to one or more Extra output fields; nothing was parsed for this input field.
I331-I336	Parsed some of the input data in Name_Or_Firm_Line#, the rest of the data is in the Extra output field.
I351-I352	All of the input data in Firm_Line# went to one or more Extra output fields; nothing was parsed for this input field.
I371-I372	Parsed some of the input data in Firm_Line#, the rest of the data is in the Extra output field.
I511-I516	All of the input data in Date# went to one or more Extra output fields; nothing was parsed for this input field.

Information code	Description
I531-I536	Parsed some of the input data in Date#, the rest of the data is in the Extra output field.
I711-I716	All of the input data in Email# went to one or more Extra output fields; nothing was parsed for this input field.
I731-I736	Parsed some of the input data in Email#, the rest of the data is in the Extra output field.
I751-I756	All of the input data in Phone# went to one or more Extra output fields; nothing was parsed for this input field.
I771-I776	Parsed some of the input data in Phone#, the rest of the data is in the Extra output field.
I811-I816	All of the input data in SSN# went to one or more Extra output fields; nothing was parsed for this input field.
I831-I836	Parsed some of the input data in SSN#, the rest of the data is in the Extra output field.
I851-I856	All of the input data in UDPM# went to one or more Extra output fields; nothing was parsed for this input field.
I871-I876	Parsed some of the input data in UDPM#, the rest of the data is in the Extra output field.
I901-I912	All of the input data in Date# went to one or more Extra output fields; nothing was parsed for this input field.
I951-I962	Parsed some of the input data in Multiline#, the rest of the data is in the Extra output field.

3.5.4.16.3 Diacritical character conversion chart

In the Data Cleanse transform, there is an option where you can remove the diacritical characters from the data on output. The following table shows the diacritical characters and the ASCII equivalent letter that replaces the diacritical character.

Note

The diacritical character is listed first, separated by a comma and then the ASCII replacement letter.

Table 171: Diacritical characters conversion chart

À,A	Ĕ,E	Ļ,L	Ś,S	Ź,Z	ē,e	ľ,l	ŝ,s
Á,A	Ė,E	Ľ,L	Ŝ,S	Ż,Z	ĕ,e	ŀ,l	ş,s

Related Information

Other standardization options [page 1157]

3.5.5 Platform transforms

3.5.5.1 Case

Specifies multiple paths in a single transform (different rows are processed in different ways).

The Case transform simplifies branch logic in data flows by consolidating case or decision making logic in one transform. Paths are defined in an expression table.

3.5.5.1.1 Data inputs

Only one data flow source is allowed.

3.5.5.1.2 Editor

The Case transform editor consists of a Schema In pane and a Case tab.

The Case tab includes:

- An expression table that lists labels and their CASE expressions
- An embedded Smart Editor for the CASE expression
- A *Functions* button that open the Function Wizard
- An ellipses (...) button that opens a full-size Smart Editor

1. Use the buttons, or right-click the expression table to insert or delete cases.

   While using this table, the window also allows you to:

   - Select multiple rows
   - Apply delete functionality to a multiple selection
   - Press Delete or Insert keys to delete or add an expression
2. In the expression table, click a label to rename it.
3. Enter the expression in the editor (drag columns from the input schema).

   For large expressions, open the smart editor. Both the smart editor and the function wizard can assist you with expression creation.
4. To add a DEFAULT case, select the *Produce default output when all expressions are false* check box. The label changes to read *Produce default output with label: default*. Change the label name if desired.

   When you add a DEFAULT case, Data Services will send rows to this case when all other case conditions are false.

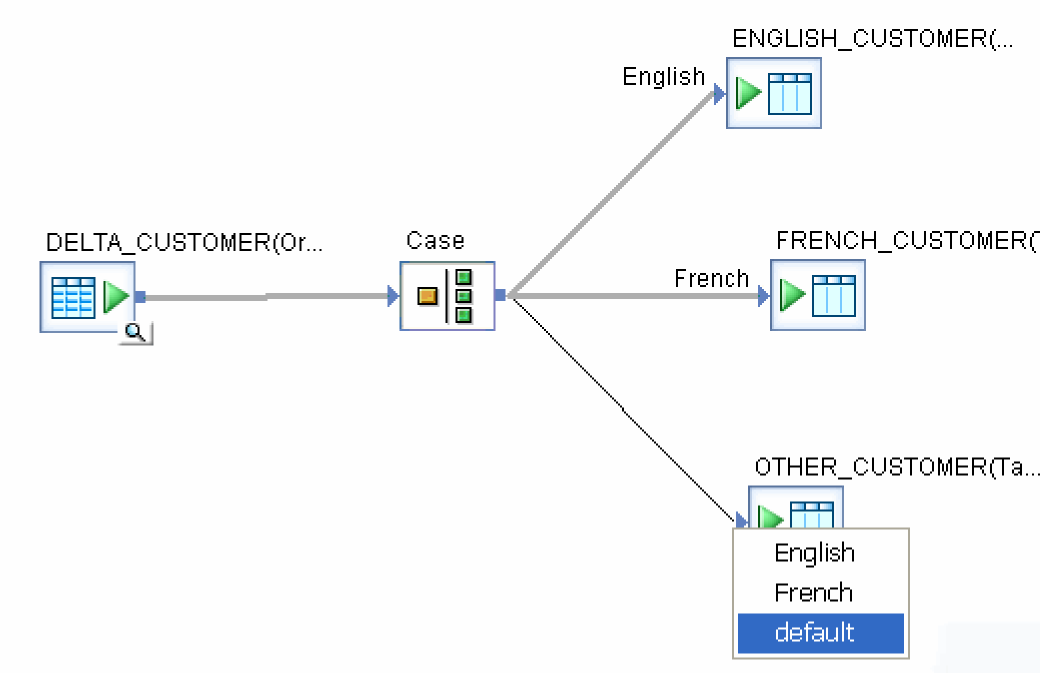
3.5.5.1.3 Options

Option	Description
Expression	CASE expression for the corresponding label.

Option	Description
	DEFAULT is the expression used when all other CASE expressions evaluate to false. To enable DEFAULT, select the *Produce default output when all expressions are false* check box. The label changes to read *Produce default output with label: default*. Change the label name if desired.
Label	Name of the connection description indicating where data will go if the corresponding CASE condition is true.
Preserve expression order	This option is available only when the *Row can be TRUE for one case only* option is checked. Select this option if expression order is important to you. When this option is NOT checked, you can increase the performance of the Case transform, because Data Services will reorder your expressions to process them in a less CPU intensive manner first. This reordering of expressions can change your results, because there is no way to guarantee which expression will evaluate to TRUE first.
Produce default output with label or *Produce default output when all expressions are false*	This option changes depending on whether it is selected. Select *Produce default output with label* to send rows to this case when all other case conditions are false.
Row can be TRUE for one case only	If this option is selected, the row is passed to the first case whose expression returns TRUE. Otherwise, the row is passed to all the cases whose expression returns TRUE. For jobs created in the 6.0 release or earlier, this option is set to FALSE. When you create a case transform in 6.1or later, this option defaults to TRUE

3.5.5.1.4 Data outputs

Connect the output of the Case transform with another object in the workspace. Choose a case label from a pop-up menu. Each label represents a case expression (WHERE clause) created in the Case editor.



The connections between the Case transform and objects used for a particular case must be labeled. Each output label in the Case transform must be used at least once.

To delete a case connection, right-click the connection label and select *Delete*.

The Case transform can be used to implement IF-THEN-ELSE logic rather than using a conditional flow. However:

- Conditionals operate at the work flow level
- Case transforms operate within data flows

3.5.5.2 Map_Operation

Modifies data based on mapping expressions and current operation codes. The operation codes can be converted between data manipulation operations.

> Note
>
> If you configure both mapping expressions and operation codes, Data Services runs mapping expressions before any row type conversions. In addition, mapping expressions are optional, so if you don't have any configured Data Services performs operation codes only.

Writing map expressions per column and per row type (INSERT/UPDATE/DELETE) allows you to:

- change the value of data for a column.
- execute different expressions on a column, based on its input row type.
- use the before_image function to access the before image value of an UPDATE row.

> Note
>
> You can use mapping expressions on only top-level schemas. They do not work on nested schemas.

This transform can also change operation codes on data sets to produce the desired output. For example, if a row in the input data set has been updated in some previous operation in the data flow, you can use this transform to map the UPDATE operation to an INSERT. The result of converting UPDATE rows into INSERT rows is the preservation the rows in the target.

Data Services can push Map_Operation transforms to the source database.

Related Information

Effective_Date [page 1081]
real [page 1036]
before_image [page 1528]

3.5.5.2.1 Data inputs

A data set with rows flagged with any operation codes.

The input data set can contain hierarchical data.

Use caution when using columns of data type `real` in this transform. Comparison results are unpredictable for this data type.

3.5.5.2.2 Options

Tab	Option	Description
Mapping	*Update mapping* *Insert/Normal mapping* *Delete mapping*	Allows you to enter and edit optional mapping expressions for output columns and row types.
Map Operations	*Output row type*	Indicate the new operations desired for the input data set. Choose from the following operation codes: INSERT, UPDATE, DELETE, NORMAL, or DISCARD.

3.5.5.2.3 Data outputs

A data set with rows flagged as specified by the mapping operations.

Rows in the input data set can contain any of the following operation codes:

- NORMAL
- INSERT
- DELETE
- UPDATE

Any of these operation codes can be mapped to:

- NORMAL
- INSERT
- DELETE
- UPDATE

In addition, the DISCARD option can be assigned. Discarded rows are not passed through to the output of the transform.

By default, every input operation type maps to itself. For each specified mapping, every row in the input data set that matches the input mapping operation is converted to the specified output operation.

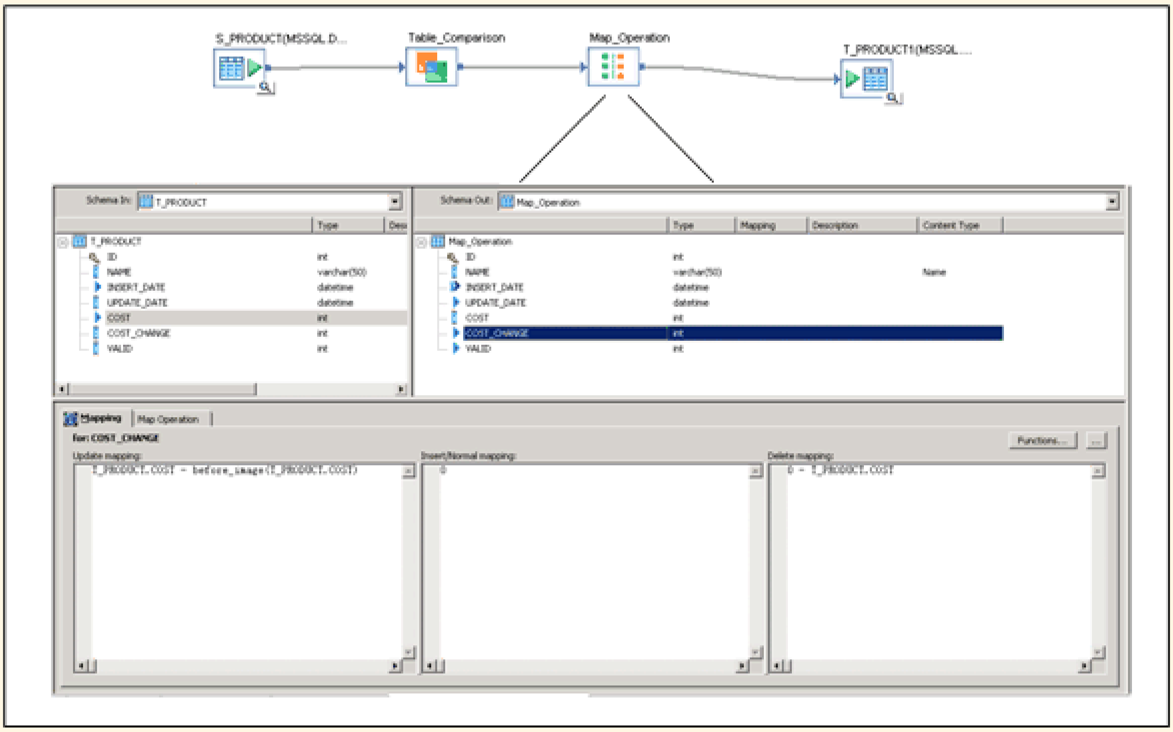
Example

Showing a change in cost

In this example, the original target table shows the cost field value as 9,000 and the cost_change field value as 0. Later on, the input data changes so that the cost field value is 1,000.

To see what the change in cost is after the input changes, you would do the following:

1. Set up the Table_Comparison transform to determine the row type (for example, INSERT or UPDATE).
2. In the Map_Operation transform, the Mapping tab would contain an expression for each column and each row type.
    - For the INSERT row type, fill the COST_CHANGE field with 0.
    - For the UPDATE row type, the before image value of the COST field (before_image(T_PRODUCT1.COST)) would be subtracted from the updated value of the COST field (T_PRODCUT1.COST). This gives you a COST_CHANGE field value of negative 8000 (1,000 - 9,000 = -8,000).
    - For the DELETE row type, the COST_CHANGE field is set as 0 - T_PRODUCT1.COST.



Schema In: T_PRODUCT

	Type
T_PRODUCT	
ID	int
NAME	varchar(50)
INSERT_DATE	datetime
UPDATE_DATE	datetime
COST	int
COST_CHANGE	int
VALID	int

Schema Out: Map_Operation

	Type	Mapping	Description	Content Type
Map_Operation				
ID	int			
NAME	varchar(50)			Name
INSERT_DATE	datetime			
UPDATE_DATE	datetime			
COST	int			
COST_CHANGE	int			
VALID	int			

Mapping | Map Operation

For: COST_CHANGE

Update mapping:

```
T_PRODUCT.COST - before_image(T_PRODUCT.COST)
```

Insert/Normal mapping:

```
0
```

Delete mapping:

```
0 - T_PRODUCT.COST
```

3. The Map Operation tab would have the following settings:

Input row type	Output row type
normal	normal
update	update
insert	insert
delete	update

Example

Changing a field value and a row type

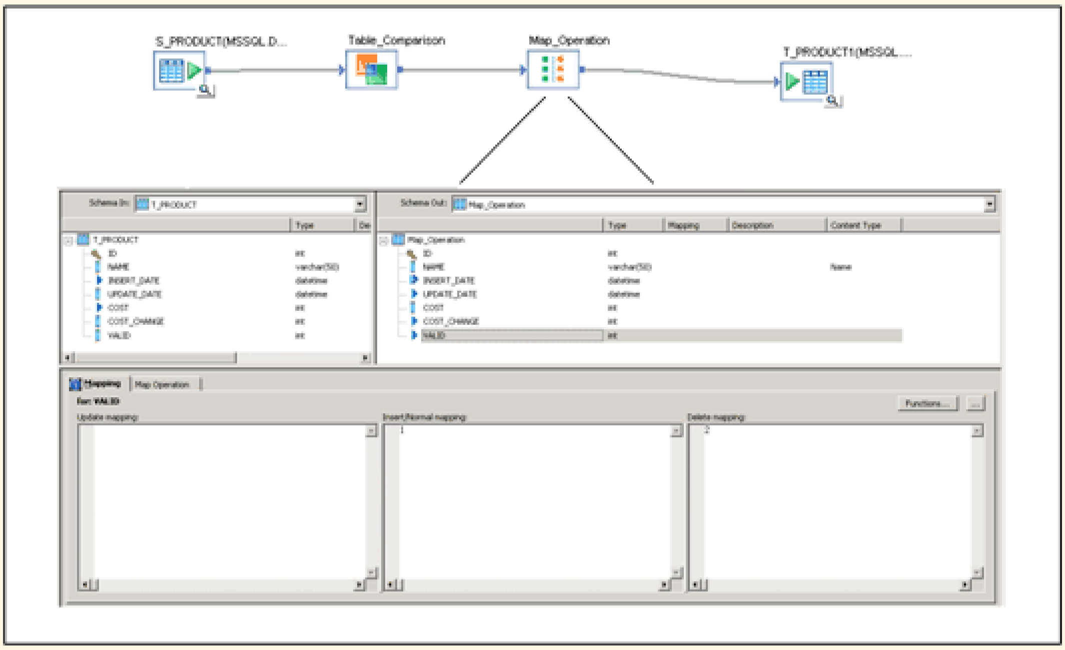
In this example, an expression is created to set the VALID field to 0 and to convert the DELETE row type to an UPDATE row type.

The VALID field (1=valid, 0=invalid) indicates if a product is in production or not. You do not want to delete the product from the target even though it has been deleted from the source. Instead, you want to update the valid field in the target to 0.

Note

When configuring both mapping expressions and operation codes, Data Services runs mapping expressions before any row type conversions.

The Mapping tab would appear as follows:



Schema In: T_PRODUCT

T_PRODUCT	Type
ID	int
NAME	varchar(50)
INSERT_DATE	datetime
UPDATE_DATE	datetime
COST	int
COST_CHANGE	int
VALID	int

Schema Out: Map_Operation

Map_Operation	Type	Mapping	Description	Content Type
ID	int			
NAME	varchar(50)			Name
INSERT_DATE	datetime			
UPDATE_DATE	datetime			
COST	int			
COST_CHANGE	int			
VALID	int			

For: VALID

Update mapping:

Insert/Normal mapping: 1

Delete mapping: 2

The Map Operation tab would have the following settings:

Input row type	Output row type
normal	normal
update	update
insert	insert
delete	update

Related Information

before_image [page 1528]

Table_Comparison [page 1110]

3.5.5.3 Merge

Combines incoming data sets, producing a single output data set with the same schema as the input data sets.

3.5.5.3.1 Data inputs

A data set from two or more sources with rows flagged as any operation code.

All sources must have the same schema, including:

- The same number of columns
- The same column names
- The same data types of columns

If the input data set contains hierarchical data, the names and data types must match at every level of the hierarchy.

3.5.5.3.2 Options

None.

3.5.5.3.3 Data outputs

A data set consisting of rows from all sources, with any operation codes. The output data has the same schema as the source data, including nested schemas.

The output data set contains a row for every row in the source data sets. The transform does not strip out duplicate rows. If columns in the input set contain nested schemas, the nested data is passed through without change.

If the data types of columns in the sources do not match the target, add a query in the data flow before the Merge transform. In the query, apply a data type conversion to the columns with data types that do not match the target column data types.

You must apply other operations such as DISTINCT in a query following the Merge transform.

3.5.5.4 Query

The Query transform retrieves a data set that satisfies conditions that you specify. A Query transform is similar to a SQL SELECT statement.

Related Information

Query transform output schema [page 1445]
Query transform input schema [page 1443]
Smart editor [page 1021]

3.5.5.4.1 Data inputs

A query has data inputs, which are data sets from one or more sources with rows flagged as any operation code.

> i Note
>
> Use caution when using columns of data type `real` in this transform. Comparison results are unpredictable for the `real` data type.

3.5.5.4.2 Data outputs

The Query transform retrieves a data set that satisfies conditions that you specify. A Query transform is similar to a SQL SELECT statement.

A query has data outputs, which are data sets based on the conditions that you specify using the schema specified in the output schema area.

3.5.5.4.3 Editor

Use the Query editor to specify the Schema In, Schema Out, and Options for the Query transform.

The areas can be resized in order to expand the area in which you are working. You can also expand and contract the columns to change the width of properties displayed in the input and output schema areas.

3.5.5.4.4 To search in an input or output schema

1. In the Query editor Find tab, enter the search term in the *Find what* box or select from previous search terms in the drop-down list.
2. In the *Schemas* list, choose the schemas in which to search.
3. In the *Elements* list, choose the types of mappings in which to search.
4. In the *Where* list, choose the properties to search within.

> **Note**
>
> You can search within one or all properties, but not within two or three specific properties at a time.

5. Select the *Match case* check box to constrain your search to the capitalization entered.
6. Click *Find*.
   The Designer searches the query for the words you specified within the constraints you defined.

> **Note**
>
> The Designer searches for columns loaded into memory. If columns are not loaded into memory, you must expand the schema to load the columns into memory before clicking *Find* and searching for the columns.

All matches are shown in the box below the find constraints. When you click to select a table or column name, the table or column is automatically highlighted and shown in the corresponding input or output schema area.

Initially, the Designer lists the matching columns in the order that they appear within the schemas. If you are searching both schemas, the Designer lists the first match found in the input schema first and the last match found in the output schema last. You can sort the list of matches by property. Each time you click a property heading, the Designer resorts the matches, cycling through original order, ascending order, and descending order.

Arrow icons confirm column and sort type. For example, if you sort the data by the *Description* property and in ascending order, an "up" arrow appears next to the *Description* heading. Click the heading again and a "down" arrow appears to indicate that the data is now sorted in descending alpha-numeric order. Click again and the match list returns to its original sort order.

3.5.5.4.5 Query transform input schema

The input schema area displays all schemas input to the Query transform as a hierarchical tree. Each input schema can contain zero or more of the following elements:

- Columns
- Nested schemas

Icons preceding columns are combinations of the following graphics:

Icon	Description
🔑	Primary key.
▯	Column that is not used in output mapping.
▶	Column that is used in output mappings.

The *Input* list at the top left of the query editor indicates the schema that is currently selected. As you select schemas or columns in the input schema area, the *Input* list displays the corresponding schema. Conversely, you can select a schema in the *Input* list to move easily to a required schema.

You can right-click elements in the input schema area and select the following menu commands:

Command	Applicable elements	Effect
Copy	Columns, schemas	Stores a copy of the selected elements in the clipboard, leaving the elements in the input schema area.
Find	Anywhere in input schema area	Locates an output element with the name or description you enter.
Refresh	Anywhere in input schema area	Refreshes the display of the input schema area.
Parent	Columns	Selects the parent schema of the selected column.
Collapse	Columns, schemas	Collapses a selected schema or a selected column's parent schema (to facilitate viewing/navigation).
Generate DTD...		Generates a DTD format that corresponds to the structure of the selected schema (either NRDM or relational). Generates all data types as varchar.
Generate XML Schema...		Generates an XML Schema that corresponds to the structure of the selected schema (either NRDM or relational). All data types match those of the selected schema.
Propagate Column From...	Columns	Carries a selected column schema from an upstream source or transform through intermediate objects to the input schema. Simple mappings are created in each object with no change to the data type or data itself.
Map to Output	Columns, schemas	Creates a simple mapping from the input schema area to the output schema area.
Create File Format...		Creates a file format from a relational table schema. All data types match those of the original table schema.
Properties	Columns, schemas	Displays the properties of the selected element. You cannot modify the properties.

3.5.5.4.6 Query transform output schema

The output schema area displays the schema output from the Query transform as a hierarchical tree. The output schema can contain one or more of the following elements:

- Columns
- Nested schemas
- Functions

Icons preceding columns are combinations of the following graphics:

Icon	Description
🔑	Primary key.
▶	Column that has a simple mapping. A simple mapping is either a single column or an expression with no input column (that is, an expression that does not vary with input).
⏩	Column that has a complex mapping. A complex mapping is any mapping that is not simple.
✗	(Red cross superimposed on any icon) Incorrect mapping. Data Services does not perform a complete validation during design, so the editor may not flag an incorrect mapping. For a complete validation, select ▶ *Validation* > *Validate* ◀.

The Schema Out pane shows the following:

- The current schema in the Schema Out list at the top and in the output schema area. The current schema determines:
  - ○ The output elements that you can modify (add, map, or delete).
  - ○ The scope of the SELECT through ORDER BY tabs in the options area.
- Non-current schemas appear dim in the output schema area.

Related Information

Change the current schema [page 1445]

3.5.5.4.7 Change the current schema

There are several ways to change the current schema in a Query transform:

- Select a schema from the Output list.
- Right-click a schema, column, or function in the output schema area and select *Make Current*.
- Double-click one of the non-current (dim) elements in the output schema area.

When you connect a target table to a query with an empty output schema, SAP Data Services automatically fills the query's output schema with the columns from the target table, without mappings.

The software only fills the target schema in the output of a query when you connect a target table to a query with an empty output schema. If the output schema contains any column mappings, the software does not overwrite those mappings. Similarly, if you connect a query to one target, and then disconnect that target and connect to another target, the output schema will show the columns from the first target connected.

The software does not fill the output schema from a file, an XML message, an IDoc, or any other target.

There are several techniques to change the output schema:

- Drag and drop (or copy and paste) columns or nested schemas from the input schema area to the output schema area (this provides simple column mappings).
  If you drop a column on an existing column, you can remap that column. Select Remap Column to update only the column mapping or select Remap with Data Type to update the column mapping and data type. Alternatively, you can select Insert Above or Insert Below to add the column as a new mapping or Cancel if you do not want to add the column to the output schema.
- Right-click the current schema and select *New Output Column* or *New Output Schema*. You can provide simple column mappings by dragging input columns over the new output columns. For complex mappings, use the options area.
- Right-click the current schema and select *New Function*. The function must already be imported into the repository. You can add adapter functions and SAP RFC or BAPI functions. These functions return multiple columns (in contrast to the functions used in mappings and Where clauses, which return single values). In the Define Input Parameter(s) window, map all first-level input parameters for the function to the input parameters of the query.
- Right-click columns in the current schema to assign and reverse primary key settings on output columns. A key icon indicates primary keys.
- Right-click the current schema and select *Unnest* to flatten output schemas. Use this command when a job has a source with a nested schema (such as an XML file), and you map columns from this source to a flat target table schema.

You can right-click elements in the output schema area and select commands. Generally, the elements must be within the current schema.

Command	Applicable elements	Effect
Cut	All	Removes the selected elements from the output schema area and stores a copy of the elements in the clipboard.
Copy	All	Stores a copy of the selected elements in the clipboard, leaving the elements in the output schema area.
Paste	All	Inserts the elements stored in the clipboard at the current cursor location (this must be within the current schema). Only visible when the clipboard contains something. If the cursor overlaps an existing column, you are prompted to insert above, insert below, remap column, or cancel.

Command	Applicable elements	Effect
		Note Copying an input element and pasting it in the output schema area provides a simple mapping from the input element to the output element. You can also do this by dragging the input element to the output schema area.
Delete	All	Removes the selected elements from the output schema area (without making a copy).
Find...	All	Locates an output element with the name or description you enter.
Make Current	All outside the current schema	Makes the selected schema, or the schema of the selected element, the current schema.
New Output Column...	Schemas	Adds an output column to the current schema with the name and properties you enter.
New Output Schema...	Schemas	Adds a nested schema to the current schema with the name you enter.
New Function Call	Schemas	Adds a function or stored procedure call to the current schema. The function or procedure must already be imported into the repository. You can add adapter functions and SAP RFC or BAPI functions. These functions return multiple columns (in contrast to the functions used in mappings and Where clauses that return single values). In the Define Input Parameter(s) window, map all first-level input parameters for the function to the input parameters of the query.
Modify Function Call	Functions	Allows you to modify the selected function. In the Define Input Parameter(s) window, map all first-level input parameters for the function to the input parameters of the query.
Propagate Column From	Columns	Carries a selected column schema from an upstream source or transform through intermediate objects to the output schema. Simple mappings are created in each object with no change to the data type or data itself.
Unnest	Nested schemas	Toggles to flatten or re-nest the selected schema into the parent schema in the query output. An unnested schema will not appear in the succeeding

Command	Applicable elements	Effect
		transform or target; only its columns appear. Unnested schemas appear in the Query transform output schema area as table icons with a black arrow that points to the left.
Nest with sub-schemas	Nested schemas	Re-nests the selected schema and all sub-schemas into the parent schema in the query output.
Unnest with sub-schemas	Nested schemas	Flattens the selected schema and all sub-schemas into the parent schema in the query output. Unnested schemas and sub-schemas do not appear in the succeeding transform or target; only the columns appear. Unnested schemas and sub-schemas appear in the Query transform output schema area as table icons with a black arrow that points to the left.
Primary Key	Columns	Toggles the primary key attribute of the column on (check mark appears next to the command) or off (no check mark appears next to the command). A key icon indicates that a column is a primary key.
Optional	Schemas	Toggles to make a schema optional.
Generate DTD		Generates a DTD format that corresponds to the structure of the selected schema (either NRDM or relational). Generates all data types as varchar.
Generate XML Schema		Generates an XML Schema that corresponds to the structure of the selected schema (either NRDM or relational). All data types match those of the selected schema.
Create File Format		Creates a file format from a relational table schema. All data types match those of the original table schema.
Properties	All	Displays the properties of the selected element.

Related Information

Query transform output schema [page 1445]

3.5.5.4.8 Options

The options area of the Query Editor contains several tabs where you enter information to specify the data you want retrieved. Specifying information on these tabs is similar to specifying a SQL SELECT statement. Tabs containing entries are flagged by a special ℹ icon.

When you drag and drop (or copy and paste) input columns to the output schema, Data Services inserts values in the Mapping and FROM tabs. For simple mappings, this is often sufficient.

For more complex mappings, complete the appropriate tabs.

Table 173: Query Editor tab descriptions

Tab	Description
Mapping	Specifies how the selected output column will be derived (or mapped).
SELECT	Specifies distinct rows to output (discarding any identical duplicate rows).
FROM	Lists all input schemas. Allows you to specify join pairs and join conditions as well as enter join rank and cache for each input schema. The resulting SQL FROM clause is displayed.

WHERE	Specifies conditions that determine which rows are output.
	Enter the conditions in SQL syntax, like a WHERE clause in a SQL SELECT statement. For example:
	`TABLE1.EMPNO = TABLE2.EMPNO`
	`AND TABLE1.EMPNO > 1000`
	`OR TABLE2.EMPNO < 9000`
	Use the *Functions*, *Domains*, and *smart editor* buttons for help building expressions.

GROUP BY	Specifies how the output rows are combined (if required).
ORDER BY	Specifies how the output rows are sorted (if required).
Advanced	Creates separate sub data flows to process resource-intensive query clauses.
Find	Enables you to search for a specific word or term in the input and/or output schemas.

Note

Use the SELECT through ORDER BY tabs to specify additional constraints for the current schema, similar to SQL SELECT statement clauses.

Advanced tab [page 1454]
Find tab [page 1455]

3.5.5.4.9 Query Editor tabs

3.5.5.4.9.1 Mapping tab

Use the Mapping tab to specify how the selected output column is derived (or mapped). You can specify any valid expression.

Most commonly, mapping expressions contain table columns and functions.

- Enter input column names or drag columns from the input schema and drop them in the box on the Mapping tab.
- Insert functions by entering them directly, using the smart editor, or by clicking the Functions button to open the function wizard.

> Note
>
> You cannot add comments to a mapping clause in a Query transform. For example, the following syntax is not supported in the Mapping tab:

```
table.column # comment
```

If you add comments, the job will not run and you cannot successfully export it. Use the object description or workspace annotation feature instead.

After you map your source to the Query transform, you might determine that you need to use another transform before you send the data to the Query transform. For example, you might add a validation transform to ensure that only data with a certain format is passed or you might add a Case transform to send only a subset of the data.

In general, when you change an input schema to the Query transform, the Designer checks the existing top-level mappings to determine if any remapping is required.

- If the mapping contains a column with a table name that is not a current input schema name and the column is in the new input schema, the Designer automatically replaces the table name with the new input schema name. Specifically, the Designer automatically updates the input schema name for each matching column in the following option tabs of the Query editor:
  - Mapping
  - FROM
  - WHERE
  - ORDER BY
  - GROUP BY
- If the mapping contains a column that was in the obsolete table, but the column does not exist in the new input schema, you must either remove the column or remap it from the original source.

The Designer does not automatically remap the input schema for the following situations:

- When you connect a new source to the Query transform before you disconnect the old source. You must click the *Schema Remapping* button on the Mapping tab to update the input schema name for columns in the Mapping, WHERE, GROUP BY, and ORDER BY tabs.
- When the source is a nested schema and you either change the source to a similar nested schema, or you add or delete a transform before the Query transform. Click the *Schema Remapping* button to update the Mapping input schema name.

3.5.5.4.9.1.1 To remap when automatic remapping was not done in the Query transform

1. In the Mapping tab, click the *Schema Remapping* button. The *Replace Obsolete Schema window* opens.
2. In the *Specify obsolete schema* drop-down list, choose the source schema that you disconnected from the Query transform.
   This list displays only the top-level input schema. For an obsolete nested schema, enter the name of the top-level schema.
3. In the *Choose correct schema* list, choose the output schema of the transform that you added between the source and Query transform.
4. Click *Remap*. A message displays the number of columns that were remapped; for example:

```
Schema "ODS_SALESORDER" was replaced by schema "Validation_Pass" in 11 column
names.
```

3.5.5.4.9.2 SELECT tab

Use the SELECT tab to output only distinct rows (discarding any identical duplicate rows).

To discard duplicate rows, select the *Distinct rows* check box. This is similar to specifying a SELECT DISTINCT SQL statement.

3.5.5.4.9.3 FROM tab

Use the FROM tab to specify input schemas as well as join information, such as join pairs, join type, and the join condition used in the current output schema. The specified information is similar to the FROM clause in a SQL SELECT statement.

The *FROM* tab is divided into three areas:

- The uppermost area contains information about the source tables connected to the Query transform in the data flow. The Input schemas column is populated with the names of the source tables.
- The middle area, *Join pairs*, allows you to specify the tables to be joined, the type of join, and the join condition.
- The lower area, *FROM clause*, displays the SQL FROM clause and is automatically updated as you add join conditions. This area is read-only, but can be copied to the clipboard.

The following table describes the columns displayed in the *Join pairs* area.

Column name	Description
Left	The left source of a join. For the first join pair, select the input schema from the drop-down list of available schemas. For subsequent join pairs, the result of the previous join pair is taken as the left source and the schema cannot be specified.
Join Type	The type of join. Valid values are Inner join and Left outer join. If a table is not explicitly joined to another table, then it is cross-joined (Cartesian Product) to the result of the final join defined by the join pairs.
Right	The right source of a join. Any input schema not used in a previous join pair.
smart editor ...	Optional: click the icon to open the smart editor. Within the smart editor *Data* tab, you can drag and drop columns to specify the join condition.
Propose Join ◉	Optional: Click *Propose Join* to have Data Services generate a join expression. The SQL clause is automatically updated after you change the left source, right source, or join type.
Join condition	A join condition is required for each join pair. Where possible, Designer automatically suggests a join condition based on the input schemas of the join pair. To edit the join condition, you can enter the join condition field or use the smart editor.

i Note

If your expression contains varchar comparisons, Data Services ignores trailing blanks in the data. For Oracle data, use the rtrim or rpad functions if the number of trailing blanks might differ on either side of the comparison.

3.5.5.4.9.4 WHERE tab

Use the WHERE tab to set conditions that determine which rows are output. Enter the conditions in SQL syntax, as you would a WHERE clause in a SQL SELECT statement. The *Propose* button generates possible join conditions. You can specify the following conditions:

Condition	Example
Data set filters	`TABLE1.EMPNO > 1000`

Multiple conditions using logical operators	`TABLE1.EMPNO > 1000`
	`OR TABLE2.EMPNO < 9000`

Join conditions for inner joins only Note Although it is technically possible to specify inner join conditions in the WHERE tab, the best practice is to specify inner join conditions in the FROM tab.	`TABLE1.EMPNO = TABLE2.EMPNO`

You can specify any valid expression. To enter conditions, do one of the following:

- Enter expressions in the editor.
- Drag columns from the input schema area to the editor.
- Use the Functions button. Use the pushdown_sql function to have Data Services create WHERE clauses dynamically based on data rather than pre-specifying the clause.

Note

If your expression contains varchar comparisons, Data Services ignores trailing blanks in the data. For Oracle data, use the rtrim or rpad functions if the number of trailing blanks might differ on either side of the comparison.

3.5.5.4.9.5 GROUP BY tab

Use the GROUP BY tab to specify a list of columns for which you want to combine output. For each unique set of values in the group by list, Data Services combines or aggregates the values in the remaining columns. For example, you might want to group sales order records by order date to find the total sales ordered on a particular date.

To add a column to the Group By list, select the column in the input schema area and drag it to the box in the *GROUP BY* tab. The Designer adds the column to the bottom of the list.

The first column listed is used for primary grouping, the second column listed is used for secondary grouping, and so forth. To change the groupings, use one of the following options:

- Right-click the column and select *Move Up* or *Move Down*.
- Select the column and click the down or up arrow in the top right corner of the GROUP BY tab.

To remove a column, use one of the following options:

- Right-click the column and select *Delete*.
- Select the column and click the delete icon in the top right corner of the GROUP BY tab.

To group by complex expressions (instead of by specific column values), use another query to produce a single column containing the grouping expression. Insert the new query immediately before this transform in your data flow, and specify the created column on the GROUP BY tab.

If you specify a group by list, then all columns in the output schema must be either in the group by list or mapped to an aggregate function, such as avg, count, max, min, or sum.

This tab is similar to the GROUP BY clause in a SQL SELECT statement.

3.5.5.4.9.6 ORDER BY tab

Use the ORDER BY tab to specify the columns you want used to sort the output data set. To add a column, select the column in the input schema area and drag it to the box on the ORDER BY tab. The Designer adds the column to the bottom of the list.

The first column listed is used for primary sorting, the second column listed is used for secondary sorting, and so forth. To change the column order, use one of the following options:

- Right-click the column and select *Move Up* or *Move Down*.
- Select the column and click the down or up arrow in the top right corner of the *ORDER BY* tab.

To remove a column, use one of the following options:

- Right-click the column and select *Delete*.
- Select the column and click the delete icon in the top right corner of the *ORDER BY* tab.

The default sort order is ascending. To change the order, select *Ascending* or *Descending* from the adjacent drop down box.

3.5.5.4.9.7 Advanced tab

Use the Advanced tab to set up Data Services so that it creates separate sub data flows. Sub data flows process any of the following resource-intensive query clauses:

- DISTINCT
- GROUP BY
- JOIN
- ORDER BY

pushdown_sql [page 1640]

3.5.5.4.9.8 Find tab

Use the Find tab to search for a specific word or term in the input schema or the output schema.

Related Information

To search in an input or output schema [page 1442]

3.5.5.4.10 Joins in the Query transform

You can use the Query editor to define joins involving two or more tables. Specifying information on the FROM and WHERE tabs has the effect of creating FROM and WHERE clauses in a SQL SELECT statement. Supported join types are inner join, left outer join, and cross-product.

Begin by specifying join pairs and join conditions in the FROM tab. As needed, restrict the result set in either the FROM or WHERE tab depending on the information that you need the query to return.

> Note
>
> The best practice is to define all joins in the FROM tab. However, inner joins can be defined in the WHERE tab using a WHERE clause.

For each pair of sources, the generated join proposal includes a join condition based on column names, foreign keys, or primary keys:

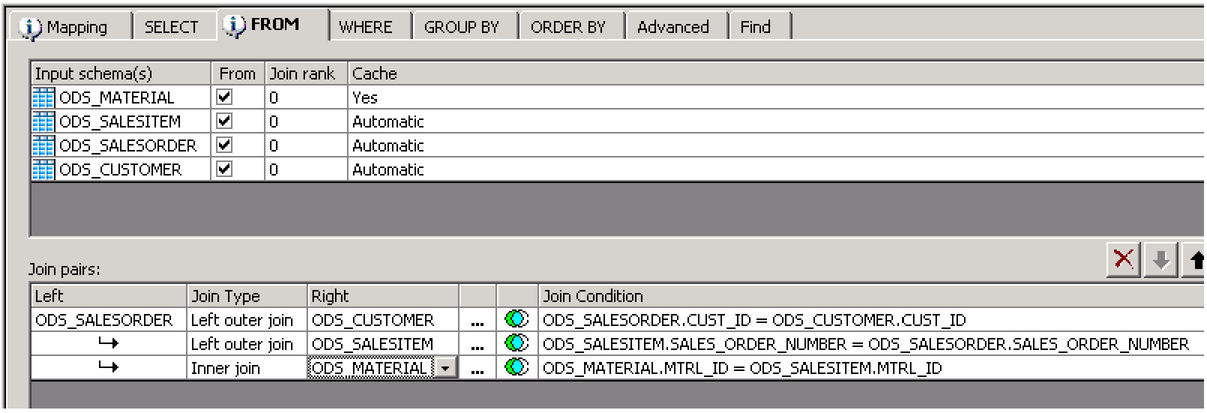
- Foreign key: If a foreign key relationship exists, Data Services adds a join condition to the expression for the columns related through keys. For example, if foreign key K2 of table T2 references primary key K1 of table T1, Data Services includes the join condition: T1.K1=T2.K2
- Primary key and column name: If a foreign key relationship does not exist, Data Services adds a join condition to the expression for columns with the same name where at least one column is part of a primary key. For example, suppose there is no foreign key relationship between tables T and S; however, both tables contain column A. Column A is part of the primary key in table S. In this example, Data Services includes the join condition: T.A = S.A

If neither foreign key nor primary key is satisfied, Data Services proposes no join condition for that pair of sources.

3.5.5.4.10.1 About join pair lists

The FROM tab allows you to create a SQL FROM clause by specifying join pair information including the tables to join, join type, and join condition. Join pairs are subject to the following requirements:

- In order to be used in a join pair, a table must be an input schema to the query.
- Inner joins and left outer joins can be specified in the same FROM clause.
- Any table from the schema list can be used as a source in at most one join pair. If a table is not explicitly joined to another table, then it will be cross-joined (Cartesian product) to the result of the final join defined by the join pairs list. A cross join (Cartesian product) is a special case of an inner join with an ON condition that always evaluates to TRUE. In other words, a cross join matches every row of one table with every row of another table.
- The join pairs list may be empty in the following cases:
  - the input schema for the query contains only one source.
  - each of the input schemas are intended to be cross-joined.
  - inner joins are defined using a WHERE clause in the WHERE tab.
- Identify a left source only for the first pair in the *Join pairs* list. All subsequent join pairs take the results of the preceding join pair as the left source.
  For example, in the following screenshot, the first join pair is a left outer join with ODS_SALESORDER as the left source and ODS_CUSTOMER as the right source. The result of that join becomes the left source of the second join pair which is a left outer join with ODS_SALESITEM as the right source. Finally the result of the two left joins becomes the left source of an inner join with ODS_MATERIAL as the right source.



Input schema(s)	From	Join rank	Cache
ODS_MATERIAL	☑	0	Yes
ODS_SALESITEM	☑	0	Automatic
ODS_SALESORDER	☑	0	Automatic
ODS_CUSTOMER	☑	0	Automatic

Join pairs:

Left	Join Type	Right			Join Condition
ODS_SALESORDER	Left outer join	ODS_CUSTOMER	...		ODS_SALESORDER.CUST_ID = ODS_CUSTOMER.CUST_ID
↳	Left outer join	ODS_SALESITEM	...		ODS_SALESITEM.SALES_ORDER_NUMBER = ODS_SALESORDER.SALES_ORDER_NUMBER
↳	Inner join	ODS_MATERIAL	...		ODS_MATERIAL.MTRL_ID = ODS_SALESITEM.MTRL_ID

- The join condition of a join pair cannot be empty and must refer to tables that are used in previous join pairs and the table used in the current join pair.
  For example, the second join pair in the screenshot above may not refer to the table ODS_MATERIAL in its join condition because ODS_MATERIAL was not used in the previous join pair. The second join pair may only refer to ODS_SALESORDER, ODS_CUSTOMER, and ODS_SALESITEM.
- If the Query transform contains only inner joins, the WHERE tab may be used to specify join conditions. However, although valid, specifying join conditions in both the FROM tab and WHERE tab is not recommended. If conditions are specified in both the WHERE and FROM tabs, they are combined to form the join conditions for the query at job execution time.
- If a query contains a left outer join, any conditions specified in the WHERE tab are treated as filters. The join conditions for a left outer join may include multiple tables and are defined in the FROM tab.
- A Query transform in an ABAP data flow cannot contain mixed inner and left outer joins. The Query transform may have only inner joins, only left outer joins, or no joins at all.

3.5.5.4.10.2 Constructing a Join Query

You can use the Query editor to specify joins involving two or more tables. The resulting SQL join types may be inner join, left outer join, or cross product.

To construct a join query:

1. Within a data flow, connect the source tables to a Query transform.
2. Click the Query transform to open the Query editor.
3. Optionally, exclude input schemas by deselecting the *FROM* checkbox in uppermost area.

   You may want to exclude an input schema if you no longer need its columns in the output schema, ORDER BY, and GROUP BY clauses.

   It also may be useful to exclude nested input schemas. However, at least two input schemas must be selected in order to create a join.
4. In the lower pane of the Query editor, click the *FROM* tab.
5. Specify the join pairs and join conditions.

   After the first join pair is specified, subsequent join pairs use the result of the previous pair as the left source. The following table describes the columns displayed in the *Join pairs* area.

Column name	Description
Left	The left source of a join. For the first join pair, select the input schema from the drop-down list of available schemas. For subsequent join pairs, the result of the previous join pair is taken as the left source and the schema cannot be specified.
Join type	The type of join. Valid values are Inner join and Left outer join. If a table is not explicitly joined to another table, then it will be cross-joined (Cartesian Product) to the result of the final join defined by the join pairs.
Right	The right source of a join. Any input schema not used in a previous join pair.
smart editor ...	Optional: click the icon to open the smart editor. Within the smart editor *Data* tab, you can drag and drop columns to specify the join condition.
Propose Join	Optional: Click *Propose Join* to have Data Services generate a join expression. The SQL clause is automatically updated after you change the left source, right source, or join type.
Join condition	A join condition is required for each join pair.

Column name	Description
	Where possible, Designer automatically suggests a join condition based on the input schemas of the join pair. To enter or edit the join condition, you can type in the join condition field or use the smart editor.

If your FROM clause contains only left outer joins or a mix of left outer joins and inner joins, you may want to change the order that the software executes the join pairs. To change the order, select a cell within a join pair row and then click the up arrow or down arrow in the upper right corner of the *Join pairs* area. Note that changing the execution order of the join pairs changes the results.

If your FROM clause contains only inner joins, changing the execution order does not change the results.

6. As necessary, to filter the result set of a left outer join, place a restriction in the ON clause or within the WHERE tab.
7. Optionally, specify the join ranks for each table in the *Join rank* column.

   The join rank indicates the rank of the source relative to other tables and files in the data flow. The join rank has no effect on the actual result produced, but can have a profound effect on join performance. The software joins sources with higher join ranks before it joins sources with lower join ranks. The order of execution depends on join rank and, for left outer joins, the order defined in the FROM clause.

   The join rank must be a non-negative integer. When set to its default value of 0, the software determines the join order. The join rank specified in the Query editor overrides any join rank specified in a source. For new jobs, specify the join rank in the Query editor.
8. As necessary, specify desired caching in the *Cache* column.

   Cache indicates whether the software should read the data from the source and load it into memory or pageable cache. Caching a source increases performance only when the data source is used as the right source of a join.

   The cache value in the Query transform takes precedence over the value specified in a source. For newly created data flows, it is preferable to specify the cache value in the Query transform.

   The default value in the Query transform is *Automatic*. Automatic assumes the value specified in the source.

   > Note
   >
   > The cache type, either in-memory or pageable, is set at the data flow level.

3.5.5.4.10.3 Join Examples

3.5.5.4.10.3.1 Joins using two sources

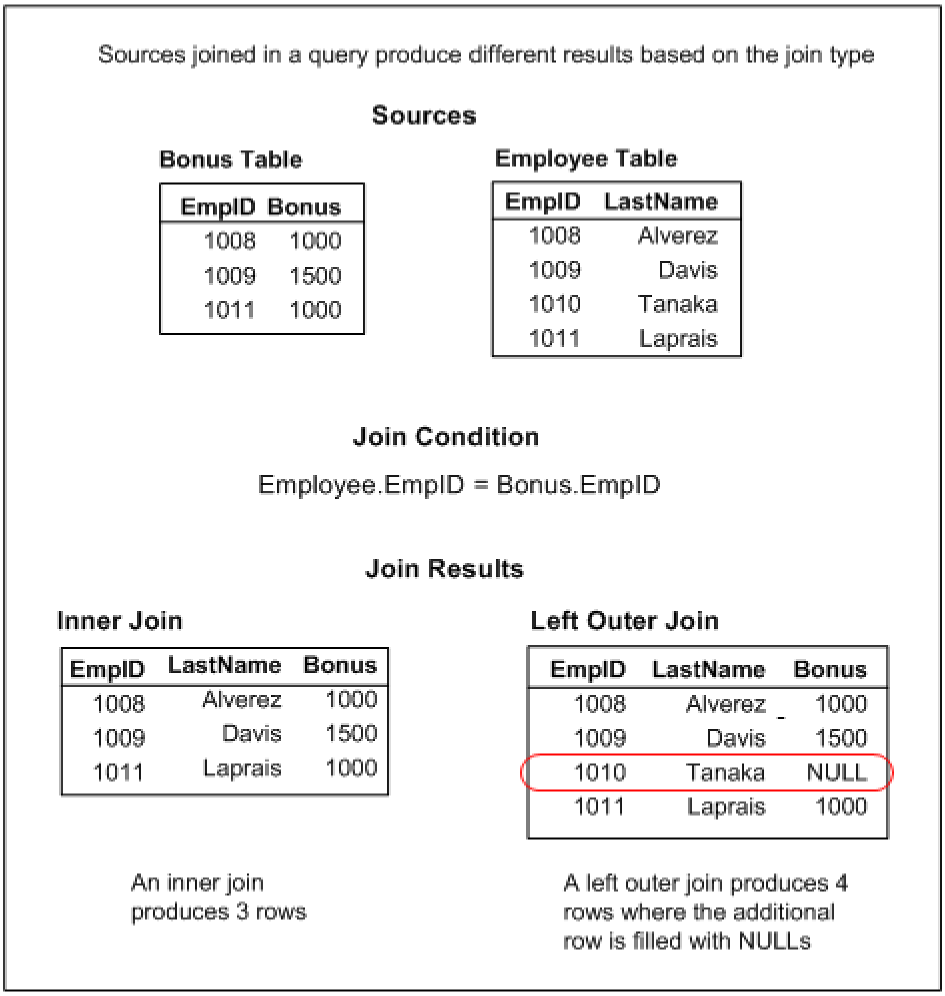
About inner and left outer joins

Sources joined in a Query transform produce different results based on the join type.

When joining two sources, an inner join returns rows from both sources where a match is found.

A left outer join returns the rows that meet the join condition, plus all of the rows in the left source that did not meet the join condition. Therefore, all rows in the left source are reproduced at least once in the result. Only data from the right source that satisfies the join condition appears in the result.

For rows from the left table that do not have corresponding data from the inner table, the missing values are assigned as null. In an inner join between the tables, the same rows would be absent in the result. The following diagram shows the difference in the join results for the sample data in the illustration:



Sources joined in a query produce different results based on the join type

Sources

Bonus Table

EmpID	Bonus
1008	1000
1009	1500
1011	1000

Employee Table

EmpID	LastName
1008	Alverez
1009	Davis
1010	Tanaka
1011	Laprais

Join Condition

Employee.EmpID = Bonus.EmpID

Join Results

Inner Join

EmpID	LastName	Bonus
1008	Alverez	1000
1009	Davis	1500
1011	Laprais	1000

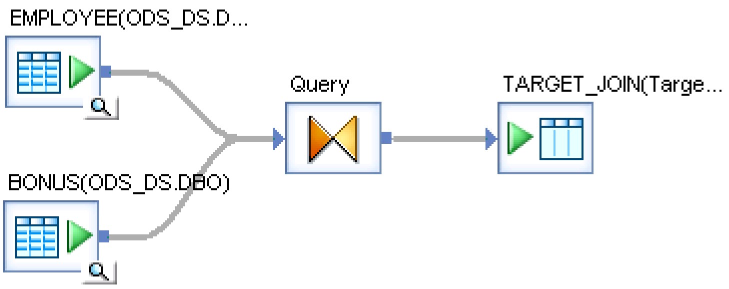
Left Outer Join

EmpID	LastName	Bonus
1008	Alverez	1000
1009	Davis	1500
1010	Tanaka	NULL
1011	Laprais	1000

An inner join produces 3 rows

A left outer join produces 4 rows where the additional row is filled with NULLs

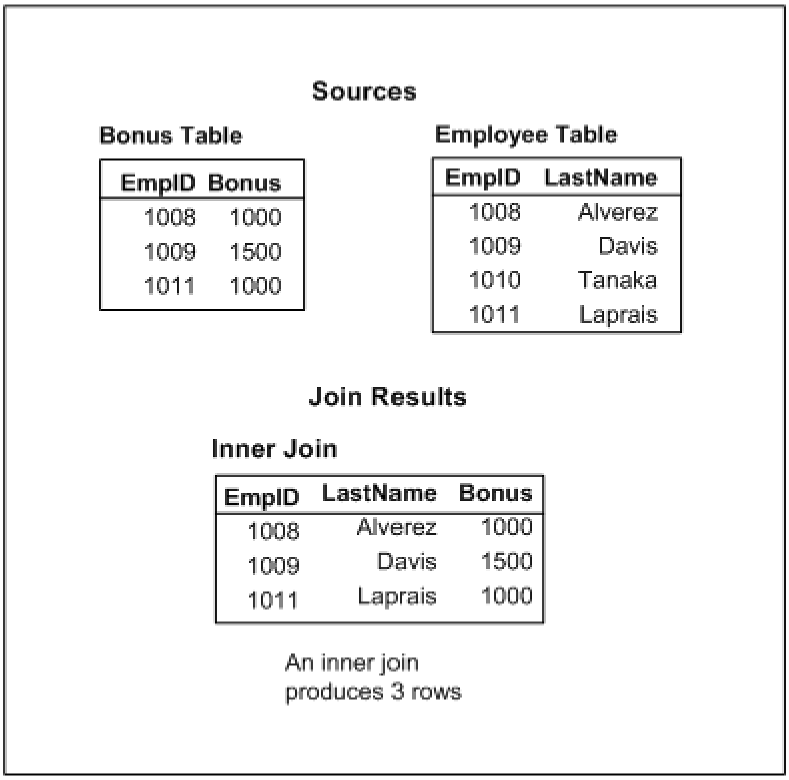
In Data Services, the two tables in the data flow would be sources to a Query transform and the join results would appear in the target table as shown below.



Inner join example

To produce a list of only the employees receiving bonuses, the data in the Employee Table and Bonus Table sources below are joined using an inner join to produce three rows where each row contains values from both sources.

The outer table is `Employee` and the inner table is `Bonus`.



Sources

Bonus Table

EmpID	Bonus
1008	1000
1009	1500
1011	1000

Employee Table

EmpID	LastName
1008	Alverez
1009	Davis
1010	Tanaka
1011	Laprais

Join Results

Inner Join

EmpID	LastName	Bonus
1008	Alverez	1000
1009	Davis	1500
1011	Laprais	1000

An inner join
produces 3 rows

The syntax of the SQL is:

```
SELECT     EMPLOYEE.EMPID, EMPLOYEE.LASTNAME,
BONUS.BONUS
FROM EMPLOYEE INNER JOIN BONUS
ON      (EMPLOYEE.EMPID = BONUS.EMPID)
```

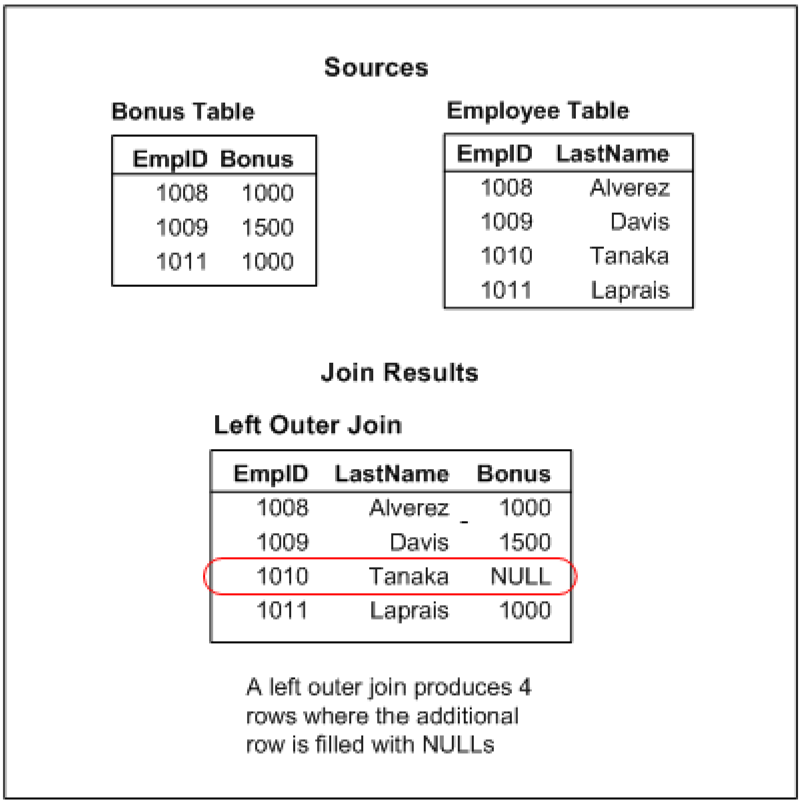
Use the Query editor *FROM* tab to define the Join pairs list as follows:

Left	`Employee`
Join Type	Inner join
Right	`Bonus`
Join Condition	`EMPLOYEE.EMPID = BONUS.EMPID`

Left outer join example

To produce a list of all employees and show which are receiving bonuses the data in the Employee Table and Bonus Table sources below are joined with a left outer join to produce four rows where the extra row contains a NULL.

The outer table is `Employee` and the inner table is `Bonus`.



Sources

Bonus Table

EmpID	Bonus
1008	1000
1009	1500
1011	1000

Employee Table

EmpID	LastName
1008	Alverez
1009	Davis
1010	Tanaka
1011	Laprais

Join Results

Left Outer Join

EmpID	LastName	Bonus
1008	Alverez	1000
1009	Davis	1500
1010	Tanaka	NULL
1011	Laprais	1000

A left outer join produces 4 rows where the additional row is filled with NULLs

The SQL query is:

```
SELECT     EMPLOYEE.EMPID, EMPLOYEE.LASTNAME,
BONUS.BONUS
```

```
FROM EMPLOYEE LEFT OUTER JOIN BONUS
ON      (EMPLOYEE.EMPID = BONUS.EMPID)
```

Use the Query editor *FROM* tab to define the Join pairs list as follows:

Left	`Employee`
Join Type	Left outer join
Right	`Bonus`
Join Condition	`EMPLOYEE.EMPID = BONUS.EMPID`

3.5.5.4.10.3.2 Mixed inner and left outer joins

When joining more than two tables in the Query editor, a left source is identified in the first pair of tables in the *Join pairs* list. All subsequent join pairs take the results of the preceding join pair as the left source.

Mixed joins example

The example below illustrates how sequential joins can produce a result showing all of the departments that have employees and the employees' bonuses. In this case, the Department table would be the left source and the Employee table would be the right source of an inner join. The results of that inner join would then be joined to the Bonus table using a left outer join The results of the inner join would be the left source and the Bonus table would be the right source.

The joins produce four rows with the bonus information NULL where there was no value in the bonus table.

Sources:

Department table		Employee table			Bonus table	
DeptID	**Department**	**EmpID**	**LastName**	**DeptID**	**EmpID**	**Bonus**
01	Accounting	1008	Alverez	01	1008	1000
02	Finance	1009	Davis	02	1009	1500
03	Sales	1010	Tanaka	01	1011	1000
04	Marketing	1011	Laprais	01		

Join Results:

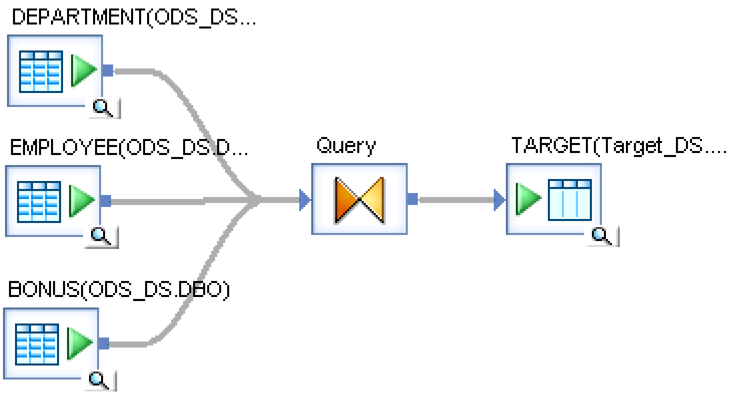
DeptID	Department	LastName	Bonus
1	Accounting	Alverez	1000
1	Accounting	Tanaka	NULL
1	Accounting	Laprais	1000

DeptID	Department	LastName	Bonus
2	Finance	Davis	1500

The SQL query is:

```
SELECT     DEPARTMENT.DEPTID, DEPARTMENT.DEPARTMENT,
  EMPLOYEE.LASTNAME, BONUS.BONUS
FROM (DEPARTMENT INNER JOIN EMPLOYEE
(ON DEPARTMENT.DEPTID=EMPLOYEE.DEPTID))
LEFT OUTER JOIN BONUS
ON      (EMPLOYEE.EMPID = BONUS.EMPID)
```

In Data Services, the three tables in the data flow would be sources to a Query transform and the join results would appear in the target table as shown below.



Use the Query editor *FROM* tab to define the Join pairs list as follows:

Left	Join Type	Right	Join Condition
DEPARTMENT	Inner join	EMPLOYEE	DEPARTMENT.DEPTID=EMPLOYEE.DEPTID
—»	Left outer join	BONUS	EMPLOYEE.EMPID=BONUS.EMPID

3.5.5.4.10.3.3 Restricting left outer joins

About restricting left outer joins

An unrestricted left outer join between two tables results in all of the rows from the left outer table along with data from the inner table that satisfies the join condition. NULL values are assigned in rows that do not contain data.

The result set for a left outer join that is restricted depends on whether the restriction is placed in the ON condition or in the WHERE clause. Where you place the restriction ultimately depends on what information you need the query to return. The following table shows the result set defined in each case and how to define the query in the Query editor.

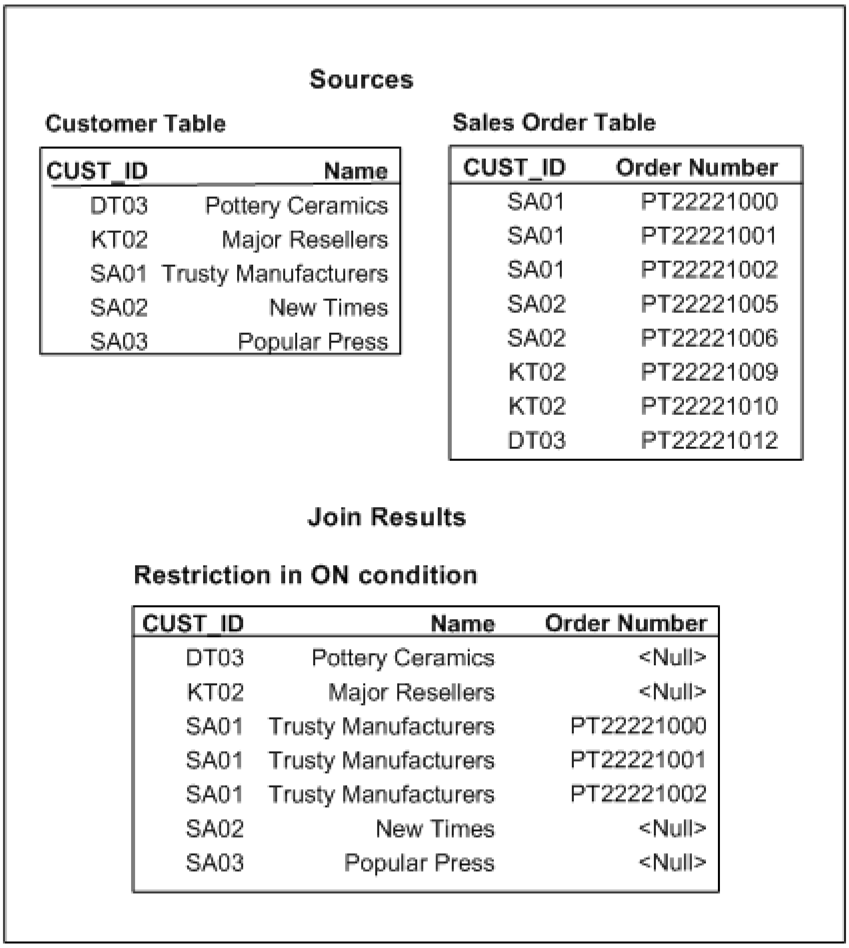
Result set	Restriction	Query editor tab to use
Joined table includes all rows of the left source (including null values).	ON	FROM
Joined table includes only rows for which the restriction is true.	WHERE	WHERE

i Note

For inner joins, it does not matter where the restriction is placed; the result set is the same in either case.

Restriction placed in the ON condition example

For example, assume CUSTOMER is the left source and SALESORDER is the right source of a left outer join. The diagram below shows data in the source tables and the results of a left outer with the restriction placed in the ON condition.



Sources

Customer Table

CUST_ID	Name
DT03	Pottery Ceramics
KT02	Major Resellers
SA01	Trusty Manufacturers
SA02	New Times
SA03	Popular Press

Sales Order Table

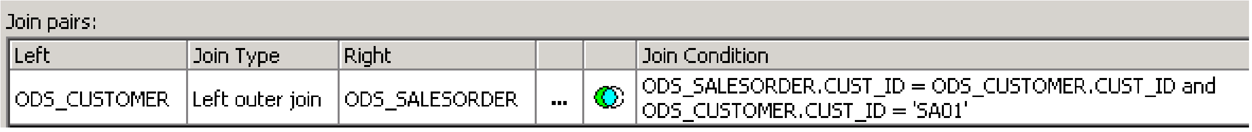
CUST_ID	Order Number
SA01	PT22221000
SA01	PT22221001
SA01	PT22221002
SA02	PT22221005
SA02	PT22221006
KT02	PT22221009
KT02	PT22221010
DT03	PT22221012

Join Results

Restriction in ON condition

CUST_ID	Name	Order Number
DT03	Pottery Ceramics	<Null>
KT02	Major Resellers	<Null>
SA01	Trusty Manufacturers	PT22221000
SA01	Trusty Manufacturers	PT22221001
SA01	Trusty Manufacturers	PT22221002
SA02	New Times	<Null>
SA03	Popular Press	<Null>

The join condition specified in the FROM clause contains the clause `AND CUSTOMER.CUST_ID = 'SA01'` and the result returns all rows of the left source, CUSTOMER, including those rows with NULL values. The Join pairs area of the FROM tab would appear as follows:



Join pairs:

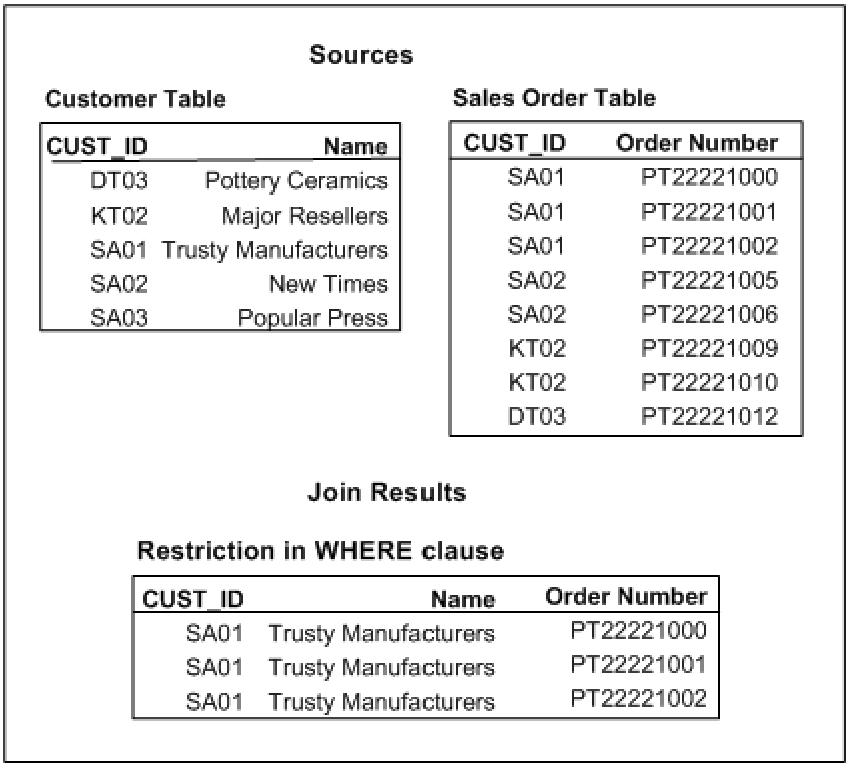
Left	Join Type	Right			Join Condition
ODS_CUSTOMER	Left outer join	ODS_SALESORDER	...		ODS_SALESORDER.CUST_ID = ODS_CUSTOMER.CUST_ID and ODS_CUSTOMER.CUST_ID = 'SA01'

The SQL query is:

```
SELECT ODS_CUSTOMER.CUST_ID, ODS_CUSTOMER.NAME1,
 ODS_SALESORDER.SALES_ORDER_NUMBER
FROM DBO.ODS_CUSTOMER ODS_CUSTOMER LEFT OUTER JOIN
 DBO.ODS_SALESORDER ODS_SALESORDER
ON (ODS_SALESORDER.CUST_ID=ODS_CUSTOMER.CUST_ID)
AND (ODS_CUSTOMER.CUST_ID = 'SA01')
```

Restriction placed in the WHERE clause example

Referring again to the example of CUSTOMER as the left source and SALESORDER as the right source of a left outer join, if the restriction `CUSTOMER.CUST_ID = 'SA01'` is placed in the WHERE clause, the result of a left outer join returns only the rows for which the restriction is true. The data in the source tables and results of the join are shown in the diagram below.



Sources

Customer Table

CUST_ID	Name
DT03	Pottery Ceramics
KT02	Major Resellers
SA01	Trusty Manufacturers
SA02	New Times
SA03	Popular Press

Sales Order Table

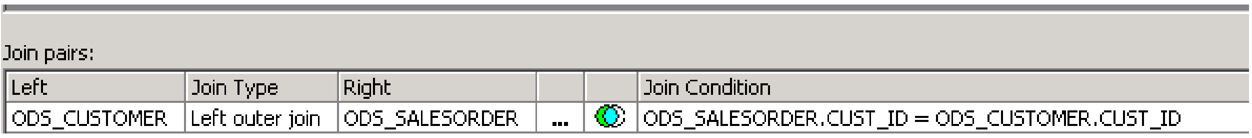
CUST_ID	Order Number
SA01	PT22221000
SA01	PT22221001
SA01	PT22221002
SA02	PT22221005
SA02	PT22221006
KT02	PT22221009
KT02	PT22221010
DT03	PT22221012

Join Results

Restriction in WHERE clause

CUST_ID	Name	Order Number
SA01	Trusty Manufacturers	PT22221000
SA01	Trusty Manufacturers	PT22221001
SA01	Trusty Manufacturers	PT22221002

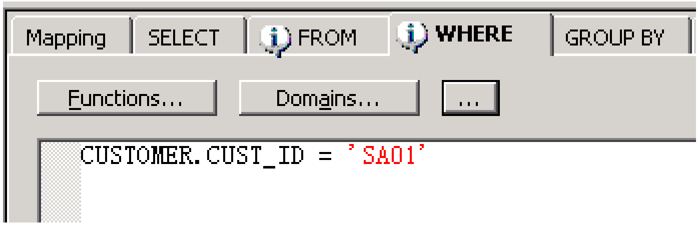
The Join pairs area of the FROM tab would appear as follows:



Join pairs:

Left	Join Type	Right			Join Condition
ODS_CUSTOMER	Left outer join	ODS_SALESORDER	...	◐	ODS_SALESORDER.CUST_ID = ODS_CUSTOMER.CUST_ID

and the WHERE tab would contain the restriction:



```
CUSTOMER.CUST_ID = 'SA01'
```

The SQL query is:

```
SELECT ODS_CUSTOMER.CUST_ID, ODS_CUSTOMER.NAME1,
 ODS_SALESORDER.SALES_ORDER_NUMBER
FROM DBO.ODS_CUSTOMER ODS_CUSTOMER LEFT OUTER JOIN
 DBO.ODS_SALESORDER ODS_SALESORDER
ON (ODS_SALESORDER.CUST_ID=ODS_CUSTOMER.CUST_ID)
WHERE (ODS_CUSTOMER.CUST_ID = 'SA01')
```

3.5.5.4.10.4 Viewing Optimized SQL

Before running a job, you can view the SQL code that SAP Data Services generates for table sources in data flows. By examining the SQL code, you can verify that the software generates the commands you expect. If necessary, you can alter your design to improve the data flow.

To view the SQL code:

1. Validate and save data flows.
2. Open a data flow in the workspace.
3. Select *Display Optimized SQL* from the *Validation* menu.

   Alternately, you can right-click a data flow in the object library and select *Display Optimized SQL*.

   The *Optimized SQL* window opens and shows a list of datastores and the optimized SQL code for the selected datastore. By default, the *Optimized SQL* window selects the first datastore.

   The software only shows the SELECT generated for table sources and INSERT INTO... SELECT for targets. It does not show the SQL generated for SQL sources that are not table sources, such as:

   - Lookup function
   - Key_generation function
   - Key_Generation transform
   - Table_Comparison transform

4. Select a name from the list of datastores on the left to view the SQL that this data flow applies against the corresponding database or application.

> **Note**
>
> The *Optimized SQL* window displays the existing SQL statement in the repository. If you changed your data flow, save it so that the *Optimized SQL* window displays your current SQL statement.

3.5.5.4.10.5 Outer join compared to the Lookup function

You can produce a similar data set using the lookup function. However, the lookup function is limited to the following actions:

Lookup function	Left Outer join
Returns only one column value for each comparison	Returns all column values for each comparison
Can be used against only one source at a time	Provides similar capability to multiple lookup calls
Cannot be used to produce the same results as non-equality joins (for example, `A.x<B.y`)	Allows non-equality joins
Permits default values other than nulls	
Can be cached when desired	

In addition, sources in an outer join query must be joined in a hierarchical order:

- A source can only be the inner table of one outer join
- A source cannot be "outer joined" with itself in a single Query transform

3.5.5.5 Row_Generation

Produces a data set with a single column. The column values start with the number that you set in the *Row number starts at* option. The value then increments by one to a specified number of rows.

3.5.5.5.1 Data inputs

None.

3.5.5.5.2 Editor

The Row_Generation transform editor includes the target schema, and transform options.

3.5.5.5.3 Options

Option	Description
Cache	Indicates whether the software should read the required data from the source and load it into memory or pageable cache. Because an inner source of a join must be read for each row of an outer source, you might want to cache a source when it is used as an inner source in a join. Options are: ● *Yes*: The source is always cached unless it is the outer-most source in a join. ● *No*: The source is never cached. The default is *Yes*. Cache specified in the Query transform editor FROM tab overrides any cache specified in a source. For new jobs, specify the cache only in the Query transform editor.
Join rank	Indicates the rank of the output data set relative to other tables and files joined in a data flow. The software joins sources with higher join ranks before joining sources with lower join ranks. Join rank specified in the Query transform editor FROM tab overrides any join rank specified in a source. For new jobs, specify the join rank only in the Query transform editor. Must be a non-negative integer. Default value is 0.
Row count	A positive integer indicating the number of rows in the output data set. For added flexibility, you can enter a global variable or substitution parameter.
Row number starts at	An integer with which row numbering starts. If you set this option to 1, the first row will be labeled 1, the second row will be labeled 2, and so on. If you leave this blank, numbering will start at zero (0). For added flexibility, you can enter a global variable or substitution parameter.

3.5.5.5.4 Data outputs

The Row_Generation transform produces a data set with a single column and the number of rows specified in the *Row count* option. The rows contain integer values in sequence starting from the value that you entered in the *Row number starts at* option, and incrementing by one in each row.

3.5.5.6 SQL

Performs the indicated SQL query operation.

Use this transform to perform standard SQL operations when other built-in transforms cannot perform them.

The options for the SQL transform include specifying a datastore, join rank, cache, array fetch size, and entering SQL text.

> Note
>
> The SQL transform supports a single `SELECT` statement only.

3.5.5.6.1 Data inputs

None. This transform does not allow an input data set.

3.5.5.6.2 Options

Option	Description
Array fetch size	Indicates the number of rows retrieved in a single request to a source database. The default value is 1000. Higher numbers reduce requests, lowering network traffic, and possibly improve performance. The maximum value is 5000. This option is available for source tables from DB2, Informix, ODBC, Oracle, and SQL Server datastores. When retrieving a column with an Oracle long data type, Data Services automatically sets Array Fetch Size to 1. If a column has an Oracle long data type, Data Services can only retrieve one row at a time.

Option	Description
Cache	Indicates whether the software should load output from the transform into memory or pageable cache. Because an inner source of a join must be read for each row of an outer source, you might want to cache output when it is used in a subsequent transform as an inner source in a join. Options are: ● *Yes*: The source is cached. ● *No*: The source is not cached. The default is *Yes*. Cache specified in the Query transform editor FROM tab overrides any cache specified in a previous transform within the data flow. For new jobs, specify the cache only in the Query transform editor.
Database type	Database type and versions available in the selected datastore. The *Database type* box allows you to quickly set SQL transform values in data flows if you have multiple configurations in a datastore. This option also allows you to supply unique SQL text for each database type and version in any SQL transform instance. When you select a database type, Data Services provides the value you set previously for SQL text in that particular database type. To add or remove items in the *Database type* list box, edit the datastore configuration information using the Datastore Editor. The following describes how Data Services determines SQL text values. For more information about the Datastore Editor and its dialogs, see *Datastore editor* [page 861]. ● If the datastore has more than one configuration and there are different database types or versions, then Data Services determines the initial SQL text values for the additional database types and versions from the *Use values from* box in the Create New Configuration dialog box (a sub-dialog of the Datastore Editor). Note Join rank, Cache, and Array fetch size values remain the same as those set in the initial configuration. You cannot have more than one set of these values in a datastore. ● If you also select the *Restore values if they already exist* check box in the Create New Configuration dialog box, Data Services looks for previously defined values that once existed for that database type or version. It is possible for a data flow to contain SQL transform values for a database type or version, even if its datastore configuration was deleted. Data Services retains all SQL transform values saved with every datastore configuration. If such values exist, then Designer restores those values. Otherwise, it gets the values from the configuration you select from the *Use values from* option. If the SQL text in a SQL transform is not correct for the database type, modify the SQL text. If the SQL text has any hard-coded owner names or database names in it, consider replacing them with variables to limit the number of modifications you need for new database types.

Option	Description
	Note Because Data Services only provides values for variables during run time, do not use variables in the SQL text of a SQL transform when you use the *Update Schema* button. To support portability, add variables afterwards.
Datastore	The name of the datastore that Data Services uses to access the tables referred to in *SQL text*.
Join rank	Indicates the rank of the output data set relative to other tables and files joined in a data flow. The software joins sources with higher join ranks before joining sources with lower join ranks. Join rank specified in the Query transform editor FROM tab overrides any join rank specified in a source. For new jobs, specify the join rank only in the Query transform editor. Must be a non-negative integer. Default value is 0.
SQL text	The text of the SQL query. This string is passed to the database server. You do not need to put enclosing quotes around the SQL text. You can put enclosing quotes around the table and column names, if required by the syntax rules of the DBMS involved.
Update schema	Click this option to automatically calculate and populate the output schema for the SQL SELECT statement.

3.5.5.6.3 Data outputs

There are two ways of defining the output schema for a SQL transform:

- Automatic: After you type the SQL statement, click *Update schema* to execute a described select statement against the database which obtains column information returned by the select statement and populates the output schema.
- Manual: Output columns must be defined in the output portion of the SQL transform.
  The number of columns defined in the output of the SQL transform must equal the number of columns returned by the SQL query.
  The column names and data types of the output columns need not match the column names or data types in the SQL query. Data Services conversion rules apply.
  When possible, Data Services optimizes data flows by pushing expressions down to an underlying database manager. In a single transaction, Data Services can push down expressions so that they are performed by the underlying database manager. However, when Data Services evaluates an expression which includes operands of more than one data type, Data Services attempts to convert the operands to the same data type first. (Except for national character-set data types which can be pushed down while others in an expression are not.). Errors are flagged for illegal conversion.
  The output data set cannot contain hierarchical data.

Exercise care when specifying the output columns. Typically the column data types of the two sets of columns should be an exact match. If you choose to have different data types, you need to ensure that they are compatible—if they are not, you will get a runtime error from the underlying database manager.

varchar [page 1038]

3.5.5.7 Validation

The Validation transform qualifies a data set based on rules for input schema columns. You can apply multiple rules per column or bind a single reuseable rule (in the form of a validation function) to multiple columns.

The Validation transform can identify the row, column, or columns for each validation failure. You can also use the Validation transform to filter or replace (substitute) data that fails your criteria.

When you enable a validation rule for a column, a check mark appears next to it in the input schema.

3.5.5.7.1 Validation Rules tab options

Open the Validation transform editor by clicking the name of the transform in your data flow. On the Validation Rules tab, the top pane lists all of available rules and the bottom pane lets you define substitution values for failed rules to send to the Pass output schema.

The following table describes the options for the Validation Rules tab.

Type	Option	Description
Rules buttons	Add	Click to add a new rule. Launches the *Rule Editor* dialog box.
	Edit	Select an existing rule and click to edit the rule. You can also double-click a rule to open the Rule Editor.
	Remove	Select one or more rows and click to delete the rule(s).
Rules columns	Enabled	Select to enable the rule; clear to disable it. ou can also enable or disable a rule in the Rule Editor dialog box.

Type	Option	Description
	Rule	The syntactical name of the rule.
	Ignore if NULL	If set to Yes, Data Services skips (ignores) the rule if any of the associated column values are NULL. You set this option in the Rule Editor.
	Action on Fail	Identifies what action to take when the row fails: send the row to the Fail target, Pass target, or both. If you choose *Send to Pass* or *Send to Both*, you can choose to substitute a value or expression for the failed values that go to the Pass output using the bottom pane of the Validation Rules tab.
	Name	The common name as defined in the *Name* field of the Rule Editor.
	Description	An optional description as defined in the Rule Editor.
If rule(s) fails and send to Pass, substitute:	Remove button	Select one or more rows and click to delete the substitution(s).
	Enabled	Select to enable the substitution; clear to disable it.
	Column	Identifies the column to which the substitution will apply. Double-click the cell to enable the drop-down list.
	Expression	Defines the substitution constant, variable, or function call. Double-click the cell to type in the cell. During job execution, Data Services converts substitute values to a corresponding column data type: integer, decimal, varchar, date, datetime, timestamp, or time.
	Ellipses button	As an alternative to typing a value in the Expression cell, click the ellipses button to launch the Smart Editor, where you can configure variables, substitution parameters, and functions for defining the substitution.

Related Information

Validation Transform Options tab [page 1474]

3.5.5.7.2 Validation Transform Options tab

The Validation Transform Options tab has the following options:

Option		Description
On failure:	Collect data validation statistics	Select this option to generate statistics for columns that failed validation to view in the Data Validation dashboards metadata reports.
	Collect sample data	Select this option to capture sample data for columns that failed validation to view in Data Validation dashboard metadata reports.
Output Rule Violation Information	Create column DI_ROWID on Validation_Fail	Select to include a DI_ROWID column in the Fail output schema (selected by default).

Related Information

Validation Rules tab options [page 1472]

3.5.5.7.3 Rule Editor

You use the Rule Editor to define or edit a validation rule. Launch the Rule Editor from the Validation Rules tab of the Validation transform by clicking *Add* or double-clicking an existing rule to edit it.

The Rule Editor lets you configure a rule either based on an existing validation function or a rule defined in the validation transform that is based on a single column input.

Rules defined with a validation function have the following characteristics:

- Reusable
- Accept multiple input parameters
- Prefereble for more complex rules
- Can be created in SAP Information Steward and imported and used in Data Services

Rules defined with a column validation have the following characteristics:

- Not reusable; the rule definition is part of the transform (not shared outside the transform)
- Binds to only one input column
- Better for simple rules

Also note there are two types of validation functions as categorized in the object library:

- Imported from Information Steward: These functions were created in Information Steward and cannot be edited in Data Services
- Locally created: Created and editable in Data Services

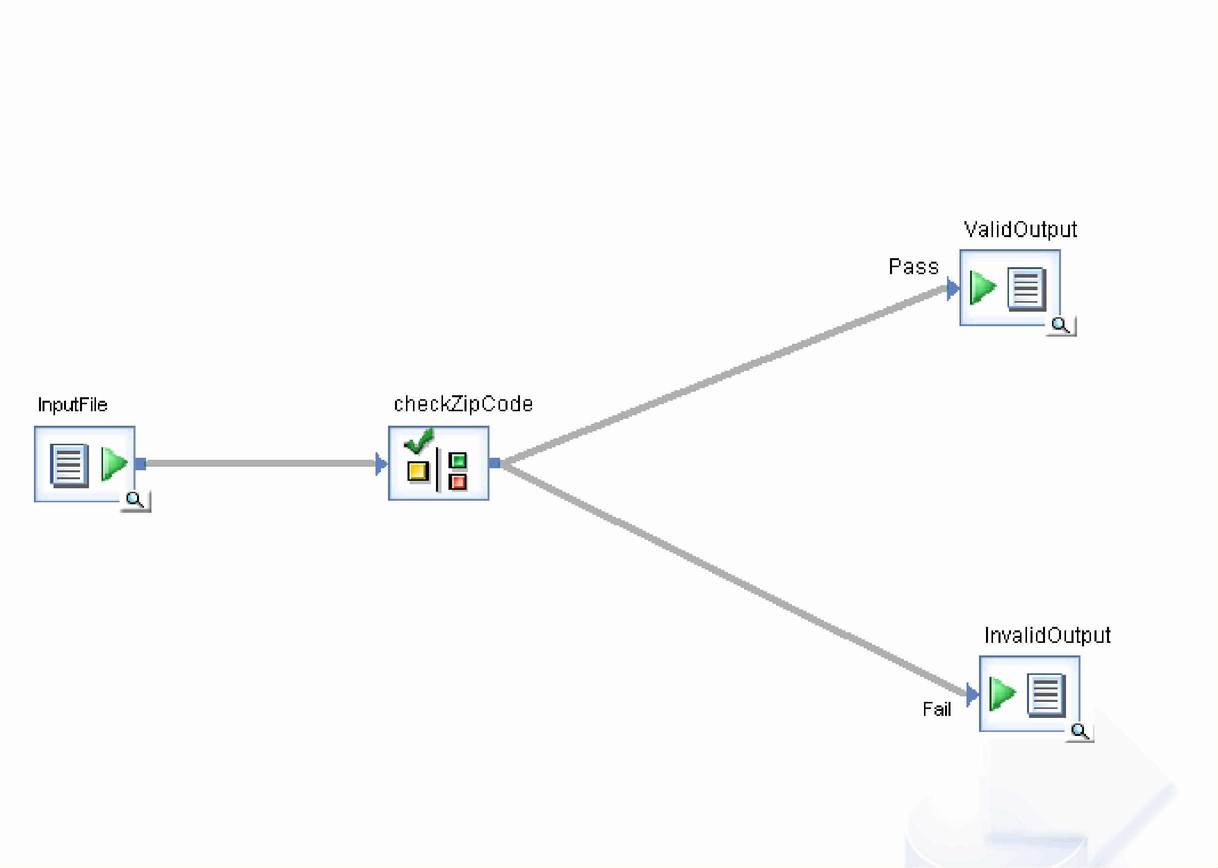
3.5.5.7.3.1 To define a validation rule based on a column

1. In a data flow with the Validation transform connected to an input schema, click the transform name to open its editor.
2. On the Validation Rules tab, click *Add*.
   The Rule Editor displays with the *Enabled* check box selected by default.
3. Type a name for the rule and optionally add a description.
4. Select an *Action on fail*:
   - Send To Fail
   - Send To Pass
   - Send To Both
5. Select *Column Validation*.
6. Select a *Column* from the drop-down list.
7. Define a condition. All conditions must be Boolean expressions. Or, select *Custom Condition* to enable access to the smart editor (ellispses button) or function wizard (*Functions* button).

Example

Defining a validation rule for a five-digit ZIP code pattern

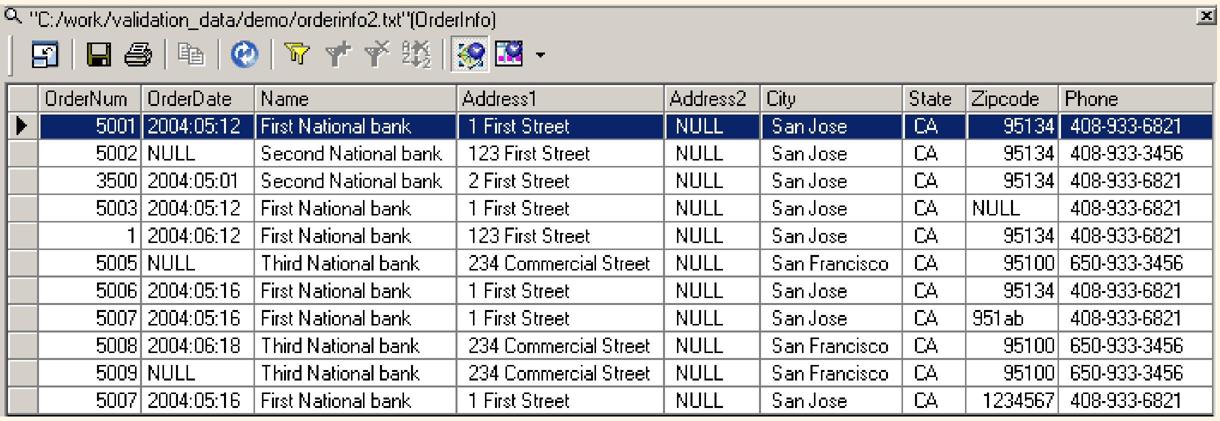
The following example defines a Validation transform that verifies that the data for ZIP code is a five-digit number.



1. Open the Validation transform editor.
2. Click *Add*.
3. Name the rule **checkzip**.
4. For *Action on Fail*, select *Send To Both*.
5. Select *Column Validation*.
6. Select the *Customers.Zipcode* column.
7. Select the *LIKE* condition.
8. Specify the pattern as **99999**, which matches any five-digit number.
9. Click *OK*.
10. On the *Validation Rules* tab, for the option, *If any rule fails and send to Pass, substitute with:* double-click a cell under *Column* and select *Customers.Zipcode*.
11. Double-click in the cell under *Expression* and type **'Invalid'**.

If the zip code does not match the pattern, Data Services replaces the value with the string **Invalid**.

The following graphic shows the input data.



"C:/work/validation_data/demo/orderinfo2.txt"(OrderInfo)

OrderNum	OrderDate	Name	Address1	Address2	City	State	Zipcode	Phone

3.5.5.7.3.2 Defining a validation rule using a custom validation function

This section describes how to first add and define the new custom validation function in the object library, then how to use the function to define a validation rule.

3.5.5.7.3.2.1 To define a custom validation function in the object library

This procedure describes how to add and define the a custom validation function in the object library. The next procedure describes how to use the validation function to define a validation rule.

In this example, the function determines whether the ZIP column contains 5-digit ZIP codes by checking each character and ensuring that each character is a digit. To verify the character is a digit, the function checks to see if its ASCII value is between 48 and 57 inclusive (corresponding to 0 through 9 respectively).

1. From the *Custom Function* tab of the object library, right-click *Validation Functions* and select *New*.
   The *Custom Function* dialog box displays with *Validation function* selected.
2. Enter the name **`ZipIsValid`** for the new function and click *Next*.
   The smart editor displays.
3. To define the parameters and variables for this function, select the *Variables* tab in the smart editor window.
4. Right-click the *Parameters* node and select *Insert*.
5. Enter a parameter name such as **`$ZipToValidate`**.
6. Select the appropriate data type such as *varchar* with a length of **`5`**.
7. For the *Parameter type* select *Input*.

   > i Note
   >
   > Validation functions can have multiple input parameters; additional output parameters are not used.

8. Click *OK*.
   The parameter $ZipToValidate appears under the *Parameters* node.
9. Add five local variables named $Z1 through $Z5, which represent the five characters in the column. Right-click *Local*, select *Insert*, enter the name, select the data type *int*, and click *OK*.

The five variables appear under the *Local* variables node.

10. In the text panel of the smart editor, enter the following validation script:

```
$Z1 = ascii(substr($ZipToValidate, 1, 1));
$Z2 = ascii(substr($ZipToValidate, 2, 1));
$Z3 = ascii(substr($ZipToValidate, 3, 1));
$Z4 = ascii(substr($ZipToValidate, 4, 1));
$Z5 = ascii(substr($ZipToValidate, 5, 1));

if ( $Z1 < 48 OR $Z1 > 57 )
 return 0;
if ( $Z2 < 48 OR $Z2 > 57 )
 return 0;
if ( $Z3 < 48 OR $Z3 > 57 )
 return 0;
if ( $Z4 < 48 OR $Z4 > 57 )
 return 0;
if ( $Z5 < 48 OR $Z5 > 57 )
 return 0;

return 1;
```

> Note
>
> The Validation transform only supports custom functions that return an integer data type. If a return value is not a zero, then Data Services processes it as TRUE.

11. Click *OK*.
    The new function displays in the object library under the *Validation Function* node.

Continue to the next procedure to use the validation function in a validation rule.

3.5.5.7.3.2.2 To define a validation rule using a validation function

This procedure describes how to use a custom validation function to define a validation rule.

1. Add a data flow with a source and a Validation transform and connect them.
2. Click the transform name to open the Validation transform editor.
3. On the *Validation Rules* tab, click *Add*.
   The Rule Editor displays with the *Enabled* check box selected by default.
4. In the Rule Editor, name the rule.
5. Select the *Action on fail: Send to Fail*.
6. With the *Validation Function* option selected, from the drop-down list select the ZipIsValid function.
   The Bindings table populates with the required parameters for the function.
7. Define the parameter argument. For the $ZipToValidate parameter, double-click the cell under *Argument* and select the column *ZIP*.
8. Click *OK* to save the rule.
   The rule appears in the Rules list on the *Validation Rules* tab.

When you run the job, the rule will apply the reusable validation function to the ZIP column and check each character to validate each is a digit.

3.5.5.7.3.3 Rule Editor options

The following table describes the options in the Rule Editor dialog box.

Option	Description
Name	The rule name as created by the user.
Description	An optional descripion provided by the user.
Enabled	Select to apply the rule when running the job. Clear to disable the rule. You can also enable or disable the rule on the *Validation Rules* tab.
Ignore if NULL	Select to not apply the validation rule for any incoming values that are NULL, and send all NULL values to the Pass data output.
Action on Fail	Identifies what action to take when the row fails: send the row to the Fail target, Pass target, or both. If you choose *Send to Pass* or *Send to Both*, you can choose to substitute a value or expression for the failed values that go to the Pass output in the bottom pane of the *Validation Rules* tab.
Validation Function	Select to define the rule based on a validation function. The function must have already been created in the object library before it will be available in the drop-down list.
Bindings	Each parameter required by the function displays. Provide an argument for each parameter. The argument can be a constant, column (from the input schema), substitution variable, data flow variable, or global variable. You can type the value into the cell, or select the drop-down arrow to display the available columns and variables. Clear the *Score* check box to not include the binding in the Fail output. See the following example for more information about Score.
Column Validation	Select to base the rule on a single input column.
Column	Click the drop-down arrow to select a column on which to process the rule.
Condition	Select a condition (and usually in conjunction with an expression) to define the column-based rule. Available condition operators include: *<, >, <=, >=, <>, =* *IS NULL, IS NOT NULL* *LIKE* *IN SET* *BETWEEN*: Use to specify a range of values.

Option	Description
	Match Pattern: Lets you enter a pattern based on the Data Services match_pattern function. *Exists in Table*:Select to specify that a column's value must exist in another table's column. Click the drop-down arrow to open the *Input Parameter* window and browse to the desired input. This option uses the LOOKUP_EXT function. Define the NOT NULL constraint for the column in the LOOKUP table to ensure the *Exists in table* condition executes properly. *Custom Condition*: Select to create more complex expressions by linking to the smart editor (ellipses button) or function wizard (Function button). An edit box opens for you to enter your expression.

Example

Understanding Score

Say you are using a validation function to define a validation rule that checks for valid ZIP codes and has two input parameters: $Country and $ZIP. The function might be written as follows:

```
 if ($Country = 'US')
  if (match_pattern ($ZIP,'99999')=1)
   return 1; #For the country US, the ZIP code must match the 5-digit pattern
  else
  return 0; #Fails if ZIP code does not match pattern for US
return 1; #If country is not US, always true
```

Using this function in a Validation transform binds the rule to the columns Country and ZIP. However in the Rule Editor when defining the parameter, you would select the *Score* check box for the ZIP column but not for the Country column because the goal is to validate the ZIP format. The $Country parameter is being used as a filter (to sort out U.S. ZIP codes), not for validation.

Sample input:

Row_ID	Country	ZIP
1	US	12345
2	US	123
3	Belgium	123

Fail output with Score selected for ZIP:

Row_ID	Country	ZIP	DI_ERROR_ACTION	DI_ERROR_COLUMNS
2	US	123	F	Validation failed rule(s): ZIP

RuleViolation output:

Row_ID	DI_RULENAME	DI_COLUMNNAME
2	IsValidZip	ZIP

Therefore, if you later want to generate a report on why rows failed, only the ZIP column will appear as having has bad data, not the Country column.

Related Information

match_pattern [page 1622]
lookup_ext [page 1605]

3.5.5.7.4 Data outputs

The Validation transform can output up to three data outputs: Pass, Fail, and RuleViolation. Data outputs are based on the condition that you specify in the transform. You set the data outputs when you connect the output of the Validation transform with a Pass object, a Fail object, or both a Pass and Fail object in the workspace.

You can also load Pass and Fail data into multiple targets.

<table>
<tr><th>Option</th><th>Description</th></tr>
<tr><td>Pass</td><td>When you choose a Pass type data output, the output schema is identical to the input schema.</td></tr>
<tr><td>Fail</td><td>When you choose a Fail type data output, Data Services adds the following columns to the Fail output schema: DI_ERRORACTION and DI_ERRORCOLUMNS.
<ul>
<li>DI_ERRORACTION: This column indicates where Failed data was sent:
<table>
<tr><th>Indicator</th><th>Description</th></tr>
<tr><td>B</td><td>Sent to both Pass and Fail outputs.</td></tr>
<tr><td>F</td><td>Sent to the Fail output.</td></tr>
</table>
Note
If you choose to send failed data to the Pass data output, Data Services does not track the results. Because Data Services does not add columns to Pass output types, you may substitute a value for failed data that you send to the Pass data output. The input schema is maintained in the Pass output.</li>
<li>DI_ERRORCOLUMNS: This column displays all error messages for columns with failed rules. The names of input columns associated with each message are separated by colons. For example: <ValidationTransformName> failed rule(s): c1:c2</li>
</ul></td></tr>
</table>

Option	Description
	ℹ Note If a row has conditions set for multiple columns and the Pass, Fail, and Both actions are specified for the row, then the precedence order is Fail, Both, Pass. For example, if one column's action is Send to Fail and the column fails, then the whole row is sent only to the Fail output. Other actions for other validation columns in the row are ignored.
RuleViolation	You use the RuleViolation output to capture each row that represents the unsuccessful execution of a validation rule. The following output schema columns contain data to help you understand which rule failed: ● DI_ROWID: Multiple validation rules can fail on a single input row; however, the output schema Fail only emits a single row to report each failure. To get complete information about every failed rule, this column associates rows sent to the Fail output to those recorded in the RuleViolation output. To link the DI_ROWID to the actual data row, on the Validation Transform Options tab make sure the *Create column DI_ROWID on Validation_Fail* is selected, which includes DI_ROWID in the Fail output schema. ● DI_RULENAME and DI_COLUMNNAME: You can associate columns with multiple rules, and a rule can be associated with multiple columns, so each row identifies both the rule name and the column name so you can uniquely identify a particular rule-column pair. Only columns with *Score* selected in the Rule Editor will be added.

3.5.5.7.5 Nested schemas

The Validation transform can be used with nested schemas. You can associate any scalar column in a nested schema with a validation rule. You can use other nested columns in a validation condition as long as they share the same parents with the column on which the rule is defined. Data Services generates additional columns (DI_ERRRORACTION and DI_ERRORCOLUMNS) for the Fail output target at the top level of the schema only. Columns must be expressed with fully qualified names.

3.5.5.8 XML_Map

The XML_Map transform is a data transform engine designed for hierarchical data. It provides functionality similar to a typical XQuery or XSLT engine. The XML_Map transform takes one or more source data sets and produces a single target data set. Flat data structures such as database tables or flat files are also supported as both source and target data sets. You can use the XML_Map transform to perform a variety of tasks. For example:

- You can create a hierarchical target data structure such as XML or IDoc from a hierarchical source data structure.
- You can create a hierarchical target data structure based on data from flat tables.
- You can create a flat target data set such as a database table from data in a hierarchical source data structure.

XML_Map transform works in two modes- Normal and Batch mode. In normal mode, data is handled on a row by row basis before sending it to the next transform. In batch mode, data is handled as block of rows, before sending it to the next transform. There are different transform icons to indicate each mode.

3.5.5.8.1 Data inputs

Normal mode - One or more data sets. Each data set can be a hierarchical data source such as XML, IDoc, or a hierarchical output structure from a previous transform. It can also be row-based data such as a database table, spreadsheet, or flat file.

Batch mode - Single data set accepted. The data set can only be a hierarchical data source such as XML, IDoc, or a hierarchical output structure from a previous transform. It can also be row-based data such as a database table, spreadsheet, or flat file.

3.5.5.8.2 Data outputs

Normal mode - A single data set. The data set may be a hierarchical structure or row-based flat data.

Batch mode - A single data set. The data set is always a hierarchical structure or flat dataset. The Batch key columns become first-level columns of the row. The rest of the columns become second-level columns and cannot be edited.

3.5.5.8.3 Editor

Use the XML_Map editor to specify the Schema In, Schema Out, and Options for the XML_Map transform.

The areas can be resized in order to expand the area in which you are working. You can also expand and contract the columns to change the width of properties displayed in the input and output schema areas.

3.5.5.8.4 Options

Use batch mode to accumulate blocks of rows before you send those rows to the next transform. For example, using batch mode with SAP functions may improve performance.

You can group the data by *Batch size* and optionally by the *Batch key columns* in batch mode.

Options	Description
Batch size	This option specifies the maximum size of second-level rows for each batch. It could be a positive number, a global variable, or a substitution parameter. The default value of batch size is 10000.

Options	Description
Batch key columns	This option specifies the input columns on which a given batch is constructed. Batch key columns become root-level columns of the ouptut schema. When batch key column is selected, "*Input already sorted by batch key columns*" checkbox option is available. Checking it indicates that input is sorted, so the transform doesn't need to do sorting itself. Note If the Batch key column is not specified, then *Batch size* defines the size of the block of rows.

3.5.5.8.5 Batch mode operation

When the XML_Map transform is run in batch mode, the number of rows in the first nested level is grouped by the *Batch size* and optionally by the *Batch key columns*.

When the *Batch key columns* option is selected, the input for the XML_Map transform is sorted based on *Batch key columns*. Sorting is done to detect batch key changes. If the *Batch key columns* option is not selected, then there is no sort operation. Each batch is constructed purely based on the maximum *Batch size*. There are no first-level columns.

Based on the type of input, each batch is constructed. The batch is sent out when it reaches the maximum *Batch size*, and optionally if the *Batch key* changes.

3.5.5.8.5.1 Using Batch mode in XML_Map transform

Follow these steps to configure the XML_Map transform for batch mode.

> Note
>
> Only one input is allowed for the XML_Map transform in batch mode.

1. In the XML_Map transform editor, select *Batch Mode*.

   > Note
   >
   > A special symbol indicates that the XML_Map transform is in batch mode.

2. Construct each batch based on the *Batch size*, and optionally the *Batch key columns*.
3. Select the maximum *Batch size* value of second level rows for each batch.

   > Note
   >
   > Default value is 10000 and it could be a positive number, a global variable, or a substitution parameter.

4. If you opt for *Batch key columns*, then drag the selected column name from the input schema into the *Batch key columns* list box.

   > ℹ Note
   >
   > - The whole input schema moves one level down in the output schema, making it nested.
   > - Batch key columns become part of the output schema at the top-level. However, if you want to modify the output schema, then add downstream transforms.
   > - If the Batch key columns are not selected, then there is no sort operation. Each batch is constructed purely based on maximum batch size. There are no first-level columns.

5. Select the checkbox *input already sorted by batch key columns* if you need to indicate that input is sorted.

The batch is sent out when it reaches the maximum batch size, and optionally if the batch key changes.

3.5.5.8.6 Searching in an input or output schema

1. In the XML_Map editor *Find* tab, enter the search term in the *Find what* box or select from previous search terms in the drop-down list.
2. In the *Schemas* list, choose the schemas in which to search.
3. In the *Elements* list, choose the types of mappings in which to search.
4. In the *Where* list, choose the properties to search within.

   > ℹ Note
   >
   > You can search within one or all properties, but not within two or three specific properties at a time.

5. Select the *Match case* check box to constrain your search to the capitalization entered.
6. Click *Find*.
   The Designer searches the transform configuration for the words you specified within the constraints you defined.

   > ℹ Note
   >
   > The Designer searches for columns loaded into memory. If columns are not loaded into memory, you must expand the schema to load the columns into memory before clicking *Find* and searching for the columns.

All matches are shown in the box below the find constraints. When you click to select a table or column name, the table or column is automatically highlighted and shown in the corresponding input or output schema area.

Initially, the Designer lists the matching columns in the order that they appear within the schemas. If you are searching both schemas, the Designer lists the first match found in the input schema first and the last match found in the output schema last. You can sort the list of matches by property. Each time you click a property heading, the Designer resorts the matches, cycling through original order, ascending order, and descending order.

Arrow icons confirm column and sort type. For example, if you sort the data by the *Description* property and in ascending order, an “up” arrow appears next to the *Description* heading. Click the heading again and a “down” arrow appears to indicate that the data is now sorted in descending alpha-numeric order. Click again and the match list returns to its original sort order.

3.5.5.8.7 XML_Map transform input schema

The input schema area displays all input schemas for the XML Map transform. Each input schema can contain zero or more of the following elements:

- Columns
- Nested schemas

Icons preceding columns are combinations of the following graphics:

Icon	Description
🔑	Primary key.
▯	Column that is not used in output mapping.
▶	Column that is used in output mappings.

The *Schema In* list at the top left of the query editor indicates the schema that is currently selected. As you select schemas or columns in the input schema area, the *Schema In* list displays the corresponding schema. Conversely, you can select a schema in the *Schema In* list to move easily to a required schema.

You can right-click elements in the input schema area and select the following menu commands:

Command	Applicable elements	Effect
Copy	Columns, schemas	Stores a copy of the selected elements in the clipboard, leaving the elements in the input schema area.
Find	Anywhere in the input schema area	Locates an output element with the name or description you enter.
Refresh	Anywhere in the input schema area	Refreshes the display of the input schema area.
Parent	Columns	Selects the parent schema of the selected column.
Collapse	Columns, schemas	Collapses a selected schema or a selected column's parent schema (to facilitate viewing/navigation).
Generate DTD	Root schema only	Generates a DTD format that corresponds to the structure of the selected schema (either NRDM or relational). Generates all data types as varchar.
Generate XML Schema	Root schema only	Generates an XML Schema that corresponds to the structure of the selected schema (either NRDM or relational). All data types match those of the selected schema.
Create File Format	Schemas	Creates a file format from a relational table schema. All data types match those of the original table schema.
Create HDFS File Format	Schemas	Creates an HDFS file format from a relational table schema. All data types match those of the original table schema.
Properties	Columns, schemas	Displays the properties of the selected element. ℹ Note You cannot modify the element properties.

3.5.5.8.8 XML_Map transform output schema

The output schema area displays the schema output from the XML_Map transform. The output schema can contain one or more of the following elements:

- Columns
- Nested schemas

Icons preceding columns are combinations of the following graphics:

Icon	Description
🔑	Primary key.
▶	Column that has a simple mapping. A simple mapping is either a single column or an expression with no input column (that is, an expression that does not vary with input).
⏩	Column that has a complex mapping. A complex mapping is any mapping that is not simple.
❌	(Red cross superimposed on any icon) Incorrect mapping. ℹ Note Data Services does not perform a complete validation during design, so the editor may not flag an incorrect mapping. For a complete validation, select ▶ *Validation* > *Validate* ◀.

The Schema Out pane shows the following:

- The current schema in the Schema Out list at the top and in the output schema area. The current schema determines:
  - The output elements that you can modify (add, map, or delete).
  - The scope of the Iteration Rule through ORDER BY tabs in the options area.
- Non-current schemas appear dim in the output schema area.

3.5.5.8.9 Change the current schema

There are several ways to change the current schema in a XML_Map transform:

- Select a schema from the Output list.
- Right-click a schema or column in the output schema area and select *Make Current*.
- Double-click one of the non-current (dim) elements in the output schema area.

When you connect a target table to an XML_Map transform with an empty output schema, Data Services automatically fills the transform's output schema with the columns from the target, without mappings.

The software only fills the target schema in the output of a transform when you connect a target table to a transform with an empty output schema. If the output schema contains any column mappings, the software does not overwrite those mappings. Similarly, if you connect a transform to one target, and then disconnect that target and connect to another target, the output schema will show the columns from the first target connected.

There are several techniques to change the output schema:

- Drag and drop (or copy and paste) columns or nested schemas from the input schema area to the output schema area (this provides simple column mappings).
  If you drop a column on an existing column, you can remap that column. Select *Remap Column* to update only the column mapping or select *Remap with Data Type* to update the column mapping and data type. Alternatively, you can select *Insert Above* or *Insert Below* to add the column as a new mapping or *Cancel* if you do not want to add the column to the output schema.
- Right-click the current schema and select *New Output Column* or *New Output Schema*. You can provide simple column mappings by dragging input columns over the new output columns. For complex mappings, use the options area.
- Right-click columns in the current schema to assign and reverse primary key settings on output columns. A key icon indicates primary keys.
- Right-click the current schema and select *Unnest* to flatten output schemas. Use this command when a job has a source with a nested schema (such as an XML file), and you map columns from this source to a flat target table schema.

You can right-click elements in the output schema area and select commands. Generally, the elements must be within the current schema.

Command	Applicable elements	Effect
Cut	All	Removes the selected elements from the output schema area and stores a copy of the elements in the clipboard.
Copy	All	Stores a copy of the selected elements in the clipboard, leaving the elements in the output schema area.
Paste	All	Inserts the elements stored in the clipboard at the current cursor location (this must be within the current schema). Only visible when the clipboard contains something. If the cursor overlaps an existing column, you are prompted to insert above, insert below, remap column, or cancel. Note Copying an input element and pasting it in the output schema area provides a simple mapping from the input element to the output element. You can also do this by dragging the input element to the output schema area.
Delete	All	Removes the selected elements from the output schema area (without making a copy).
Find...	All	Locates an output element with the name or description you enter.

Command	Applicable elements	Effect
Make Current	All outside the current schema	Makes the selected schema, or the schema of the selected element, the current schema.
New Output Column...	Schemas	Adds an output column to the current schema with the name and properties you enter.
New Output Schema...	Schemas	Adds a nested schema to the current schema with the name you enter.
Propagate Column From	Columns	Carries a selected column schema from an upstream source or transform through intermediate objects to the output schema. Simple mappings are created in each object with no change to the data type or data itself.
Unnest	Nested schemas	Flattens the selected schema. The selected schema disappears and a flat list of columns appears.
Primary Key	Columns	Toggles the primary key attribute of the column on (check mark appears next to the command) or off (no check mark appears next to the command). A key icon indicates that a column is a primary key.
Optional	All	Toggles to make a schema or column optional.
Repeatable	Nested schemas	Toggles to make a schema repeatable.
Generate DTD	Root schema only	Generates a DTD format that corresponds to the structure of the selected schema (either NRDM or relational). Generates all data types as varchar.
Generate XML Schema	Root schema only	Generates an XML Schema that corresponds to the structure of the selected schema (either NRDM or relational). All data types match those of the selected schema.
Create File Format	Nested schemas	Creates a file format from a relational table schema. All data types match those of the original table schema.
Create HDFS File Format	Nested schemas	Creates an HDFS file format from a relational table schema. All data types match those of the original table schema.
Properties	All	Displays the properties of the selected element.

3.5.5.8.10 Configure mappings

The mapping configuration area of the XML_Map editor contains several tabs where you enter information to specify the data you want retrieved. Tabs containing entries are flagged by a special ℹ icon.

When you drag and drop (or copy and paste) input columns to the output schema, Data Services inserts a value in the Mapping tab. For simple mappings, this may be sufficient. For more complex mappings, complete the appropriate tabs.

Tab	Description
Mapping	Specifies how the selected output column will be derived (or mapped).
Iteration Rule	Specifies how instances for the current schema are created from instances of the source(s). An iteration rule can only be created for a repeatable target schema. Additionally, in most situations, a repeatable target schema must have an iteration rule.

WHERE	Specifies conditions that determine which instances of the target schema are output.
	Enter the conditions in SQL syntax, like a WHERE clause in a SQL SELECT statement. For example:
	`TABLE1.EMPNO = TABLE2.EMPNO`
	`AND TABLE1.EMPNO > 1000`
	`OR TABLE2.EMPNO < 9000`
	Use the *Functions*, *Domains*, and *smart editor* buttons for help building expressions.

DISTINCT	Specifies the list of distinct columns from the input or output schema (if required). **Restriction** You can not mix input and output columns in the DISTINCT list.
GROUP BY	Specifies how the output instances are combined (if required).
ORDER BY	Specifies how the output instances are sorted (if required).
Advanced	Specifies whether to run the transform in a separate process, and defines additional options for input schemas. Options set in the Advanced tab apply to the entire XML_Map transform.
Find	Enables you to search for a specific word or term in the input and/or output schemas.

Note

Use the WHERE through ORDER BY tabs to specify additional constraints for the current schema, similar to SQL SELECT statement clauses.

3.5.5.8.10.1 Mapping tab

Use the Mapping tab to specify how the selected output column is derived (or mapped). You can specify any valid expression.

Most commonly, mapping expressions contain table columns and functions.

- Enter input column names or drag columns from the input schema and drop them in the box on the Mapping tab.
- Insert functions by entering them directly, using the smart editor, or by clicking the Functions button to open the function wizard.

After you map your source to the XML_Map transform, you might determine that you need to use another transform before you send the data to the XML_Map transform. For example, you might add a validation transform to ensure that only data with a certain format is passed or you might add a Case transform to send only a subset of the data.

In general, when you change an input schema to the XML_Map transform, the Designer checks the existing top-level mappings to determine if any remapping is required.

- If the mapping contains a column with a table name that is not a current input schema name and the column is in the new input schema, the Designer automatically replaces the table name with the new input schema name. Specifically, the Designer automatically updates the input schema name for each matching column in the following mapping configuration tabs of the XML_Map editor:
  - Mapping
  - Iteration Rule
  - WHERE
  - DISTINCT
  - ORDER BY
  - GROUP BY
- If the mapping contains a column that was in the obsolete table, but the column does not exist in the new input schema, you must either remove the column or remap it from the original source.

The Designer does not automatically remap the input schema for the following situations:

- When you connect a new source to the XML_Map transform before you disconnect the old source. You must click the *Schema Remapping* button on the Mapping tab to update the input schema name for columns in the Mapping, WHERE, GROUP BY, and ORDER BY tabs.
- When the source is a nested schema and you either change the source to a similar nested schema, or you add or delete a transform before the XML_Map transform. Click the *Schema Remapping* button to update the Mapping input schema name.

Schema to schema mapping

You can map a source schema to a target schema by making the target schema current and entering the source schema path in the Mapping tab. In this case, the software assumes the source and target schemas have the same structure, including the number, order and data type of columns in each level of the structure.

When you specify schema to schema mapping, you cannot also have an iteration rule, but you may specify columns in the DISTINCT, WHERE, GROUP BY, and ORDER BY tabs.

Merge To operation

When you make a target schema current in the Mapping tab, the *Merge To* operation becomes available. The Merge To operation allows you to copy and paste a target schema at the same level, create mappings to different sources for the copied target schema and the original schema, and then merge the result sets. In any transforms that follow the XML_Map transform, only the original target schema is displayed.

3.5.5.8.10.1.1 To remap when automatic remapping was not done in the XML_Map transform

1. In the Mapping tab, click the *Schema Remapping* button. The *Replace Obsolete Schema window* opens.
2. In the *Specify obsolete schema* drop-down list, choose the source schema that you disconnected from the XML_Map transform.
   This list displays only the top-level input schema. For an obsolete nested schema, enter the name of the top-level schema.
3. In the *Choose correct schema* list, choose the output schema of the transform that you added between the source and XML_Map transform.
4. Click *Remap*.
   A message displays the number of columns that were remapped; for example:

```
Schema "ODS_SALESORDER" was replaced by schema "Validation_Pass" in 11 column
names.
```

3.5.5.8.10.2 Iteration Rule tab

Use the Iteration Rule tab to define how the output data set for the selected output schema is calculated. An iteration rule is associated only with a repeatable target node, and defines how to construct the instances of the target schema from the source data. It is a mechanism to specify the input data sets and the way the software should join them to create the target data set.

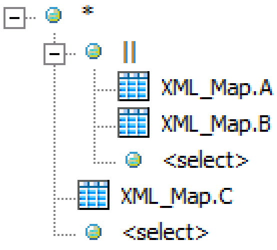
Data Services supports different kinds of joins in the iteration rule: INNER JOIN, LEFT OUTER JOIN, CROSS JOIN, and PARALLEL JOIN. PARALLEL JOIN is not a standard SQL join.

In the iteration rule tab, a hierachical tree represents a logical combination of operations and input schemas that form a rule. Each operation in the rule is displayed as a node and may contain other operations or input schemas as children.

For example, a rule that performs a parallel operation on example tables A and B, and then combines that output set with table C by using a cross operation might logically look like this:

```
(A || B) * C
```

In the iteration rule tab, this same rule might look like this:



Constructing iteration rules

Use the iteration rule tab to create iteration rules for each repeatable schema in your output:

- To add a new element to the rule, click the *<select>* placeholder under an operation node and choose the new operation or input schema from the drop-down list.
  Elements that can be added to an iteration rule include the following:
  - *INNER JOIN*
    Performs a SQL INNER JOIN on the sources. Create the expression to use for the join condition in the On area of the rule editor.
    When you create the expression, you can use the following types of columns:
    - Source columns from the sources under the current operation and the left side of the current iteration rule tree.
    - Source columns from the sources that appear in the iteration rules associated with the parent schemas of the current target schema.
    - Target columns from the parent schemas of the current target schema.

    When using a source column, the path from the column being used to the source schema must contain no repeatable schemas.
    When using a target column, it must be a scalar column and descend from the parent schema of the schema where the iteration rule is defined. In addition, the path from the parent schema to the target column must contain no repeatable schemas.
  - *LEFT OUTER JOIN*
    Performs a SQL LEFT OUTER JOIN on the sources. Create the expression to use for the join in the On area of the rule editor.
    When you create the expression, you can use the following types of columns:
    - Source columns from the sources under the current operation and the left side of the current iteration rule tree.
    - Source columns from the sources that appear in the iteration rules associated with the parent schemas of the current target schema.
    - Target columns from the parent schemas of the current target schema.

    When using a source column, the path from the column being used to the source schema must contain no repeatable schemas.
    When using a target column, it must be a scalar column and descend from the parent schema of the schema where the iteration rule is defined. In addition, the path from the parent schema to the target column must contain no repeatable schemas.

- ○ ** - Cross operation*
  Produces a Cartesian product of two or more sources. When the sources have no parent-child relationship, the behavior is the same as a standard SQL CROSS JOIN. When the sources have a parent-child relationship, the Cartesian operation provides a mechanism to iterate through all instances of the repeatable elements identified by the source schemas in the operation in the document order.
- ○ || - Parallel operation
  The Parallel operation is not a standard SQL operation. It takes two or more sources and combines corresponding rows in each source to generate the output set. For example, the first rows in a pair of input tables is combined to become the first row of the output set, the second rows are combined to become the second output row, and so on.
  If the sources have different numbers of rows, the output set will contain the same number of rows as the largest source. For extra rows in the output set that contain data from only one source, the additional columns that would contain data from the other sources are considered empty.
- ○ Available input schemas

- To remove an element from the rule, click the element and choose *<delete>* from the drop-down list.
  If you remove an operation node, any child operations or schemas will also be removed from the rule.
- To change an operation type, click the operation node and choose the new operation from the drop-down list.

i Note

There is no limit to the number of sources that may be used in an iteration rule.

Automatic rule generation

The iteration rule can be generated automatically. After you have created mappings for the columns under the current target schema, click *Propose rule* in the Iteration Rule tab. The software generates the iteration rule tree. Always validate that the generated iteration rule matches your requirements. Modify the rule as needed, and add the ON condition expression when appropriate.

You can also propose rules recursively. When you click *Propose rule recursively*, the software recursively moves through the target tree under the current target schema, finds all repeatable schemas, and generates the iteration rule for each repeatable schema based on the mappings under the schema.

i Note

Automatic rule generation is a best-guess function. For example, the software cannot know the ON condition, or whether to use INNER JOIN or LEFT OUTER JOIN. Use the automatic rule generation as a guide and always verify that the iteration rule that it creates fits your needs.

3.5.5.8.10.3 WHERE tab

A WHERE clause can be created for any target schema in the output structure. Use the WHERE tab to set conditions that determine which rows are output. Enter the conditions in SQL syntax, as you would a WHERE clause in a SQL SELECT statement. The WHERE tab applies to the current output schema.

You can specify any valid expression. To enter conditions, do one of the following:

- Enter expressions in the editor.
- Drag columns from the input or output schema area to the editor.
- Use the Functions button. Use the pushdown_sql function to have Data Services create WHERE clauses dynamically based on data rather than pre-specifying the clause.

  Note

  The pushdown_sql fuction can be used if the immediate input to the XML_Map transform is the table source where you want to push the WHERE clause.

Source and target columns may be used in the WHERE expression.

Restriction

Source columns must come from the source schemas in the current iteration rule or those that appear in the iteration rules associated with the parent schemas of the current target schema. Additionally, the path from the column being used to the source schema must contain no repeatable schemas.

Target columns must come from the current target schema or parent schemas of the current target schema. Additionally, the path from the column being used to the target schema must contain no repeatable schemas.

Note

If your expression contains varchar comparisons, Data Services ignores trailing blanks in the data. For Oracle data, use the rtrim or rpad functions if the number of trailing blanks might differ on either side of the comparison.

3.5.5.8.10.4 DISTINCT tab

Use the DISTINCT tab to specify the input or output schema columns that should be used to determine whether a row is distinct. If the column specified in the DISTINCT tab contains a distinct value, the row is a new output row. The DISTINCT tab applies to the current output schema.

To add a column to the Distinct columns list, select the column in the output schema area and drag it to the box in the *DISTINCT* tab. The Designer adds the column to the bottom of the list.

To remove a column, use one of the following options:

- Right-click the column and select *Delete*.
- Select the column and click the delete icon in the top right corner of the DISTINCT tab.

To consider the entire output row as distinct, select the *Whole row is DISTINCT* option.

Note

You cannot specify both source and target columns at the same time in the DISTINCT tab.

When source columns are used, they must descend from the source schemas in the current iteration rule. In addition, the path from the source schema to the column must contain no repeatable nodes.

When target columns are used, they must descend from the current target schema. In addition, the path from the current target schema to the column must contain no repeatable nodes.

3.5.5.8.10.5 GROUP BY tab

Use the GROUP BY tab to specify a list of columns for which you want to combine output. For each unique set of values in the group by list, Data Services combines or aggregates the values in the remaining columns. For example, you might want to group sales order records by order date to find the total sales ordered on a particular date. The GROUP BY tab applies to the current output schema.

To add a column to the Group By list, select the column in the input or output schema area and drag it to the box in the *GROUP BY* tab. The Designer adds the column to the bottom of the list.

The first column listed is used for primary grouping, the second column listed is used for secondary grouping, and so forth. To change the groupings, use one of the following options:

- Right-click the column and select *Move Up* or *Move Down*.
- Select the column and click the down or up arrow in the top right corner of the GROUP BY tab.

> Note
>
> You can specify either source or target columns in the GROUP BY column list.
>
> When source columns are used, they must descend from the source schemas in the current iteration rule. In addtion, the path from the source schema to the column must contain no repeatable nodes.
>
> When target columns are used, they must descend from the current target schema. In addition, the path from the current target schema to the column must contain no repeatable nodes.

To remove a column, use one of the following options:

- Right-click the column and select *Delete*.
- Select the column and click the delete icon in the top right corner of the GROUP BY tab.

If you specify a group by list, then all columns in the output schema must be either in the group by list or mapped to an aggregate function, such as avg, count, max, min, or sum.

Grouping methods

While the GROUP BY operation is similar to the standard SQL GROUP BY operation, it does not always operate in exactly the same way. The XML_Map transform groups output items in different ways depending upon the columns specified and whether or not aggregation functions are used:

- Simple grouping
  The XML_Map transform groups output items together according to the unique values of the GROUP BY list when the following conditions are met:
  - Source or target columns are specified in the GROUP BY list.
  - If source columns are specified, no aggregation functions are defined in the target schema.

  In this grouping method, the operation does not remove any items from the output data set.

- Group aggregation
  The XML_Map transform performs grouping exactly like a standard SQL GROUP BY clause when the following conditions are met:
  - Source columns are specified in the GROUP BY list.
  - Aggregation functions are defined under the current target schema.
  - Columns in the aggregation functions descend from the sources in the current iteration rule.
  - Paths from the iterating sources to the columns do not contain any repeatable nodes.

  > Note
  >
  > All columns in the output schema must be either part of the group by list or mapped to an aggregate function such as avg, count, max, min, or sum.
- Instance aggregation
  The XML_Map transform evaluates the aggregation functions for each of the items in the output data set when the following conditions are met:
  - Aggregation functions are defined under the current target schema.
  - Columns used in the aggregation functions descend from the sources in the current iteration rule.
  - Paths from the sources to the columns being used contain repeatable nodes.

  The XML_Map transform also evaluates the aggregation functions for each of the items in the output data set when the following conditions are met:
  - Aggregation functions are defined under the current target schema.
  - Columns used in the aggregation functions descend from the current target schema.
  - Paths from the current target schema to the columns being used contain repeatable nodes.

> ⚠ Restriction
>
> You cannot use both group and instance aggregation at the same time.

3.5.5.8.10.6 ORDER BY tab

Use the ORDER BY tab to specify the columns you want used to sort the output data set. The ORDER BY tab applies to the current output schema.

To add a column, select the column in the input or output schema area and drag it to the box on the ORDER BY tab. The Designer adds the column to the bottom of the list.

The first column listed is used for primary sorting, the second column listed is used for secondary sorting, and so forth. To change the column order, use one of the following options:

- Right-click the column and select *Move Up* or *Move Down*.
- Select the column and click the down or up arrow in the top right corner of the *ORDER BY* tab.

You can specify either source or target columns in the ORDER BY tab.

When source columns are used, they must descend from the source schemas in the current iteration rule. In addition, the path from the source schemas to the column must contain no repeatable nodes.

When target columns are used, they must descend from the current target schema. In addition, the path from the current target schema to the column must contain no repeatable nodes.

To remove a column, use one of the following options:

- Right-click the column and select *Delete*.
- Select the column and click the delete icon in the top right corner of the *ORDER BY* tab.

The default sort order is ascending. To change the order, select *Ascending* or *Descending* from the adjacent drop down box.

3.5.5.8.10.7 Advanced tab

Use the options in the Advanced tab to run the XML_Map transform in a separate process, or to configure options for the input schema(s). The options in the Advanced tab apply to the entire XML_Map transform.

Use the Input schemas table to configure additional options for the input schema(s) used in the transform:

Option	Description
Cache	Indicates whether the software should read the required data from the source and load it into memory or pageable cache. Because an inner source of a join must be read for each row of an outer source, you might want to cache a source when it is used as an inner source in a join. Available values: • *Automatic* (default) • *Yes* • *No* Cache specified in the Advanced tab of the XML_Map transform editor overrides any cache specified in a source.

3.5.5.8.10.8 Find tab

Use the Find tab to search for a specific word or term in the input schema or the output schema.

Related Information

Searching in an input or output schema [page 1485]

3.5.5.8.11 Example: Nesting data with the XML_Map transform

In this example, assume you have a database table containing a list of company employees and department information. You want to create a structure that has a list of departments, each containing a list of employees and a new column that contains the number of employees in the department.

Source	Target

`Employee`
` |-departmentID`
` |-departmentName`
` |-employeeName`
` |-employedDate`
	`Company`
	` |-department (*)`
	`    |-departmentID`
	`    |-departmentName`
	`    |-employee (*)`
	`       |-employeeName`
	`       |-employedDate`
	`    |-totalEmployees`

1. Create iteration rules for the `department` and `employee` schemas.

   Both schemas require information from the `Employee` source table, so they must iterate on that; no JOINs or other operators are required.
2. Create a new department instance for each individual department, based on the department ID.

   Include the `Company.department.departmentID` target column in the DISTINCT tab for the `department` schema. Each time a new value in that column is encountered, a new `department` instance will be created.
3. Identify and create an `employee` instance for each employee that belongs to the department.

   Because the ID for the current department is already known, you can use it in an expression in the WHERE tab for the `employee` schema to include only the correct employees:

   ```
   Employee.departmentID = Company.department.departmentID
   ```

   When the `employee` instance iterates against the source, only rows that have the matching department ID will be selected.
4. Aggregate the number of employees in the department.

   The `employee` instances have already been created, so you can use those to create a mapping expression for the `totalEmployees` column:

   ```
   count(Company.department.employee)
   ```

3.5.5.8.12 Example: Unnesting data with the XML_Map transform

In this example, assume that you have an XML structure that contains information about purchase orders. You want to generate a flat list for the items in all of the purchase orders, ordered by the total sales for each item.

<table>
<tr><th>Source</th><th>Target</th></tr>
<tr><td><pre>
purchaseOrders
    |-purchaseOrder (*)
    |-sellerParty
       |-sellerID
       |-sellerName
    |-buyerParty
       |-buyerID
       |-buyerName
    |-orderLine
       |-item (*)
          |-name
          |-quantity
          |-unitPrice
          |-currency
</pre></td><td><pre>
item
 |-sellerID
 |-buyerID
 |-itemName
 |-totalSales
 |-currency
</pre></td></tr>
</table>

1. Create an iteration rule for the `item` output schema.

   Because the output schema requires data from columns in multiple nested schemas, use a cross (*) operation to flatten the data.

   ```
   *
   |-purchaseOrders.purchaseOrder
   |-purchaseOrders.purchaseOrder.orderLine.item
   ```

   The input ports are always assumed to be repeatable, which means that the software expects that multiple documents of `puchaseOrders` may come in.
2. Sort the output set by the total sales for each item.
   a) Calculate the total sales amount for each item.

      Use information from the source columns in an expression in the mapping for the `totalSales` column:

      ```
      orderLine.item.quantity * orderLine.item.unitPrice
      ```
   b) Order the output set.

      Include the `item.totalSales` target column in the ORDER BY tab for the `item` output schema.

3.5.5.8.13 Example: Transforming a hierarchical source to a different hierarchical target

In this example, assume that you have a hierarchical structure that contains a catalog of books. The catalog includes information associated with each book, such as name, price, quantity sold, and information about the author. You want to transform this data into a structure that is instead organized by author. You also want to calculate the total sales for each book.

<table>
<tr><th>Source</th><th>Target</th></tr>
<tr><td><pre>
catalog
 |-book
    |-Name
    |-Price
    |-Quantity
</pre></td><td><pre>
authors
 |-Author
    |-Name
       |-firstName
       |-lastName
    |-Address
</pre></td></tr>
</table>

Source	Target
|-Author |-firstName |-lastName |-Author_nt_1 |-street |-city |-state |-zip	|-Author_nt_1 |-street |-city |-state |-zip |-book |-Name |-Price |-Quantity |-totalSales

1. Create an iteration rule for the `Author` output schema.

   Because the output schema requires data from columns in multiple nested schemas, use a cross (*) operation to flatten the data.

   ```
   *
   |-catalog.book
   |-catalog.book.Author
   ```

2. Create a new Author instance for each individual author, based on the first and last name of the author.

   Include the `authors.Author.Name.firstName` and `authors.Author.Name.lastName` target columns in the DISTINCT tab for the `Author` target schema. Each time a new combination of the values in those columns is encountered, a new `Author` instance will be created.

3. Sort the Author instances by the name of each author.

   Include the `authors.Author.Name.firstName` and `authors.Author.Name.lastName` target columns in the ORDER BY tab for the `Author` target schema.

4. Because there may be more than one line for the street portion of the author's address, create an iteration rule for the `Author_nt_1` output schema.

   ```
   catalog.book.Author.Author_nt_1
   ```

5. Map the author information from the source schema to the target schema.

   Include the appropriate source column or schema in the Mapping tab for each output column or schema:

Target column or schema	Mapping expression
authors.Author.Name.firstName	`catalog.book.Author.firstName`
authors.Author.Name.lastName	`catalog.book.Author.lastName`
authors.Author.Address.Author_nt_1	`catalog.book.Author.Author_nt_1`
authors.Author.Address.Author_nt_1.street	`catalog.book.Author.Author_nt_1.street`
authors.Author.Address.city	`catalog.book.Author.city`
authors.Author.Address.state	`catalog.book.Author.state`
authors.Author.Address.zip	`catalog.book.Author.zip`

6. Create an iteration rule for the `book` output schema.

Like the `Author` output schema, the `book` output schema requires a combination of the `catalog.book` and `catalog.book.Author` source schemas. Use a cross (*) operation to flatten the data.

```
*
|-catalog.book
|-catalog.book.Author
```

7. Identify and create a `book` instance for each book that belongs to the author.

   Because the first and last names of the author of the book are already known, you can use them in an expression in the WHERE tab for the `book` schema to include only the correct books:

   ```
   catalog.book.Author.firstName = authors.Author.Name.firstName AND
   catalog.book.Author.lastName = authors.Author.Name.lastName
   ```

8. Map book information from the source schema to the target schema.

   Include the appropriate source column in the Mapping tab for each output column:

Target column	Mapping expression
authors.Author.book.Name	`catalog.book.Name`
authors.Author.book.Price	`catalog.book.Price`
authors.Author.book.Quantity	`catalog.book.Quantity`

9. Calculate the total sales for each book.

   Use information from the source columns in an expression in the mapping for the totalSales column:

   ```
   catalog.book.Price * catalog.book.Quantity
   ```

3.5.6 Text Data Processing transforms

3.5.6.1 Entity Extraction transform

The Entity Extraction transform performs linguistic processing on content by using semantic and syntactic knowledge of words. You can configure the transform to identify paragraphs, sentences, and clauses and it can extract entities and facts from text. Typically, you use the Entity Extraction transform when you have text with specific information you want to extract and then use in downstream analytics and applications.

3.5.6.1.1 Extraction options

The Entity Extraction transform includes options that control which language, dictionaries, and rules to use for extraction. The *Processing Options* group includes specific configuration parameters for processing.

3.5.6.1.1.1 Common

The *Common* option group includes a setting to run the transform as a separate process.

Option	Description
Run as Separate Process	*Yes*: Splits the transform into a separate process. *No*: Keeps the transform as a single, possibly multithreaded, process.

3.5.6.1.1.2 Languages

The *Languages* option group includes settings to process content in different languages, such as English, German, and French. If the input content is in a language other than the specified languages, you might see unexpected results.

Option	Description
Language	Specifies the language for processing your content. You may select another language from the list of available languages displayed alphabetically in the drop-down menu. • The default language setting is 'Auto'. You may select another language from the list, to override the automatic identification. If the transform cannot identify the language, it uses the setting of the *Default Language* option. Note If content arrives in XML, and is organized in sections, the tranform identifies the language of each section. • If you select a language other than 'Auto', only entities defined for that language will be extracted for the entire document. When the language is set to 'Auto', any specified dictionaries or rule files the name of which do not identify a language will always be applied. However, dictionaries and rule files that do identify a language (e.g. English) in the file name will be applied only to input identified in that language. Note You will not be able to run extraction unless you have a language directory that contains the files for at least one language. By default, the language directory is installed on a client as well as a server during installation. The default location for the language directory is: `<LINK_DIR>/TextAnalysis/languages`.
Default Language	Specifies the default language that the transform should assume if the Language option was *Auto* and the transform could not identify a language. If the value 'None' is chosen as the value for *Default Language*, and the language cannot be identified, a non-fatal error occurs and processing continues.

Option	Description
	If the name of some other available language is chosen as the default language, and the transform fails to identify a language on the first attempt, only entities defined for the chosen language will be extracted.
Filter By Entity Types	Specifies a list of entity types (supported by the selected language) to use for filtering the extraction output. Note When the Language = 'Auto', this list is the union of all of the available entity types from the installed languages. By default, a drop-down menu showing '...' displays. Clicking this launches the *Ordered Options Window - [Filter By Entity Types - Option]* dialog. Select or remove one or more entity types from the list of available entity types for that language. Note Entity type support varies among languages.

3.5.6.1.1.3 Processing Options

The *Processing Options* group includes configuration settings for the transform. They affect how the transform will process the content before generating the extraction output.

The *Dictionary Only* option is most useful when you want to extract entities based solely on entities defined in a dictionary. For example, you want to match exactly the product and customer names from your custom dictionary and you are not interested in any other extraction output. In such a case, getting predefined entities from the extraction process will not be of interest.

> Note
>
> Predefined entities are entities associated with different languages and are part of the language modules. These entities are extracted by default.

The *Processing Timeout* option is most useful when you want to limit the amount of time spent on processing large content or content that take a very long time to process.

Option	Description
Dictionary Only	Use this option to limit the extraction process to use entities defined only in the specified dictionaries. You must specify a dictionary file to use this option.

Option	Description
	Note If you select this option, the extraction output will not include any predefined entities. Along with this option, if you also select the *Rule* option, the extraction output will include entities and facts defined in the rules along with entities from the specified dictionaries.
Advanced Parsing	Specifies whether advanced parsing information should be produced during extraction. Advanced parsing enriches linguistic processing including richer noun phrase structure, noun phrase coordination, and syntactic function attributes that can be leveraged in custom rules. This option is available only for the English language. By default, *YES* and *NO* display. If you select the *YES* option for non-English languages, an error message displays.
Processing Timeout	Use this option to stop processing the content after a set amount of time. By default, the *Processing Timeout* option is set to 60 seconds. The Processing Timeout value can be one of the following: `-1` indicates no timeout should be enforced. `>=1` indicates the amount of time (in seconds) after which processing should abort.
Document Properties	Specifies whether document properties of a binary document should be extracted, if they are present in the document. A value of *YES* causes the extraction, and a value of *NO* (the default) causes no extraction. Document properties are name-value pairs. The Entity Extraction transform extracts only the following document properties for binary documents: • APP_NAME: The name of the software that was used to create the document • APP_VERSION: The version of the software that was used to create the document • AUTHOR: The name of the person who created the document • COMPANY: The name of the company that owns the document • TITLE: The title of the document • DATE_CREATED: The date on which the document was created Document properties, if available, are extracted as entities. The SOURCE for the properties is called DOC_PROPERTY and only the following fields are defined for DOC_PROPERTY entities: • ID: The entity ID of the document property • SOURCE: DOC_PROPERTY • TYPE: The name of the document property • STANDARD_FORM or SOURCE_FORM: The value of the document property • CONVERTED_TEXT: The textual content of the binary document Any other output columns are not applicable to DOC_PROPERTY extraction rows, and have their value set to `-1`.

3.5.6.1.1.4 Dictionaries

The *Dictionaries* option group includes settings to process content by specifying one or more dictionaries that should be used when performing extraction. It also enables filtering by entity types defined in each dictionary.

The *Dictionaries* option group is comprised of individual dictionaries. You can configure the transform to use multiple dictionaries. These options are found under ▶ *Dictionaries* ▶ *Dictionary* ▶ *Dictionary File* ◀.

Option	Description
Dictionary	Use this option to add dictionaries that should be used during extraction or delete an existing dictionary. Right-click this option and select the option to duplicate an entry or to delete an entry. Once the entry is duplicated, change the duplicate dictionary file by selecting the dictionary to use from the directory structure.
Dictionary file	Use the *Browse* option under the drop-down menu to select a valid, compiled dictionary file to use for extraction. ℹ Note To include the dictionaries during extraction, they need to be accessible to the job server. If the dictionary files are located on a remote computer, include the path to those files (that can be resolved by the job server).
Filter By Entity Types	Specifies a list of entity types (defined in the selected dictionary) to use for filtering the extraction output. By default, a drop-down menu showing '...' displays. Clicking this launches the *Ordered Options Window - [Filter By Entity Types - Option]* dialog. Select or remove one or more entity types from the available entity list.

Related Information

Designer Guide: Dictionary overview [page 320]
Designer Guide: Executing Jobs, Changing Job Server options, To use mapped drive names in a path [page 432]

3.5.6.1.1.5 Rules

The *Rules* option group includes settings to process content by specifying one or more extraction rules to use when performing extraction. It also enables filtering by rule names defined in each rule file.

The *Rule* option group includes individual rules. You can configure the transform to use multiple rules. These options are found under ▶ *Rules* ▶ *Rule* ▶ *Rule File* ◀.

Option	Description
Rule	Use this option if you want to add rules that should be used during extraction or to delete an existing rule. Right-click on this option and select the option to duplicate an entry or to delete an entry. Once the entry is duplicated, change the duplicate rule file by selecting the rule you want to use from the directory structure.
Rule File	Use the *Browse* option under the drop-down menu to select a valid, compiled rule file to use for extraction. To include the rules during extraction, they need to be accessible to the job server. If the rule files are located on a remote computer, include the path to those files (that can be resolved by the job server). Note A rule file typically contains multiple rules. You can use the rule filtering option to select a specific rule in a rule file.
Filter By Rule Names	Specifies a list of rule names (defined in the selected rule file) to use for filtering the extraction output. By default, a drop-down menu showing '...' displays. Clicking this launches the *Ordered Options Window - [Filter By Rule Names - Option]* dialog. Select or remove one or more rules from the filtering list.

Related Information

Designer Guide: Rule Overview [page 320]

Designer Guide: Executing Jobs, Changing Job Server options, To use mapped drive names in a path [page 432]

3.5.6.1.2 Input fields

The following is a Data Services recognized input field that you can use in the input mapping for the Entity Extraction transform.

Name	Data Type	Description
TEXT	Long, blob, or varchar	Mandatory field. It includes content to be processed by the transform to extract entities and/or facts. The content must be in a text format such as a text, HTML, XML, or certain binary-formats (such as PDF).
TEXT_ID	Long, int, or varchar	Optional field. Unique identifier to be used for tracing the content in case of an error.

Name	Data Type	Description
		Note - An unsupported data type is ignored during runtime and instead either the file name (if read from an unstructured text file format) or the string `TEXT` input field is be used as the content identifier. - When a `varchar` or `long` column is mapped to the `TEXT_ID` input field and a value used to construct an error message contains more than 1K bytes, the value will be truncated to 1K.

3.5.6.1.3 Output fields

The following are Data Services recognized output fields that you can use in the output mapping for the Entity Extraction transform. The fields are listed in the order they appear on the *Output* tab.

Generated field name	Data Type	Description
ID	int	Represents a parent-child relationship between entities and/or facts. This value is unique within the scope of the processed input text. Note If you process two different input documents using the same data flow and store the output to a database, you should not use this field as a primary key.
PARENT_ID	int	Represents a parent-child relationship between entities and/or facts. If present, it provides a link to a parent ID value. If not present, this value is set to -1 to indicate there is no relationship.
STANDARD_FORM	varchar (2000)	The standard form of an entity, fact, or subfact. Generally it is the longest, most precise or official name associated with the value of the corresponding `TYPE` column. Note The standard form and the source form for an entity are often the same.
TYPE	varchar (255)	The type of an entity or fact. It may also represent subtypes or subfact types if applicable. For example, “Mr. Jones” will be identified as a `PERSON` entity and “car” as a `COMMON_VEHICLE/LAND` entity subtype.

Generated field name	Data Type	Description
		Note "/" is used as a separator to identify subtypes.
SOURCE_FORM	varchar (2000)	The name of an entity, fact, or subfact as mentioned in the input text.
SOURCE	varchar (10)	The origin of an entity or fact. Meaning, how the match was determined, based on one of the following: • SYSTEM - indicating that the entity was matched using the system files. • DICTIONARY - indicating that the entity was matched using a dictionary. • RULE - indicating that the entity or fact was matched using an extraction rule file.
OFFSET	int	The character offset of an entity or a fact in the CONVERTED_TEXT field.
LENGTH	int	The character length of an entity or a fact in the CONVERTED_TEXT field.
PARAGRAPH_ID	int	A unique identifier of the paragraph in the CONVERTED_TEXT field containing the entity or fact.
SENTENCE_ID	int	A unique identifier of the sentence in the CONVERTED_TEXT field containing the entity or fact.
CONVERTED_TEXT	long	The content text representation in UTF-16 encoding of the input text. Note When the CONVERTED_TEXT output column is selected, the first entity/fact output row for any input document will contain the UTF-16 textual representation of the input document. Any of the subsequent entity/fact output rows for the input document will not contain textual representation of the input document.

Example

Extraction text and output fields values

The following table shows partial results of the extraction output you may see when the following sample text is processed by the Entity Extraction transform. It shows values for the following fields:

- ID
- PARENT_ID
- STANDARD_FORM
- TYPE
- SOURCE_FORM

- SOURCE

Sample input text: "Mr. Jones is very upset with Green Insurance. The offer for his totaled vehicle is too low. He states that Green offered him $1250.00 but his car is worth anywhere from $2500 to $4500. Mr. Jones would like Green's comprehensive coverage to be in line with other competitors."

ID	PARENT_ID	STANDARD_FORM	TYPE	SOURCE_FORM	SOURCE
1	-1	Mr. Jones	PERSON	Mr. Jones	SYSTEM
2	-1	Mr. Jones is very upset with Green Insurance.	Sentiment	Mr. Jones is very upset with Green Insurance.	RULE
3	2	Mr. Jones	Topic	Mr. Jones	RULE
4	2	very upset	StrongNegative-Sentiment	very upset	RULE
5	2	Green Insurance	Topic	Green Insurance	RULE
6	-1	Green Insurance	PROP_MISC	Green Insurance	SYSTEM
7	-1	The offer for his totaled vehicle is too low.	Sentiment	The offer for his totaled vehicle is too low.	RULE
8	7	totaled vehicle	Topic	totaled vehicle	RULE
9	7	too low	MinorProblem	too low	RULE
10	-1	totaled vehicle	COMMON_VEHICLE/OTHER	totaled vehicle	SYSTEM
11	-1	He states that Green offered him $1250.00 but his car is worth anywhere from $2500 to $4500.	Sentiment	He states that Green offered him $1250.00 but his car is worth anywhere from $2500 to $4500.	RULE
12	11	car	Topic	car	RULE
13	11	worth anywhere from $2500 to $4500	WeakPositiveSentiment	worth anywhere from $2500 to $4500	RULE
14	-1	Green	PROP_MISC	Green	SYSTEM
15	-1	$1250.00	CURRENCY	$1250.00	SYSTEM
16	-1	car	COMMON_VEHICLE/LAND	car	SYSTEM
17	-1	from $2500 to $4500	CURRENCY	from $2500 to $4500	SYSTEM
18	-1	Mr. Jones	PERSON	Mr. Jones	SYSTEM

ID	PARENT_ID	STANDARD_FORM	TYPE	SOURCE_FORM	SOURCE
19	-1	Mr. Jones would like Green's comprehensive coverage to be in line with other competitors.	Request	Mr. Jones would like Green's comprehensive coverage to be in line with other competitors.	RULE
20	19	Mr. Jones	Topic	Mr. Jones	RULE
21	19	would like	GeneralRequest	would like	RULE
22	19	Green's comprehensive coverage	Topic	Green's comprehensive coverage	RULE
23	-1	Green	PROP_MISC	Green	SYSTEM
24	-1	other competitors	COMMON_PERSON /GROUP	other competitors	SYSTEM
25	-1	other competitors	COMMON_ ORGANIZATION/ COMMERCIAL	other competitors	SYSTEM

In the above example, row 1 shows ID as 1 (unique identifier) with PARENT_ID as -1 (no parent relationship). The TYPE column shows entity (PERSON), facts (Sentiment), and subfacts (StrongNegativeSentiment). To view the content of the CONVERTED_TEXT field in the Designer, use the `long_to_varchar` function to perform the conversion.

Designer Guide: XML extraction and parsing for columns [page 366]

3.6 Functions and Procedures

In Data Services, functions take input values and produce a return value. Procedures take input values and perform a set of operations without returning a specific value. Input values can be parameters passed into a data flow, values from a column of data, or variables defined inside a script. This section discusses functions and procedures, including detailed descriptions of built-in functions—the input parameters and required syntax, and the return values and data types.

3.6.1 About functions

3.6.1.1 Functions compared with transforms

Some functions can produce the same or similar values as transforms. However, functions and transforms operate in a different scope:

- Functions operate on single values, such as values in specific columns in a data set.
- Transforms operate on data sets, creating, updating, and deleting rows of data.

SAP Data Services does not support functions that include tables as input or output parameters, except functions imported from SAP Applications.

3.6.1.2 Operation of a function

The function's operation determines where you can call the function. For example, the Lookup database function operates as an iterative function. The lookup function can cache information about the table and columns it is operating on between function calls. By contrast, conversion functions, such as to_char, operate as stateless functions. Conversion functions operate independently in each iteration. An aggregate function, such as max, requires a set of values to operate. Neither the lookup function (iterative) nor the max function (aggregate) can be called from a script or conditional where the context does not support how these functions operate.

The function type determines where a function can be used:

Type	Description
Aggregate	Generates a single value from a set of values. Aggregate functions, such as max, min, and count, use the data set specified by the expression in the *Group By* tab of a query. Can be called only from within a Query transform—not from custom functions or scripts.
Iterative	Maintains state information from one invocation to another. The life of an iterative function's state information is the execution life of the query in which they are included. The lookup function is an iterative function. Can be called only from within a Query transform—not from functions or scripts.
Stateless	State information is not maintained from one invocation to the next. Stateless functions such as to_char or month can be used anywhere expressions are allowed.

3.6.1.3 Arithmetic in date functions

Data Services performs some implicit data type conversions on date, time, datetime, and interval values.

Related Information

Date arithmetic [page 1039]

3.6.1.4 Including functions in expressions

You can use functions in the following:

- Transforms (Query , Case, SQL, Map_Operation)
- Script objects
- Conditionals
- Other custom functions

Before you use a function, you need to know if the function operation makes sense in the expression you are creating.

For example:

- The `max` function cannot be used in a script or conditional where there is no collection of values on which to operate.
- Parameters can be output by a work flow but not by a data flow.

You can use two editors to add an existing function to an expression. These are:

- Smart editor
  Embedded in other editor windows like the Script Editor, Conditional Editor, and Query Editor, the smart editor offers color coded syntax, a right-click menu, keyboard short cuts, and a list of available variables, data type formats, and functions that you can use to define a function.
- Function wizard
  You can use the function wizard to define the parameters for an existing function. The function wizard offers the most help when defining complex functions.

Related Information

Smart editor [page 1021]

3.6.1.4.1 To create an expression that includes an existing function

1. Go to the script, query, or conditional editor in which you will include the expression.
2. Enable the smart editor and begin entering your expression.
3. When you want to include the function, click the *Functions* button.

   The Designer opens the Select Function window of the function wizard.

4. Select a category in the *Function categories* box.

   A list of functions in that category appears in the Function name box. The functions shown depend on the object you are using. For example, the functions available for ABAP data flows are a subset of those available for data flows.

   In some cases, it does not make sense to use a function even though it is available. For example, the SQL function can be called in a mapping expression or a WHERE clause, but it would result in a SQL statement inside the SQL statement generated to execute a data flow.
5. Select a specific function in the *Function name* list.

   A description of the function appears below the boxes.
6. Click *Next*.
7. Enter the values required by the function in the text boxes.

   The page shown for each function is unique. Each page is designed to help you construct the current function. The example below shows the most common layout, however more complex functions may use different layouts.

   Click in a box to see a description of the parameter at the bottom of the window. Use the down-arrow button to select input parameters. Use the smart editor button (...) to see a larger input box.
8. Click *Finish*.

   The function and the parameters appear in the smart editor.

3.6.1.4.2 To edit an existing function call in an expression

You can edit function calls from a variety of editors. For example, you can edit them from the smart editor, script editor and so on. Using the function wizard to edit your complex function calls may save some time as the different pieces of the function are parsed into separate arguments. Then, you can identify the options you need to change.

> Note
>
> If your function contains specific spacing, line breaks or comments, you may not want to invoke the function wizard. Using the function wizard to edit an existing function call removes your formatting, spacing and comments. After you finish editing in the function wizard, the function text appears on one line with minimal spacing between the parameters.

1. Go to the expression that contains the function call that you want to change.
2. Right-click on the text of the function call and select *Edit Function*.
   The function wizard opens.
3. Make changes to the function call, and then click *Finish*.
   The function wizard closes and you can see the results of your function call.

Operation of a function [page 1512]

Including functions in expressions [page 1513]

3.6.2 Built-in functions

SAP Data Services provides a set of built-in functions.

In the software, database and application functions, custom functions, and most built-in functions can be executed in parallel within the transforms in which they are used.

You can run each resource-intensive functions, such as lookup_ext and count_distinct, as a separate sub data flow that uses separate resources (memory and computer) from each other.

Related Information

Performance Optimization Guide: Degree of parallelism and functions [page 2146]
Designer Guide: Distributed data flow execution [page 301]
Catch error functions [page 847]

3.6.2.1 Database and application functions

You can import the metadata for database and application functions and use them in Data Services applications. You can also import stored functions and procedures.

At run time, Data Services passes the appropriate information to the database or application from which the function was imported.

The metadata for a function includes the input and output parameters and their data types. If there are restrictions on data passed to the function, such as requiring uppercase values or limiting data to a specific range, you must enforce these restrictions in the input. You can either test the data before extraction or include logic in the data flow that calls the function.

About procedures [page 1697]
Designer Guide: Imported stored function and procedure information [page 221]

3.6.3 Descriptions of built-in functions

This section describes each built-in function available in Data Services.

The following table lists the names and descriptions of functions, as well as the function's category in the function wizard and smart editor.

Function	Category	Description
abs	Math	Returns the absolute value of an input number.
add_months	Date	Adds a given number of months to a date.
ascii	String	Returns the decimal value of the first character for the given string using ASCII character set. If the character passed is not a valid ASCII character, -1 is returned.
avg	Aggregate	Calculates the average of a given set of values.
base64_decode	Miscellaneous	Returns the source data after decoding the base64-encoded input.
base64_encode	Miscellaneous	Returns the base64-encoded data in the engine locale character set.
before_image	Miscellaneous	Returns the before image value of a row. This function is available for the Map_Operation transform only and is applicable to UPDATE rows.
cast	Conversion	Returns a value in the cast data type.
ceil	Math	Returns the smallest integer value greater than or equal to an input number.
chr	String	Get character representation of provided ASCII value.
concat_date_time	Date	Returns a datetime from separate date and time inputs.
count	Aggregate	Counts the number of values in a table column.
count_distinct	Aggregate	Count the number of distinct non-null values in a table column.
current_configuration	Miscellaneous	Returns the name of the datastore configuration in use at runtime.
current_system_configuration	Miscellaneous	Returns the name of the system configuration in use at runtime. If no system configuration is defined, returns a NULL value.
dataflow_name	Miscellaneous	Returns the data flow name in which this call exists. If the call is not in a data flow, returns NULL.
datastore_field_value	Miscellaneous	Retrieves the value of a specified datastore field.
date_diff	Date	Returns the difference between two dates or times.
date_part	Date	Extracts a component of a given date.
day_in_month	Date	Determines the day in the month on which the given date falls.
day_in_week	Date	Determines the day in the week on which the given date falls.

Function	Category	Description
day_in_year	Date	Determines the day in the year on which the given date falls.
db_type	Miscellaneous	Returns the database type of the datastore configuration in use at runtime.
db_version	Miscellaneous	Returns the database version of the datastore configuration in use at runtime.
db_database_name	Miscellaneous	Returns the database name of the datastore configuration in use at runtime.
db_owner	Miscellaneous	Returns the real owner name for the datastore configuration that is in use at runtime.
decode	Miscellaneous	Returns an expression based on the first condition in the specified list that evaluates to TRUE.
decrypt_aes	Cryptographic	Decrypts the input string using the user-specified passphrase and key length using the AES algorithm.
decrypt_aes_ext	Cryptographic	Decrypts cipher text using the AES key generated using the specified passphrase and salt. The passphrase and salt must be the same as those used to encrypt the data.
double_metaphone	String	Encodes the input string using the Double Metaphone algorithm and returns a string.
encrypt_aes	Cryptographic	Encrypts the input string using the user-specified passphrase and key length using the AES algorithm.
encrypt_aes_ext	Cryptographic	Encrypts plain text and encodes it in base64 using the AES key generated by using the specified passphrase, salt, and key length. Given the same input, the encrypted output should be the same. The caller of this function must ensure that the space to hold encrypted text is at least 1.33 times larger than the original plain text.
error_timestamp	Miscellaneous (Can only be found when creating a script)	Returns the timestamp of the caught exception.
error_context	Miscellaneous (Can only be found when creating a script)	Returns the context of the caught exception. For example, "|Session datapreview_job|data flow debug_DataFlow|Transform Debug"
error_message	Miscellaneous (Can only be found when creating a script)	Returns the error message of the caught exception.
error_number	Miscellaneous (Can only be found when creating a script)	Returns the error number of the caught exception.

Function	Category	Description
exec	System	Sends a command to the operating system for execution.
extract_from_xml	Conversion	Extracts XML directly from single column in a database table, and converts it into its internal nested relational data model (NRDM). To access this function, you must open the function wizard from within a new function call.
file_exists	Miscellaneous	Checks to see if a given file or directory exists.
fiscal_day	Date	Converts a given date into an integer value representing a day in a fiscal year.
floor	Math	Returns the largest integr value less than or equal to an input number.
gen_row_num_by_group	Miscellaneous	Returns group row number of the record.
gen_row_num	Miscellaneous	Returns an integer value beginning with 1 then incremented sequentially by 1 for each additional call. This function can be used to generate a column of row IDs.
gen_uuid	Miscellaneous	Returns a unique varchar string identifier.
get_domain_description	Miscellaneous	Returns the description of a value when given the domain name and the value.
get_env	Environment	Returns a value for the specified environmental variable.
get_error_filename	Environment	Returns the full path and file name for the error log.
get_file_attribute	Miscellaneous	Returns date created, date modified, or size (in bytes) of a physical file.
get_monitor_filename	Environment	Returns the full path and file name for the monitor log.
get_trace_filename	Environment	Returns the full path and file name for the trace log.
greatest	Miscellaneous	Returns greatest of the list of one or more expressions.
host_name	Miscellaneous	Returns the name of the computer on which the job is executing.
ifthenelse	Miscellaneous	Allows conditional logic in mapping and selection operations.
index	String	Returns the index of a given word in a string.
init_cap	String	Changes the characters in a string to title case.
interval_to_char	Conversion	Returns a string representation of the interval.
is_group_changed	Miscellaneous	Returns 1 if the group is changed, 0 otherwise.
is_set_env	Environment	Verifies if the specified environment variable is set.

Function	Category	Description
is_valid_date	Validation	Indicates if an expression can be converted into a valid date value.
is_valid_datetime	Validation	Indicates if an expression can be converted into a valid datetime value.
is_valid_decimal	Validation	Indicates if an expression can be converted into a valid decimal value.
is_valid_double	Validation	Indicates if an expression can be converted into a valid double value.
is_valid_int	Validation	Indicates if an expression can be converted into a valid integer value.
is_valid_real	Validation	Indicates if an expression can be converted into a valid real value.
is_valid_time	Validation	Indicates if an expression can be converted into a valid time value.
isempty	Miscellaneous	Indicates if a nested table contains data.
isweekend	Date	Indicates that a date corresponds to Saturday or Sunday.
job_name	Miscellaneous	Returns the name of the job in which the call to this function exists.
job_run_id	Miscellaneous	Retrieves the job run ID for the current job execution.
julian	Date	Converts a date to its integer Julian value, the number of days between the start of the Julian calendar and the date.
julian_to_date	Conversion	Converts a Julian value to a date.
key_generation	Database	Generates keys for the specified table, after determining the appropriate starting value.
last_date	Date	Returns the last date of the month for a given date.
least	Miscellaneous	Returns the least in a list of one or more expressions.
length	String	Returns the number of characters in a given string.
literal	String	Returns an input constant expression without interpolation. Allows you to assign a pattern to a variable without interpolation.
ln	Math	Returns the natural logarithm of the given numeric expression.
load_to_xml	Conversion	Generates XML text from NRDM and loads it into a single database column (Assumes the database supports XML text in its columns).

Function	Category	Description
log	Math	Returns the base-10 logarithm of the given numeric expression.
long_to_varchar	Conversion	Converts a data type from long to varchar.
lookup	Lookup	Finds a value in one table or file based on values in a second table or file.
lookup_ext	Lookup	Finds data from a database table, flat file, or memory datastore table.
lookup_seq	Lookup	Finds a value in one table based on values in a second table or file, and ensures that the sequence matches.
lower	String	Changes the characters in a string to lowercase.
lpad	String	Pads a string with characters from a specified pattern.
lpad_ext	String	Pads a string with logical characters from a specified pattern.
ltrim	String	Removes specified characters from the start of a string.
ltrim_blanks	String	Removes blank characters from the start of a string.
ltrim_blanks_ext	String	Removes blank and control characters from the start of a string.
mail_to	System	Sends the specified e-mail message.
match_pattern	String	Matches whole input strings to simple patterns supported by Data Services. This function does not match substrings.
match_regex	String	Matches whole input strings to the pattern that you specify with regular expressions (regular expressions based on the POSIX standard) and flags. This function does not match substrings.
max	Aggregate	Returns the maximum value from a list.
min	Aggregate	Returns the minimum value from a list.
mod	Math	Returns the remainder when one number is divided by another.
month	Date	Determines the month in which the given date falls.
num_to_interval	Conversion	Converts a numeric value to an interval.
nvl	Miscellaneous	Replaces NULL values.
power	Math	Returns the value of the give expression to the specified power.
previous_row_value	Miscellaneous	Returns the column value of previous row.
print	String	Prints the given string to the trace log.

Function	Category	Description
pushdown_sql	Miscellaneous	Allows you to create dynamic WHERE clauses.
quarter	Date	Determines the quarter in which the given date falls.
raise_exception	Miscellaneous	Calling this function causes an exception to be generated.
raise_exception_ext	Miscellaneous	Same as raise_exception, but takes a second parameter for an exit code.
rand	Math	Returns a random number between 0 and 1.
rand_ext	Math	Returns a random number between 0 and 1.
replace_substr	String	Returns a string where every occurrence of a given search string in the input is substituted by the given replacement string.
replace_substr_ext	String	Takes an input string, replaces specified occurrences of a specified sub-string with a specified replacement and returns the result. You can also use this function to search for hexadecimal or reference characters.
repository_name	Miscellaneous	Returns a database connection string and owner name. For example: `beq-local.DBUser.` This is the ID for the repository from which the job is run.
round	Math	Rounds a given number to the specified precision.
rpad	String	Pads a string with characters from a given pattern.
rpad_ext	String	Pads a string with logical characters from a given pattern.
rtrim	String	Removes given characters from the end of a string.
rtrim_blanks	String	Removes blank characters from the end of a string.
rtrim_blanks_ext	String	Removes blank and control characters from the end of a string.
sap_openhub_processchain_execute	SAP	Starts the process chain that extracts data from an SAP NetWeaver Business Warehouse (BW) and loads the extracted data into an Open Hub Destination table.
sap_openhub_set_read_status	SAP	Sends the read status for the Open Hub table to SAP NetWeaver BW.
search_replace	String	Searches input parameters and replaces by matching criteria and values specified by search table.
set_cdc_checkpoint	Miscellaneous	Sets a check-point for a Microsoft SQL Server changed-data-capture (CDC method) job for data flows that run in a WHILE loop.
set_env	Environment	Sets an environmental variable temporarily to a specified value.

Function	Category	Description
sleep	Miscellaneous	Suspends the execution of the data flow or work flow from where it is called.
soundex	String	Encodes the input string using the Soundex algorithm and returns a string. Use when you want to push down the function to the database-level.
sql	Database	Runs a SQL operation in the specified database.
sqrt	Math	Returns the square root of the given expression.
smtp_to	System	Sends the specified e-mail message using the SMTP protocol.
substr	String	Returns a specific portion of a string starting at a given point in the string.
sum	Aggregate	Calculates the sum of a given set of values.
sysdate	Date	Returns the current date as listed by the Job Server's operating system.
system_user_name	Miscellaneous	Returns the user name used to log into the Job Server's operating system.
systime	Time	Returns the current time as listed by the operating system.
table_attribute	Miscellaneous	Retrieves the value of a specified table attribute.
to_char	Conversion	Converts a date or numeric type to a string.
to_date	Conversion	Converts a string to a date.
to_decimal	Conversion	Converts a varchar to a decimal.
to_decimal_ext	Conversion	Converts a varchar to a decimal, including precision as a parameter.
total_rows	Database	Returns the number of rows in a particular table in a datastore.
trunc	Math	Truncates a given number to the specified precision.
truncate_table	Miscellaneous	Allows you to explicitly expunge data from a memory table.
upper	String	Changes the characters in a string to uppercase.
varchar_to_long	Conversion	Converts a data type from varchar to long.

Function	Category	Description
wait_for_file	Miscellaneous	Returns the existing files that match the input file pattern.
week_in_month	Date	Determines the week in the month in which the given date falls.
week_in_year	Date	Determines the week in the year in which the given date falls.
WL_GetKeyValue	String	Returns the value of a given keyword in Web log search strings.
word	String	Returns one word out of a string.
word_ext	String	Returns the word identified by its position in a delimited string.
workflow_name	Miscellaneous	Returns the work flow in which this call exists. Returns the name of the inner most work flow in cases where several work flows enclose this function call. If no work flow is found, returns job name.
year	Date	Determines the year in which the given date falls.

Related Information

Catch error functions [page 847]

3.6.3.1 abs

Returns the absolute value of a number.

Syntax

```
abs(<num>)
```

Return value

decimal, double, int, or real

The absolute value of the given number, **<num>** . The type of the return value is the same as the type of the original number.

Where

<num>	The source number.

Example

Function	Results
`abs(12.12345)`	`12.12345`
`abs(-12.12345)`	`12.12345`

3.6.3.2 add_months

Adds a given number of months to a date.

Syntax

```
add_months(<original_date, months_to_add>)
```

Return Value

date

Where

<original_date>	Specify the starting year.month.date.
<months_to_add>	Number of months to add to the original date.

Details

The **<months_to_add>** can be any integer. If **<original_date>** is the last day of the month or if the resulting month has fewer days than the day component of **<original_date>**, then the result is the last day of the resulting month. Otherwise, the result has the same day component as **<original_date>**.

Function	Results
`add_month('1990.12.17', 1)`	`'1991.01.17'`
`add_month('2001.10.31',4)`	`'2002.2.28'`

3.6.3.3 ascii

Returns decimal value of ASCII code of the first character in the input string.

Syntax

```
ascii(input_string)
```

Return Value

Int

Where

<input_string>	The source string.

Details

Returns the decimal value of the ASCII code of the first character in the input string. Returns -1 if the first character is not a valid ASCII character.

Example

Function	Results
`ascii('AaC')`	65

3.6.3.4 avg

Calculates the average of a given set of values.

Syntax

```
avg(<value_list>)
```

Return value

decimal, double, int, or real

The calculated average of **`<value_list>`**. The average is calculated to the same precision as the input value.

Where

`<value_list>`	The source values for which to calculate an average, such as a table column.

Example

To calculate the average of values in the salary column of a table, use the avg function in a query:

- In the *Mapping* tab of the query editor, enter:

  ```
  avg(SALARY)
  ```

- In the *Group By* tab in the query editor, specify the columns for which you want to group the salary, such as the department column. For each unique set of values in the group by list, such as each unique department, Data Services calculates the average salary.

3.6.3.5 base64_decode

Returns the source data after decoding the base64-encoded input.

Syntax

```
base64_decode(<base64-encoded input>, 'UTF-8')
```

Return Value

varchar or blob

Returns the source data after decoding the base64-encoded input. If the input is NULL or the size of the data is 0, Data Services returns NULL. Otherwise, it returns the base64-decoded data that conforms to RFC 2045.

Where

<base64-encoded input >	The base64-encoded input data. Supports varchar and blob data types.
UTF-8	The code page of the output data. UTF-8 is required for Data Integrator version 11.7.3. This paramater is not required when the input data type is blob.

Related Information

base64_encode [page 1527]

3.6.3.6 base64_encode

Returns the base64-encoded data in the engine locale character set.

Syntax

```
base64_encode(<input data>, 'UTF-8')
```

Return Value

varchar or blob

Returns base64-encoded data. If the input data is NULL or the size is 0, Data Services returns NULL. Otherwise, it returns the base64-encoded data that conforms to RFC 2045.

Where

`<input data>`	The input data that needs to be encoded to base64. Supports varchar and blob data types.
UTF-8	The code page of the input data. UTF-8 is required for Data Integrator version 11.7.3. This parameter is not required when the input data type is blob.

Related Information

base64_decode [page 1527]

3.6.3.7 before_image

Retrieves the before image value of a row. This function is available for the Map_Operation transform only and is applicable to UPDATE rows.

Note

You cannot use quoted strings in the parameter value for before_image. Because of this limitation, you cannot use global variable. For example, `before_image(T1.Col1)` is valid, but `before_image('T1.Col1')` is not.

Syntax

```
before_image(<column_name>)
```

Return value

Inline

The return value is the same as the input column value. For example, if the input column (column_name) is an integer, the software returns an integer.

Where

<column_name>	The name of the table column.

Example

```
before_image(Epml.SALARY)
```

Related Information

Map_Operation [page 1436]

3.6.3.8 cast

Explicitly converts an expression of one data type to another.

Syntax

```
cast(expression,data_type)
```

Return Value

Returns the same value in data_type.

Where

<expression>	Input expression that needs to be cast to target data type.
<data_type>	Target data type. This must be a built-in Data Services data type and specified as a constant string, for example, 'decimal`(28,7)`'. See the Target Data Type table below for syntax.

Details

The cast function explicitly converts the value of the first parameter into the built-in data type specified in the second parameter. The Cast Type Compatibility Matrix shows all explicit data type conversions that are valid for this function.

Cast type compatibility matrix

From / To	Date	Date time	Decimal	Double	Int	Interval	Real	Time	Time stamp	Varchar
Date	X	X							X	X
Date time	X	X						X	X	X
Decimal			X	X	X	X	X			X
Double			X	X	X	X	X			X
Int			X	X	X	X	X			X
Interval			X	X	X	X	X			X
Real			X	X	X	X	X			X
Time		X						X	X	X
Time stamp	X	X						X	X	X
Varchar	X	X	X	X	X	X	X	X	X	X

Target data type syntax

Data type	Syntax
varchar	'varchar(length)'
decimal	'decimal(precision,scale)'
integer	'int'
real	'real'
double	'double'
timestamp	'timestamp'
datetime	'datetime'
date	'date'

Target data type syntax	
Data type	**Syntax**
time	'time'
interval	'interval'

Table 174: Example

Input	Output
cast('20.3','decimal(3,1)')	20.3

3.6.3.9 chr

Converts a decimal ASCII code to a character.

Syntax

```
chr (integer_expression)
```

Return Value

ASCII character

Where

integer_expression	Integer from 0 through 255. Returns NULL if the integer expression is not in this range.

Details

This function returns the character associated with the specified ASCII code decimal number. If you specify a value of less than 0 or greater than 255 for the integer_expression parameter, SAP Data Services returns a NULL value. Use chr to insert control characters into character strings. For example, `chr(9)` can be used to insert <tab>.

Example

Function	Results
`chr(65)`	'A'

3.6.3.10 ceil

Returns the smallest integer value greater than or equal to a number.

Syntax

```
ceil(<num>)
```

Return value

decimal, double, int, or real

The indicated integer, cast as the same type as the original number, **<num>**.

Where

<num>	The source number.

Example

Function	Results
`ceil(12.12345)`	`13.00000`
`ceil(12)`	`12`
`ceil(-12.223)`	`-12.000`

3.6.3.11 concat_date_time

Returns a datetime from separate date and time inputs.

Syntax

```
concat_date_time(<date, time>)
```

Return value

datetime

The datetime value obtained by combining the inputs.

Example

```
concat_date_time(MS40."date",MS40."time")
```

3.6.3.12 count

Counts the number of values in a group.

Syntax

```
count(<column>)
```

Return value

int

The number of rows in the column that have a non-NULL value.

Where

`<column>`	The column in the input table in which to count values.

Example

To determine the number of customers located in a specific sales region, use the count function with a filter defined in the *Where* tab of the query editor. The following WHERE clause selects the rows in the REGION column with the value `TX`:

```
REGION = "TX"
```

With the target column selected, enter the count function in the *Mapping* tab of the editor:

```
count(REGION)
```

3.6.3.13 count_distinct

Returns the number of distinct non-null values in a group.

Syntax

```
count_distinct (expression)
```

Return Value

Integer

Where

expression	Any valid expression of any type except NRDM or long data type.

Example

In a customer table, the customer's region is stored in a column named `REGION`. To count the number of distinct regions the customers come from, use the count_distinct function with a filter defined in the *Where* tab of the query editor. Enter the count_distinct function in the *Mapping* tab of the editor, as follows:

```
count_distinct(REGION)
```

Input

Name	Region	Country
Cust 1	East	US
Cust 2	East	US
Cust 3	West	US
Cust 4	East	France

Output

```
count_distinct(REGION) = 2
```

If you need to calculate the number of distinct regions per country, add the country column to the group by clause, as follows:

`count_distinct(REGION)`	Country
2	US
1	France

Note

If you want to provide more resources to execute the `count_distinct` function, select *Run as a separate process*. This option creates a separate sub data flow process for the `count_distinct` function when Data Services executes the data flow.

Related Information

Designer Guide: Distributed data flow execution [page 301]

3.6.3.14 current_configuration

Returns the name of the datastore configuration that is in use at runtime. If the datastore does not support multiple configurations, for example, the datastore is a memory datastore, the name of the datastore is returned instead.

Syntax

```
current_configuration(ds_name)
```

Return Value

varchar

Where

<ds_name>	The name you enter when you create the datastore.

Example

Create a job and add a script with, for example, the following line.

```
print('Datastore Configuration used at runtime: [current_configuration()]')
```

Returns, for example, the following to the trace log:

```
Datastore configuration used at runtime: Test_DS
```

3.6.3.15 current_system_configuration

Returns the name of the system configuration used at runtime. If no system configuration is defined, returns a NULL value.

Syntax

```
current_system_configuration()
```

Return Value

varchar

Example

Create a job and add a script with, for example, the following line.

```
print('System Configuration used at runtime: [current_system_configuration()]')
```

This line returns, for example, the following to the trace log:

```
System configuration used at runtime: Production
```

3.6.3.16 dataflow_name

Returns the data flow name in which this call exists. If the call is not in a data flow, returns NULL.

Syntax

```
dataflow_name()
```

Return Value

varchar

Example

```
print('Data Flow Name: [dataflow_name()]')
```

3.6.3.17 datastore_field_value

Retrieves the value of a specified datastore field.

Syntax

```
datastore_field_value(<ds_name, field_name>)
```

Return Value

varchar

Where

`<ds_name>`	The name you enter when you create the datastore.
`<field_name>`	The name of the field.

Details

The `<field_name>` should match the name seen in the language of the datastore. In the datastore editor click the Show ATL button to see the valid field names. If a specified field is not found or the datastore is invalid, NULL is returned. If the `<field_name>` is 'password' NULL is returned.

Example

Function	Results
`datastore_field_value('mssql', 'sql_server_database')`	`'DBUser'`

3.6.3.18 date_diff

Returns the difference between two dates or times.

Syntax

```
date_diff(<date1, date2, fmt_str>)
```

Return Value

int

Where

`<date1, date2 >`		
`<fmt_str>`	The string describing the format of the dates. Choose from the following values:	
	D	Day
	H	Hours
	M	Minutes
	S	Seconds
	MM	Months

	YY	Years

Details

This function is equivalent to interval_to_char(date1 - date2, 'fmt_str'), except if date1 is smaller than date2, the date_diff function returns a positive value.

Example

Function	Results
`date_diff(start_date,sysdate(),'D')`	The number of days between the date in the column start_date and today's date.
`date_diff(start_time,systime(),'M')`	The number of minutes between the time in the column start_time and the current time.

3.6.3.19 date_part

Extracts a component of a given date.

Syntax

```
date_part(<in_date, fmt_str>)
```

Return Value

int

Where

<in_date>	The input date.	
<fmt_str>	The string describing the format of the extracted part of the date. Choose from the following values:	
	YY	Year

	MM	Month
	DD	Day
	HH	Hours
	MI	Minutes
	SS	Seconds

Details

This function takes in a datetime and extracts the component requested as an integer.

Note

`<Year>` is displayed as four digits, not two.

Example

Function	Results
`date_part('1990.12.31', 'YY')`	`1990`
`date_part('1991.01.17 23:44:30', 'SS')`	`30`

3.6.3.20 day_in_month

Determines the day in the month on which the input date falls.

Syntax

```
day_in_month(<date1>)
```

Return value

int The number from 1 to 31 that represents the day in the month that `<date1>` occurs.

Where

`<date1>`	The source date.

This function extracts the day component from the date value.

Example

Function	Results
`day_in_month(to_date('Jan 22, 1997','mon dd, yyyy'))`	22
`day_in_month(to_date('02/29/1996','mm/dd/yyyy'))`	29
`day_in_month(to_date('1996.12.31','yyyy.mm.dd'))`	31

3.6.3.21 day_in_week

Determines the day in the week on which the input date falls.

Syntax

```
day_in_week(<date1>)
```

Return value

int

The number from 1 (Monday) to 7 (Sunday) that represents the day in the week that `<date1>` occurs.

Where

`<date1>`	The source date.

This function allows you to categorize dates according to the day of the week the date falls upon. For example, all dates for which this function returns a "3" occur on Wednesday.

Example

Function	Results
`day_in_week(to_date('Jan 22, 1997','mon dd, yyyy'))`	3 (Wednesday)
`day_in_week(to_date('02/29/1996','mm/dd/yyyy'))`	4 (Thursday)
`day_in_week(to_date('1996.12.31','yyyy.mm.dd'))`	2 (Tuesday)

3.6.3.22 day_in_year

Determines the day in the year on which the input date falls.

Syntax

```
day_in_year(<date1>)
```

Return value

int

The number from 1 to 366 that represents the day in the year that **<date1>** occurs.

Where

<date1>	The source date.

Example

Function	Results
`day_in_year(to_date('Jan 22, 1997','mon dd, yyyy'))`	22
`day_in_year(to_date('02/29/1996','mm/dd/yyyy'))`	60

Function	Results
`day_in_year(to_date('1996.12.31','yyyy.mm.dd'))`	`366` (1996 was a leap year.)

3.6.3.23 db_type

Returns the database type of the datastore configuration in use at runtime.

This function is useful if your datastore has multiple configurations. For example, you can use this function in a SQL statement instead of using a constant. This allows the SQL statement to use the correct database type for each job run no matter which datastore configuration is in use.

Syntax

```
db_type(<ds_name>)
```

Return Value

varchar

Possible db_type() return values for datastore types are as follows:

Datastore Types	Possible db_type() Return Value
Adapter	Adapter
Database	Attunity_Connector, DB2, Informix, Memory, Microsoft_SQL_Server, ODBC, Oracle, SAP, SAP_BW, SQL_Anywhere, SAP Sybase (for SAP Sybase ASE), Sybase_IQ, Teradata
JDE One World	DB2, Microsoft_SQL_Server, ODBC, or Oracle
JDE World	ODBC
Oracle Applications	Oracle
PeopleSoft	Microsoft_SQL_Server, or Oracle
SAP Applications	SAP
SAP BW Source	SAP
SAP BW Target	SAP_BW
SAP Master Data Services	HANA

Datastore Types	Possible db_type() Return Value
Siebel	DB2, Microsoft_SQL_Server, or Oracle

Where

<ds_name>	The datastore name you enter when you create the datastore.

Example

If you have a SQL transform that performs a function that has to be written differently for database types, you can tell SAP Data Services what to do if the database type is Oracle.

In this example, the sql() function is used within a script.

```
IF (db_type('sales_ds') = 'Oracle')
BEGIN
    IF (db_version('sales_ds') = 'Oracle 9i')
        $sql_text = '…';
    ELSE
           $sql_text = '…';
END
Sql('sales_ds', '{$sql_text}');
```

3.6.3.24 db_version

Returns the database version of the datastore configuration in use at runtime. This function is useful if your datastore has multiple configurations. For example, you can use this function in a SQL statement instead of using a constant. This allows the SQL statement to use the correct database version for each job run no matter which datastore configuration is in use.

Syntax

```
db_version(<ds_name>)
```

Return Value

varchar

Possible db_version() return values are:

Database type	Version
Oracle	Currently supported versions
Microsoft SQL Server	Currently supported versions
DB2 UDB	Currently supported versions
Informix IDS	Currently supported versions
SQL Anywhere	Currently supported versions
SAP Sybase ASE	Currently supported versions
SAP Sybase IQ	Currently supported versions
Teradata	Currently supported versions
""	An empty string is returned for any other database type

Where

<ds_name>	The datastore name you enter when you create the datastore.

Example

If you have a SQL transform that performs a function that has to be written differently for different versions of Oracle, you can tell Data Services which text to use for each database version. In this example, the sql() function is used within a script.

```
IF (db_type('sales_ds') = 'Oracle')
BEGIN
    IF (db_version('sales_ds') = 'Oracle 9i')
        $sql_text = '…';
    ELSE
           $sql_text = '…';
END
Sql('sales_ds', '{$sql_text}');
```

3.6.3.25 db_database_name

Returns the database name of the datastore configuration in use at runtime.

This function is useful if your datastore has multiple configurations and is accessing an MS SQL Server or SAP Sybase ASE database. For a datastore configuration that is using either of these database types, you enter a database name, when you create a datastore. This function returns that database name.

For example, master is a database name that exists in every Microsoft SQL Server and SAP Sybase ASE database. However, if you use different database names, you can use this function in, for example, a SQL statement instead of using a constant. This allows the SQL statement to use the correct database name for each job run no matter which datastore configuration is in use.

This function returns an empty string for datastore configurations without MS SQL Server or SAP Sybase ASE as the Database Type.

Syntax

```
db_database_name(<ds_name>)
```

Return Value

varchar

Where

<ds_name>	The datastore name you enter when you create the datastore.

Example

If you have a SQL transform that performs a function that has to be written differently for different versions of database types, you can tell Data Services which text to use for each database version. In this example, the sql() function is used within a script.

```
IF (db_type('sales_ds') = 'DB2')
    $sql_text = '…';
ELSE
BEGIN
    IF (db_type('sales_ds') = 'MicroSoft_SQL_Server')
        $db_name = db_database_name('sales_ds');
        $sql_text = '…';
END
Sql('sales_ds', '{$sql_text}');
```

3.6.3.26 db_owner

Returns the real owner name for the datastore configuration that is in use at runtime.

This function is useful if your datastore has multiple configurations because with multiple configurations, you can use alias owner names instead of database owner names. By using aliases instead of real owner names, you limit the amount of time it takes to port jobs to different environments.

For example, you can use this function in a SQL statement instead of using a constant. This allows the SQL statement to use the correct database owner for each job run no matter which datastore configuration is in use.

Syntax

```
db_owner(<ds_name>, <alias_name>)
```

Return Value

varchar

Where

`ds_name`	The datastore name that you entered when you created the datastore.
`alias_name`	The name of the alias that you created in the datastore, then mapped to the real owner name when you created a datastore configuration.

Example

```
$real_owner = db_owner('sales_ds', 'sales_person');
```

3.6.3.27 decode

Returns an expression based on the first condition in the specified list of conditions and expressions that evaluates to TRUE.

Syntax

```
decode(<condition_and_expression_list,><default_expression>)
```

Return value

<expression> or **<default_expression>**

Returns the value associated with the first **<condition>** that evaluates to TRUE. The data type of the return value is the data type of the first **<expression>** in the **<condition_and_expression_list><.>**

If the data type of any subsequent **<expression>** or the **<default_expression>** is not convertible to the data type of the first **<expression>**, Data Services produces an error at validation. If the data types are convertible but do not match, a warning appears at validation.

Where

<condition_and_expression_list>	A comma-separated list of one or more pairs that specify a variable number of conditions. Each pair contains one **<condition>** and one **<expression>** separated by a comma. You must specify at least one **<condition>** and **<expression>** pair. The **<condition>** evaluates to TRUE or FALSE. The **<expression>** is the value that the function returns if the **<condition>** evaluates to TRUE.
<default_expression>	An expression that the function returns if none of the conditions in **<condition_and_expression_list>** evaluate to TRUE. You must specify a **<default_expression>**.

Details

The `decode` function provides an easier way to write nested `ifthenelse` functions. In nested `ifthenelse` functions, you must write nested conditions and ensure that the parentheses are in the correct places, as the following example shows:

```
ifthenelse ((EMPNO = 1), '111',
  ifthenelse((EMPNO = 2), '222',
      ifthenelse((EMPNO = 3), '333',
        ifthenelse((EMPNO = 4), '444',
          'NO_ID'))))
```

In the `decode` function, you list the conditions, as the following example shows. Therefore, `decode` is less error prone than nested `ifthenelse` functions.

```
decode ((EMPNO = 1), '111',
(EMPNO = 2), '222',
(EMPNO = 3), '333',
(EMPNO = 4), '444',
'NO_ID')
```

To improve performance, Data Services pushes this function to the database server when possible. Thus, the database server, rather than Data Services, evaluates the `decode` function.

Use this function to apply multiple conditions when you map columns or select columns in a query. For more flexible control over conditions in a script, use the IF keyword in the Data Services scripting language.

If a condition compares a varchar value with trailing blanks, the decode function ignores the trailing blanks.

To compare a NULL value (NULL constant or variable that contains a NULL constant), use the IS NULL or IS NOT NULL operator. If you use the Equal (=) or Not equal to (<>) operator, the comparison against a NULL value always evaluates to FALSE.

Example

Function	Results

`decode((COUNTRY = 'FRANCE'),`
`'French',`
`  (COUNTRY = 'GERMANY'), 'German',`
`  (COUNTRY = 'ITALY'), 'Italian',`
`  (COUNTRY = 'TAIWAN'), 'China',`
`  (COUNTRY = 'USA'), 'America',`
`  (COUNTRY IS NULL), 'Unknown',`
`      'Others')`
	If the value in the column COUNTRY is `FRANCE`, the value returned is `French`. If COUNTRY is `NULL`, the value returned is `Unknown`. If COUNTRY does not contain any of the values listed, the `decode` function returns the value `Others`.

3.6.3.28 decrypt_aes

This function decrypts the input string using the user-specified passphrase and key length using the AES algorithm.

Syntax

```
decrypt_aes(<encrypted_input_string, passphrase, key_length_in_bits>)
```

Return value

Returns plain string as varchar.

In case of a failure, the function throws an exception of type execution error which results in termination of the job. You can catch the exception by using try/catch handlers.

If the encrypted input string is empty, then the return value is an empty string.

If the encrypted input string is NULL, then the return value is NULL.

Where

<encryptedinput_string>	A varchar input string to be decrypted.
<passphrase>	A varchar character string.
<key_length_in_bits>	An int value of 128, 192, or 256.

Example

For security purposes, you should secure the passphrase in a database and read it using a sql() function into a local or global variable. Then you can pass the variable to the passphrase parameter.

```
 #read the passphrase
from a secured source such as a database
$G_passphrase = sql('PASSWORD_DATASTORE', 'select PASSPHRASE from PASSWORD');
encrypt_aes(SOURCE.SSN,
$G_passphrase, 128);
```

Similar to other string functions, this function can be called from a custom function, in the column mapping of a Query transform or in a script in the work flow.

3.6.3.29 decrypt_aes_ext

This function decrypts the input string using the user-specified passphrase, salt, and key length using the AES algorithm. The passphrase and salt must be the same as those used to encrypt the data.

It generates an AES key of the specified key length using the specified passphrase and the key generation algorithm PKCS5_PBKDF2_SHA256. This key is used for decrypting the encrypted input string.

Syntax

```
decrypt_aes_ext(<Varchar Encrypted_input_string, Varchar Passphrase, Varchar
salt, Int Key_length_in_bits>)
```

Return value

Returns plain string as varchar.

In case of a failure, the function throws an exception of type execution error, which results in the termination of the job. You can catch the exception by using try/catch handlers.

If the encrypted input string is empty, then the return value is an empty string.

If the encrypted input string is NULL, then the return value is NULL.

If you fail to provide the same passphrase and key length used for encryption to this function, then the call does not fail but instead returns an incorrect output.

Where

<Encrypted_input_string>	A varchar input string to be decrypted.
<Passphrase>	A varchar character string with at least one character.
<Salt>	A varchar that must be exactly eight ASCII characters.
<Key_length_in_bits>	An int value of 128, 192, or 256.

Example

For security purposes, you should secure the passphrase and salts in a database and read it using a sql() function into a local or global variable. Then you can pass the variable to the passphrase parameter.

```
#read the passphrase from a secured source such as a database
$G_passphrase = sql('PASSWORD_DATASTORE', 'select PASSPHRASE from PASSWORD');
$G_salt = sql('PASSWORD_DATASTORE', 'select SALT from PASSWORD');

decrypt_aes_ext(ENCRYPTED.SSN, $G_passphrase, $G_salt, 128);
```

Similar to other string functions, this function can be called from a custom function, in the column mapping of a Query transform, or in a script in the work flow.

3.6.3.30 double_metaphone

Encodes the input string using the Double Metaphone algorithm and returns a string.

Syntax

```
double_metaphone(<input_str, alternate, return_if_empty>)
```

Return Value

varchar

Returns the string containing the double metaphone encoding of the input string. The length of the return string depends on the length of the input string, but it is always shorter than the input string.

Where

<input_str>	The source string to encode.

`<alternate>`	A flag to control how encoded strings are returned. When input as 0, return the primary encoding. If there is no primary encoding, then return null or the input string, depending on how `<return_if_empty>` is set. When the input is not 0, return the alternate encoding. If there is no alternate encoding, then return null or the input string, depending on how `<return_if_empty>` is set. When the parameter is null or invalid (non-numeric), it is defaulted to 0.
`<return_if_empty>`	A flag to determine whether to return null or the input string when there is no encoding. When input as 0, return null. Otherwise, return the input string when there is no encoding. When the parameter is null or invalid (non-numeric), it is defaulted to 1. When input is empty, there is no primary or secondary encodings. When `<return_if_empty>`=0, then return null. When `<return_if_empty>`=1, then return the empty string.

Details

Only use this function for input strings in English. Non-English characters are ignored.

When input is null, then return is null.

When the second or third parameter has an invalid value, default to 0 and 1, respectively.

Example

Function	Result
`Print(double_metaphone('Hello',0,0);`	Prints the double metaphone of the word “Hello.”
`double_metaphone($VAR, 1,1);`	If the string stored in $VAR does not have encoding available, then return the original string.
`double_metaphone($VAR,'a','b');`	Returns the primary double metaphone encoding or the variable $VAR when the primary encoding does not exist.

3.6.3.31 encrypt_aes

This function encrypts the input string using the user-specified passphrase and key length using the AES algorithm.

Syntax

```
encrypt_aes(<input_string, passphrase, key_length_in_bits>)
```

Return value

Returns encrypted string as varchar. The size of the encrypted string is usually twice as large as the size of plain text, therefore you must have enough space to hold the encrypted string.

In case of a failure, the function throws an exception of type execution error which results in termination of the job. You can catch the exception by using try/catch handlers.

If the input string is empty, then the return value is an encrypted string. The encrypted string is different for multiple calls of encrypt_aes() function with an empty input string.

If the input string is NULL, then the return value is NULL.

Where

<input_string>	A varchar input string to be encrypted.
<passphrase>	A varchar character string.
<key_length_in_bits>	An int value of 128, 192, or 256.

Example

For security purposes, you should secure the passphrase in a database and read it using a sql() function into a local or global variable. Then you can pass the variable to the passphrase parameter.

```
 #read the passphrase
from a secured source such as a database
$G_passphrase = sql('PASSWORD_DATASTORE', 'select PASSPHRASE from PASSWORD');
encrypt_aes(SOURCE.SSN,
$G_passphrase, 128);
```

Similar to other string functions, this function can be called from a custom function, in the column mapping of a Query transform, or in a script in the work flow.

3.6.3.32 encrypt_aes_ext

This function encrypts the input string using the user-specified passphrase, salt, and key length using the AES algorithm.

It generates an AES key of specified key length using the specified passphrase, salt, and the key generation algorithm PKCS5_PBKDF2_SHA256. This key is used for encrypting the input string.

Syntax

```
encrypt_aes_ext(<Varchar Input_string, Varchar Passphrase, Varchar salt, Int
Key_length_in_bits>)
```

Return value

Returns encrypted string as base64 encoded string. The size of the encrypted string is 1.3 times larger than the size of plain text. Therefore you must have enough space to hold the encrypted string.

In case of a failure, the function throws an exception of type execution error, which results in the termination of the job. You can catch the exception by using try/catch handlers.

If the input string is empty, then the return value is empty.

If the input string is NULL, then the return value is NULL.

Where

<Input_string>	A varchar input string to be encrypted.
<Passphrase>	A varchar character string.
<Salt>	A varchar that must be exactly eight ASCII characters.
<Key_length_in_bits>	An int value of 128, 192, or 256.

Example

For security purposes, you should secure the passphrase and salts in a database and read it using a sql() function into a local or global variable. Then you can pass the variable to the passphrase parameter.

```
#read the passphrase from a secured source such as a database
$G_passphrase = sql('PASSWORD_DATASTORE', 'select PASSPHRASE from PASSWORD');
$G_salt = sql('PASSWORD_DATASTORE', 'select SALT from PASSWORD');

encrypt_aes_ext(SOURCE.SSN, $G_passphrase, $G_salt, 128);
```

Similar to other string functions, this function can be called from a custom function, in the column mapping of a Query transform, or in a script in the work flow.

3.6.3.33 error_context

Returns the context of the caught exception.

Syntax

```
error_timestamp()
```

Return value

varchar 512

Example

"|Session datapreview_job|Dataflow debug_DataFlow|Transform Debug"

Related Information

Catch error functions [page 847]

3.6.3.34 error_message

Returns the error message of the caught exception.

Syntax

```
error_message()
```

Return value

varchar 512

Related Information

Catch error functions [page 847]

3.6.3.35 error_number

Returns the error number of the caught exception.

Syntax

```
error_number()
```

Return value

int

Related Information

Catch error functions [page 847]

3.6.3.36 error_timestamp

Returns the timestamp of the caught exception.

Syntax

```
error_timestamp()
```

Return value

timestamp

Related Information

Catch error functions [page 847]

3.6.3.37 exec

Sends a command to the operating system for execution. With this function, you can add a program to a Data Services job.

Syntax

```
exec(<command_file, parameter_list, flag>)
```

Return value

Varchar(1020)

Returns up to 1020 characters that depend on the value of **<flag>** .

Where

<command_file>	A string that indicates the location and file name to execute. This string is relative to the Job Server location. It can be an absolute or relative path. The files and directories in the path must be accessible from the Job Server's computer. The **<command_file>** can be a Windows batch file, a UNIX shell script, or a binary executable. To run other interpreted scripts, the **<command_file>** must be the name of the command interpreter (e.g., 'perl') and the script must be the first parameter in the **<parameter_list>** .
<parameter_list>	A string that lists the values to pass as arguments to the command file. Separate parameters with spaces. When passing no parameters to an executable, enter an empty string (' ').
<flag>	An integer that specifies what information appears in the return value string, and how to respond upon error—how to respond if **<command_file>** cannot be executed or exits with a nonzero operating system return code.

Table 175: Exec function flags

Flag	If successful, returns:	On error:	Notes:
0	Standard output	Raises an exception: `System function failure.`	
1	NULL string	Raises an exception: `System function failure.`	Use this flag to track error states in either of the following cases:

Flag	If successful, returns:	On error:	Notes:
			• The command never produces output • The calling job does not need output
2	Standard output	NULL string	Use this flag if you do not intend to track the status of the command other than the presence or absence of output.
3	NULL string	NULL string	
4	Standard output	Data Services error message string	Refer to "Details "
5	NULL string	Data Services error message string	Refer to "Details "
8	The concatenation of the return code and the combined stdout and stderr (standard error).	Returns the concatenation of the return code and the combined stdout and stderr (standard error).	Refer to "Details "
256	NULL string	NULL string	Use this flag if you want your program to run independently of Data Services. Unlike flags 0-8, if you use flag 256, Data Services will not wait until the command (executable program) completes before continuing with job processing. In this case, the command runs independently of Data Services and stdout, stderr, and return code cannot be returned. Raises an exception (`System function failure)` if the program cannot be launched (e.g., program file not found).

Details

- The program that this function executes must not wait for any user input (e.g., a prompt for a password). For flags 0-8, Data Services waits for the program to complete, therefore if the program hangs for input Data Services will hang also. For flag 256, Data Services will continue if the program hangs for input.
- For flags 4 and 5, the return value format for a Data Services error message string is:

  ```
  'error-number: error-message-text'
  ```

  where the first field is exactly 7 characters wide, and the second begins at index 10. If the program cannot be executed, the error number is 50307. If the program exits with a non-zero return code, the error number is 50306. The text is from Business Objects' errormessage.txt. For example:

  ```
  '  50306: Function <exec> failed to execute program 'foo.exe'. Program
  terminated with exit code 3.'
  ```
- For flag 8, the return value format is:

  ```
  'return-code: stdout-and-stderr'
  ```

  where the first field is exactly 7 characters wide and the second begins at index 10. The return code is produced by the program. Zero indicates success. Consult your program's documentation to determine the meaning of other codes.
  For example:

  - `' 0: 8 file(s) copied.'`
  - `' 1: The system cannot find the file specified.'`
  - `' 1: a.tmp -> /usr/tmp/a.tmp cp: *.lcl: The system cannot find the file specified.'`
  - `' -2: manmix(): fatal application error.'`

  The 7-character format enables you to easily extract the first field (the return code from the executed command) as a string of digits (which Data Services automatically converts to an integer wherever necessary), and the second field as a regular string. For example:

  - In a script:

    ```
    $foo = exec('foo.bat', ' ', 8);
    ```

    ```
    $foo_rc = substr($foo, 1, 7);
    ```

    ```
    $foo_txt = substr($foo, 10, 1020);
    ```
  - In a data flow, map

    ```
    exec('foo.bat', '', 8)
    ```

    to an output column “foo” in a query. Then in a subsequent query, refer to that column's components in a mapping or WHERE clause. For example:

    ```
    substr(query.foo, 1, 7);
    ```

    ```
    substr(query.foo, 10, 1020);
    ```

Use of remote shells

Use a remote shell to run a command elsewhere on the network:

- The **`<command_file>`** named in an exec call can be 'rsh' on either Windows or UNIX systems to invoke the remote shell facility. This is a means of running a command on a machine elsewhere on the network. For example:
  - `exec('rsh', '<RemoteMachineName> <CommandToRunRemotely> <CmdArg1> <CmdArg2>', 0);`
  - `exec('rsh', '<RemoteBox> -l<RemoteUser> <RemoteCommand> <CmdArg>', 3);`

  Invoke the remote shell facility sparingly, as the remote connection setup, remote authentication, and increased message traffic reduce performance.
- For **`<flag>`** values 4, 5, and 8, the return code which Data Services receives is that of the rsh (or remsh) command (i.e., 0 if it successfully gets a remote connection and authorization, nonzero otherwise). There is no relation between this and the return value of the remote command (this is inherent in the remote shell mechanism on all the operating systems). To work around this, wrap the remote command in a `.bat` file (Windows) or shell script (UNIX) which will get the command's return code (%errorlevel% if Windows, $? if UNIX), and print it to stdout or stderr. For example:
  - `exec('rsh', '<RemoteMachineName> <remcmdWrapper>.bat <CmdArg1> <CmdArg2>', 8);`
  - `exec('rsh', '<RemoteBox> -l<RemoteUser> /usr/acta/<remcmdWrapper> <CmdArg>', 4);`
- The system administrator of the remote machine must set up access for the Data Services user. The `.rhosts` and/or the `hosts.equiv` file must have an entry allowing this access.
  - If the remote machine is Windows, the Remote Shell Service must be running on it.
  - If the remote machine is UNIX, the Remote Shell daemon rshd must be running on it.

  Consult your operating system documentation for more information.

Example

The examples below can be used with Windows or UNIX. If you were using the first two examples for UNIX, substitute 'sh', 'csh', 'ksh', 'bash' or 'tcsh' for 'cmd'. Also, the first two examples call 'cmd' rather than the program directly. You need to use 'cmd' (or its equivalent) if either:

- The “command” is a built-in of the shell (e.g., 'DIR' is not a program in Windows)
- Piping (a single '|' in an argument) occurs
- In either Windows or UNIX, the vertical bar symbol sends the output of one command to another command. Only use a vertical bar inside quotes. In Data Services, the double vertical bar symbol (||) concatenates strings. Only use a double vertical bar outside quotes.

Also, remember that the '\', '/' symbols are interchangeable when using Windows. However, only '/' is accepted as a directory separator on UNIX.

```
exec('cmd', 'dir ' || $filename, 8);
exec('cmd', 'x:/bin/program1.exe | x:/bin/postprocess.bat', 4);
exec(SRC.PROGNAME, ARGTBL.ARGS || ' lastArg', 2);
exec('c:\Data Services\bin\clone_and_rename.bat', TBL.FNAME, 1);
exec('C:\Perl5\bin\perl.exe', 'C:\sandbox\stats.pl 20 50 3000', 0);
```

3.6.3.38 extract_from_xml

This function allows you to extract XML data that is stored in one field of a database table into a query's output schema with Data Services' nested relational data model (NRDM) structure. Varchar data types are supported in the input column. You can use the following methods to extract data from clob and long data types.

- Data Services converts a clob data type input to varchar if you select the *Import unsupported data types* as VARCHAR of size option when you create a database datastore connection in the Datastore Editor.
- If your source uses a long data type, use the long_to_varchar function to convert data to varchar.

Syntax

```
extract_from_xml(<xml_column_name>,<schema_dtd_name>,<enable_validation>)
```

Value	Description
xml_column_name	The name of the input column that contains the XML text. The column data type must be varchar.
< schema_dtd_name >	The name of the DTD or XML Schema format that describes the incoming XML text. You must import the metadata for this format into Data Services. Data Services displays the format names in the *Formats* tab of the object library. The input value must be a constant since Data Services needs to know the output schema at design time.
enable_validation	Enable a comparison of the incoming XML data against the format you specify for **<schema_dtd_name>**. The XML data structure and the XML format structure must match. When this option is enabled, the data flow throws an exception if the incoming data is not valid. Enter `1` to validate. Enter `0` to disable the validation option. Validation is useful during development. It provides a more precise error if a problem occurs with the incoming XML.

Where

Once you provide parameter values, the output schema of this function will match that of the XML Format specified. You can select any of the top-level columns or the two columns Data Services generates in the NRDM for output:

- You can select any number of the top-level columns from XML schema. The return type of each column follows that defined in the XML schema.
- AL_ERROR_NUM - Returns an integer which indicates if an error occurred inside the function. A `0` indicates success and any non-zero integer indicates an error.

- AL_ERROR_MSG - Returns an error message if AL_ERROR_NUM is not 0. Otherwise, returns NULL.

Example

```
extract_from_xml(<cust_note_column>,<note_format>,1)
```

Related Information

Designer Guide: Nested Data, Scenario 1 [page 366]

3.6.3.39 file_exists

Checks to see if a given file or directory exists.

Syntax

```
file_exists(<file_path>)
```

Return Value

int

Returns 1 if a file or directory is present on the disk (even if 0 bytes long), 0 otherwise.

Where

<file_path>	The file name and path, relative to where the Job Server is running. It can be an absolute or relative path.

Example

Examples

Invoke sleep for one second when the file temp.msg exists in the directory called "c:".

```
while (file_exists('c:/temp.msg') = 1)
begin
 sleep(1000);
end
```

Set a variable to a file name and use the function to check whether the file exists:

```
$unix_file = '/tmp/t.cpp';
if (file_exists($unix_file)) $type = 'unix';
```

Set a variable based on the value of the function:

```
$i = file_exists('c:/autoexec.bat')
```

3.6.3.40 fiscal_day

Converts a given date into an integer value representing a day in a fiscal year.

Syntax

```
fiscal_day(<start_year_date, in_date>)
```

Return Value

int

Where

<start_year_date>	The first month and day of a fiscal year. Use this format: 'mm.dd'.
<in_date>	The date you want to convert. Use any valid datetime.

Example

Function	Results
`fiscal_day('03.01', '1999.04.20')`	`51`

3.6.3.41 floor

Returns the largest integer value equal to or less than a number.

Syntax

```
floor(<num>)
```

Return value

decimal, double, int, or real

The indicated integer, cast as the same type as the original number, `<num>` .

Where

`<num>`	The source number.

Example

Function	Results
`floor(12.12345)`	`12.00000`
`floor(12)`	`12`
`floor(-12.223)`	`-13.000`

3.6.3.42 gen_row_num_by_group

Generate a column of row IDs for each ID group in the specified column, beginning with integer value 1 and then incremented sequentially by 1. When the group is changed, the value is reset to 1.

Syntax

```
gen_row_num_by_group(expression_list)
```

Return Value

Integer

Where

<expression_list>	A list of one or more comma-separated expressions.

Details

This function groups the rows based on the value of expression(s) in each row in the natural order. It returns the row ID beginning with 1, then increments it sequentially by 1 for each row in the group.

In the example below, the Contract_ID column (shown under Input) shows miscellaneous ID numbers. When the `gen_row_num_by_group` function is applied to the ID column list, the IDs in the Contract_ID column are assigned a new ID number, with the first ID in the list assigned number 1. The ID number on the next row increases by 1 and is assigned the ID number 2. The ID in the following row also increases by an increment of 1, and is assigned the number 3 (as shown in the new Version_Num column under Output in the example).

If the expression(s) corresponds to a column of a table, that column must not be a NRDM or long type column.

This function should not be used with group by clause or any aggregate function.

Example

A typical use case of this function is to assign version numbers, which can become a part of the primary key in the table, as shown below.

Input			
Record	**Contract_ID**	**Revised_by**	**Revision_date**
record 1	1	John	1/1/2005
record 2	1	Mary	1/15/2005
record 3	1	Tim	2/1/2005
record 4	2	Joe	2/24/05

Input			
Record	Contract_ID	Revised_by	Revision_date
record 5	2	Sue	2/30/05

A version = gen_row_num_by_group (Contract_ID) would give an order of Contract_ID to group the contracts:

Output				
Record	Contract_ID	Version_Num	Revised_by	Revision_date
record 1	1	1	John	1/1/2005
record 2	1	2	Mary	1/15/2005
record 3	1	3	Tim	2/1/2005
record 4	2	1	Joe	2/24/05
record 5	2	2	Sue	2/30/05

3.6.3.43 gen_row_num

Returns an integer value beginning with 1 then incremented sequentially by 1 for each additional call. This function can be used to generate a column of row IDs.

Syntax

```
gen_row_num()
```

Return Value

int

Details

Each occurrence of the function in a data flow is a unique instance, resulting in a unique sequence. Two call instances return values independent of each other. The first time an instance of this function is called, the function returns a value of 1. Subsequent calls of the same instance return the previous value incremented by 1 (i.e., 2, 3, 4...).

Each time a data flow is called, all instances are reinitialized, starting at 1.

Example

Use the function in a query's mapping expression to add a column of row IDs to a target.

```
gen_row_num()
```

3.6.3.44 gen_uuid

This function returns a unique identifier.

Syntax

```
gen_uuid()
```

This function takes no parameters.

Return value

Returns a 32-character varchar string. For example, 550e8400e29b41d4a716446655440000.

3.6.3.45 get_domain_description

Returns the description of a value when given the domain name and the value.

Syntax

```
get_domain_description(<domain_name>,<domain_value>)
```

Return value

varchar

The description is returned as a quoted string. If the value is not in the domain, then a NULL is returned.

Where

<domain_name>	Fully qualified domain name, including the database owner if required. For example: **<datastorename>** . **<owner.domain>** **<datastorename>** . . **<domain>**
<domain_value>	The constant value for which you want to return a description.

Example

Function	Results
`get_domain_description('psoft..ACTION','ADL')`	"Additional"

3.6.3.46 get_env

Returns a value for the specified system environment variable.

Syntax

```
get_env('<variable_name'>)
```

Return Value

varchar(255)

Returns the value of the environment variable. Returns NULL if the environment variable is not set. You can use the is_set_env function to determine whether a variable is set.

Where

<variable_name>	The name of the environment variable. The name must be surrounded by single quotes.

Example

Function	Results
`getenv('TMP')`	`C:\Temp`

Related Information

is_set_env [page 1580]

3.6.3.47 get_error_filename

Returns the full path and file name for the error log, which Data Services generates after a job run. Data Services generates log files in the <**`<DS_COMMON_DIR>`**>`\log\`**`<Job Server>`**`\`**`<repository>`** directory. This log starts with 'error_'.

Data Services generates a different set of log files for each batch and real-time (in test mode) job run. Data Services creates only one set of log files during the life of a real-time service.

Syntax

```
get_error_filename()
```

Return Value

varchar

Example

Create a job and add a script with, for example, the following lines.

```
print('Error File Name:');
print(get_error_filename());
```

Returns, for example, the following to the trace log:

```
Error File Name:
d://DI11/log/JS_Ora/repo__riv/
error_12_10_2004_12_06_41_12__8507da25_0b33_4ac1_9b53_fcf1e004c968.txt
```

3.6.3.48 get_file_attribute

Returns the value for a specified attribute of a physical file.

Syntax

```
get_file_attribute(<filename>, <attribute>)
```

Return value

double

If the attribute is `size`.

datetime

If the attribute is either `date_created` or `date_modified`.

Where

`<filename>`	The file name and path relative to the current Job Server. Enter a file name as a relative path or an absolute path.
`<attribute>`	One of the following attributes, which must be in single quotes: date_created, date_modified, or size.

Example

Function	Results
`get_file_attibute('//order', 'date_created')`	'2004:09:15:20:25:00' The format in this example is YYYY:MM:DD:HH24:MM:SS.
`get_file_ attibute(c:\database\or-der,'size')`	'63281' Displays file size in bytes.

Limitations

- The function is not pushed down.

- This function cannot be used in an ABAP data flow.
- For MS Window systems, this function cannot return the create time from FAT formatted disk drives. It works with the NTFS (New Technology File System) format. Most systems use NTFS today because it is more powerful and offers a security advantage over FAT.

3.6.3.49 get_monitor_filename

Returns the full path and file name for the monitor log, which Data Services generates during a job run. Data Services generates log files in the **<DS_COMMON_DIR>**\log**<Job Server>****<repository>** directory. This log starts with 'monitor_'.

Data Services generates a different set of log files for each batch job run and each real-time job run (in test mode). Data Services creates only one set of log files during the life of a real-time service.

Syntax

```
get_monitor_filename()
```

Return Value

varchar

Example

Create a job and add a script with, for example, the following lines.

```
print('Monitor File Name');
print(get_monitor_filename());
```

Returns, for example, the following to the trace log:

```
Monitor File Name
d://DI11/log/JS_Ora/repo__riv/
monitor_12_1_2004_12_06_41_12__8507da25_0b33_4ac1_9b53_fcf1e004c968.txt
```

Note

A monitor log is referred to as a trace log in the Designer.

3.6.3.50 get_trace_filename

Returns the full path and file name for the trace log, which Data Services generates during a job run. Data Services generates log files in the **<DS_COMMON_DIR>**`\log\`**<Job Server>**`\`**<repository>** directory. This log starts with 'trace_'.

Data Services generates a different set of log files for each batch job run and each real-time job run (in test mode). Data Services creates only one set of log files during the life of a real-time service.

Syntax

```
get_trace_filename()
```

Return Value

varchar

Example

Create a job and add a script with, for example, the following lines.

```
print('Trace File Name');
print(get_trace_filename());
```

Returns, for example, the following to the trace log:

```
Trace File Name
d://DI11_97/log/JS_Ora/o920i1__riv/
trace_12_10_2004_12_06_41_12__8507da25_0b33_4ac1_9b53_fcf1e004c968.txt
```

3.6.3.51 greatest

Returns the greatest of the list of one or more expressions.

Syntax

```
greatest(expression_list)
```

Return Value

Data Services uses the first expression to determine the return type. After comparison, the result is converted into the return data type.

Where

`<expression_list>`	A list of one or more comma-separated expressions.

Details

GREATEST returns the greatest of the list of one or more expressions. After comparison, the result is converted into a return data type. Data Services implicitly converts expression in the list to a normalized data type before comparison.

The following rules determine the normalized data type.

- If the return data type is varchar, then all expressions are implicitly normalized to varchar before comparison.
- If the return data type is one of the date data types, then all the expressions in the list are implicitly normalized to that data type before comparison. For example, if the return data type is date, and another data type is 'datetime', then the 'datetime' data type is normalized to 'date' before comparison.
- If the return data type is numeric, then all the expressions are implicitly normalized to the highest precedence numeric expression in the list. For example, greatest (expr1,expr2,expr3,expr4) where expr1 is as integer, expr2 is a decimal (4,2), expr3 is a float, expr4 is a decimal (38,7), then the normalized data type is decimal. All the expressions in the list are converted to decimal data type before comparison. If the normalized data type is decimal, then its precision is the highest precision among all decimal data type expressions. The decimal data type expressions preserve their scale during implicit conversion. When an nteger data type expression is converted to a decimal data type, its scale is 0. When float, double and varchar data types are converted into decimal data types, their scale is 6.

Note

greatest() returns NULL when at least one argument is NULL.

Example

Input				
ID	**GRADE_Q1**	**GRADE_Q2**	**GRADE_Q3**	**GRADE_Q4**
1	'A'	'B'	'B'	'C'
2	'F'	'F'	'E'	'C'
3	'B'	'B'	NULL	NULL

Output	
MAX_GRADE=greatest `(GRADE_Q1,GRADE_Q2,GRADE_Q3,GRADE_Q4)`	
ID	**MAX_GRADE**
1	'C'
2	'F'

Output	
MAX_GRADE=greatest(GRADE_Q1,GRADE_Q2,GRADE_Q3,GRADE_Q4)	
ID	MAX_GRADE
3	NULL

3.6.3.52 host_name

Returns the name of the computer on which the job is executing.

Syntax

```
host_name()
```

Return Value

varchar

Example

```
print('Host Name: [host_name()]');
```

3.6.3.53 ifthenelse

Allows conditional logic in expressions.

Syntax

```
ifthenelse(<condition>, <true_branch>, <false_branch>)
```

Return value

<true_branch> or **<false_branch>**

Returns one of the values provided, based on the result of **<condition>**. The data type of the return value is the data type of the expression in **<true_branch>**. If the data type of **<false_branch>** is not convertible to the data type of `<true_branch>`, Data Services produces an error at validation. If the data types are convertible but don't match, a warning appears at validation.

If `<condition>` compares a varchar value with trailing blanks, the ifthenelse function ignores the trailing blanks.

To compare a NULL value (NULL constant or variable that contains a NULL constant), use the IS NULL or IS NOT NULL operator. If you use the Equal (=) or Not equal to (<>) operator to compare against a NULL value, `<condition>` always evaluates to FALSE.

Where

`<condition>`	An expression that evaluates to TRUE or FALSE.
`<true_branch>`	An expression that the function returns if `<condition>` evaluates to TRUE.
`<false_branch>`	An expression that the function returns if `<condition>` evaluates to FALSE.

To improve performance, Data Services pushes this function to the database. Thus, the database evaluates the IFTHENELSE logic rather than the Data Services engine.

Use this function to apply conditional logic when mapping columns or selecting columns in a query. For more flexible control over conditions in a script, use the IF keyword in the Data Services scripting language.

Example

Function	Results

`ifthenelse (ZIP < 94000, 'SOUTH',`
`'NORTH')`
	If the value in the column `ZIP` is less than 94000, the value returned is `SOUTH`. If `ZIP` is greater than 94000, then the value returned is `NORTH`.

3.6.3.54 index

Returns the index of a given character sequence in a string.

Syntax

```
index(<input_string>, <index_string>, <start>)
```

Return value

int

Specifies the first location of the indicated character sequence.

Where

`<input_string>`	The source string.
`<index_string>`	The character sequence sought in `<input_string>`.
`<start>`	The position where the function starts searching in `<input_string>` for the character sequence contained in `<index_string>`. `<Start>` should be a positive number between 1 and the length of `<input_string>`.

Details

The function searches for the `<index_string>` beginning at the `<start>` position in the input_string. If `<start>` is 0, it is reset to 1; if `<start>` is greater than the number of characters in `<input_string>`, the function returns NULL.

If `<index_string>` is not found in `<input_string>`, the function returns 0. The characters in `<index_string>` must match exactly the sequence of characters in `<input_string>`. The search is case-sensitive.

Example

Function	Results
`index('Accounting Department', 'DEPARTMENT', 1)`	`0`
`index('Accounting Department', 'Department', 1)`	`12`

3.6.3.55 init_cap

Changes the characters in a string to title case. This function converts the first letter of each word to uppercase and the rest of the value to lowercase. It ignores non-alphanumeric characters.

Syntax

```
init_cap(<value,'locale'>)
```

Return value

varchar

The title case string. Words are delimited by white space or characters that are not alphanumeric.

Where

`<value>`	The string to be modified.
`<locale>`	Optional parameter that converts the string to the specified locale. Note ISO 639 language code and ISO 3166 country code formats are supported.

Example

Function	Results
`init_cap('Data Services')`	'Data Services'
`init_cap(StreetAddress)`	Writes the value, for example '1234 west washington school road', in column StreetAddress as '1234 West Washington School Road'.
`Print(Init_cap('have a nice day -hypen +plus _underscore \slash $dollar *star @at   tab mIXedWORd UPPER lower !punctuations 1234digits'));`	Have A Nice Day -Hypen +Plus _Underscore \Slash $Dollar *Star @At Tab Mixedword Upper Lower !Punctuations 1234digits
`init_cap(LastName,'tr')`	The value in column`LastName` will have the first letter capitalized. If there is more than one last name in this column, that string will also have its first letter capitalized. It is also converted to the Turkish locale, using the ISO 639 language code.

Limitations

- The function is pushed down to Oracle databases only.
- You cannot use this function in an ABAP data flow.

Related Information

ISO 639 language list

ISO 3166 Country Code list

3.6.3.56 interval_to_char

Converts an interval value to a string.

Syntax

```
interval_to_char(<input_interval, interval_type>)
```

Return value

varchar

The converted string.

Where

<input_interval>	The value of type `interval` to convert.	
<interval_type>	A string describing the format of the interval. Choose from the following values:	
	D	Days
	H	Hours
	M	Minutes
	S	Seconds

Example

Function	Results
`interval_to_char(start_date - sysdate(), 'd')`	The number of days between the date in the column `start_date` and today's date.
`interval_to_char(start_time - systime(), 'm')`	The number of minutes between the time in the column `start_time` and the current time.

3.6.3.57 is_group_changed

Returns 1 if the group is changed, 0 otherwise.

Syntax

```
is_group_changed(expression)
```

Return Value

Integer

Where

`<expression>`	One or more valid input expressions separated by commas.

Details

This function groups records based on the equal value of the input expressions in parameter1 in the natural order of the input record stream. It returns 1 when the group is changed, 0 otherwise. In the following example, the results show that four of the input groups have changed.

Example

Function	Results
`is_group_changed(state,city)`	`1,0,1,0,0,1,1`

Group ID	State	City	Group change
1	California	Los Angeles	1
2	California	Los Angeles	0
3	California	San Francisco	1
4	California	San Francisco	0
5	California	San Francisco	0
6	Nevada	Reno	1
7	Colorado	Reno	1

3.6.3.58 is_set_env

Verifies if the specified system environment variable is set.

Syntax

```
is_set_env(<variable_name>)
```

Return value

int

Returns 1 if the environment variable is set, otherwise, returns 0.

Where

<variable_name>	The name of the environment variable. The name must be surrounded by single quotes.

Example

Function	Results
`is_set_env('MODE')`	Returns 1 if the MODE variable has already been set; returns 0 if the MODE variable has not been set.

3.6.3.59 is_valid_date

Indicates if an expression can be converted into a valid calendar date value. For example the following will return a negative result:

```
is_valid_date ('01/34/2002', 'mm/dd/yyyy')
```

This expression returns 0 because there is no such date as January 34th.

Syntax

```
is_valid_date(<input_expression, date_format>)
```

Return value

int

- If the expression is not NULL and valid, it returns 1.
- If the expression is not NULL and invalid, it returns 0.
- If the expression is NULL, it returns NULL.

Where

<input_expression>	The expression to be validated. If the expression does not resolve to a value of data type `varchar`, you will see a warning that the value has been converted to a `varchar`.	
<date_format>	The string identifying the date format of the input string. Construct the date format using the following codes and other literal strings or punctuation:	
	DD	2-digit day of the month
	MM	2-digit month

	MONTH	Full name of month
	MON	3-character name of month
	YY	2-digit year
	YYYY	4-digit year

Example

Function	Results
`is_valid_date (Orders.SubmitDate,'mm/dd/yyyy')`	Tests whether the string `Orders.SubmitDate` can be converted to a calendar date with the `mm/dd/yyyy` date format.

Related Information

date [page 1027]

3.6.3.60 is_valid_datetime

Indicates if an expression can be converted into valid calendar date and time values. For example the following will return a negative result:

```
is_valid_datetime ('01/14/2002 26:56:09', 'mm/dd/yyyy hh24:mi:ss')
```

This expression returns 0 because there is no such hour as "26", even on the 24 hour clock.

Syntax

```
is_valid_datetime(<input_expression, datetime_format>)
```

Return value

int

- If the expression is not NULL and valid, it returns 1.
- If the expression is not NULL and invalid, it returns 0.
- If the expression is NULL, it returns NULL.

Where

<input_expression>	The expression to be validated.	
<datetime_format>	The string identifying the datetime format of the input expression. Construct the datetime format using the following codes and other literal strings or punctuation:	
	DD	2-digit day of the month
	MM	2-digit month
	MONTH	Full name of month
	MON	3-character name of month
	YY	2-digit year
	YYYY	4-digit year
	HH24	2-digit hour of the day (00-23)
	MI	2-digit minute (00-59)
	SS	2-digit second (00-59)

Example

Function	Results
`is_valid_datetime (Orders.Received,'mm/dd/yyyy hh24:mi:ss')`	Tests whether the string `Orders.Received` can be converted to the `mm/dd/yyyy hh24:mi:ss` datetime format.

Related Information

datetime [page 1029]

3.6.3.61 is_valid_decimal

Indicates if an expression can be converted into a valid decimal value.

Syntax

```
is_valid_decimal(<input_expression, decimal_format>)
```

Return value

int

- If the expression is not NULL and valid, it returns 1.
- If the expression is not NULL and invalid, it returns 0.
- If the expression is NULL, it returns NULL.

Where

<input_expression>	The expression to be validated.
<decimal_format>	A string indicating the decimal format of the input expression. Use pound characters (#) to indicate digits and a decimal indicator. If necessary, include commas as thousands indicators. For example, to specify a decimal format for numbers smaller than 1 million with 2 decimal digits, use the following string: `'#,###,###.##'`. To indicate a negative decimal number, add a minus "-" sign at the beginning or end of this value. For example, to test if the stock price difference can be converted to decimal format, use the following function: `is_valid_decimal (Stocks.Price_difference, '-###.##')`

Example

Function	Results
`is_valid_decimal (Orders.Price,'###,###.##')`	Tests whether the string `Orders.Price` can be converted to decimal format.

3.6.3.62 is_valid_double

Indicates if an expression can be converted into a valid double value.

Syntax

```
is_valid_double(<input_expression, double_format>)
```

Return value

int

- If the expression is not NULL and valid, it returns 1.
- If the expression is not NULL and invalid, it returns 0.
- If the expression is NULL, it returns NULL.

Where

<input_expression>	The expression to be validated.
<double_format>	A string indicating the double format of the input expression. Use pound characters (#) to indicate digits and a decimal indicator. If necessary, include commas as thousands indicators. For example, to specify a double format for numbers smaller than 1 million with 2 decimal digits, use the following string: `#,###,###.##'`

Example

Function	Results
`is_valid_double (Product.Weight,'###.###')`	Tests whether the string `Product.Weight` can be converted to double format.

3.6.3.63 is_valid_int

Indicates if an expression can be converted into a valid integer value.

Syntax

```
is_valid_int(<input_expression, int_format>)
```

Return value

int

- If the expression is not NULL and valid, it returns 1.
- If the expression is not NULL and invalid, it returns 0.
- If the expression is NULL, it returns NULL.

Where

<input_expression>	The expression to be validated.
<int_format>	The format specifying the thousands separator of the input expression. For example, to specify an integer format, use the following string: #.###.###'. Valid separators include the period (.) and the comma (,). However, you can only use one valid separator type in a format. Separator defaults to the comma (,) when none is specified.

Example

Function	Results
`is_valid_int (QuarterResults.Volume,'###.###')`	Tests whether the string `QuarterResults.Volume` can be converted to the `###.###` integer format.

3.6.3.64 is_valid_real

Indicates if an expression can be converted into a valid real value.

Syntax

```
is_valid_real(<input_expression>, <real_format>)
```

Return value

int

- If the expression is not NULL and valid, it returns 1.
- If the expression is not NULL and invalid, it returns 0.
- If the expression is NULL, it returns NULL.

Where

<input_expression>	The expression to be validated.
<real_format>	A string indicating the real format of the input expression. Use pound characters (#) to indicate digits and a decimal indicator. For example, to specify a real format for numbers smaller than 1 million with 2 decimal digits, use the following string: `'#,###,###.##'`.

Example

Function	Results
`is_valid_real (QuarterResults.Mean,'#,###.#####')`	Tests whether the string `QuarterResults.Mean` can be converted to real format.

3.6.3.65 is_valid_time

Indicates if an expression can be converted into a valid time value.

Syntax

```
is_valid_time(<input_expression, time_format>)
```

Return value

int

- If the expression is not NULL and valid, it returns 1.
- If the expression is not NULL and invalid, it returns 0.
- If the expression is NULL, it returns NULL.

Where

<input_expression>	The expression to be validated.

<time_format>	The string identifying the time format of the input expression. Construct the time format using the following codes and other literal strings or punctuation:	
	HH24 MI SS	2-digit hour of the day (00-23) 2-digit minute (00-59) 2-digit second (00-59)

Example

Function	Results
`is_valid_time (Orders.ReceivedTime,'hh24:mi:ss')`	Tests whether the string `Orders.ReceivedTime` can be converted to the `hh24:mi:ss` datetime format.

3.6.3.66 isempty

Indicates if a nested table contains data.

Syntax

```
isempty(<table_name>)
```

Return value

int

The result of the content test: returns 1 if the table does not contain data; returns 0 if the table does contain data.

Where

<table_name>	The fully qualified name of the nested table to test. A fully qualified name contains the parent table names up to the top level of the table in the current context. If you only specify a table name, Data Services looks for the table among the tables available through the

	FROM clause of the current context. If you specify a partially qualified table name (only part of the table hierarchy), Data Services looks for the table among the tables available in the FROM clause of the context indicated by the partial qualification.

When performing operations on hierarchical data, the isempty function allows you to exclude rows in a higher-level table based on whether a lower-level table contains data.

Data Services determines that a nested table is empty when the table contains no rows. If the nested table contains even one row with null values in all columns, the isempty function indicates that the table has content. If the nested table is empty except for another nested table, and the second nested table does contain data, then the first nested table is not empty.

Example

You can use the isempty function to determine if there are line items associated with a sales order. For example, if the sales order is the input data set to a Query transform and you want the query to exclude orders without line items, include the following expression in the WHERE clause of the top-level context of the query:

```
isempty (order_table.line_items_table)
```

3.6.3.67 isweekend

Indicates if a date corresponds to Saturday or Sunday.

Syntax

```
isweekend(<date1>)
```

Return value

int

The result of the date test: returns 1 if the date is a Saturday or Sunday; returns 0 if not.

Where

<date1>	The value of type `date` or `datetime` to test.

Example

Function	Results
`isweekend(hire_date)`	Tests whether the date in `hire_date` is a Saturday or Sunday.
`isweekend(SYSDATE)`	Tests whether today is a Saturday or Sunday.

3.6.3.68 job_name

Returns the name of the job in which the call to this function exists.

Syntax

```
job_name()
```

Return Value

varchar

Example

```
print('Starting execution of Job: [job_name()] as user: [system_user_name()]');
```

3.6.3.69 Job_Run_ID

Syntax

Retrieves the job run ID for the current job execution.

Syntax

```
job_run_id()
```

Return value

Varchar (20)

3.6.3.70 julian

Converts a date to its integer Julian value, the number of days between the start of the Julian calendar and the date.

Syntax

```
julian(<date1>)
```

Return value

int: The Julian representation of the date.

Where

`<date1>`	The source value of type `date` or `datetime`.

Example

Function	Results
`julian(to_date('Apr 19, 1997', 'mon dd, yyyy'))`	`729436`

3.6.3.71 julian_to_date

Converts a Julian value to a date.

Syntax

```
julian_to_date(<input_julian>)
```

Return value

date

The date that corresponds to the input Julian value.

Where

`<input_julian>`	An integer representing the Julian value to be converted.

Example

Function	Results
`julian_to_date(Julian_Date)`	Converts the number indicated by `Julian_Date` to its date value.

3.6.3.72 key_generation

Generates the next value in a series, after determining the last value in the series.

The key_generation function determines the maximum existing key value in a given column in the table in the database manager and uses that value as a starting point to generate key values for the target schema.

Note

The key_generation function is not supported when using SAP tables as readers.

Syntax

```
key_generation (<table>, <key_column>, <key_increment>)
```

Return value

int

The column value found to meet the function requirements.

Where

<table>	The full path name of the file or full database specification of the table in which the **<key_column>** is located. Enclose this value in single quotation marks.
<key_column>	A column with existing keys from which this function determines the largest existing key value. Enclose this value in single quotation marks.
<key_increment>	The integer increment used between key values this function generates.

Example

Function	Results
`key_generation('target_ds.dbo.sales','order_number',1)`	Looks for the last key value in the `order_number` column in the sales database and returns the largest value plus one.

3.6.3.73 last_date

Returns the last date of the month for a given date.

Syntax

```
last_date(<in_date>)
```

Return Value

date

Where

<in_date>	The date for which the last date of the month is to be calculated.

Example

Function	Returns
`last_date('1990.10.01')`	`'1990.10.31'`

3.6.3.74 least

Returns the least of the list of one or more expressions.

Syntax

```
least(expression_list)
```

Return Value

Data Services uses the first expression to determine the return type. After comparison, the result is converted into the return data type.

Where

<expression_list>	A list of one or more comma-separated expressions.

Details

least returns the least of the list of one or more expressions. After comparison, the result is converted into a return data type. Data Services implicitly converts expressions in the list to a normalized data type before comparison.

The following rules determine the normalized data type:

1. If the return data type is varchar, then all expressions are implicitly normalized to varchar before comparison.
2. If the return data type is one of the date data types, then all the expressions in the list are implicitly normalized to that data type before comparison. For example, if the return data type is date, and another data type is 'datetime', then the 'datetime' data type is normalized to 'date' before comparison.
3. If the return data type is numeric, then all the expressions are implicitly normalized to the lowest precedence numeric expression in the list. For example, least(expr1,expr2,expr3,expr4) where expr1 is aa integer, expr2 is

a decimal (4,2), expr3 is a float, expr4 is a decimal (38,7), then the normalized data type is decimal. All the expressions in the list are converted to decimal data type before comparison. If the normalized data type is decimal, then its precision is the lowest precision among all decimal data type expressions. The decimal data type expressions preserve their scale during implicit conversion. When an integer data type expression is converted to a decimal data type, its scale is 0. When float, double and varchar data types are converted into decimal data types, their scale is 6.

Note

least() returns NULL when at least one argument is NULL.

Example

		Input		
ID	GRADE_Q1	GRADE_Q1	GRADE_Q3	GRADE_Q4
1	'A'	'B'	'B'	'C'
2	'F'	'F'	'E'	'C'
3	'B'	'B'	NULL	NULL

	Output	
	MIN_GRADE=least (GRADE_Q1,GRADE_Q2,GRADE_Q3,GRADE_Q4)	
ID	MAX_GRADE	MIN_GRADE
1	'C'	'A'
2	'F'	'C'
3	NULL	NULL

3.6.3.75 length

Returns the number of characters in a given string.

Syntax

```
length(<value>)
```

Return value

integer

The number of characters in `<value>`.

Where

`<value>`	A string indicating the column name, variable, or other element whose length is calculated.

Example

In the *Mapping* box of a query, you can use the length function to return the number of characters in each row of a column. For example, with the OUTPUT field selected in the target schema of a query, entering the following statement in the *Mapping* box:

```
length(dal_emp.ename)
```

produces the following results:

Source column (dal_emp.ename)	Target column (output)
`jones`	`5`
`nguyen`	`6`
`tanaka`	`6`

3.6.3.76 literal

Returns an input constant expression without interpolation. Data Services normally does not use variable interpolation on constants. However, if you pass in a variable as a constant expression, Data Services automatically uses variable interpolation, replacing special characters.

This is an issue with the Match_ pattern and Match_regex functions because they require these special characters. If your `pattern_string` or `regular_expresion_pattern` parameter in these functions is a constant, you may want to disable interpolation. If so, use the Literal function.

If, for example, you want to match $my_pattern with the pattern 'PART[123]'.

If you coded it simply as:

`$my_pattern = 'PART[123]'; match_pattern(product,$my_pattern);` the interpolation would actually change the pattern being matched to 'PART123', but if you code it as:

```
$my_pattern = literal ('PART[123]');
```

```
match_pattern(product, $my_pattern);
```

then it could return 1, because the pattern would remain 'PART[123]'.

Alternatively, if you do not want to use a variable, you can code it as:

```
match_pattern (product,'PART[123]');
```

because in this case no interpolation is done on the constant 'PART[123].

There is no runtime cost for the Literal function. Data Services substitutes the constant expression at compile time.

Syntax

```
literal(<input>)
```

Return value

Same as that of the value given for the input parameter but without interpolation.

Where

<input>	A constant expression of any data type.

Example

If you want to match only PART1 or PART2 or PART3 using the Match_pattern function, you must assign a pattern to a variable without interpolation. Use the Literal function in the following type of expression:

```
$pattern = literal('PART[123]');
```

For example, if you do not use the literal function, the value assigned to $my_pattern in the following sample is 'PART123' because Data Services automatically removes square brackets during interpolation.

```
$my_pattern='PART[123]';
print($my_pattern);
if (match_pattern('PART1',$my_pattern) <> 0)
 print('Matched');

else
print('Not Matched');
```

To disable interpolation, use the Literal function. The following example returns the result you want.

```
$my_pattern=LITERAL('PART[123]');
print($my_pattern);
if (match_pattern('PART1',$my_pattern) <> 0)
print('Matched');

else
print('Not Matched');
```

3.6.3.77 ln

Returns the natural logarithm of the given numeric expression.

Syntax

```
ln(numeric_expression)
```

Return Value

Float

Where

<numeric_expression>	Any numeric expression.

Details

Returns the natural logarithm of the given numeric expression. Return value is NULL if input is negative.

Example

Function	Results
`ln(5.436563656918)`	`1.693147`

3.6.3.78 load_to_xml

This function converts NRDM into XML and places it in a single column during a data load.

If the function fails due to an error when trying to produce the XML output, Data Services returns NULL for scalar columns (that you select for output) and an empty nested table for NRDM columns.

Syntax

```
load_to_xml (nested_table_name, schema_dtd_name, enable_validaton, xml_header,
replace_string_nulls, is_top_level_element, max_size)
```

Where

`nested_table_name`	The name of the NRDM table that you want to convert into an XML format.
`schema_dtd_name`	The name of the DTD or XML Schema that you want Data Services to use to format the XML text in the output column. Be sure to match the structure of the nested table to that provided by the DTD or XML Schema (or match the structure of its only child). Otherwise, Data Services will not produce output. See the `is_top_level_element` for an example of specifying an only child. Note You can generate an XML Schema or DTD from an NRDM schema using Data Services.
`enable_validation`	Enter `1` to validate. Enter `0` to disable the validation parameter. Validates that Data Services generates XML that matches the XML format you specify for schema_dtd_name.
`xml_header`	If the value specified is NULL, the header of the output XML has UTF-8 in the header. The default header generated is: <?xml version="1.0" encoding="UTF-8"?> If this value is not null, Data Services will replace the default XML header with the one you provide. Make sure the XML_header you provide matches the encoding of the target datastore where you will store the XML data.
`replace_null_string`	If this value is not null, Data Services replaces NULL values with the specified string.
`is_top_level_element`	Enter `1` if the input column representing the NRDM table matches the root element of the given DTD or XML Schema. Enter `0`, if the input column should match the only child of the root element of the DTD or XML Schema. Examples: • Imagine that an XML reader creates an NRDM structure with the root element named PO and an XML Schema po.xsd, which defines a root element also called PO . In this case, when you select the input column name

	PO as the `nested_table_name`, it matches the root element of the schema, so set the value of `is_top_level_element` to `1`. • By contrast, imagine that a database table called employees has rows which each contain information about one employee. Also, you are using an XML Schema called employees.xsd. This schema defines a root element called allEmployees and defines a single element called employee (with unbounded occurrence). In Data Services, the employee table exists in an NRDM structure with employee as the root name. If you enter employee is as the `nested_table_name`, because it does not match the root element of the schema allEmployees, set the value for `is_top_level_element` to `0`. The function returns data with allEmployees as the root element and the number of employee elements under it to match the number of rows in the input employees table.
`max_size`	The expected maximum size of the generated XML.

Example

```
load_to_xml(nested_table_name, billing_address_schema, 0, '<?xml version="1.0"
encoding="UTF-8"?>', NULL, 1, 4000)
```

Related Information

Designer Guide: Nested Data, Generating DTDs and XML Schemas from an NRDM schema [page 355]

3.6.3.79 log

Returns the base-10 logarithm of the given numeric expression.

Syntax

```
log(num)
```

Return Value

Float

Where

`<num>`	The number for which you want a base- 10 logarithm returned.

Details

Returns the base-10 logarithm of the given numeric expression. Return values is NULL if input is negative.

Example

Function	Results
`log(100.000)`	`2.000000`

3.6.3.80 long_to_varchar

Converts a data type value of a given column from long to varchar.

Syntax

```
long_to_varchar(<column_name>, <max_size, start_position>)
```

Return value

varchar

Where

`<column_name>`	The name of the column containing the long data type.
`<max_size>`	The maximum size for the converted data in the table column.
`<start_position>`	Starting character position from which data is converted. The default start position is 1. A negative num-

(Optional)	ber indicates that the starting position is counted backwards from the last character.

Example

long_to_varchar`(content_column, 4000)`

long_to_varchar`(content_column, 4000, -5000)`

Related Information

Designer Guide: XML extraction and parsing for columns, Scenario 1 [page 366]

3.6.3.81 lookup

Retrieves a value in a table or file based on the values in a different source table or file.

Note

You cannot use this function with a J. D. Edwards datastore. Use the lookup_ext function instead.

Syntax

```
lookup (<lookup_table>, <result_column>, <default_value>, <cache_spec>,
<compare_column>, <expression>)
```

Return value

any type

The value in the **`<lookup_table>`** that meets the lookup requirements. The return type is the same as **`<result_column>`**.

Where

`<lookup_table>`	The table or file that contains the result or value you are looking up (**`<result_column>`**). The **`<compare_column>`** is also located in this table. Use a fully qualified table name, including the datastore, owner, and table name. For example:

	`oracle_ds.TIGER.sales` You might need to put the owner in quotes, particularly if you use lower case letters.
`<result_column>`	The column containing the values you want to retrieve. This column is in the **`<lookup_table>`**.
`<default_value>`	The value returned when there is no matching row in the **`<lookup_table>`**.
`<cache_spec>`	The caching method the lookup operation uses. List within single quotes. There are three possible settings: NO_CACHE: Reads values from the **`<lookup_table>`** for every row without caching values. PRE_LOAD_CACHE: Loads the **`<result_column>`** and **`<compare_column>`** into memory after applying filters but before executing the function. Select this option if the number of rows in the table is small or you expect to access a high percentage of the table values. DEMAND_LOAD_CACHE: Loads **`<result_column>`** and **`<compare_column>`** values into memory as the function identifies them. Select this option if the number of rows in the table is large and you expect to access a low percentage of the table values frequently. Select this option when you use the table in multiple lookups and the compare conditions are highly selective, resulting in a small subset of data.
`<compare_column>`	The column in the **`<lookup_table>`** that the function uses to find a matching row. When the function reads a varchar column in the **`<lookup_table>`**, it does not trim trailing blanks.
`<expression>`	The value that the function searches for in the **`<compare_column>`**. This can be a simple column reference, such as a column found in both a source and the **`<lookup_table>`**. This can also be a complex expression given in terms of constants and input column references. When **`<expression>`** refers to a unique source column, you do not need to include a table name qualifier. If **`<expression>`** is from another table or is not unique among the source columns, you need a table name qualifier. If **`<expression>`** is an empty string, the function searches for a zero-length varchar value in the **`<compare_column>`**. The function ignores trailing blanks in comparisons of **`<expression >`** and values in **`< compare_column>`**.

ℹ Note

You can specify more than one `<compare_column>` and `<expression>` pair—simply add additional pairs at the end of the function statement. The values must match for all specified pairs in order for the lookup function to find a matching row.

The lookup function uses a value you provide (`<expression>`) to find a corresponding value in a file or different table. Specifically, the function searches for the row in the `<lookup_table>` where the value in the `<compare_column>` matches the value in `<expression>` . The function returns the `<result_column>` value from this matching row.

For example, if your source schema uses a customer ID to identify each row, but you want the customer name in your target schema, you can use the lookup function to return the customer name given the customer ID.

In SQL terms, the lookup function evaluates `<expression>` for each row, then executes the following command:

```
SELECT <result_column>
    FROM <lookup_table>
    WHERE <compare_column> = <expression>
```

The value returned by this SELECT statement is the result of the lookup function for the row.

You can specify multiple `<compare_column>` and `<expression>` pairs to uniquely identify the `<result_column>` value. However, the function wizard only provides fields for one pair; add extra `<compare_column>` and `<expression>` pairs to the output that the wizard generates.

When there are no matching rows in the `<lookup_table>`, the lookup function returns the `<default_value>`. When multiple matching rows exist in the `<lookup_table>`, the row returned is based on whether the lookup table is a standard RDBMS table, an SAP application table, or a flat file:

- For standard RDBMS tables, the lookup function will find the matching row with the maximum value in the `<result_column>` and return that value.
- For SAP application tables or flat files, the lookup function randomly selects a matching row and returns the value in the `<result_column>` for that row.

ℹ Note

To avoid random row selection when the `<lookup_table>` is an SAP application table or a flat file, it is recommended that you use the lookup_seq() function.

To enhance performance, you can configure the lookup function to hold the values from the `<lookup_table>` in memory. To do so, use the `<cache_spec>` setting. The optimal setting depends on the number of rows the function must read, the number of rows in the table, and the available memory.

Example

You can use the lookup function to return a text value given a numerical identifier. For example, suppose you have a source table containing a numerical identifier, such as an employee number, and you want to use the employee's name in your target.

You can use the lookup function to return the employee name based on the employee number. The lookup function uses a third table that translates the values from the source table to the desired values in the target table.

To produce the desired target column, select the column that you want to look up in the target schema. Click the *Functions* button, located over the *Mapping* text box. The function wizard opens. Under *Function categories*, select *Miscellaneous_Function*, then under *Function name*, select *lookup*. Click *Next*. The Define Input Parameters window opens.

Enter the function parameters as follows:

Option	Value
Lookup table	ODS_DS.SSB.EMPLOYEE
Result column	LastName
Default value	'NoLastName'
Cache spec	'No_CACHE'
Compare column	EmployID
Expression	EmployID

The **<expression>** value refers to a column in the source file or table and therefore does not require qualification with a table name. If this **<expression>** was from another table or was not unique among the source columns, it would require a table name qualifier.

The function wizard automatically produces the mapping text.

```
lookup(SQL_rbh.DBO.ODS_EMPLOYEE, LastName, 'NoLastName', 'NO_CACHE',
    EMP_ID, EMP_ID)
```

You can create a lookup function with two **<expression>** and **<compare_column>** pairs:

```
lookup(sap_ds..VBUP, GBSTA, 'none', 'NO_CACHE', VBELN, VBAK.VBELN, POSNR,
VBAP.POSNR)
```

This function returns the value from the GBSTA column in the VBUP table that corresponds to the VBELN value in the VBAK table and the POSNR value in the VBAP table. When no corresponding value is found, the function returns "none."

3.6.3.82 lookup_ext

Syntax

The following syntax includes line breaks for clarity.

Note

This function has a graphical editor.

```
lookup_ext(
[<lookup_table,cache_spec,return_policy>],
[<return_column_list>],
[<default_value_list>],
[<condition_list>],
[<orderby_column_list>],
[<output_variable_list>],
[<sql_override>]
set ("run_as_separate_process"='yes'),
("output_cols_info"='<?xml version="1.0"
encoding="UTF-8"?>
<output_cols_info>
<col index="1" expression="yes"/>
</output_cols_info>')
)
```

Return value

any type

The return type is the first lookup column in **`<return_column_list>`**.

Where

`<lookup_table>`	The table, file, or memory datastore that contains the result(s) or value(s) you are looking up (**`<result_column_list>`**). If the **`<lookup_table>`** is a database table, use the **`<datastore.owner.table>`** format. For example:
	`ERP_ds.OWNER.EMPLOYEES`
	If the **`<lookup_table>`** is a flat file, use the **`<file_ds.filename>`** format. For example:
	`delim."c:/temp/employees"`
	To substitute a variable for a file name, replace the data inside the double quotes, for example `delim."$employees"`. The variable used to store a file name can be a local or global variable or a parameter passed to a work flow or a data flow. If the cache specification is NO_CACHE, SAP Data Services can pass in a different file name each time it calls lookup_ext. For example, you can call lookup_ext in a WHILE loop and assign a different file name to the variable passed as the lookup file. If the cache specification is PRE_LOAD_CACHE or DEMAND_LOAD_CACHE, only the first file name passed is used. The software ignores all file names passed during subsequent calls.
	If the **`<lookup_table>`** is a memory datastore table, use the **`<memory_ds.table>`** format. For example:
	`mem_ds..employees`

`<cache_spec>`	The caching method the lookup_ext operation uses. You can select one of the following cache specifications:

	• NO_CACHE—Reads values from the `<lookup_table>` for every row without caching values. • PRE_LOAD_CACHE—Loads the `<return_column_list>`, `<compare_column>` (see `<condition_list>`), and `<orderby_column_list>` into memory after applying constant filters and before executing the function. Select this option if the number of rows in the table is small or you expect to access a high percentage of the table values. • DEMAND_LOAD_CACHE—Loads `<return_column_list>`, `<compare_column>` (see `<condition_list>`), and `<orderby_column_list>` into memory as the function identifies them. Select this option if the number of rows in the table is large and you expect to frequently access a low percentage of table values. Select this option when you use the table in multiple lookups and the compare conditions are highly selective, resulting in a small subset of data.
`<return_policy>`	Use `<return_policy>` when you expect multiple rows and want output data from one of the selected rows. This optional parameter specifies whether the return columns should be obtained from the smallest or the largest row based on values in the order by columns. The value can be MAX (default), MAX-NS, MIN, or MIN-NS. MAX-NS and MIN-NS allow the lookup_ext function to treat NULL as the smallest value instead of the largest value.
`<return_column_list>`	A comma-separated list containing the names of output columns in the `<lookup_table>`. For a given output column in the lookup table, select the *Expression?* check box in the lookup_ext editor when some of the data is in the form of expressions. If the Expression check box is selected and the data begins with an equals sign (=), the software evaluates the data as an expression and returns the result. Otherwise, it returns the column value.
`<default_value_list>`	A comma-separated list containing the default expressions for the output columns. When no rows match the lookup condition, the default values are returned for the output column. Each default expression type must be compatible with the corresponding output column type such that if the types are not exactly the same, automatic conversion is still possible. If `<default_value_list >` is empty or has fewer expressions than the number of output columns, NULL is the default. You cannot have more default expressions than the number of output columns.
`<condition_list>`	A list of triplets that specify lookup conditions. Each set in a triplet contains `<compare_column>`, `<compare_operator>` (<,<=,>, >=, =, !=, IS, IS NOT, ~), and `<compare_expression>`. The `<compare_column>` is from the `<lookup_table>`. It is compared against `<compare_expression>` to compute the output row.

	The **<compare_expression>** is written in terms of constants, variables, and columns in the calling data flow or scripts. While it cannot contain column reference from the **<lookup_table>**, it can be a simple constant, variable, or column reference or a complex expression involving arithmetic operations and function calls. Use compare operators IS and IS NOT to examine **<compare_column>** against the NULL constant. When you use IS or IS NOT as the compare operator, **<compare_expression>** must contain the NULL constant. When you use other compare operators against a **<compare_expression>** containing a NULL, the lookup condition return value will always return FALSE. Use the compare operator ~ to indicate that the column from the lookup table contains a pattern. The required pattern tags in the lookup table are: ● `mp(`**<pattern>**`)`—Indicates the match_pattern type of pattern syntax ● `mr(`**<pattern>**`)`—Indicates the match_regex type of pattern syntax ● `ms(`**<pattern>**`)`—Indicates the match_simple type of pattern syntax If **<compare_expression>** is an empty string, the function looks up a zero-length varchar value in the lookup table. The function ignores trailing blanks in the **<compare_expression>**. If you create more than one set of triplets, all triplets are implicitly joined with the AND operator to compute the final lookup condition. Example: `[c1, '=', 10,c2,'<',query.a,c3,'>=',lower(query.name)]`
<orderby_column_list>	A comma-separated list of column names from the **<lookup_table>**. Working together with **<return_policy>**, the **<orderby_column_list>** is used to determine which row to return the output when more than one row satisfies the lookup condition. When multiple rows occur, the list of rows is sorted based on columns from the **<orderby_column_list>** and choosing a row to return using the MIN/MAX **<return_policy>**. The **<orderby_column_list>** is optional. If you leave it blank, the orderby columns match the output columns. Examples: [c1,c3,c4] — Sorts the rows using column values in c1, c3, c4. [ ] — Indicated an empty list, which is a placeholder for specifying subsequent parameters.
<output_variable_list>	A comma-separated list of output variables. When more than one output column is specified in the function call, the output variables are used to receive output returns. Variables and output columns are matched by position.

	This parameter is optional unless more than one output column appears in the **`<return_column_list>`**. In the case of more than one output column, output variables must be equal in number to output columns. To enable conversion, the variable data type must be compatible with the corresponding output column. You do not need to specify output variables if the function is called using the function wizard to map output columns in the query window. Example: [$a,$b,$c]

`<sql_override>`	This parameter, available as a button called *Custom SQL* in the function wizard, must contain a valid, single-quoted SQL SELECT statement or a $variable of type VARCHAR to populate the lookup cache when the cache specification is PRE_LOAD_CACHE. This parameter replaces the SQL SELECT statement generated internally by the function for populating the cache. The SELECT statement must select at least those columns contained in **`<return_column_list>`**, **`<condition_list>`**, and **`<orderby_column_list>`**.
	Any valid SQL SELECT statement is permitted and may contain references to other tables besides the **`<lookup_table>`** to specify inner and outer joins. This parameter can only be specified when the **`<lookup_table>`** is a database table.
	If you specify this parameter with the cache specification of NO_CACHE, the software executes the sql_override query each time the function is called.
	If you specify this parameter with the cache specification of PRE_LOAD_CACHE, only the first sql_override query is executed to populate the lookup cache. All subsequent SQL statements are ignored after the lookup cache is built.
	If this parameter is specified when the cache specification is DEMAND_LOAD_CACHE, the caching mode will be converted to PRE_LOAD_CACHE and behave as if the PRE_LOAD_CACHE mode had been specified.
	EXAMPLE:
	`['select out1,`
	`                                    out2,compare1,compare2,orderby1,orderby2 from lookuptbl,othertbl where c1=10`
	`                                    and lookuptbl.c2=othertbl.c2']`
	Also, when you use **`<sql_override>`** in NO_CACHE mode, lookup_ext will dynamically execute the SQL if you pass in a dynamic SQL statement in the form of a variable.

The SET options include:

run_as_separate_process	Select (set to `yes`) to run each operation as a separate process (sub data flow) that uses separate resources (memory and computer) to improve performance and throughput. The default is `no`. `SET ("run_as_separate_process"='yes')`

output_cols_info	Identifies whether an output column contains an expression (when the *Expression* check box is selected). The default is `no`. The syntax is as follows:
	`SET ("output_cols_info"='<?xml version="1.0"`
	`encoding="UTF-8"?>`
	`<output_cols_info>`
	`<col index="1" expression="yes"/>`
	`</output_cols_info>')`
	The first column begins with index value of 1.

Optimizing database push-down

For best performance, the lookup_ext function can be pushed down to the database when the following conditions are met:

- The lookup_ext function is used in the column mapping, output schema, or `SELECT WHERE` clause of a Query transform.
- The **`<lookup_table>`** is a database table from the same datastore or a linked datastore as the reader.
- The **`<cache_spec>`** is set to `NO_CACHE`.
- The **`<return_policy>`** is set to either `MAX` or `MIN`.
- All conditions used in the **`<condition_list>`** are database expressions.
- Only the equals operator (=) are used in the lookup **`<condition_list>`**.
- The **`<run_as_separate_process>`** SET option is set to `no`.
- For lookups with multiple-result column values, the database must support the rank (or equivalent) function.

Note

For SAP HANA, MySQL, SAP Sybase ASE, and Informix databases, no analytic function support is available. As a result, push-down is supported in all cases for single-result columns, and multiple-result columns only for primary keys.

Limitations

- You cannot call the lookup_ext function from an ABAP data flow; use the lookup() function as an alternative.
- When calling lookup_ext in script objects, jobs, or work flows, the caching mode is always NO_CACHE because the software cannot determine when to release the cache after executing the function.
- In all parameters of lookup_ext, you can refer to any supported data type except the long, blob, and NRDM data types. Therefore, you cannot look up a long column or specify a column or expression of the long data type in **`<default_value_list>`**, **`<orderby_column_list>`**, or **`<condition_list>`**.
- If an optional parameter is missing, an empty placeholder ([]) must occupy that position if other optional parameters that follow the missing parameter are specified in the function call.
- It's recommended that for best performance you use the equals operator to specify the lookup condition. If the caching mode is NO_CACHE and the lookup_ext is against a database table, the underlying DBMS typically has fast access methods such as an index to retrieve data based on an indexed key. When the

caching method is PRE_LOAD_CACHE, using the equals comparison will result in more efficient memory lookup than any other comparison operators.
If the caching method is PRE_LOAD_CACHE, any lookup condition involving a constant expression will be pushed down to the database, resulting in a smaller lookup cache than the current lookup.

- Pattern evaluation uses virtual memory and is not included as part of pageable cache when the lookup table is cached. So if the lookup table has a lot of patterns, then the data flow could run out of memory. In those cases, select the *Run as a separate process* check box. This limitation also applies when using expressions in output columns.

3.6.3.83 lookup_seq

Retrieves a value in a table or file based on the values in a different source table or file and a particular sequence value.

Syntax

```
lookup_seq (<lookup_table>, <result_column>, <default_value>, <sequence_column>,
<sequence_expression>, <compare_column>, <expression>)
```

Return value

any type

The value in the **<lookup_table>** that meets the lookup_seq requirements. The return type is the same as **<result_column>**.

Where

<lookup_table>	The table or file that contains the result or value you are looking up (**<result_column>**). The **<sequence_column>** and **<compare_column>** are also

	located in this table. Use a fully qualified table name, including the datastore, owner, and table name. For example: ERP_ds.OWNER.EMPLOYEES The `<lookup_table>` is cached automatically for the operation of the function.
`<result_column>`	The column containing the values you want to retrieve. This column is in the `<lookup_table>`. When the column contains varchar values, the function does not trim trailing blanks.
`<default_value>`	The value returned when there is no matching row in the `<lookup_table>`.
`<sequence_column>`	The column in `<lookup_table>` that indicates the sequence of the row. This column often contains a date that indicates when new values were added to the row. For example, in some source tables, `<sequence_column>` is the `EFFDT` column, which indicates when the data in the row became effective.
`<sequence_><expression>`	The value the function searches for in the `<sequence_column>` to find a matching row. For example, if you are looking up values from a slowly changing dimension table and are interested in only those rows in which the data is current as of today, you could use the return value from the sysdate function for `<sequence_expression>`. If `<sequence_expression>` is an empty string, the function looks up a zero-length varchar value in the lookup table.
`<compare_column>`	The column in the `<lookup_table>` that the function uses to find a matching row.
`<expression>`	The value that the function searches for in the `<compare_column>`. This can be a simple column reference, such as a column found in both a source and the `<lookup_table>`. This can also be a complex expression given in terms of constants and input column references. When `<expression>` refers to a unique source column, you do not need to include a table name qualifier. If `<expression>` is from another table or is not unique among the source columns, you need a table name qualifier. If `<expression>` is an empty string, the function looks up a zero-length varchar value in the lookup table. The function ignores trailing blanks in comparisons of `<expression >` and values in `<compare_column>`.

Note

You can specify more than one **<compare_column>** and **<expression>** pair—simply add additional pairs at the end of the function statement. The values must match for all specified pairs in order for the lookup function to find a matching row.

The lookup_seq function uses a value you provide (**<expression>**) to find a corresponding value in a different file or table (**<lookup_table>**). When multiple rows match, the function uses the row's sequence to determine the matching row.

More specifically, the function searches for the rows in the **<lookup_table>** where the value in the **<compare_column>** matches the value in **<expression>**. When the function finds multiple matching rows, it searches in the **<sequence_column>** for the row with the closest value less than or equal to the **<sequence_expression>**. If no row has a value less than or equal to the **<sequence_expression>**, the function finds the row with the closest value to the **<sequence_expression>**. For the matching row, the function returns the value in the **<result_column>**.

For example, if your source schema uses an employee ID to identify each row, and you want the employee's salary at the end of the previous year in your target schema, you can use the lookup_seq function to return the employee salary given the employee ID and the effective date of the salary. The salary returned will be the value corresponding to the latest effective date less than or equal to the value of **<sequence_expression>**.

In SQL terms, the lookup_seq function evaluates **<expression>** for each row, then determines which sequence column value meets the requirements:

```
SELECT MAX(<sequence_column>)
    FROM <lookup_table>, <source_table>
    WHERE <sequence_column> <= <sequence_expression>
        AND <compare_column> =
            <source_table.expression>)
```

Suppose this query stores the **<sequence_column>** value returned as **<sequence_result>**. Next, the function uses the **<sequence_result>** to find the proper **<result_column>**:

```
SELECT <result_column>
    FROM <lookup_table, source_table>
    WHERE <sequence_column> = <sequence_result>
        AND <compare_column> =
            <source_table.expression>
```

The value returned by these queries is the result of the lookup_seq function for the row.

You can specify multiple **<compare_column>** and **<expression>** pairs to uniquely identify the **<result_column>** value. However, the function wizard only provides fields for one pair; add extra **<compare_column>** and **<expression>** pairs to the output that the wizard generates.

Data Services always caches the comparison table when performing a lookup_seq function.

If the lookup_seq function does not find the value of **<expression>** in **<compare_column>**, then the function evaluates and returns the **<default_value>**.

Example

You can use the lookup_seq function to return a value from a slowly changing dimension table given an identifier. For example, suppose you have a source table that contains a numerical identifier, such as an employee number, and you want to retrieve the employee's salary at a specific time in the past. You can use the lookup_seq function to return the employee's salary on a particular date based on the employee number.

The source table contains the employee number and employee name.

You want the target table to contain the employee name and salary.

Use the lookup_seq function to translate the values from the source table to the desired values in the target table. The lookup_seq function uses a third, "translation," table.

To produce the desired target column, select the column in the target schema. Next, click the *Functions* button, located over the *Mapping* text box. In the function wizard, select *Miscellaneous_functions* under Function categories, then select *lookup_seq* under Function name. Enter the function parameters as follows:

Option	Value
Translate table	ODS_DS.SSB.FINANCE
Result column	Salary
Default value	'0'
Sequence column	EffectiveDate
Sequence Expression	'12.31.1999'
Compare column	EmployeeID
Expression	EmployID

The function wizard automatically produces the mapping text

```
lookup_seq(Ora_DS.RBH.FINANCE, SALARY, '0',
    EFFECTIVEDATE, '12.3.1.1999', Employee_ID, EmployID)
```

For each employee, this lookup_seq function returns the value from the salary column for that employee that is the most recent before December 31, 1999.

3.6.3.84 lower

Changes the characters in a string to lowercase.

Syntax

```
lower(<value,'locale'>)
```

Return value

varchar

The lowercase string. The return type is the same as **<value>**. Any characters that are not letters are left unchanged.

Where

<value>	The string to be modified.
<locale>	Optional parameter that converts the string to the specified locale. Note ISO 639 language code and ISO 3166 country code formats are supported.

Example

Function	Results
`lower('Accounting101')`	'accounting101'
`upper((LastName,1,1))|lower(substr(LastName,2,LENGTH(LastName)))`	The value in column `LastName` with the first letter uppercase and the rest of the value lowercase. Note that this example does not account for two-word last names.
`lower(LastName,'tr')`	The value in column `LastName` is converted to all lowercase. It is also converted to the Turkish locale, using the ISO 639 language code.

Related Information

ISO 639 language list

ISO 3166 Country Code list

3.6.3.85 lpad

Pads the string with characters in the left from a given pattern.

This function repeats the pattern at the beginning of the input string until the final string is the appropriate length. If the input_string is already longer than the expected length, then this function truncates the string.

Syntax

```
lpad(<input_string, size, pad_string>)
```

Return value

varchar

The modified string. The return type is the same as **<value>**. Any characters that are not letters are left unchanged.

Where

<input_string>	The string source.
<size>	An integer value indicating the number of characters in the return string.
<pad_string>	A character or set of characters that this function concatenate to **<input_string>**.

Example

Function	Results
lpad('Tanaka', 15, ' ')	`'         Tanaka'`
lpad(last_name, 25, ' ')	The value in the column last_name, padded with spaces to 25 characters on the left or truncated to 25 characters.

3.6.3.86 lpad_ext

Pads the left side of the string with logical characters from a given pattern.

Note

These logical characters prohibit this function from getting pushed down to the database.

This function repeats the pattern at the beginning of the input string until the final string is the appropriate length. If the input_string is already longer than the expected length, then this function truncates the string.

Syntax

```
lpad_ext(<input_string, size, pad_string>)
```

Return value

varchar

The modified string. The return type is the same as **<value>**. Any characters that are not letters are left unchanged.

Where

<input_string>	The string source.
<size>	An integer value indicating the number of characters in the return string.
<pad_string>	A logical character or set of logical characters that this function concatenates to the **<input_string>**.

Example

Function	Results
lpad_ext('Tanaka', 15, ' ')	`'        Tanaka'`
lpad_ext(last_name, 25, ' ')	The value in the column last_name, padded with spaces to 25 characters on the left or truncated to 25 characters.

lpad_ext and lpad functions exhibit the same behavior when the functions are evaluated within Data Services. In situations where the function is pushed down to the database, the database behavior may differ when 'input_string' and/or 'pad_string' parameters contain multibyte characters.

Function	Input	Output
lpad	("abc¶¶", 10,' ')	`'   abc¶¶'`
lpad_ext	("abc¶¶", 10,' ')	`'     abc¶¶'`
lpad	("abc¶¶", 10,'')	`'abc¶¶'`
lpad_ext	("abc¶¶", 10,'')	`'abc¶¶'`
lpad	("abcd", 10, '¶')	`'¶¶¶abcd'`
lpad_ext	("abcd", 10, '¶')	`'¶¶¶¶¶¶abcd'`

3.6.3.87 ltrim

Removes specified characters from the start of a string.

Syntax

```
ltrim(<input_string>, <trim_string>)
```

Return value

varchar

The modified string. The return type is the same as <input_string>.

Where

<input_string>	The string to be modified.
<trim_string>	The characters to remove from <input_string>.

The ltrim function is case-sensitive.

The function scans <input_string> left-to-right removing all characters that appear in <trim_string> until it reaches a character not in <trim_string>.

Example

Function	Results
`ltrim('Marilyn', ' ')`	`'Marilyn'`
`ltrim('ABCABCD', 'ABC')`	`'D'`
`ltrim('ABCABCD', 'EFG')`	`'ABCABCD'`
`ltrim('ABCDEABCDE', 'ABC'`	`'DEABCDE'`

To remove all leading blanks in a string, use ltrim as follows:

```
ltrim(EMPLOYEE.NAME, ' ')
```

where EMPLOYEE.NAME specifies the NAME column in the EMPLOYEE table.

3.6.3.88 ltrim_blanks

Removes blank characters from the start of a string.

Syntax

```
ltrim_blanks(<input_string>)
```

Return value

varchar

The modified string. The return type is the same as `<input_string>`.

Where

`<input_string>`	The string to be modified.

Example

Function	Results
`ltrim_blanks('    Marilyn')`	`'Marilyn'`
`ltrim_blanks(last_name)`	The value contained in the column last_name, with all leading blanks and control characters removed.

3.6.3.89 ltrim_blanks_ext

Removes blank and control characters from the start of a string.

Syntax

```
ltrim_blanks_ext(<input_string>)
```

Return value

varchar

The modified string. The return type is the same as **<input_string>**.

Where

<input_string>	The string to be modified.

Example

Function	Results
`ltrim_blanks_ext('    Marilyn')`	`'Marilyn'`
`ltrim_blanks_ext(last_name)`	The value contained in the column last_name, with all leading blanks removed.

3.6.3.90 mail_to

Captures the specified number of lines in the trace log and error log, packages the information as e-mail, and uses your Job Server computer's mail client to send e-mail messages to your local mail server for standard e-mail processing.

Syntax

```
mail_to(<recipients_list>, <subject>, <message>, <number_of_trace_lines>,
<number_of_error_lines>)
```

Return value

int

Returns 0 if function succeeds. Returns a non-zero integer if function fails.

Where

<recipients_list>	A string containing one or more recipient e-mail addresses separated by commas (,). This string cannot be empty and must contain valid, qualified e-mail address information.
<subject>	A string containing the subject of the e-mail. This string can be empty.
<message>	A string containing the e-mail message. This string can be empty.
<number_of_trace><_lines>	The number of lines from the end of the trace log file to append to the end of the e-mail. This input cannot be empty.
<number_of_error><_lines>	The number of lines from the end of the error log file to append at the end of the e-mail. This input cannot be empty.

Only use this function within a script.

To use this function, a mail client must be installed and running on the Job Server computer that calls the function. The login account for the mail client must have the same user name and password as the SAP Data Services service. The type of client varies by the operating system:

- If the Job Server is on a computer running the Windows operating system, then the mail client must comply with MAPI (message application programming interface). In addition, the mail client must be configured as the default mail client. For example, Microsoft Outlook is a MAPI-based mail client.
- If the Job Server is on a computer running the UNIX operating system, then the mail client must be mailx-compliant.

Note

If you do not have the required mail client, contact SAP Business User Support for assistance.

Example

Function	Results
`$myvar = mail_to('admin@company.com', 'Out of memory error in the SalesFact job. Please fix the error before running recovery job.',' ', 10, 10)`	The message is sent to one recipient.
`$myvar = mail_to('admin@company.com, manager@company.com', 'Out of memory error:' || systime(), 'Out of memory error while running the data flow:' || $dataflow_name || ' in the job:' || $job_name || '.', 10, 20)`	The message is sent to two recipients. The job name and data flow names are included in the text of the message as variables. Note that the software trims blank spaces from the end of strings; this example in-

Function	Results
	cludes a blank on the beginning of the next string. You can also concatenate a string with a single blank. In the script, type "$a = ;" where $a is the local integer variable defined in the work flow. Put the cursor just ahead of the semicolon before clicking the *Functions* button to construct a mail_to statement.

Note

Often, you list e-mail addresses as nicknames in your mail service address book. If your mail system is compatible with the software mail_to function, you can use these nicknames (comma separated) as values in the **`<recipients_list>`**. In this case, the software mailer program searches your e-mail address book for the nickname and uses the corresponding qualified e-mail address for message routing.

Limitation

The mail_to function might not work properly on Windows 2000 after downloading a security patch for Microsoft Outlook that includes email prompts. In this case, you have two options:

- To change the Outlook security settings to suppress prompts, see the instructions for Microsoft article 263297 on the following Web site: http://support.microsoft.com/default.aspx?scid=kb;en-us;Q263297&id=263297&SD=MSKB#OB.
  The article describes how to suppress prompting when sending e-mail from a particular computer. In summary, first create a security policy file on the Exchange Server (usually done by an administrator). In the security policy file, turn off prompting. Then add a registry key to the Job Server (client) computer. When the Job Server computer tries to send an e-mail, the Outlook client first checks the registry key; if the key is set, Outlook checks the security policy file on the Exchange Server and suppresses prompts.
- Use the smtp_to function instead.

Related Information

Microsoft Help and Support

3.6.3.91 match_pattern

Allows you to match a whole input string to simple patterns that Data Services supports for this function. This function does not match substrings.

Return Value

integer	Returns 1 for a match, otherwise 0.

Syntax

```
match_pattern(<input_string>,<pattern_string>)
```

Where

input_string	String to be matched. Supports UNICODE characters.
pattern_string	Pattern you want to find in a whole input string. Substring matches are not supported.

Use the following characters to create a pattern:

X	Represents uppercase characters; general category Lu as per Unicode 4.0 specification (for example, Latin, Greek, Cyrillic, Armenian, Deseret, and archaic Georgian).
x	Represents non-uppercase characters: • Ll—Lowercase letter (for example Latin, Greek, Cyrillic, Armenian, Deseret, and archaic Georgian). • Lt—Title letters (for example Latin capital letter D with small letter Z). • Lm— Modifier letter (for example acute accent, grave accent). • Lo—Other letters (including Chinese, Japanese, and so on).
9	Represents numbers.
\	Escape character.
*	Any characters occurring zero or more times.
?	Any single character occurring once and only once.
[ ]	Any one character inside the braces occurring once.
[!]	Any character except those after the exclamation point (i.e. [!12] can allow any, say zip code, that does not start with a 1 or 2.

All other characters represent themselves. If you want to specify a special character as itself, then it has to be escaped. For example, [!9] means except any digit. To specify except nine, the correct pattern is [!\9].

The following table displays pattern strings that represent example values:

Example Value	Pattern string
Henrick	Xxxxxxx
DAVID	XXXXX
Tom Le	Xxx Xx
Real-time	Xxxx-xxxx
JJD)$@&*hhN8922hJ7#	XXX)$@&*xxX9999xX9#
1,553	9,999
0.32	9.99
-43.88	-99.99
Returns names with last name Jones	*Jones
Returns Henrick1 or HenrickZ	Henrick?
Returns David1 or David2 or David3	David[123]

Example

Use the `match_pattern` function in the Validation transform or in a WHERE clause of Query. The input string can be from sources such as columns, variables, or constant strings.

Use Case	Pattern	Function Call	Results

To match a zip code except one that begins with 1 or 2.	'[!12]9999'	`if (match_pattern('15014', '[!12]9999') <> 0)`
		`   print('matched');`
		`else`
		`   print('not matched');`
			Function prints "not matched".

To match a zip code except one that begins with 1 or 2.	'[!12]9999'	`if (match_pattern('55014', '[!12]9999') <> 0)`
		`   print('matched');`
		`else`
		`   print('not matched');`
			Function prints "matched".

To process only customer phone numbers that fit the same pattern.	'999-999-9999'	`WHERE MATCH_PATTERN(CUSTOMER.PHONE_NUM,'999-999-9999') <> 0`	Phone numbers that do not match the pattern throw error 0.
To check a string against a com-	'XXX)$@&*xxX9999xX9#'	`if(match_pattern('JJD)$@&*hhN8922hJ7#', 'XXX)$@&*xxX9999xX9#') <> 0)`	The result for this call is "matched".

Use Case	Pattern	Function Call	Results
plex pattern and print result to trace log.		<code>print ('matched');</code> <code>else</code> <code>print('not matched');</code>	

Related Information

literal [page 1596]

3.6.3.92 match_regex

Matches whole input strings to the pattern that you specify with regular expressions (regular expressions based on the POSIX standard) and flags. POSIX refers to the POSIX.1 standard (IEEE Std 1003.1) which defines system interfaces and headers with relevance for string handling and internationalization. The XPG3, XPG4, Single Unix Specification (SUS) and other standards include POSIX.1 as a subset. The patterns listed here in the *Reference Guide* adhere to the current standard. See *http://icu.sourceforge.net/userguide/regexp.html* for more information and updates. This function does not match substrings.

Syntax

```
match_regex (input_string, regular_expression_pattern, flags)
```

Return Value

`integer`	Returns `1` for a match, otherwise `0`.

Where

`input_string`	String to be matched. Supports UNICODE characters.
`regular_expression_pattern`	Pattern you want to find in a whole input string. Substring matches are not supported. Provide the pattern in regular expression format with a varchar data type.

`flags`	Allows you to specify additional behavior that you want to occur while Data Services searches the input_string for pattern matches. Enter NULL if you do not want to specify a flag. You can combine the options for flags using a comma. Flag options are case sensitive and need to be specified in upper case.

You can use the following regular expression patterns in the pattern parameter:

Character	Description
\a	Match a BELL, \u0007.
\A	Match at the beginning of the input. Differs from ^ in that \A will not match after a new line within the input.
\b, outside of a [Set]	Match if the current position is a word boundary. Boundaries occur at the transitions between word (\w) and non-word (\W) characters, with combining marks ignored. For better word boundaries, see ICU Boundary Analysis.
\b, within a [Set]	Match a BACKSPACE, \u0008.
\B	Match if the current position is not a word boundary.
\cX	Match a control-X character.
\d	Match any character with the Unicode General Category of Nd (Number, Decimal Digit).
\D	Match any character that is not a decimal digit.
\e	Match an ESCAPE, \u001B.
\E	Terminates a \Q ... \E quoted sequence.
\f	Match a FORM FEED, \u000C.
\G	Match if the current position is at the end of the previous match.
\n	Match a LINE FEED, \u000A.
\N{UNICODE CHARACTER NAME}	Match the named character.
\p{UNICODE PROPERTY NAME}	Match any character with the specified Unicode Property.
\P{UNICODE PROPERTY NAME}	Match any character not having the specified Unicode Property.
\Q	Quotes all following characters until \E.
\r	Match a CARRIAGE RETURN, \u000D.

Character	Description
\s	Match a white space character. White space is defined as [\t\n\f\r\p{Z}].
\S	Match a non-white space character.
\t	Match a HORIZONTAL TABULATION, \u0009.
\uhhhh	Match the character with the hex value hhhh.
\Uhhhhhhhh	Match the character with the hex value hhhhhhhh. Exactly eight hex digits must be provided, even though the largest Unicode code point is \U0010ffff.
\w	Match a word character. Word characters are [\p{Ll}\p{Lu}\p{Lt}\p{Lo}\p{Nd}].
\W	Match a non-word character.
\x{hhhh}	Match the character with hex value hhhh. From one to six hex digits may be supplied.
\xhh	Match the character with two digit hex value hh.
\X	Match a Grapheme Cluster.
\Z	Match if the current position is at the end of input, but before the final line terminator, if one exists.
\z	Match if the current position is at the end of input.
\n	Back Reference. Match whatever the nth capturing group matched. n must be a number > 1 and < total number of capture groups in the pattern. Note: Octal escapes, such as \012, are not supported in ICU regular expressions.
[pattern]	Match any one character from the set. See UnicodeSet for a full description of what may appear in the pattern.
.	Match any character.
^	Match at the beginning of a line.
$	Match at the end of a line.
\	Quotes the following character. Characters that must be quoted to be treated as literals are * ? + [( ) { } ^ $ | \ . /

You can use the following regular expression operators in a pattern parameter:

Operator	Description
|	Alternation. A|B matches either A or B.
*	Match 0 or more times. Match as many times as possible.

Operator	Description
+	Match 1 or more times. Match as many times as possible.
?	Match zero or one times. Prefer one.
{n}	Match exactly n times.
{n,}	Match at least n times. Match as many times as possible.
{n,m}	Match between n and m times. Match as many times as possible, but not more than m.
*?	Match 0 or more times. Match as few times as possible.
+?	Match 1 or more times. Match as few times as possible.
??	Match zero or one times. Prefer zero.
{n}?	Match exactly n times.
{n,}?	Match at least n times, but no more than required for an overall pattern match.
{n,m}?	Match between n and m times. Match as few times as possible, but not less than n.
*+	Match 0 or more times. Match as many times as possible when first encountered, do not retry with fewer even if overall match fails. Possessive match.
++	Match 1 or more times. Possessive match.
?+	Match zero or one times. Possessive match.
{n}+	Match exactly n times.
{n,}+	Match at least n times. Possessive match.
{n,m}+	Match between n and m times. Possessive match.
(...)	Capturing parentheses. Range of input that matched the parenthesized subexpression is available after the match.
(?: ...)	Non-capturing parentheses. Groups the included pattern, but does not provide capturing of matching text. Somewhat more efficient than capturing parentheses.
(?> ...)	Atomic-match parentheses. First match of the parenthesized subexpression is the only one tried; if it does not lead to an overall pattern match, back up the search for a match to a position before the "(?>"
(?# ...)	Free-format comment (?# comment).
(?= ...)	Look-ahead assertion. True if the parenthesized pattern matches at the current input position, but does not advance the input position.

Operator	Description
(?! ...)	Negative look-ahead assertion. True if the parenthesized pattern does not match at the current input position. Does not advance the input position.
(?<= ...)	Look-behind assertion. True if the parenthesized pattern matches text preceding the current input position, with the last character of the match being the input character just before the current position. Does not alter the input position. The length of possible strings matched by the look-behind pattern must not be unbounded (no * or + operators).
(?<! ...)	Negative look-behind assertion. True if the parenthesized pattern does not match text preceding the current input position, with the last character of the match being the input character just before the current position. Does not alter the input position. The length of possible strings matched by the look-behind pattern must not be unbounded (no * or + operators).
(?ismx-ismx: ...)	Flag settings. Evaluate the parenthesized expression with the specified flags enabled or disabled.
(?ismx-ismx)	Flag settings. Change the flag settings. Changes apply to the portion of the pattern following the setting. For example, (?i) changes to a case insensitive match.

You can use the following flags in the flag parameter:

Flag Options	Description
'CASE_INSENSITIVE'	If set, matching will take place in a case-insensitive manner.
'COMMENTS'	If set, allows use of white space and #comments within patterns.
'DOTALL'	If set, a "." in a pattern will match a line terminator in the input text. By default, it will not. Note that a carriage-return / line-feed pair in text behave as a single line terminator and match a single "." in a regular expression pattern.

Example

Use the Match_regex function in the Validation transform by accessing the Smart Editor or Function wizard or in a WHERE clause of a Query. The input string can be from sources such as columns, variables, or constant strings.

Use Case	Pattern	Function Call
To match phone numbers in (408)-933-6000 format.	'([0-9]{3}-[0-9]{3}-[0-9]{4}'	`match_regex (pho_number,'([0-9]{3}-[0-9]{3}-[0-9]{4}',NULL)`

Use Case	Pattern	Function Call
To match a string that starts with "topicA" regardless of case.	'topicA.*'	`match_regex (subject, 'topicA.*','CASE_INSENSITIVE')`

Related Information

literal [page 1596]

3.6.3.93 match_simple

Allows you to match a whole input string to simple patterns that Data Services supports for this function. This function does not match substrings.

Return Value

integer	Returns `1` for a match, otherwise `0`.

Syntax

```
match_simple(<input_string>,<pattern_string>)
```

Where

`<input_string>`	String to be matched. Supports UNICODE characters.
`<pattern_string>`	Pattern you want to find in a whole input string.

Use the following characters to create a pattern:

.	Represents any single character.
*	Represents any character zero or more times.
#	Represents any single alphabetic character including non-English letters.

$	Represents any alphabetic character, including non-English letters, zero or more times.
+	Matches the previous character one or more times.
(string)+	Matches the string one or more times.
[number1..number2]	Numeric range (integers only). Matches any number between number1 and number2.
\	Escape character
;	OR operator. If the data matches any of the identified patterns, the result is TRUE. Enclose the list with curly brackets {}. Example: `{ABC+;XYZ*}` If the data matches either `ABC+` or `XYZ*`, the result is TRUE.
<>	NOT operator. Specify the pattern after the <>. Example: `<><pattern>`
{EMPTY} and {empty}	Special predefined patterns that match empty data.
{NULL} and {null}	Special predefined patterns that match NULL data.

If the pattern is empty, then it matches all data.

If the value of a pattern column is NULL, then it will not match with any value.

All other characters represent themselves. If you want to specify a special character as itself, then it has to be escaped.

The following table displays pattern strings that represent example values:

Example Value	Pattern string
ACCT1234567	ACCT*
ZIP10000 to ZIP99999	ZIP[10000..99999]
ACCT123 or ACCOUNT234	{ACCT*;ACCOUNT*}
www.anything.com	www.$.com

Example

Use the match_simple function in the Validation transform or in a WHERE clause of Query. The input string can be from sources such as columns, variables, or constant strings. The following example illustrates sample code used in a script.

Use Case	Pattern	Function Call	Results

To match account numbers from ACCT1 to ACCT5000	ACCT[1..5000]	`if (match_simple('ACCT14',`
		`'ACCT[1..5000]')) <> 0`
		`print ('matched');`
			Function prints "matched".

Use Case	Pattern	Function Call	Results

		`else`
		`print('not matched');`	

3.6.3.94 max

Returns the maximum value from a list.

Syntax

```
max(<value_list>)
```

Return value

any type

The maximum value of the column values. The return type is the same as the values in **`<value_list>`**.

Where

`<value_list>`	The source values for which to identify a maximum.

Example

To calculate the maximum value in the salary column of a table, use the max function in a query:

- In the *Mapping* tab of the query editor, enter:

  ```
  max(SALARY)
  ```

- In the *Group By* tab in the query editor, specify the columns for which you want to find the maximum salary, such as the department column. For each unique set of values in the group by list, such as each unique department, Data Services calculates the maximum salary.

3.6.3.95 min

Returns the minimum value from a list.

Syntax

```
min(<value_list>)
```

Return value

any type

The minimum value of the column values. The return type is the same as the values in `<value_list>`.

Where

`<value_list>`	The source values for which to identify a minimum.

Example

To calculate the minimum value in the salary column of a table, use the min function in a query:

- In the *Mapping* tab of the query editor, enter:

  ```
  min(SALARY)
  ```

- In the *Group By* tab in the query editor, specify the columns for which you want to find the minimum salary, such as the department column. For each unique set of values in the group by list, such as each unique department, Data Services calculates the minimum salary.

3.6.3.96 mod

Returns the remainder when one number is divided by another.

Syntax

```
mod(number1, number2)
```

Return Value

Depends on the input numbers.

Where

`<number1>`	Number to be divided.
`<number2>`	Divisor of first number.

Details

Returns the remainder when one number is divided by another.

Note that the % operator used in Data Services syntax produces the same result.

Example

Function	Result
`mod(100.10,10));`	`0.100000`

3.6.3.97 month

Determines the month in which the given date falls.

Syntax

```
month(<date1>)
```

Return value

int

The number from 1 to 12 that represents the month component of `<date1>`.

Where

`<date1>`	The source date.

Example

Function	Results
`month(to_date('Jan 22, 1997', 'mon dd, yyyy'))`	1
`month(to_date('3/97', 'mm/yy'))`	3

3.6.3.98 num_to_interval

Converts a numeric value to an interval.

Syntax

```
num_to_interval(<number1, format>)
```

Return value

interval

The converted interval.

Where

`<number1>`	The value of type `int`, `real`, `decimal`, or `numeric` to convert.
`<format>`	A string describing the format of the interval. Choose from the following values: D: Days H: Hours M: Minutes S: Seconds

Example

Function	Results
`num_to_interval(elapsed_days, 'D')`	The value from the column `elapsed_days` converted to an interval of days.
`start_time + num_to_interval(elapsed_seconds, 'S')`	This example assumes that it is acting on an input schema which contains (at least) the columns 'start_time' and 'elapsed_seconds' (for example, the start_time might be '2005-12-01 00:00:00' and elapsed_seconds might be 200). So, this example indicates a time which is the number of elapsed seconds after the start time ('2005-12-01 00:03:20').

3.6.3.99 nvl

Replaces NULL values.

Syntax

```
nvl(<expression1>, <replacement_value>)
```

Return value

any type

The value of **<expression1>** if not NULL, otherwise, the value of **<replacement_value>**.

Where

<expression1>	The value to be tested for NULL.
<replacement_value>	The value to replace **<expression1>** if **<expression1>** is NULL. **<replacement_value>** must be the same data type as **<expression1>**.

Example

Function	Results
`nvl(modification_date, sysdate())`	If the column `modification_date` for a row hasn't been set, this function inserts today's date.
`nvl(lookup(r3..vbpa, kunnr, 'NULL', vbeln, vbak.vbeln, posnr, vbap.posnr, parvw, 'RE'), lookup(r3..vbpa, kunnr, 'NULL', vbeln, vbak.vbeln, posnr, vbap.posnr, parvw, 'RG'))`	Both expressions are determined by the result of lookup functions.

3.6.3.100 power

Returns the value of the given expression to the specified power.

Syntax

```
power(num, num)
```

Return Value

Float data type

Where

<num>	Numeric expression representing base number.
<num>	Numeric expression representing power.

Details

Returns the value of the given expression to the specified power.

Example

Function	Results
`power(2.2,3));`	`10.648000`

3.6.3.101 previous_row_value

Returns the column value of the previous row.

Note

Each call to the previous_row_value() function will return the value stored during the previous call of this function. In other words, if the function is not called for each row, the results of this function might not be what you expect (not the previous row's value). This scenario can happen if you, for example, use the previous_row_value() inside an ifthenelse() function:

```
If_then_else (table1.status = 'new', 0 , previous_row_value(table1.value))
```

A better solution in the example above would be :

```
If_then_else (table1.status = 'new', 0 , 1) * previous_row_value(table1.value)
```

or use two different queries: one for the previous_row_value() and one for the final result including the if_then_else().

Syntax

```
previous_row_value(expression)
```

Return Value

Data type of the input parameter. First row always returns `NULL`.

Where

`<expression>`	Valid Input expression.

Details

This function is useful in Query transforms. It returns the previous row's value. For example, the input stream of the column might be `1;2;3;4` for the first four rows. The function returns `NULL;1;2;3`.

Example

Following is list of records of sales figures for each day:

Date Revenue

rec 1 1/1/2005 1000

rec 2 1/2/2005 1100

rec 3 1/3/2005 900

rec 4 1/4/2005 1200

The requirement is to calculate the delta of the revenue with the previous day. So the query uses an order by on Date and calculate Revenue - Previous_Row_Value (revenue) which results in:

Date Revenue Delta = Revenue - Previous_Row_Value

rec 1 1/1/2005 1000 NULL

rec 2 1/2/2005 1100 +100

rec 3 1/3/2005 900 -200

rec 4 1/4/2005 1200 +300

3.6.3.102 print

Prints the given string to the trace log.

Syntax

```
print(<input_string>)
```

Return value

int

Value is **<input_string>** when the string contains valid data. Value is NULL and no string prints when the string contains NULL data.

Where

`<input_string>`	The message to be written to the trace log.

Example

Function	Results
`print('Reached decision point for running full or incremental data flows')`	Writes "Reached decision point for running full or incremental flows" to trace log and returns `<input_string>`.
`print('The date is: [$start_date]')`	Writes "The date is 2000.06.03" to trace log and returns `<input_string>`.
`print('[$month_sal*12]')`	Writes "48000" to trace log and returns `<input_string>`.
`print('Total Sal is: [$month_sal*12]');`	Writes "Total Sal is: 48000" to trace log and returns `<input_string>`.
`print('The return value from the SQL() function is > [$y]');`	Writes "The return value from the SQL() function is > 23456" to trace log and returns `<input_string>`.

3.6.3.103 pushdown_sql

Allows you to create dynamic WHERE clauses.

Syntax

```
pushdown_sql (<datastore>, <input_string>)
```

Return Value

None.

Where

`<datastore>`	The name of the datastore containing the data you want to retrieve. Data Services creates a WHERE clause and pushes it down to this database. Surround the datastore name by single quotes.
`<input_string>`	A character string that forms the WHERE clause. Surround the character string by single quotes. Typically, this is a column from another source to the query, such as an XML message. Delimit columns or parameters with curly braces. For example, {XML_IN.STATUS_QUERY}. If the string contains a curly brace, use the backslash escape key to delimit the curly brace.

Details

The pushdown_sql function allows you to create WHERE clauses that change based on data input. With the pushdown_sql function, the WHERE clause need not be pre-specified. The pushdown_sql function is particularly useful in real-time jobs, if you want to select data based on input from an XML message.

Unlike other functions, the pushdown_sql function can only be used in the WHERE clause of a Query transform. You cannot use the pushdown_sql function in other places, such as in a query's mapping, in a conditional, or in a script.

Data Services must be able to push the WHERE clause that it creates from this function to the database. This function works best, therefore, when used in a Query transform where the immediate input is the table source where you want to push the WHERE clause.

Data Services does not parse the SQL contained in the input string. Therefore, the input must be well-formed with correct syntax.

Note

Data Services does not allow use of the backslash escape key to delimit curly braces within the pushdown_sql function. So, if your input string contains a curly brace, you must make the string into a variable. Therefore, instead of entering 'a\{b\}c', you would pass your data through as 'a{$x}c' where $x = '\{b\}'.

Example

Suppose the datastore EC_DS contains the table BIKES, which stores information about different models. And suppose the QUERY_REQUEST column in the XML_IN message contains requests for information from this table. For example, a value in the QUERY_REQUEST column might be:

```
TYPE = 'MOUNTAIN' and PRICE < 1500
```

In a data flow used in a real-time job, you can use the pushdown_sql function in a query to select data from the BIKES table based on the data in the XML_IN message. You can return the data in another XML message.

Function	Results

`pushdown_sql ('EC_DS',`
`'{XML_IN.QUERY_REQUEST}')`
	Data Services includes the following WHERE clause in the SQL SELECT statement:
	`WHERE TYPE = 'MOUNTAIN' and PRICE <`
	`1500`

3.6.3.104 quarter

Determines the quarter in which the given date falls.

Syntax

```
quarter(<date1>)
```

Return value

int

The number from 1 to 4 that represents the quarter component of **<date1>**.

Where

<date1>	The source date.

Example

Function	Results

`quarter(to_date('Jan 22, 1997', 'mon`
`dd, yyyy'))`
	`1`

`quarter(to_date('5/97', 'mm/yy'))`	`2`

3.6.3.105 raise_exception

Calling this function causes an exception to be generated.

Syntax

```
raise_exception(<error_msg>)
```

Return Value

int

Returns '1' always.

Where

`<error_msg>`	The string which will be written to the Job Server's error log.

Details

The work flow or job may or may not be terminated based on whether a try-catch block surrounds the call.

Example

```
ifthenelse(sal < 1000000, 0, raise_exception('Salary exceeds 1 million dollars.'))
```

3.6.3.106 raise_exception_ext

Calling this function causes an exception to be generated with an exit code.

Syntax

```
raise_exception_ext(<error_msg>),(<exit_code>)
```

Return Value

int

Returns '1' always.

Where

<error_msg>	The string which will be written to the Job Server's error log.
<exit_code>	Code the job exits with, if the exception is not caught in a try/catch block. Use a number in range 1 to 255 (zero means "success" to all operating systems).

Details

The work flow or job may or may not be terminated based on whether a try-catch block surrounds the call.

Example

```
ifthenelse(sal < 1000000, 0, raise_exception_ext('Salary exceeds 1 million
dollars.', sal/1000000 + 1))
```

3.6.3.107 rand

Returns a random number between 0 and 1.

Syntax

```
rand()
```

Return value

real

The random number. The return value is between 0 and 1.

Example

Function	Results
`100 * rand()`	A random number between 0 and 100.

3.6.3.108 rand_ext

Similar to, and more powerful than the rand function, rand_ext returns a random number between 0 inclusive and 1 exclusive. This function uses the linear-congruential generator (LCG) algorithm, $x_n = (ax_{n-1} + b)\mathrm{mod}\ m$ where:

x_n is an integer from 0 to m-1 and the initial value of x_n is called the "seed" (x_0). For each call to the random number generator, Data Services calculates a new x_n by taking the value of the previous result x_{n-1}, multiplying by *a*, adding *b*, then taking the remainder mod *m*.

Data Services uses this formula to generate an integer from 0 to m-1. After Data Services calculates x_n, it divides that number by *m* to obtain a number equal to or greater than 0 and less than 1.

By specifing the same seed number, you can regenerate an exact number sequence (for use in repeat experiments).

Syntax

```
real rand_ext([seed])
```

Return value

real

The random number. The return value is between 0 and 1.

Where

<seed>	(Optional) Can be any positive integer greater than or equal to 0. If unspecified, Data Services uses the current time to create a seed.

Example

Function	Results
`100 * rand_ext()`	A random number between 0 and 100.

3.6.3.109 replace_substr

Takes an input string, replaces each occurrence of a specified substring with a specified replacement, and returns the result.

Syntax

```
replace_substr(<in_str, search_str, replace_str>)
```

Return Value

varchar

Where

<in_str>	The input string that you are changing. If NULL, return will be NULL.
<search_str>	String to search for. If **<search_string>** is NULL, varchar is returned and will be the same as in_str.
<replace_str>	If **<replace_string>** is omitted or NULL, all occurrences of **<search_string>** are removed.

Example

Function	Result

`replace_substr('a penny saved is a`
`penny earned',`
`'penny', 'million')'`
	`'a million saved is a million earned'`

3.6.3.110 replace_substr_ext

Takes an input string, replaces specified occurrences of a specified sub-string with a specified replacement and returns the result. It is also possible to search for the following:

- a hexadecimal value that refers to a UNICODE character
- a non-printable character reference such as a form feed or new line

Syntax

```
replace_substr_ext(in_str, search_str,
replace_str,start_at_occurance,number_of_occurances)
```

Return Value

varchar

Where

`in_str`	The input string that you are changing. If NULL, returns NULL.
`search_str`	String to search for: You can use /x0000 to specify the hexadecimal value for a special character. For example, if you use /x000A, then if Data Services encounters /x it will convert the next 4 characters to a hexadecimal value. This function converts the hexadecimal value to a UNICODE character. This option provides more flexibility when you use a search string. You can also represent special characters using the escape character '/'. The following are supported. `/a` Bell (alert) `/b` Backspace `/f` Formfeed `/n` New line `/r` Carriage return `/t` Horizontal tab `/v` Vertical tab To include the escape character '/' in the search string, escape it using '//'. For example, if the input is 'abc/de', Data Services converts `search_str` to 'abcde'. While if the input is 'abc//de', Data Services converts `search_str` to 'abc/de'. If `search_str` is NULL, Data Services returns a varchar with the data in `in_str`.
`replace_str`	String that replaces `search_str`. If **`<replace_string>`** is omitted or NULL, all occurrences of **`<search_str>`** are removed.

`start_at_occurence`	Start replacing at this occurrence. If NULL, start at the 1st occurrence. For example, enter 2 to replace or remove the second occurrence of a `search_str`.
`number_of_occurences`	Number of occurrences to replace. If NULL, replace all occurrences. For example, enter 2 to replace or remove two sequential occurrences of the `search_str`.

Example

Function	Result
Replace 'a' with 'B' starting from second occurrence and replaces two occurrences: `replace_substr_ext('ayyyayyyayyyayyy', 'a', 'B', 2, 2)'`	`'ayyyByyyByyyayyy'`
Search a string containing 'a' followed by a new line and replace it with 'B' starting from second occurrence and replaces two occurrences: `replace_substr_ext('ayyya</n>yyya</n>yyyayyy', 'a/n', 'B', 2, 2)`	`'ayyyByyyByyyayyy'`
Search a string containing 'a' followed by a new line and replace it with 'B' starting from second occurrence and replaces two occurrences: `replace_substr_ext('ayyya</n>yyya</n>yyyayyy', 'a/x000a', 'B', 2, 2)`	`'ayyyByyyByyyayyy'`

3.6.3.111 repository_name

Returns a database connection string and owner name. For example: `beq-local.DBUser.` This is the ID for the repository from which the job is run.

Syntax

```
repository_name()
```

Return Value

varchar

Example

```
print('Repository Name: [repository_name()]')
```

3.6.3.112 round

Rounds a given number to the specified precision.

Syntax

```
round(<num1>, <precision>)
```

Return value

decimal, double, int, or real

The rounded number. The return type is the same as the original number, **<num1>**.

Where

<num1>	The source number.
<precision>	An integer indicating the number of decimals in the result. If **<precision>** is negative, digits left of the decimal point are rounded.

Example

Function	Results
`round(120.12345, 2)`	120.12
`round(120.12999, 2)`	120.13
`round(120, -2)`	100
`round(120.123, 5)`	120.12300

3.6.3.113 rpad

Pads a string with characters from a given pattern.

The function repeats the pattern at the end of the input string until the final string is the appropriate length. If the input string is already longer than the expected length, this function truncates the string.

Syntax

```
rpad(<input_string>, <size>, <pad_string>)
```

Return value

varchar

The new string.

Where

`<input_string>`	The source string.
`<size>`	An integer value indicating the number of characters in the resulting string.
`<pad_string>`	A character or set of characters that this function concatenates to `<input_string>`.

Example

Function	Results
`rpad('Tanaka',15,' ')`	`'Tanaka         '`
`rpad(last_name,25,' ')`	The value in the column `last_name`, padded with spaces to 25 characters, or truncated to 25 characters.

3.6.3.114 rpad_ext

Pads a string with logical characters from a given pattern.

Note

These logical characters prohibit this function from getting pushed down to an Oracle database.

The function repeats the pattern at the end of the input string until the final string is the appropriate length. If the input string is already longer than the expected length, this function truncates the string.

Syntax

```
rpad_ext(<input_string>, <size>, <pad_string>)
```

Return value

varchar

The new string.

Where

`<input_string>`	The source string.
`<size>`	An integer value indicating the number of characters in the resulting string.
`<pad_string>`	A character or set of characters that this function concatenates to **`<input_string>`**.

Example

Function	Results
`rpad_ext('Tanaka',15,' ')`	`'Tanaka         '`
`rpad_ext(last_name,25,' ')`	The value in the column `last_name`, padded with spaces to 25 characters, or truncated to 25 characters.

rpad_ext and rpad functions exhibit the same behavior when the functions are evaluated within Data Services. In situations where the function is pushed down to the database, the database behavior may differ when 'input_string' and/or 'pad_string' parameters contain multibyte characters.

Function	Input	Output
rpad	("abc¶¶", 10,' ')	`'abc¶¶   '`
rpad_ext	("abc¶¶", 10,' ')	`'abc¶¶     '`
rpad	("abc¶¶", 10,'')	`'abc¶¶'`
rpad_ext	("abc¶¶", 10,'')	`'abc¶¶'`
rpad	("abcd", 10, '¶')	`'abcd¶¶¶'`
rpad_ext	("abcd", 10, '¶')	`'abcd¶¶¶¶¶¶'`

3.6.3.115 rtrim

Removes specified characters from the end of a string.

Syntax

```
rtrim(<input_string>, <trim_string>)
```

Return value

varchar

The modified string. The return type is the same as `<input_string>`.

Where

`<input_string>`	The string to be modified.
`<trim_string>`	The characters to remove from `<input_string>`.

The function scans `<input_string>` right-to-left removing all characters that appear in `<trim_string>` until it reaches a character not in `<trim_string>`.

Removes trailing blanks only if `<trim_string >`contains trailing blanks. If the length of the modified string becomes zero after trimming, the function returns '' (empty string).

To remove all trailing blanks in a string, use the rtrim_blanks function.

Example

Function	Results
`rtrim('Marilyn ', ' ')`	'Marilyn'
`rtrim('ZABCABC', 'ABC')`	'Z'
`rtrim('ZABCABC', 'EFG')`	'ZABCABC'

3.6.3.116 rtrim_blanks

Removes blank characters from the end of a string.

Syntax

```
rtrim_blanks(<input_string>)
```

Return value

varchar

The modified string. The return type is the same as **<input_string>**.

Where

<input_string>	The string to be modified.

If the length of the modified string becomes zero after trimming, the function returns '' (empty string).

Example

Function	Results
`rtrim_blanks('Marilyn ')`	'Marilyn'
`rtrim_blanks(last_name)`	The value contained in the column `last_name` with trailing blanks removed.

3.6.3.117 rtrim_blanks_ext

Removes blank and control characters from the end of a string.

Syntax

```
rtrim_blanks_ext(<input_string>)
```

Return value

varchar

The modified string. The return type is the same as **<input_string>**.

Where

<input_string>	The string to be modified.

If the length of the modified string becomes zero after trimming, the function returns '' (empty string).

Example

Function	Results
`rtrim_blanks('Marilyn ')`	'Marilyn'
`rtrim_blanks(last_name)`	The value contained in the column `last_name` with trailing blanks and control characters removed.

3.6.3.118 sap_openhub_processchain_execute

Performs the following tasks:

- Starts the process chain that extracts data from an InfoProvider (InfoArea, InfoCube, or DataStore object) on SAP NetWeaver Business Warehouse and loads the extracted data into an Open Hub Destination table.
- Monitors the process chain status and the Open Hub Destination request notification.

When the function returns successfully, an Open Hub table source in SAP Data Services can then read the data from the Open Hub Destination table.

Note

You can only use this function in a script. It is not valid in a query or audit object.

Below is the function syntax as a reference. The function wizard is explained in the next section.

Syntax

```
sap_openhub_processchain_execute('<datastore>','<open_hub_table>',
'<process_chain>',<$logid>,<$ReturnTxt>)
```

Where

<datastore>	Specifies the datastore name. You can specify either a constant string or a substitution parameter. The data type is varchar(256).

	Note The maximum length depends on the Data Services repository type. For most repository types the maximum length is 256, for MySQL the length is 64, and for MS SQL server the length is 128.
`<open_hub_table>`	Specifies the Open Hub Destination table. You can specify either a constant string or a substitution parameter. The data type is varchar(30).
`<process_chain>`	Specifies the name of the process chain that extracts data from the InfoProvider in SAP NetWeaver BW and loads the data to the Open Hub Destination table. You can specify either a constant string or a substitution parameter. The data type is varchar(30).
`<$logid >`	(Optional) Specifies a variable to obtain a value that depends on the function return value (see "Relationship between return value and value of logid variable" below). The required variable data type is varchar(25).
`<$ReturnTxt>`	(Optional) Specifies a variable to retrieve the description of the return status of the process chain. The required variable data type is varchar, and you can define the length you want for this variable.

Return value

varchar(1)

Returns one of the following values.

Return value	Description
B	Open Hub Destination is being read by another user.
E	Data Services error while executing the function.
R	Process chain execution failed with errors in BW system.
X	Process chain execution has been canceled in BW system.
S	Function successfully executed the Open Hub extraction Data Transfer Process (DTP) and received extraction request notification.

Relationship between return value and value of logid variable

The value of the logid output variable depends on the function return value, as the following table shows.

Return value	$logid variable value	$ReturnText variable value	Action
B	Process chain log ID of the other user that is currently reading the Open Hub Destination	Status of current Open Hub extraction	Either wait and try again or stop executing the data flow that contains the Open Hub Destination table.
E	Data Services error log number	Data Services error text	Stop executing the data flow that contains the Open Hub Destination table, and analyze the Data Services error.
R	Your process chain log ID	Error from process chain	Stop executing the data flow that contains the Open Hub Destination table, and use the log ID in the BW system to see the detail state of the process chain error.
X	Your process chain log ID	Error from process chain	Stop executing the data flow that contains the Open Hub Destination table, and use the log ID in the BW system to see the detail state of the process chain error.
S	Open Hub extraction request ID	Status of your Open Hub extraction	Use the request ID in the BW system to obtain detail loading statistics (such as number of packets loaded and number of records loaded).

Example

The following sample script commands check the return value, generate an exception, and print the error if the function is not successful.

```
$status = sap_openhub_processchain_execute('open_hub_datastore',
'Materials','Materials_PC',<$lpcogid>,
<$returntxt>);
If ($status != 'S') raise_exception ('Materials_PC process chain execution failed
' || $returntxt);
```

Restrictions

The following are restrictions for using Open Hub Destinations:

- Only one job at a time can read an Open Hub Destination table.
- A process chain of an Open Hub Destination can contain only one of its Data Transfer Processes (DTPs).
- A process chain cannot contain DTPs for more than one Open Hub Destination.

3.6.3.118.1 To define an sap_openhub_processchain_execute function

1. To access the function wizard for sap_openhub_processchain_execute from the Script Editor, click *Functions* or *...* at the top of the window.
2. Select *sap_openhub_processchain_execute* from the list of functions.
   The *Define Parameters* window opens.
3. Select an SAP BW Source datastore name from the drop-down list. You can also select a substitution variable from the list. If you type in a datastore name, put single quotes around the name.
4. Select the name of a Open Hub table from the drop-down list. Only the names of the imported Open Hub Tables appear in this list.
5. Select the name of a Process Chain from the drop-down list.
6. Specify a variable that will get the BW log ID for the process chain after the function executes. You must define the variable before you can use it.
7. Specify a variable that will get the description of the status after the function executes. You must define the variable before you can use it.

3.6.3.119 sap_openhub_set_read_status

Sends the read status for the Open Hub table to SAP NetWeaver BW. A successful read status causes SAP NetWeaver BW to delete the data from the Open Hub Destination table.

Syntax

```
sap_openhub_set_read_status('<datastore>','<destination>',
<status>,<$returntxt>)
```

Where

`<datastore>`	Specifies the datastore name. You can specify either a constant string or a substitution parameter. The data type is varchar(256).

	Note The maximum length depends on the Data Services repository type. For most repository types the maximum length is 256, for MySQL the length is 64, and for MS SQL server the length is 128.
`<destination>`	Specifies the Open Hub Destination in the BW system. You can specify either a constant string or a substitution parameter. The data type is varchar(30).
`<status>`	Specifies the read status. Possible values are either a variable or one of the following string constants: ● 'X' for Read Successful ● Any other value indicates that the Read failed. The data type is varchar(1).
`<$returntxt>`	(Optional) Specifies a variable to return the status log of the function. The required variable data type is varchar, and you can define the length you want for this variable.

Return value

varchar(1)

Returns one of the following values.

Return value	Description
S	Success
E	Error

Example

The following sample script commands sends the status of the Open Hub table read to the BW system and prints the status.

```
$status = sap_openhub_set_read_status('BR9", 'PS_BOOK_5', 'X', $returntxt):
print ('Status: ' || $status);
```

3.6.3.120 search_replace

Performs a simple search and replace based on a string value, word value, or an entire field. You can specify search and replace values with an internal table, an existing external table or file, or with a custom SQL command.

In all cases, the search and replace values are loaded into memory to optimize performance while performing the operation.

Note

We recommend that you use search_replace as a function call in the query output and not as a mapping in a column. By using it as a function call, you can use the wizard interface to fill in the function's parameters, and you can return to the wizard at any time to change the parameters. This method also allows you to create multiple output columns when multiple input expressions are used. Using the function in a script or regular mapping is possible, but the syntax can be hard to read and difficult to maintain.

Below is the function syntax as a reference. The function wizard is explained in the next section.

Syntax

```
search_replace([<sr_table_spec>,<search_column>,<replace_column>],<sr_type>,
[<case_sensitivity>],[<default_replace_value>],[<input_column_list>],
[<output_column_list>],[<output_variable_list>]) SET (...)
```

Where

<sr_table_spec>	A constant string that specifies the search and replace table or file. It has three possible valid forms: **<Datastore.owner.table>** — Specifies a database table containing the search and replace values. **<Fileformat.filename>** — Specifies a fixed or delimited file containing the search and replace values. **NULL** — Used when the search and replace is performed using custom SQL or an internal table defined in the SET options.
<search_column>	Specifies the column name in the table or file containing the search values. If **<sr_table_spec>** is an internal table, this should be set to **NULL**. The data contained in this column must be of the varchar type.
<replace_column>	Specifies the column name in the **<sr_table_spec>** table or file containing the replacement values. If **<sr_table_spec>** is an internal table, this should be set to **NULL**. All data contained in this column must be of the varchar type.
<sr_type>	A string that specifies the type of search and replace operation to perform. It has three possible values: **'SR_FIELD'** — Matches the entire contents of the search field, and replaces the entire contents of the search field.

<table>
<tr><th></th><th></th></tr>
<tr><td></td><td><p><code>'SR_WORD'</code> — Replaces only the word that matches the search value. Any unmatched data remains in the search field. A word is defined as a set of characters set apart by whitespace.</p><p><code>'SR_STRING'</code> — Replaces only a specific substring of characters found next to or between other characters in the search field. Any unmatched data remains in the search field.</p></td></tr>
<tr><td><code>&lt;case_sensitivity&gt;</code></td><td><p>A value that indicates whether or not the search and replace operation is case sensitive.</p><p><code>yes</code> — case sensitive</p><p><code>no</code> — not case sensitive</p></td></tr>
<tr><td><code>&lt;default_replace_value&gt;</code></td><td><p>A varchar that specifies the default replacement value if the search value is not found.</p><p>This applies only when <code>&lt;sr_type&gt;</code> is set to <code>'SR_FIELD'</code>.</p></td></tr>
<tr><td><code>&lt;input_column_list&gt;</code></td><td>A varchar that specifies a comma-separated list of input expressions on which the search and replace operation should be performed.</td></tr>
<tr><td><code>&lt;output_column_list&gt;</code></td><td>A varchar that specifies a comma-separated list of output columns.</td></tr>
<tr><td><code>&lt;output_variable_list&gt;</code></td><td><p>A varchar that specifies a comma-separated list of output variables.</p><p>When more than one output column is specified in <code>&lt;output_column_list&gt;</code>, the output variables are used to receive output returns. Variables and output columns are matched by position.</p><p>This parameter is optional except when more than one output column is specified in <code>&lt;output_column_list&gt;</code>.</p></td></tr>
<tr><td>SET options</td><td><p>Specifies custom SQL or search and replace values in XML format.</p><p>For an internal search and replace table:</p><pre>SET (
"internal_table"=
'<?xml version="1.0" encoding="UTF-8"?>
   <searchTable>
      <item>
         <Search><value></Search>
         <Replace><value></Replace>
      </item>
      ...
      ...
   </searchTable>
')</pre><p>For custom SQL:</p><pre>SET (
"external_custom_sql"=
'<?xml version="1.0" encoding="UTF-8"?>
   <database_datastore&gt;</pre></td></tr>
</table>

```
      <datastore_name>
   </database_datastore>
   <search_column>
      <search_column_name>
   </search_column>
   <replace_column>
      <replace_column_name>
   </replace_column>
   <SQLText>
      <custom_sql_string>
   </SQLText>
')
```

Return value

varchar

Example

Search for Mr in input_column and replace with M to output_column using an internal search and replace table.

```
search_replace(NULL,'SR_STRING',1,,'input_column','output_column',) SET (
"internal_table"='<?xml version="1.0" encoding="UTF-8"?>
   <searchTable>
      <item>
         <Search>Mr</Search>
         <Replace>M</Replace>
      </item>
   </searchTable>
)
```

Note

The search_replace function wizard makes it easy to select search and replace columns, and if needed, define search terms and replacement values.

3.6.3.120.1 To define a search_replace function

1. Right-click the output schema of a Query transform, and click *New Function Call*.
2. Choose the *String Functions* category, and click *search_replace*.
3. Click *Next*.
   The search_replace function wizard opens.
4. Select the search type to perform.

Search type	Description
Full string	Matches and replaces the entire contents of the input expression.
Word	Replaces only the word that matches the search value. Any unmatched data is not modified. A word is defined as a set of characters set apart by whitespace.

Search type	Description
Substring	Replaces only a specific substring of characters found next to or between other characters in the input expression. Any unmatched data is not modified. For a substring search, the search values are ordered by length from largest to smallest, and each substring is only substituted once.

5. If you want to ignore casing differences between the specified search values and the values from the input expressions, uncheck *Case sensitive*.
6. Define the input expressions to search. You can select a column name from the input schema, or you can use any expression that uses one or more input columns.
7. Define the output column names and lengths for the replacement values. You can rename the output column by selecting the value and pressing **F2**.
8. Configure the search and replace table.
   - For an internal table, select *Internal* and specify search values and corresponding replacement values. The values for an internal table are stored in the metadata repository as part of the function definition.
   - For an external relational table, select *External*. Specify a valid datastore or file format as the Source, and select the columns containing the search and replacement values.
   - For custom SQL, select *Custom SQL*. Choose the source datastore, and specify the columns containing the search and replacement values. Define the custom SQL text to run.
9. Specify the default replacement value for any rows that do not match the defined search values. If the replacement value is a fixed string, you must enclose it in single quotes.

   > Note
   >
   > The default replacement value applies only for a full string search, not for word or substring searches.

   If no default replacement value is defined, the original values are preserved; no replacements are made for expressions that were not found.
10. If you want to force the search_replace function to execute in a separate process, check *Run as a separate process*. The search and replace table is always loaded into memory, so for large tables, running this function as a separate process can improve performance.

> Example
>
> Case-sensitive substring search and replace
>
> In this example, the longest search value is replaced first. As a result, the substring AUS does not become AUSA, but is correctly replaced with Australia.
>
> Internal Search and Replace table:
>
> | Search value | Replace value |
> |---|---|
> | US | USA |
> | AUS | Australia |
>
> Search and Replace results:
>
> | Value on input | Value on output |
> |---|---|
> | California, US | California, USA |
> | Melbourne, AUS | Melbourne, Australia |

Related Information

Performance Optimization Guide: Distributing Data Flow Execution, Splitting a data flow into sub data flows, Run as a separate process option [page 2153]

3.6.3.121 set_cdc_checkpoint

Sets a check-point in a data flow for a Microsoft SQL Server changed-data-capture (CDC method) job. Use for data flows that run in a WHILE loop to retrieve changed data for each iteration of the loop. Call this function for all the datastores used in all the data flows of the job.

Syntax

```
set_cdc_checkpoint(<datastore>)
```

Return value

int

Returns 1 if successful, otherwise 0.

Where

<datastore>	The name of the CDC-enabled datastore containing the tables used to obtain the changes.

Example

```
set_cdc_checkpoint('MyCdcSource');
```

3.6.3.122 set_env

Sets a system environment variable to a specified value for the duration of a job.

Syntax

```
set_env('<variable_name>', <variable_value>)
```

Return value

int

Returns 1 if successful, otherwise, 0.

Where

<variable_name>	The name of an environment variable. The name must be surrounded by single quotes.
<variable_value>	The value you want assigned to the environment variable. If the value is text, you must surround the text by single quotes. Data Services only sets the variable to this value for the duration of the current job.

Use the get_env and set_env functions to set and retrieve variables across operations in a job.

Example

Function	Results

`set_env('TMP','C:\Data Services`
`\Temp')`
	Sets the value of the TMP environment variable to "C:\Data Services\Temp" and returns a 1.

Related Information

get_env [page 1568]

3.6.3.123 sleep

Suspends the execution of the calling data flow or work flow.

Syntax

```
sleep(<num_millisecs>)
```

Return Value

int

Returns '1', always.

Where

<num_millisecs>	The number of milliseconds to "sleep".

details

Calling this function causes the thread that executes this function to halt operations for the given number of milliseconds. To force a job to halt operations (until a condition becomes true), call this function in a work flow, not in a data flow.

Example

The following example invokes sleep for one second when a file exists in a directory called 'c'.

```
while (file_exists('c:/temp.msg') == 0)
begin
sleep(1000);
end
```

3.6.3.124 soundex

Encodes the input string using the soundex algorithm and returns a string. Use this function when you want to push-down to the database-level. Results may vary when you push-down to different database types.

Syntax

```
soundex(<input_str>)
```

Return Value

varchar(4)

Returns a string containing the soundex encoding of the input string. The return string length is always four characters.

Where

`<input_str>`	The source string that will be encoded.

Details

Only use this function for input strings in English. Non-English characters are ignored.

Any invalid leading characters in the input string are ignored.

If an input string cannot be encoded, then '0000' is returned.

Example

Function	Result
`Print(soundex('Hello');`	Prints the soundex of the word "Hello."
`$VAR=soundex(emp_name);`	Returns the soundex encoding for the string stored in the variable emp_name and then assigns it to $VAR
`$VAR=soundex('1234567');`	Returns '0000' because the input data is numeric.

3.6.3.125 sql

Runs a SQL operation against tables in the specified database.

Syntax

```
sql(<datastore, sql_command>)
```

Return value

varchar(1020)

Returns the first 1020 characters from the query's output. Typically, if `<sql_command>` is a SELECT statement, the return value is the first row value of the first column. If `<sql_command>` is not a SELECT statement, the return value is typically NULL. You must remember this if you assign the value returned to a variable.

Where

`<datastore>`	A string containing the name of the datastore where the tables involved in the SQL operation reside. This name is the name you specified when you created the datastore in Data Services. Include this string in single quotation marks.
`<sql_command>`	A string containing the text of the SQL command to execute. This string must be enclosed in single quotation marks ('). If the string contains quoted values, the internal quotation marks must be single quotation marks preceded by the escape character, backslash (\\). Data Services makes column and table names uppercase when sending the **`<sql_command>`** to Oracle to resolve. To specify a lowercase column or table name from an Oracle database, enclose the name with double quotation marks (").

Example

Function	Results

`sql('source_ds',`
`'SELECT EmpID FROM Emp WHERE sal > 100000')`
	Runs the SQL command against the database connected through the datastore `source_ds`.

`sql('source_ds','SELECT customer.LastName`
`FROM customer`
`WHERE customer.State = \'CA\'')`
	Returns the last names of the customers in California from the customer table. Note that the quotation marks around the state value require a backslash to indicate that the single quotation marks are considered part of the **`<sql_command>`** string.

`sql('oracle_ds', ('SELECT "start_time-`
`stamp"`
`FROM "status_table"`
`WHERE "extract_name" = \'DF_RecoverDim\'`
`AND "stop_timestamp" = NULL')`
	Returns the timestamp from a status table for the completed data flow. An Oracle datastore requires double quotation marks around the lowercase column and table names.

`$start_date=sql('warehouse_ds',`
`'SELECT finish_timestamp`
`FROM time_table`
`WHERE table_name= "Component_Orders" ');`
	In this script example, because the function returns a varchar value, it is not possible to assign the return value to a date variable directly. Modify your statement to the next example.

`$temp_char=sql('warehouse_ds',`
`'SELECT finish_timestamp FROM time_table`
`WHERE table_name= "Component_Orders" ');`
`$start_date=to_date($temp_char,'dd-mon-`
`yyyy');`
	This script example assumes the database returns the date in `dd-mon-yyyy` format. If you are unsure of the format the database returns, then force it to return the date in a specific format by doing a conversion. To accomplish this, use the to_char function in Oracle or the convert function in MS SQL.

3.6.3.126 sqrt

Returns the square root of the given expression.

Syntax

```
sqrt(num)
```

Return Value

Float

Where

<num>	The number for which you want the square root.

Details

Return value is NULL if the input is negative.

Example

Function	Results
`sqrt(625.25));`	25.005000

3.6.3.127 smtp_to

Captures the specified number of lines in the trace and error logs, packages the information into an e-mail, and sends it to the recipient(s) via an SMTP server. This function is typically used in a script, for example in a conditional clause, while loop, or try-catch block.

Syntax

```
smtp_to(<recipients_list>, <subject>, <message>, <number_of_trace_lines>,
<number_of_error_lines>)
```

Return value

int

Returns 0 if function succeeds. Returns a non-zero integer if function fails.

Where

<recipients_list>	A string containing one or more recipient e-mail addresses separated by commas (,). This string cannot be empty and must contain valid, qualified e-mail address information.
<subject>	A string containing the subject of the e-mail. This string can be empty.
<message>	A string containing the e-mail message. This string can be empty.
<number_of_trace> **<_lines>**	The number of lines from the end of the trace log file to append to the end of the e-mail. This input cannot be empty.
<number_of_error> **<_lines>**	The number of lines from the end of the error log file to append at the end of the e-mail. This input cannot be empty.

Example

smtp_to function

Function	Results
`$myvar = smtp_to('admin@company.com', 'Out of memory error in the SalesFact job. Please fix the error before running recovery job.',' ',10, 10)`	The message goes to one recipient, admin@company.com.
`$myvar = smtp_to('admin@company.com, manager@company.com', 'Out of memory error:' || systime(), 'Out of memory error while running the data flow:' || $dataflow_name || ' in the job:' || $job_name || '.', 10, 20)`	The message goes to two recipients, admin@company.com and manager@company.com. The job name and data flow names are included in the text of the message as variables. Note that Data Services trims blank spaces from the end of strings; this example includes a blank on the beginning of the next string. You can also concatenate a string with a single blank.

<table>
<tr><th>Function</th><th>Results</th></tr>
<tr><td></td><td>In the script, type <code>$a = ;</code> where <code>$a</code> is the local integer variable defined in the work flow. Put the cursor just ahead of the semicolon before clicking the <em>Functions</em> button to construct a smtp_to statement.</td></tr>
<tr><td><code>$address_list = 'nkumar@businessobjects.com,pkulkarn@businessobjects.com';</code>
<code>$subject_text = 'Testing SMTP job smtp011';</code>
<code>$message_text = 'The job smtp011 has the following trace lines & errors';</code>
<code>$trace_log = 8;</code>
<code>$error_log = 19;</code>
<code>$smtp_output = 9;</code>
<code>print ('before execution :- ' || $smtp_output);</code>
<code>$smtp_output = smtp_to($address_list,$subject_text,$message_text,</code>
<code>$trace_log,$error_log);</code>
<code>print ('after execution :- ' || $smtp_output);</code></td><td>The smtp_to function also supports global variables. This example from a script shows the smtp_to function substituting the values from global variables.</td></tr>
<tr><td>Create a custom function my_smtp that contains the following:
<code>begin return(smtp_to('nkumar@ness-gsg.com','Testing job smtp012','Test message of smtp012 job',4,5)); End</code>
Use the custom function my_smtp in a script as follows:
<code>print('before smtp :- '); my_smtp( );</code>
<code>print('after smtp :- ');</code></td><td>You can use smtp_to in any user-defined custom function and invoke it in a script.</td></tr>
</table>

> **Note**
>
> The smtp_to function does not support nicknames.

3.6.3.127.1 To define and enable the smtp_to function

1. In the function editor, click the *System* Function Category.
2. Click the *smtp_to* function name.
3. Click *Next*.
4. Define the input parameters as described in the *Where* table previously in this function description.
5. Click *Finish*.
6. Open the Data Services Server Manager:

- In Windows, click *Start* > *Programs* > *SAP Data Services* **<x.x>** > *Data Services Server Manager*.
- In UNIX, run the Server Manager by entering:

```
$ cd $LINK_DIR/bin/
```

```
$ . ./al_env.sh
```

```
$ ./svrcfg
```

7. The Data Services Server Manager Utility window opens.
8. Enter the SMTP server settings:
   - *Server name*: Type the name or IP address of the SMTP server (for example mail.company.com)
   - *Sender*: Type the e-mail address that will appear in the *From* field of the e-mail.
9. In the Server Manager window, click *Apply*.

3.6.3.128 substr

Returns a specific portion of a string starting at a given point in the string.

Syntax

```
substr(<input_string>, <start>, <length>)
```

Return value

varchar

The modified string. The return data type is the **<input_string>**. If the length is a constant, then it is a varchar of the given length.

Where

<input_string>	The string to be modified.
<start>	The position of the first character in the new string. The function counts characters from the beginning of **<input_string>**. In normal data flows, the first character is position number 1. If **<start>** is 0, the new string begins with the first character (position 1).

	If <start> is negative, the function counts characters from the end of <input_string>. The new string begins with the character in that position from the end of the string. If <start> is greater than the number of characters in <input_string>, the function returns NULL. If <length> is 0 or negative and <start> is not greater than the number of characters in <input_string>, the function returns empty string.
<length>	The number of characters in the resulting string. If <length >is 0 or negative, the function returns an empty string. If <length> is greater than the number of characters remaining in <input_string> after <start> , the function returns only the remaining characters. The function keeps the trailing blanks in the remaining <input_string> after <start>.

Example

Function	Results
`substr('94025-3373', 1, 5)`	`'94025'`
`substr('94025-3373', 7, 4)`	`'3373'`
`substr('94025', 7, 4)`	`NULL`
`substr('Dr. Schultz', 4, 18)`	`'Schultz'`
`substr('San Francisco, CA',-4, 18)`	`', CA'`

3.6.3.129 sum

Calculates the sum of a given set of values.

Syntax

```
sum(<value_list>)
```

Return value

decimal, double, int, or real

The total of the values. The return type is the same as the values in **`<value_list>`**.

Where

`<value_list>`	The source values to sum.

Example

To calculate the sum of values in the salary column of a table, use the sum function in a query:

- In the *Mapping* tab of the query editor, enter:

  ```
  sum(SALARY)
  ```

- In the *Group By* tab in the query editor, specify the columns for which you want to find the total salary, such as the department column. For each unique set of values in the group by list, such as each unique department, Data Services calculates the sum of the salary.

3.6.3.130 sysdate

Returns the current date as listed by the Job Server's operating system.

Note

The value that the sysdate function returns is a datetime value. Internally Data Services reads both the date and the time when it runs a sysdate function. The data that is used by the job depends on the data type of a particular column. For example, if the data type of a column in a query is `date`, Data Services only uses the date for calculations. The time data is ignored. If you change the data type to `datetime`, both a date and a time are used.

Syntax

```
sysdate()
```

Return value

date

Today's date.

Example

Function	Results
`isweekend(sysdate())`	Tests whether today is a Saturday or Sunday.
`to_char(sysdate(), 'yyyy.mm.dd')`	Converts the sysdate function's `datetime` value to a string that displays only the date. For example, you can use this to exclude part of the `datetime` data by only providing a format for the data you want to display in a report. To convert a `datetime` value to a string containing only the date, use this expression and change the column's data type to `varchar`.

3.6.3.131 system_user_name

Returns the user name used to log into the Job Server's operating system.

Syntax

```
system_user_name()
```

Return Value

varchar

Example

```
print('Starting execution of Job: [job_name()] as user: [system_user_name()]');
```

3.6.3.132 systime

Returns the current time as listed by the Job Server's operating system.

Syntax

```
systime()
```

Return value

time

The current time.

Example

Function	Results
`$timestamp = sql('my_datastore',('UPDATE status_table SET job_start_time = \' '|| to_char(systime(),'hh24:mi:ss.ff'))||'\'');`	This expression updates the `job_start_time` column of the `status_table` with the current time. It also formats the time data.
`to_char(systime(),'hh24:mi:ss.ff')`	Trims date data from the systime() function in cases where it is added by default. Set the column that contains this expression to the data type `varchar`. The data type for a column that calls the systime() function should be `time`. If the data type is set to `datetime`, Data Services will add the default date for the `datetime` data type (1900:01:01) because systime() does not read dates.

3.6.3.133 table_attribute

Retrieves the value of the specified table attribute.

Syntax

```
table_attribute(<table_name, attribute_name>)
```

Return Value

varchar

The value of the table attribute. If the specified attribute does not exist, NULL is returned.

where

<table_name>	Use the following format: 'datastore.owner.table'. If a valid table by this name does not exist, NULL is returned. This parameter is case sensitive.
<attribute_name>	The name of a table attribute. Valid attributes for a table are listed in the table's Properties window. This parameter is case sensitive.

Example

Function	Result
table_attribute('mssql.awez.CUSTOMER', 'Number_Of_Inserts')	'1788'

3.6.3.134 to_char

Converts a date or numeric data to a string. It supports the Oracle 9i timestamp data type up to 9 digits precision for sub-seconds.

Syntax

```
to_char(<date or numeric_expression>, <format>)
```

Return value

varchar

Where

A formatted string describing **<numeric_expression>**.

<numeric expression>	The source int, real, double or decimal value.
<format>	A string indicating the format of the generated string. Note Please provide format to ensure correct results. Choose from the following codes:

Format	Description	Example
9	Number (suppress leading/trailing zeros) Includes a leading - for negative numbers or one leading space for pos no's.	to_char(123,'9999') = ' 123'
0	Number Including leading/trailing zeros.	to_char(123,'09999') = ' 0123' to_char(123,'9999D.00') = ' 123.00'
D<.|,>	Position of decimal point followed by character to be used as decimal separator. Currently only dot(.) and comma(,) are supported as decimal points. Currently only dot(.) and comma(,) are supported as decimal points.	to_char(12.34,'99D.99') = ' 12.34'
G<.|,| space >	Position of group separator followed by character to be used as group separator. Currently only dot(.), comma(,) and space(' ') are supported as group separator.	to_char(1234,' 9G,999') = ' 1,234'
x	String containing unsigned hexadecimal integer, using "abcdef". Output is not padded if number is not 2 bytes long.	to_char(123,'xx') = ' 7b' to_char(12,'x') = ' c'
X	String containing unsigned hexadecimal integer, using "ABCDEF". Output is not padded if number is not 2 byte long.	to_char(123,'XX') = ' 7B' to_char(12,'X') = ' C'
O	String containing unsigned octal integer. This option is "not" case sensitive. Output is not padded if number is not 2 bytes long.	to_char(12,'oo') = ' 14' to_char(1,'o') = ' 1'

A formatted string describing `<date>`.

`<date>`	The source date, time, or datetime value.
`<format>`	A string indicating the format of the generated string. Choose from the following codes: DD: 2-digit day of the month MM: 2-digit month MONTH: Full name of month MON: 3-character name of month YY: 2-digit year YYYY: 4-digit year HH24: 2-digit hour of the day (00-23)

	MI: 2-digit minute (00-59) SS: 2-digit second (00-59) FF: Up to 9-digit sub-seconds

Other values included in **<format>** appear in the result unchanged.

Example

Function	Results

`to_char(call_date,`
`'dd-mon-yy hh24:mi:ss.ff')`
	The date value from the `call_date` column formatted as a string, such as:
	`28-FEB-97 13:45:23.32`

The hyphens and spaces in **<format>** in the example are reproduced in the result; all the other characters are recognized as part of a parameter string in the table above and substituted with appropriate current values.

Related Information

timestamp [page 1037]

3.6.3.135 to_date

The to_date function converts a string to a date based on the input format.

If the input string has more characters than the format string, the extra characters in the input string will be ignored and will be initialized to the default value.

For example, to_date('10.02.2007 13:25:45', 'DD.MM.YYYY') will convert the date to 10.02.2007 00.00.00. The time part in the input string will be ignored and initialized to 0.

This function also supports the Oracle 9i `timestamp` data type. Its precision allows up to 9 digits for sub-seconds.

Syntax

```
to_date(<input_string>, <format>)
```

Return value

date, time, or datetime

A date, time, or both representing the original string.

Where

<input_string>	The source string.
<format>	A string indicating the format of the source string. Choose from the following codes: DD: 2-digit day of the month MM: 2-digit month MONTH: Full name of month MON: 3-character name of month YY: 2-digit year YYYY: 4-digit year HH24: 2-digit hour of the day (00-23) MI: 2-digit minute (00-59) SS: 2-digit second (00-59) FF: Up to 9-digit sub-seconds

Example

Function	Results
`to_date('Jan 8, 1968', 'mon dd, yyyy')`	`1968.01.08` stored as a date.

Related Information

timestamp [page 1037]

3.6.3.136 to_decimal

Converts a varchar to a decimal.

Syntax

```
to_decimal(<in_str, decimal_sep, thousand_sep, scale>)
```

Return Value

decimal

Uses a precision of 28 and the given scale.

Where

<in_str>	The number string. Null implies a NULL return.
<decimal_sep>	The character that separates the decimal component from the whole number component.
<thousand_sep>	The character that separates thousands from hundreds in the whole number component.
<scale>	The number of digits to the right of the decimal point in the returned value.

Details

Takes a string that represents a number and converts it to a decimal. If the input string is invalid, a 0 is returned.

Example

Function	Result
`to_decimal('99,567.99', '.', ',', 3)`	`99567.990`

3.6.3.137 to_decimal_ext

The to_decimal_ext function supports the use of DECIMAL data types with up to 96 precision. This function converts a varchar to a decimal and includes precision as a parameter.

Syntax

```
to_decimal_ext(<in_str, decimal_sep, thousand_sep, precision, scale>)
```

Return Value

decimal

Uses the given precision and scale.

Where

`<in_str>`	The number string. Null implies a NULL return.
`<decimal_sep>`	The character that separates the decimal component from the whole number component.
`<thousand_sep>`	The character that separates thousands from hundreds in the whole number component.
`<precision>`	The total number of digits in the returned value.
`<scale>`	The number of digits to the right of the decimal point in the returned value.

Details

Takes a string that represents a number and converts it to a decimal. Returns 0 if the input string is invalid.

Example

Function	Result
`to_decimal_ext('99,567.99', '.', ',', 38,3)`	`99567.990`

3.6.3.138 total_rows

Returns the number of rows in a particular table in a datastore. This function can be used with any type of datastore.

Syntax

```
total_rows(<datastore.owner.table_name>)
```

or for a memory datastore:

```
total_rows(<datastore..table_name>)
```

Return value

int

The number of rows in the table.

Where

<datastore>	The name of the datastore containing the table.
<owner>	The name of the datastore owner. Not used for memory tables.
<table_name>	The name of the database table or memory table containing the rows you want to count.

Example

Function	Results
`total_rows (ora_ds.scott.emp_table)`	Retrieves the total number of rows from an Oracle table.
`total_rows (mem_ds..bigtable)`	Retrieves the total number of rows from a memory table.

3.6.3.139 trunc

Truncates a given number to the specified precision, without rounding the value.

Syntax

```
trunc(<num1>, <precision>)
```

Return value

decimal, double, int, or real

The truncated number. The return type is the same as the original number, **<num1>**.

Where

<num1>	The source number.
<precision>	An integer indicating the number of decimals in the result. If **<precision>** is negative, digits to the left of the decimal point are truncated and the value is padded with zeros.

Example

Function	Results
`trunc(120.12345, 2)`	120.12
`trunc(120.12999, 2)`	120.12
`trunc(180, -2)`	100
`trunc(120.123, 5)`	120.12300

3.6.3.140 truncate_table

Allows you to explicitly expunge data from a memory table or truncate physical files used for a persistent cache table. With regard to memory tables, this function provides finer control than the active job has over your data and memory usage. Use this function with memory tables and persistent cache tables.

Syntax

```
trunc(<ds..tab_name>)
```

Return value

int

The return value is always 1.

Where

`<ds>`	The datastore containing the memory table or persistent cache table.
`<tab_name>`	The name of the memory table from which you want to expunge data or the name of the persistent cache table from which you want to truncate physical files.

Example

Function	Results
`truncate_table (ds..bigtable)`	Truncates rows from the memory table or persistent_cache table.

Usage scenarios

1. A data flow in your job creates a persistent cache table which can be used by subsequent data flows within the job (through the lookup_ext function, for example).
   You can add a custom function directing the truncate_table() function to remove the persistent cache table after running all data flows within the job.
2. Create a job that includes a script to clean up all unused persistent cache tables. When run, the job would truncate your physical files and free disk space.

3.6.3.141 upper

Changes the characters in a string to uppercase.

Syntax

```
upper(<value>,'locale')
```

Return value

varchar

The uppercase string. The return type is the same as **<value>**. Any characters that are not letters are left unchanged.

Where

<value>	The string to be modified.
<locale>	Optional parameter that converts the string to the specified locale. Note ISO 639 language code and ISO 3166 country code formats are supported.

Example

Function	Results
`upper('Accounting101')`	`'ACCOUNTING101'`
`upper(substr(LastName,1,1))|lower(substr(LastName,2,LENGTH(LastName)))`	The value in column `LastName` with the first letter uppercase and the rest of the value lowercase. Note that this example does not account for two-word last names.
`upper(LastName, 'tr')`	The value in column `LastName` is converted to all lowercase. It is also converted to the Turkish locale, using the ISO 639 language code.

Related Information

ISO 639 language list

ISO 3166 Country Code list

3.6.3.142 varchar_to_long

Converts a data type value of a given column from varchar to long.

Syntax

```
varchar_to_long(<column_name>)
```

Return value

long

Where

`<column_name>`	The name of the table column for which you want to convert a data type from varchar to long.

Related Information

Designer Guide: XML extraction and parsing for columns, Scenario 2 [page 366]

3.6.3.143 wait_for_file

This function looks for the specified file pattern in the file system. If it does not find the file(s), it waits for the specified timeout period, polling for the file(s) at every polling interval. The value specified in poll_interval determines how often to poll for the file pattern until timeout is reached. After timeout, the job stops, and polling for the file ceases.

Syntax

```
wait_for_file ( file_name_pattern, timeout, poll_interval,max_match, file_name_list, list_size, list_separator)
```

Return Values

int

Values are:

- 0 - No file matched.
- 1 - At least one file is matched.
- -1 - Timed out.
- -2 - At least one input value is illegal.

Where

`<file_name_pattern>`	The file name and path, relative to where the Job Server is running. It can be an absolute or relative path. File name can contain wildcard characters.
`<timeout>`	Wait timeout in milliseconds. If timeout is 0, then the function does not block. If timeout is -1, then the function will wait indefinitely for at least one file to exist that matches the file pattern. Any other negative value is illegal. On a computer where millisecond timing accuracy is not available, timeout is rounded up to the nearest legal value available on that system.
`<poll_interval>`	Polling interval in milliseconds to look for the existence of file(s). On a computer where millisecond timing accuracy is not available, the polling interval is rounded up to the nearest legal value available on that system. If the poll interval exceeds the timeout value then, it will be rounded up to timeout value.
`<max_match >`	Optional. Specifies the maximum number of matched file names that function should return. The default value is 0. -1 specifies all the matched file names.
`< file_name_list >`	Optional. Output varchar variable that returns the list of matched file names. Order of the file names in the list is determined the way operating system returns the file names.
`< list_size>`	Optional. Output integer variable that returns the list size.
`<list_separator>`	Optional. File name list separator character(s). Default value is comma (,).

Details:

This function waits a maximum of up to timeout interval for at least one file to exist that matches the pattern. Poll interval determines how often to poll for files.

Example

This function is used in a script at the beginning of a job. A job will suspend until a file is present, as shown in the following business use case example:

During the night, an external process puts source files in a file system that Data Services can access. Usually this process is finished at 1:00 AM, but it can be later. You schedule the job to start at 1:00 AM, but in the first step of the job use a script that checks for the existence of the last file. If the file does not exist, the job will wait for some time and try again later. Once the file is present, the job will continue. A timeout needs to be set to stop the job when the file is still not present at 9:00 AM in the morning.

3.6.3.144 week_in_month

Determines the week in the month in which the given date falls.

This function considers the first week of the month to be first seven days. The day of the week is ignored when calculating the weeks.

Syntax

```
week_in_month(<date1>)
```

Return value

int

The number from 1 to 5 that represents which week in the month that **<date1>** occurs.

Where

<date1>	The source date.

Example

Function	Results
`week_in_month(to_date('Jan 22, 1997', 'mon dd, yyyy'))`	4
`week_in_month(to_date('Jan 21, 1997', 'mon dd, yyyy'))`	3

3.6.3.145 week_in_year

Returns the week in the year in which the given date falls.

This function returns the week in the year in two ways:

- 'WW' - Absolute week number of the given date.
- 'IW' - ISO week number of the given date.

Syntax

```
week_in_year(inputdate,weektype)
```

Return value

int

Where

<inputdate>	The source date
<weektype>	Optional. The values are 'WW', or 'IW'. Default value is "WW".

Description

The number from 1 to 53 that represents the week number in a year. This function considers the first week of the year to be the first seven days while determining the absolute week number. Under the ISO standard, a week always begins on a Monday, and ends on a Sunday. The first week of a year is that week which contains the first Thursday of the year. An ISO week number may be between 1 and 53. Under the ISO standard, week 1 will always have at least 4 days. If 1-Jan falls on a Friday, Saturday, or Sunday, the first few days of the year are defined as being in the last (52nd or 53rd) week of the previous year.

Example

Some business applications use week numbers to categorize dates. For example, a business may report sales amounts by week, and identify each period as "9912", representing the 12th week of 1999. (An ISO week is more meaningful than an absolute week for such a purpose.)

Following are more example results for week_in_year applied to three different input dates:

Function	Results
`week_in_year(to_date('Jan 01, 2001','mon dd, yyyy'))`	1
`week_in_year(to_date('2005.01.01', 'yyyy.mm.dd'),'WW')`	1

Function	Results
`week_in_year(to_date('2005.01.01', 'yyyy.mm.dd'),'IW')`	`53`

3.6.3.146 WL_GetKeyValue

Returns the value of a given keyword in Web log search strings.

Syntax

```
WL_GetKeyValue(<string>, <keyword>)
```

Example

If you search for **`BusinessObjects`** on Google, the following appears in a Web log:

```
GET "http://www.google.com/search?hl=en&lr=&safe=off&q=BusinessObjects&btnG=Google
+Search"
WL_GetKeyValue('http://www.google.com/search?
hl=en&lr=&safe=off&q=BusinessObjects&btnG=Google+Search','q') returns
'BusinessObjects'.
```

3.6.3.147 word

Returns one word out of a string.

Syntax

```
word(<input_string>, <word_num>)
```

Return value

varchar

A string containing the indicated word. The return type is the same as **`<input_string>`**.

Where

<input_string>	The source string.
<word_num>	A nonnegative integer specifying the index of the target word in the string. The first word in a string is word number 1. If **<word_num>** is 0 or greater than the number of words in **<input_string>**, then the word function returns a NULL string.

A word is defined to be any string of consecutive non-white space characters terminated by white space, or the beginning and end of **<input_string>**. White space characters are the following:

- Space
- Horizontal or vertical tab
- Newline
- Linefeed

Example

Function	Results
`word('Accounting Department', 1)`	`'Accounting'`
`word('Accounting', 1)`	`'Accounting'`
`word('Accounting', 2)`	`NULL`

3.6.3.148 word_ext

Returns the word identified by its position in a delimited string.

This function is useful for parsing Web log URLs or file names.

Syntax

```
word_ext(<string>, <word_num, separator(s)>)
```

Return value

varchar

A string containing the indicated word. Return type is the same as **`<string>`**.

Where

`<string>`	The source string.
`<word_num>`	A nonnegative integer specifying the index of the target word in the string. The first word in a string is word number 1. If **`<word_num>`** is 0 or greater than the number of words in **`<string>`**, then the word function returns a NULL string.
`<separator(s)>`	Any character specified.

A word is defined to be any string of consecutive non-white space characters terminated by white space, or the beginning and end of **`<string>`**. White space characters are the following:

- Space
- Horizontal or vertical tab
- Newline
- Linefeed

Example

Function	Results
`word_ext('www.sap.com',2,'.')`	`'sap'`
`word_ext('www.cs.wisc.edu', -2, '.')`	`'wisc'` A negative word number means count from right to left.
`word_ext('www.cs.wisc.edu', 5, '.')`	`NULL`
`word_ext('aaa+=bbb+=ccc+zz=dd', 4, '+=')`	`'zz'` If 2 separators are specified (+=), the function looks for either one.
`word_ext(',,,,,aaa,,,,bb,,,c ', 2, ',')`	`'bb'` This function skips consecutive delimiters.

3.6.3.149 workflow_name

Returns the name of the current work flow.

Syntax

```
workflow_name()
```

Return Value

varchar

Details

In cases where several work flows enclose this function, the function returns the name of the inner most work flow. If no work flow is found, the function returns the job name.

Example

```
print('Work Flow Name: [workflow_name()]')
```

3.6.3.150 year

Determines the year in which the given date falls.

Syntax

```
year(<date1>)
```

Return value

int

The number that represents the year component of **<date1>**.

Where

<date1>	The source date.

Example

Function	Results
`year(to_date('Jan 22, 1997','mon dd, yyyy'))`	1997
`year(to_date('03/97', 'mm/yy'))`	1997
`year(to_date('03/19', 'mm/yy'))`	2019

3.6.4 Custom functions

You can create your own functions by writing script functions in SAP Data Services scripting language using the smart editor. Saved custom functions appear in the function wizard and the smart editor under the *Custom* category. They also are displayed in the object library under the *Custom Functions* tab. You can edit and delete custom functions from the object library.

In the object library on the *Custom Functions* tab, there are multiple categories of custom functions:

- Custom Functions
- Validation Functions:
  - Imported from Information Steward: These functions were created in Information Steward and imported; they are not editable in Data Services.
  - Locally Created: These are reusable, custom, validation functions created in Data Services.

Consider these guidelines when you create your own functions:

- Functions can call other functions.
- Functions cannot call themselves.
- Functions cannot participate in a cycle of recursive calls. For example, function A cannot call function B, which calls function A.
- Functions return a value.
- Functions can have parameters for input, output, or both. However, data flows cannot pass parameters of type output or input/output.

Before creating a custom function, you must know the input, output, and return values and their data types. The return value is predefined to be `Return`.

Related Information

Scripting Language [page 1709]

3.6.4.1 To create a custom function

1. Choose ▶ *Tools* ▶ *Custom Functions* ◀.
2. In the Custom Function list, right-click and select *New*.

   Alternatively, from the object library, right-click and select New in the Custom Functions tab.
3. Enter the name of the new function.
4. Enter a description for your function.
5. Click *Next* to open the smart editor.

   In the smart editor, you can define the return type, parameter list, and any local variables to be used in the function.
6. In the Variables tab, right-click *Return* and select *Properties...*

   By default, the return data type is set to int. To change this, select another return data type from the Data type list. Click OK.
7. In the Variables tab, right-click *Parameters* and choose *Insert*.
8. Define parameter properties by choosing a Data type and a Parameter type (Input, Output, or Input/Output).

   > **Note**
   >
   > Data flows cannot pass variable parameters of type output and input/output.
9. Click *OK*.

   Repeat steps 7 - 9 for each parameter required in your function. After you add one parameter, the right-click menu allows you to choose where to insert each new one.

   Use this menu to create, delete, or edit variables and parameters.
10. To define variables used by the function, but not passed outside the function, right-click *Local* and choose *Insert*.
11. Choose a data type in the Variable Properties window and click *OK*.

    Repeat this step for each variable required in your function.
12. Complete the text for your function.
13. Click the *Validate* icon to validate your function.

    
    If your function contains syntax errors, you will see a listing of those errors in an embedded pane below the editor.
14. To see where the error occurs in the text, double-click on an error.

    The smart editor redraws to show the location of the error.
15. When your function is valid, click *OK* to save the function, and the variables and parameters inside.

    Variables and parameters for an existing custom function are local to each function. Therefore, they are not displayed in the Variables and Parameters window (accessible from ▶ *Tools* ▶ *Variables* ◀). Variables and parameters for custom functions can be viewed in the smart editor library, under the Variables tab, when you edit the custom function.

Related Information

Smart editor [page 1021]

3.6.4.2 To edit an existing function

Choose *Tools* › *Custom Functions*, select the function and select *Next*.

The smart editor opens with the function displayed and the variables and parameters that exist for this function shown under the Variables tab.

Alternatively:

- Go to the Custom Function tab in the object library and double-click the function you want to edit.
- Go to the Custom Function tab in the object library, right-click the function, and select *Edit*.

Related Information

Custom functions [page 1694]
To edit an existing function call in an expression [page 1514]

3.6.4.3 To replicate a custom function

1. From the object library, right-click a custom function and select *Replicate*.

   The Custom Function editor opens with only the Function name field enabled.
2. Enter a new name for the function.

   The name must be valid and different from the original name.
3. Click *Finish*.

   The new custom function appears in the object library.

3.6.4.4 To delete a custom function

Go to the Custom Function tab in the object library, right-click the function, and select *Delete*.

If you delete a function from the list of custom functions, you must remove references to the function from expressions in scripts, conditionals, queries, and other custom functions.

3.6.5 About procedures

Data Services supports the use of stored procedures for DB2, ODBC, Oracle, Microsoft SQL Server, SAP HANA, SAP Sybase SQL Anywhere, SAP Sybase ASE, SAP Sybase IQ, and Teradata databases. You can call stored procedures from the jobs you create and run in Data Services.

3.6.5.1 Overview

A stored procedure is a generic term used to describe an executable object, or a named entity that is stored in a database and can be invoked using input and output parameters. Generally, a stored procedure is one or more precompiled SQL statements. By calling a stored procedure from within Data Services, you can invoke business logic you have already coded thus enabling you to quickly and conveniently develop data extraction and data management tasks. Stored procedures can also be used to:

- Maintain business logic rules and provide a single point of control to ensure rules are accurate and enforced
- Significantly reduce network overhead with client/server applications because:
  - Procedures are stored on the database server
  - Compiled execution plans for procedures are retained in the data dictionary

Data Services supports stored procedures for DB2, ODBC, Oracle, Microsoft SQL Server, SAP HANA, SAP Sybase SQL Anywhere, SAP Sybase ASE, SAP Sybase IQ, and Teradata databases. Data Services also supports stored functions and packages for Oracle databases. Queries, scripts, conditionals, and custom functions can all be configured to include stored procedures, stored functions, and packages.

Stored procedures must exist in the database before you can use the procedure in Data Services. Create a stored procedure in a database using the client tools provided with the database, such as Oracle SQL *Plus. After it is created, a stored procedure can be called by users who have execution privileges for the procedure. After they are imported into Data Services, stored procedures can be used like functions in Data Services jobs.

Stored procedures include parameters. Each parameter has a name, a data type, and a mode (`IN`, `INOUT`, or `OUT`). A stored procedure can use a NULL or default parameter value for its input and can produce more than one output parameter value.

3.6.5.2 Requirements

To use stored procedures with Data Services, the following requirements must be met:

- The client and server versions must match.
- Only user-defined stored procedures can be used. Data Services does not support stored procedures provided by a database system.
- User-defined stored procedures or stored functions must meet the following additional requirements:

- The return type (the data type of the result value) must be a Data Services supported data type, such as `varchar`, `date`, or `int`.

  > ℹ Note
  >
  > This release does not support the long data type in stored procedures.

- The name of the stored procedure—the combination of the datastore name, owner name, and procedure name—must be unique. Data Services only imports the first procedure or function with a particular name. Using Oracle for example, if you have multiple procedures or functions with the same name in a package and want to use all of them, you must rename the procedures, giving each a unique name. A procedure is overloaded when multiple versions exist in a particular package. Overloading is not supported in Data Services.

- Data Services validates the user name specified in the datastore which was used to import the stored procedure. This ensures that the data flow that calls a stored procedure enforces restrictions associated with that procedure, such as:
  - Data input restrictions
  - Execution privileges
- To use stored procedures with Teradata, you must first enable the use of stored procedures within the Teradata ODBC driver options and invoke the stored procedures in the same session mode in which it was enabled.
  For Windows, in the *Teradata ODBC Driver Options* screen used for configuration of the Teradata ODBC driver, check the box *Disable CALL to EXEC Conversion*, set the session mode as desired in the *Session Mode* drop-down list, and click *OK* to save the change. You must invoke the stored procedures in the same session mode.
  For UNIX platforms, edit the file `odbc.ini` to set the option **`Disable CALL To EXEC Conversion=YES`**. Set the session mode option as desired, and save the file. You must invoke the stored procedures in the same session mode.
  For more information about Teradata ODBC driver configuration, see your Teradata ODBC driver configuration documentation.

3.6.5.3 Creating stored procedures in a database

This section provides:

- An example scenario for using a stored procedure
- Tips for creating stored procedures on each database
- Example syntax for DB2, Oracle, SAP HANA, SQL Server, and SAP Sybase ASE databases based on the example scenario

Since syntax varies between databases, the SQL statements needed to create a stored procedure for any scenario vary. The client tools used to pass the SQL statements to the database server also vary. Refer to your database documentation for more detailed descriptions and examples regarding how to create stored procedures.

In the following example, the source database has a stored procedure `Get_emp_rec` that retrieves an employee's name and hire date from the Employee table using a given employee number. The stored procedure takes an input parameter `Emp_number` and returns two values `Emp_name` and `Hire_date` via output parameters.

The schema of the database table Employee is as follows:

Name	Null?	Type
empno	Not Null	Integer
ename	Null	Varchar(20)
job	Null	Varchar(9)
mgr	Null	Integer
hiredate	Null	Date
sal	Null	Decimal(7,2)
comm	Null	Decimal(7,2)
deptno	Null	Integer

3.6.5.3.1 Creating stored procedures in DB2

In DB2, a parameter can be `IN`, `OUT` or `INOUT`. Any SQL data type can be used as a data type of a parameter. User defined data types are not supported.

Example

The DB2 syntax for the stored procedure

```
CREATE PROCEDURE GET_NAME_USING_ID (IN NID INTEGER, OUT outVar varchar(20))
language SQL
reads sql data
BEGIN
select first_name into outVar FROM CONTACT where id = NID;
END
```

`Reads sql data` and `language SQL` are two of the many options that DB2 stored procedures support. Refer to the DB2 documentation for the DB2 stored procedure options and their meaning.

Related Information

Creating stored procedures in a database [page 1698]

3.6.5.3.2 Creating stored procedures in Oracle

Oracle supports both stored procedures and stored functions. Any stored procedure that returns a value is called a stored function. Oracle is the only database to allow return values with data types other than an integer.

In Oracle, stored procedures are created using the `CREATE [OR REPLACE] PROCEDURE` statement, and stored functions are created using the `CREATE [OR REPLACE] FUNCTION` statement. The `OR REPLACE` option allows you to override an existing definition of a procedure or function with the same name.

Oracle supports `IN`, `OUT`, and `INOUT` parameters. An `INOUT` parameter allows you to pass in a parameter, modify it, and return the modified value. You can use the DEFAULT keyword or the assignment operator to give an `IN` parameter a default value. When an `IN` parameter has a default value, you can omit the parameter from the argument list when you call the procedure. If you do specify an argument value in the call, the specified value overrides the default value. `INOUT` and `OUT` parameters must be specified.

Example

Syntax

The Oracle syntax for the stored procedure:

```
CREATE OR REPLACE PROCEDURE
get_emp_rec (Emp_Number IN NUMBER,
Emp_Name OUT VARCHAR, Emp_Hiredate OUT DATE) AS
BEGIN
SELECT ename, hiredate
INTO Emp_Name, Emp_Hiredate
FROM Employee
WHERE empno = Emp_Number;
END;
/
```

In this example, the parameters are declared as IN and OUT, but Oracle also supports an INOUT parameter type, which allows you to pass in a parameter, modify it, and return the modified value. INOUT parameters can take default values. This means that the parameter can be omitted from the actual parameter list when you call the procedure. INOUT and OUT parameters must be specified.

An Oracle package is an encapsulated collection of related program objects (e.g., procedures, functions, variables, constants, cursors, and exceptions) stored together in the database. Data Services allows you to import procedures or functions created within packages and use them the same way as top-level procedures or functions.

Data Services does not support overloading of procedures or functions. Overloading a procedure means creating multiple procedures with the same name in the same package, each taking arguments of a different number or data type. If you have multiple procedures or functions with the same name in the same package (and you want to use all of them), you need to rename the procedures or functions so that they all have distinct names. Otherwise, Data Services will only import the first procedure or function by that name.

Related Information

Creating stored procedures in a database [page 1698]

3.6.5.3.3 Creating stored procedures in SAP HANA

SAP Data Services supports SAP HANA stored procedures with zero, one, or more output parameters.

Data Services supports scalar data types for input and output parameters. Table data types are not supported; if you try to import a procedure with table type, you will receive an error message. Data Services does not support data types such as binary, blob, clob, nclob, or varbinary for SAP HANA procedure parameters.

Procedures can be called from a script or a Query transform as a new function call.

Example

Syntax

The SAP HANA syntax for the stored procedure:

```
CREATE PROCEDURE GET_EMP_REC (IN EMP_NUMBER INTEGER, OUT EMP_NAME VARCHAR(20),
OUT EMP_HIREDATE DATE) AS
BEGIN
     SELECT ENAME, HIREDATE
        INTO EMP_NAME, EMP_HIREDATE
     FROM EMPLOYEE
     WHERE EMPNO = EMP_NUMBER;
END;
```

Limitations

SAP HANA provides limited support of user-defined functions (usually written in L), which can return one or several scalar values. The usage of such functions is limited to the projection list and the GROUP BY clause of an aggregation query on top of an OLAP cube or a column table. These functions are not supported by Data Services.

SAP HANA procedures cannot be called from a WHERE clause.

Related Information

Creating stored procedures in a database [page 1698]

3.6.5.3.4 Creating stored procedures in MS SQL Server or SAP Sybase ASE

In Microsoft SQL Server and SAP Sybase ASE, a stored procedure may have a group number (between 1 and 32767), which is an optional integer used to group procedures of the same name so they can be dropped together with a single `DROP PROCEDURE` statement.

The first procedure you create with a name automatically is assigned group number 1. While you can execute this procedure without specifying the group number, other procedures with the same procedure name must be called with the group number. For example, `execute orderproc;2` and so on. Data Services imports the procedure with the group number 1, i.e., the first procedure, unless you specify the name including the group number, such as `orderproc;2`.

A parameter can be either an input parameter (default) or an output parameter. A parameter can not be both input and output. In the following sample, the first parameter `@Emp_Number` is an input parameter and the other two parameters, `@Emp_Name` and `@Emp_Hiredate`, are output parameters. Output parameters are specified using the keyword `OUTPUT`. Input parameters can take default values (database defaults). If a default value is defined, the procedure can be executed without specifying a value for that parameter. You specify a parameter name with "@" as the first character.

An optional integer return value is automatically added to each stored procedure to store its return status. In the following example, if the `SELECT` statement is successful, "`0`" is returned as the return value. The parameter name of the return value is `RETURN_VALUE`. Microsoft SQL Server and SAP Sybase ASE stored procedures can be used like Oracle stored functions in Data Services because they include this return value.

A user-defined function is a new feature of SQL Server 2000. Data Services supports user-defined stored procedures, but not user-defined functions at this time.

Example

The MS SQL Server and SAP Sybase ASE syntax

```
CREATE PROCEDURE GET_EMP_REC @Emp_Number int, @Emp_Name varchar(20) OUTPUT,
@Emp_Hiredate datetime OUTPUT AS
SELECT @Emp_Name = ename, @Emp_Hiredate = hiredate
FROM Employee
WHERE empno = @Emp_Number
RETURN 0
```

Related Information

Creating stored procedures in a database [page 1698]

3.6.5.4 Importing metadata for stored procedures

Use the Import by Name command to import stored procedures into Data Services. You must know the name of the stored procedure, stored function, or package you want to import. Use the name of the stored procedure, the package name only, or, if you are using a Microsoft SQL Server or SAP Sybase ASE database, use the name of the stored procedure and the group number, such as `orderproc;2`.

Stored procedures are created and structured very much like functions. Imported stored procedures appear on the Datastores tab of the object library. Each is listed in the Functions category of the database datastore from which the procedure was imported. It is displayed with the following syntax:

```
<datastore>.<owner>.<proc_name>.
```

If a stored procedure was defined within an Oracle package, the name of the procedure is displayed as

```
<datastore>.<owner>.<package>.<proc_name>.
```

To view the signature of the procedure, right-click the imported stored procedure and select Open (or simply double-click the procedure).

- A stored procedure has a signature that consists of its defined parameters including two output parameters added by Data Services during import, `AL_SP_RETCODE` and `AL_SP_ERRMSG`.
- If the database you are using provides a return code for a stored procedure, it is displayed in the signature as `AL_SP_RETURN`.
- Each parameter has a name, a data type, and a mode (`IN`, `INOUT`, or `OUT`). The mode is indicated by icons shown before the parameter name.
- Oracle stored functions have a signature that consists of parameters and a return data type. When you call a function, the return value is named `AL_SP_RETURN`.

> i Note
>
> If you change the signature of a stored procedure, for example you add a new parameter, re-import the metadata for the procedure from the database.

Related Information

Checking execution status [page 1708]

Designer Guide: Datastores, Ways of importing metadata [page 221]

3.6.5.5 Structure of a stored procedure

Imported information for a stored procedure includes:

- Name and owner
- Return data type if the stored procedure has a return value or code
- Parameters

For each parameter, Data Services imports the following information:

- Name
- Mode (`IN`, `OUT`, or `INOUT`)
- data type (length, precision and scale if applicable)

  > i Note
  >
  > In an Oracle stored procedure declaration, it is illegal to constrain char and varchar2 parameters with a length, or to constrain number parameters with a precision and/or scale. These constraints are taken from the procedure arguments. Therefore, the length of a char or varchar and the precision and scale of a number data type parameter are not stored in the data dictionary.

  However, Data Services does not allow the length of a varchar data type or the precision of a number data type to be 0. (Data Services converts char data types in Oracle to varchar.) When importing a stored procedure, Data Services fills in the default length for a varchar or the precision and scale for a number parameter. For varchar, Data Services sets the length to 4000. For number, Data Services sets precision and scale to the values set in the Advanced section of the Create New Datastore window. At runtime, the length of varchar and the precision and scale of number come from the procedure arguments.

- Position within the parameter list
- Nullable (whether a default value exists)

Data Services omits a parameter if any of the following data type conditions is true:

- Is not a Data Services supported data type or is `long`
- Data type is missing in the database dictionary
- Is a composite data type (e.g., table, record, or cursor)

After Data Services imports a stored procedure, the Designer reports warnings about any omitted parameters.

> Note
>
> Even if a stored procedure has an omitted parameter, the procedure is callable if the parameter has a default value defined. If the omitted parameter does not have a default value, the procedure is not callable and Data Services throws a runtime error.

If a stored procedure has a return value, its result type (the data type of the result value) must be a Data Services supported database server data type. Otherwise, the procedure cannot be imported and used within Data Services applications.

For each stored procedure, Data Services automatically adds two optional output parameters, `AL_SP_RETCODE` and `AL_SP_ERRMSG`. These parameters allow you to check the execution status of the stored procedure.

Checking execution status [page 1708]
Data Types [page 1027]

3.6.5.6 Calling stored procedures

This section discusses calling stored procedures.

3.6.5.6.1 In general

You can call a stored procedure just as you call custom functions you create in Data Services.

- When you call a stored procedure inside a script, conditional or custom function, Data Services evaluates the call as an independent SQL statement.
- When you call a stored procedure in a query's column mapping or WHERE clause, (Oracle only) Data Services can combine the SQL for the stored procedure with the SQL for the query.
- You can also call a stored procedure in a SQL transform. You must use proper syntax. Data Services does not validate SQL in a SQL transform.

- A stored procedure can be used within an expression. For example:

```
ora_ds.acta_user.get_emp_sal (EMPLOYEE.NAME) + 10
ora_ds.acta_user.get_emp_sal (EMPLOYEE.NAME) < 100
```

Stored procedures can require input values for some parameters but not others. You must determine the requirements of the stored procedure and prepare the appropriate inputs. In addition, Data Services supports the following:

- Input parameters can be constants or expressions
- If an input parameter has a default value, you can omit the parameter in the call by leaving the parameter unspecified in the function wizard. The database will use the parameter's default value when evaluating the stored procedure call.
- All `OUT` or `INOUT` parameters must be specified except the two Data Services adds at import AL_SP_RETCODE and AL_SP_ERRMSG.
- All `OUT` or `INOUT` parameters must be variables (except in a query output schema). A variable must be declared before use.
- If a stored procedure returns a value (such as an Oracle function or a MS SQL Server or SAP Sybase ASE stored procedure), you can use the procedure in an expression.
- You can call a stored procedure as a step inside: an output schema of a query, script, or custom function. For example:

```
As an Oracle user you create two Oracle stored procedures: GET_EMP_SALARY and
SET_EMP_SALARY
CREATE OR REPLACE FUNCTION GET_EMP_SALARY(Emp_Name IN VARCHAR)
RETURN NUMBER AS
Return_value NUMBER;
BEGIN
SELECT sal
INTO Return_value
FROM Employee
WHERE ename = Emp_Name;
RETURN Return_value;
END;
CREATE OR REPLACE PROCEDURE SET_EMP_SALARY(Emp_Name IN VARCHAR,Emp_Sal IN
NUMBER) AS
BEGIN
UPDATE Employee
SET sal = Emp_Sal
WHERE ename = Emp_Name;
END;
```

After importing the stored procedures into an Oracle datastore, you can use the stored procedures in a script. For example:

```
$new_sal = ora_ds.bodi_user.get_emp_salary('MARTIN') + 100;
ora_ds.bodi_user.set_emp_salary('MARTIN', $new_sal);
```

Related Information

From queries [page 1706]

To include a stored procedure in a query output schema [page 1707]

3.6.5.6.2 From queries

You can call stored procedures from Query transforms.

Mapping and WHERE clauses

In a query's column mapping or WHERE clause, you can use a stored procedure in an expression, subject to the same constraints as other expressions. However, when stored procedures are used in a query's column mapping or WHERE clause, SAP Data Services can combine the SQL statement for the stored procedure call with the SQL statement for the query and submit one request to the database.

For the software to combine the SQL statements, the stored procedure must meet the following conditions:

- It must be from an Oracle database.
- It must be a stored function.
- All its parameters must be IN parameters; none can be an OUT or INOUT parameter.
- All parameter values must be specified. You cannot leave a parameter unspecified, such as to use the default value.
- All parameter values must be constants or expressions with only constants or database table column names; none can have functions or operations.
- The data types of the procedure's parameters and the return type (the data type of its result value) must be supported data types. The software must not omit any of the parameters when importing the procedure.
- Data Definition Language (DDL) operations like creating tables, views etc. and transaction control statements such as `COMMIT`/`ROLLBACK` cannot be performed inside the stored procedure.

In addition, when importing the function, you must select the Callable from SQL expression check box on the Import By Name window.

The software will push down a stored procedure call to Oracle if the first five conditions are met and the *Callable from SQL expression* check box is selected. If a stored procedure call contains any DDL statements, it ends the current transaction with `COMMIT` or `ROLLBACK`, or it issues any `ALTER SESSION` or `ALTER SYSTEM` commands. Therefore, you should deselect the *Callable from SQL expression* option on the Import By Name window to ensure that the function call will not be pushed down to database.

When a stored procedure call cannot be pushed down to database, it is submitted to database as a separate SQL statement.

Query output schemas

When a stored procedure can provide at least one return value or has any `INOUT` or `OUT` parameters other than AL_SP_RETCODE or AL_SP_ERRMSG, you can call the procedure by including it as an object in the output schema of a query.

When using a stored procedure in a query output schema, you must map `INOUT` or `OUT` parameters and return values to a column of the output schema. In this case, you cannot map these parameters to variables.

Related Information

In general [page 1704]

Importing metadata for stored procedures [page 1702]

3.6.5.6.2.1 To include a stored procedure in a query output schema

1. In a data flow diagram, click a query name to open the query editor.
2. In the query editor, right-click the query name in the output schema and select *New Function Call*.

   Alternately, you can right-click an existing stored procedure object in the output schema area of the query editor and select *Modify Function Call*.

   SAP Data Services provides a function wizard to help you include input and output parameters and the return value for a procedure call. The imported stored procedures are listed for each datastore on the first page of the function wizard.
3. Select a function category. Notice that the function names change depending on the category you select.
4. Under Function name, select a stored procedure, then click *Next*.
5. In the *Define Input Parameter(s)* window, enter the input parameters for the stored procedure, then click *Next*.
6. In the *Select Output Parameter* window, select the procedure's output parameters that you want to map to the query output.

   In the *All output parameters* box, select the parameters you want to map, and click the arrow key to move them into the *Selected output parameters* box.

   You can map more than one INOUT or OUT parameter and the return value as output columns from a single procedure call.
7. Click *Finish*.

   The software adds those parameters to the query's output schema. In this example, the output schema of the Query transform would have two columns, EMP_NAME and EMP_HIREDATE.

3.6.5.6.3 Without the function wizard

You can enter an existing stored procedure call on the *Mapping* tab or the *Where* tab in a query editor.

When entering a stored procedure call without using the function wizard:

- Match the parameter values you enter to the signature of the stored procedure in Data Services. Values must be specified in the same order that the parameters are defined.
- Use `AL_UNSPECIFIED_PARAM` in place of a missing parameter, such as when you want to use the default value for an `IN` parameter.
- Use the correct naming convention for the stored procedure:

  - <datastore>.<owner>.<proc_name>
  - <datastore>.<owner>.<package>.<proc_name>.

  If the name is case-sensitive in the database (and not all uppercase), enter the name as it appears in the database and use double quotation marks (") around the name to preserve the case.

The two output parameters added by Data Services during import, AL_SP_RETCODE and AL_SP_ERRMSG, are optional. You do not need to provide arguments for these two parameters if you are not interested in the values stored in them.

Related Information

Checking execution status [page 1708]

3.6.5.7 Checking execution status

To allow you to monitor the execution status of a stored procedure, Data Services adds two parameters to the signature of each stored procedure when importing the procedure:

- AL_SP_RETCODE, varchar(256). There are three possible values:
  - ACTA_SP_OK — The stored procedure call succeeded.
  - ACTA_SP_DB_CONN_EXCEPTION — The database connection cannot be created because of a connection error, invalid user, password, or host name.
  - ACTA_SP_CALL_ERROR — The connection completes but the call fails in the database. Details for the cause of the error are available in AL_SP_ERRMSG.
- AL_SP_ERRMSG, varchar(1024)

Data Services adds these two parameters to the end of the signature, following any user-defined parameters.

With these parameters, there are two techniques you can use to handle errors if a stored procedure fails during execution:

- Throw an error that stops the job immediately. An error message is logged in the errorlog.txt file.
  To use this method, do not map as output parameters the two parameters Data Services adds to imported stored procedures.
- Save the Oracle error messages into the AL_SP_ERRMSG parameter. This method allows the query, script, conditional, or custom function that contains the stored procedure call to continue its execution.
  To use this method, define parameters for AL_SP_RETCODE and AL_SP_ERRMSG. Use the execution status stored in AL_SP_RETCODE to control your application logic. For example, if you store the value of AL_SP_ERRMSG in a variable, you can use the print function to print the variable to the job log. With this method, the error message is not logged in the errorlog.txt file.

3.7 Scripting Language

This section describes the SAP Data Services scripting language. You can use the language to write scripts and custom functions (also known as user-script functions). Further, you can use scripting language to write expressions such as complex column mapping expressions and WHERE clause conditions.

The software uses this language internally to save the objects you create into repository tables. You can export saved objects to a file (.atl) and later import the file to another repository. This technique is commonly used when migrating to a new environment or when backing up a repository before initiating an upgrade.

3.7.1 To use the scripting language

1. Open an editor for an object in the Designer workspace such as a script, conditional, or transform.
2. Inside any of these editors, use the smart editor to enter a script or expression using the language syntax described in this section.

Related Information

Language syntax [page 1709]
Sample scripts [page 1720]

3.7.2 Language syntax

With the Data Services scripting language, you can assign values to variables, call functions, and use standard string and mathematical operators. The syntax used in the Data Services scripting language can be used in an expression as well as in a script.

3.7.2.1 Syntax for statements in scripts

Jobs and work flows can use scripts to define detailed steps in the flow of logic. A script can run functions and assign values to variables, which can then be passed to other steps in the flow.

Statements in a script object or custom function must end with a semicolon (`;`). Comment lines must start with a # character.

Related Information

Sample scripts [page 1720]

3.7.2.2 Syntax for column and table references in expressions

Expressions are a combination of constants, operators, functions, and variables that evaluate to a value of a given data type. Expressions can be used inside script statements or added to data flow objects. Because expressions can be used inside data flow objects, they often contain column names.

The Data Services Scripting Language recognizes column and table names without special syntax. For example, you can indicate the `start_date` column as the input to a function in the *Mapping* tab of a query as follows:

```
to_char(start_date, 'dd.mm.yyyy')
```

The column `start_date` must be in the input schema of the query.

If there is more than one column with the same name in the input schema of a query, indicate which column is included in an expression by qualifying the column name with the table name. For example, indicate the column `start_date` in the table `status` as follows:

```
status.start_date
```

Note that column and table names as part of SQL strings may require special syntax based on the DBMS that the SQL is evaluated by. For example, select all rows from the `LAST_NAME` column of the `CUSTOMER` table as follows:

```
sql('oracle_ds','SELECT CUSTOMER.LAST_NAME
FROM CUSTOMER')
```

Because the column name is all upper case in Oracle, no special syntax is required. However, select all rows from the `start_date` column in the Oracle table `Status` as follows:

```
sql('oracle_ds','SELECT "Status"."start_date"
FROM "Status"')
```

The table name and column are defined in Oracle to have a special case. To preserve this case, enclose the identifiers in double quotation marks.

3.7.2.3 Strings

This section contains the following information about strings:

- Quotation marks
- Escape characters
- Trailing blanks

Related Information

Quotation marks [page 1711]
Escape characters [page 1711]
Trailing blanks [page 1712]
NULL values and empty strings [page 1715]

3.7.2.3.1 Quotation marks

The type of quotation marks to use in strings depends on whether you are using identifiers or constants

Identifier	Name of an object (for example, table, column, data flow, or function).
Constant	A fixed value used in computation. There are two types of constants: ● String constants (for example, 'Hello World' or '1995.01.23') ● Numeric constants (for example, 2.14)

Identifiers need quotation marks if they contain special (non-alphanumeric) characters. For example, you need a double quote for " `compute large numbers` " because it contains blanks.

Use single quotes for string constants.

3.7.2.3.2 Escape characters

If a constant contains a single quote (`'`) or backslash (`\`) or another special character used by the Data Services scripting language, then those characters need to be escaped. For example, the following characters must be preceded with an escape character to be evaluated properly in a string. Data Services uses the backslash (\) as the escape character.

Character	Example
`single quote (')`	`'World\'s Books'`
`backslash (\)`	`'C:\\temp'`

3.7.2.3.3 Trailing blanks

Data Services does not strip trailing blanks from strings that are used in scripts or custom functions. To remove trailing blanks, use the rtrim or rtrim_blank function.

3.7.2.4 Variables

Variable names must be preceded by a dollar sign ($).

- Local variables used in a script or expression must be defined in the job or work flow that calls the script using the *Variables and Parameters* window.
- Global variables used in a script or expression must be defined at the job level using the Variables and Parameters window.
- The return value must be passed outside the function using the following statement:

  ```
  RETURN(<expression>)
  ```

  where expression defines the value to be returned.
- Local variables used in a custom function must be defined using the smart editor.
- Existing variables and parameters displayed in the smart editor are filtered by the context from which the smart editor is opened.

Related Information

Designer Guide: Variables and Parameters [page 398]

To create a custom function [page 1695]

3.7.2.5 Variable interpolation

You can embed expressions within constant strings, and Data Services will evaluate the variables and substitute the value into the string—the concatenation operator (||) is not required.

Here is an example using the concatenation operator:

```
$st_date=sql('warehouse_ds','SELECT max(start_timestamp)
    FROM dw_process_log
    WHERE table_name='\"'||$Table_Name||'\"
print('The value of the start date
    is:'||sysdate()+5);
```

The statement can be simplified to the following:

```
$st_date=sql('warehouse_ds','SELECT max(start_timestamp)
    FROM dw_process_log
    WHERE table_name={$Table_Name}'
```

```
print('The value of the start date
    is:[sysdate()+5]');
```

Curly braces ({}) and square brackets ([]) enclose the embedded expressions:

- The square brackets ([]) indicate that the value of the expression should be substituted.
- The curly braces ({}) indicate that the value of the expression should be quoted with single quotation marks.

Strings including curly braces or square brackets cause a processing error. You can avoid the error by preceding the braces or brackets with a backslash (\).

3.7.2.6 Functions and stored procedures

A script, expression or custom function can call most built-in or custom functions. A function cannot call itself or call another function that would lead to a recursive call. For example, function A cannot call function A, nor can function A call function B if function B calls function A.

You can also use functions and stored procedures imported from a DBMS. Use the exact case for names of imported functions and stored procedures

- Built-in functions are listed in the function wizard and smart editor grouped by category.
- You can find the list of Custom functions in both function wizard and the smart editor.
- Imported functions and stored procedures are listed in the function wizard and smart editorunder the datastore used to import them.

Related Information

To create a custom function [page 1695]

Importing metadata for stored procedures [page 1702]

3.7.2.7 Operators

The operators you can use in scripts and expressions are listed in the following table, in order of precedence. Note that when operations are pushed to a DBMS to perform, the precedence is determined by the rules of the DBMS.

Operator	Description
+	Addition
-	Subtraction
*	Multiplication
/	Division
=	Assignment, comparison
<	Comparison, less than

Operator	Description
`<=`	Comparison, less than or equal to
`>`	Comparison, greater than
`>=`	Comparison, greater than or equal to
`!=`	Comparison, not equal to
`||`	Concatenate
`%`	Return the remainder when one number is divided by another
`AND`	Logical AND
`OR`	Logical OR
`NOT`	Logical NOT
`IS NULL`	Comparison, is a NULL value
`IS NOT NULL`	Comparison, is not a NULL value

When you use the smart editor to add operators, you can type in operators or use the built-in key pad. Access the key pad from the smart editor's tool bar.

You can use a comparison in the following ways:

- In a script or script function as a condition; for example:

  ```
  if ($x IN (1,2,3)), while ($x IN (1,2,3)) and ifthenelse()
  ```
- In a data flow such as in a WHERE clause ifthenelse() function, case transform, etc.
- As a condition of the IF block, WHILE block or TRY CATCH block

The following examples illustrate valid comparison expression syntax:

```
expression = expression
expression != expression
expression < expression
expression > expression
expression <= expression
expression >= expression
expression IS NULL
expression IS NOT NULL
expression IN (expression list)
expression IN domain
expression LIKE constant
expression NOT LIKE constant
```

`NOT` (any of the above comparisons); for example `NOT ($x IN (1,2,3))`

```
comparison OR comparison
comparison AND comparison
```

Note that the following syntax is not valid:

```
$x NOT IN (1,2,3)
EXIST or NOT EXIST
```

3.7.2.8 NULL values

Indicate NULL values using the keyword NULL. For example, you can check whether a column (COLX) is null or not:

```
COLX IS NULL
COLX IS NOT NULL
```

Data Services does not check for NULL values in data columns. Use the function `nvl` to remove NULL values.

Related Information

nvl [page 1636]

3.7.2.8.1 NULL values and empty strings

Data Services uses the following two rules with empty strings:

- When you assign an empty string to a variable of type varchar, Data Services treats the value of the variable as a zero-length string. An error results if you assign an empty string to a variable that is not a varchar. To assign a `NULL` value to a variable of any type, use the `NULL` constant.
- As a constant (`''`), Data Services treats the empty string as a varchar value of zero length. Use the `NULL` constant for the null value.

> Note
>
> Oracle does not distinguish an empty string from a `NULL` value. When you insert an empty string or a `NULL` value into a varchar column, Oracle treats both the empty string and `NULL` value as `NULL` values. Therefore, Data Services treats the value as a `NULL` value.

Data Services uses the following three rules with `NULL`s and empty strings in conditionals:

- The Equals (=) and Not Equal to (<>) comparison operators against a null value always evaluates to `FALSE`. This `FALSE` result includes comparing a variable that has a value of `NULL` against a `NULL` constant.
  The following table shows the comparison results for the variable assignments `$var1 = NULL` and `$var2 = NULL`:

Condition	Translates to	Returns
`If (NULL = NULL)`	`NULL` is equal to `NULL`	`FALSE`
`If (NULL != NULL)`	`NULL` is not equal to `NULL`	`FALSE`
`If (NULL = '')`	`NULL` is equal to empty string	`FALSE`
`If (NULL != '')`	`NULL` is not equal to empty string	`FALSE`
`If ('bbb' = NULL)`	`bbb` is equal to `NULL`	`FALSE`

Condition	Translates to	Returns
`If ('bbb' != NULL)`	`bbb` is not equal to `NULL`	`FALSE`
`If ('bbb' = '' )`	`bbb` is equal to empty string	`FALSE`
`If ('bbb' != '')`	`bbb` is not equal to empty string	`TRUE`
`If ($var1 = NULL )`	`NULL` is equal to `NULL`	`FALSE`
`If ($var != NULL)`	`NULL` is not equal to `NULL`	`FALSE`
`If ($var1 = '' )`	`NULL` is equal to empty string	`FALSE`
`If ($var != '')`	`NULL` is not equal to empty string	`FALSE`
`If ($var1 = $var2 )`	`NULL` is equal to `NULL`	`FALSE`
`If ($var != $var2)`	`NULL` is not equal to `NULL`	`FALSE`

The following table shows the comparison results for the variable assignments `$var1 = ''` and `$var2 = ''`:

Condition	Translates to	Returns
`If ($var1 = NULL)`	`Empty string` is equal to `NULL`	`FALSE`
`If ($var != NULL)`	`Empty string` is not equal to `NULL`	`FALSE`
`If ($var1 = '')`	`Empty string` is equal to empty string	`TRUE`
`If ($var != '')`	`Empty string` is not equal to empty string	`FALSE`
`If ($var1 = $var2)`	`Empty string` is equal to `Empty string`	`TRUE`
`If ($var != $var2)`	`Empty string` is not equal to `Empty string`	`FALSE`

- Use the IS NULL and IS NOT NULL operators to test the presence of null values. For example, assuming a variable is assigned: `$var1 = NULL;`

Condition	Translates to	Returns
`If ('bbb' IS NULL`	bbb is `NULL`	`FALSE`
`If ('bbb' IS NOT NULL)`	bbb is not `NULL`	`TRUE`
`If ('' IS NULL`	Empty string is `NULL`	`FALSE`
`If ('' IS NOT NULL)`	Empty string is not `NULL`	`TRUE`
`If ($var1 IS NULL)`	`NULL` is `NULL`	`TRUE`
`If ($var IS NOT NULL)`	`NULL` is not `NULL`	`FALSE`

- When comparing two variables, always test for `NULL`. In this scenario, you are not testing a variable with a value of `NULL` against a `NULL` constant (as in the first rule). Either test each variable and branch accordingly or test in the conditional as shown in the second row of the following table.

Condition	Recommendation
`if($var1 = $var2)`	Do not compare without explicitly testing for `NULL`s. Using this logic is not recommended because any relational comparison to a `NULL` value returns `FALSE`.
`if ( (($var1 IS NULL) AND ($var2 IS NULL)) OR ($var1 = $var2))`	Will execute the `TRUE` branch if both `$var1` and `$var2` are `NULL`, or if neither are `NULL` but are equal to each other.

3.7.2.9 Debugging and Validation

If you are using the smart editor to create a script or a custom function, select the *Validate* icon in the tool bar (or right-click and select *Validate*). Errors are listed in the smart editor window under the text box. Double-click each error to see where it occurred in your script.

Otherwise:

- Select the *Debug* > *Validate* > *Current View* command to check the syntax of expressions used in the definition of the current object. Errors are displayed in the Output window.
- Select the *Debug* > *Validate* > *All Objects in View* command to check the syntax of expressions used in the current object definition and the definitions of all objects called by the current object. Errors are displayed in the Output window.

By default, Data Services lists ten errors before it aborts parsing. By reporting ten errors for each validation, Data Services allows you to shorten the edit-validate-test cycle. You can repair several errors in each iteration of the cycle.

If you want to change this default setting, select *Tools* > *Options* > *Job Server* > *General* and set the options as follows:

Section:	Enter "Parser".
Key:	Enter "NumErrors".
Value:	Enter a positive number.

For each error, Data Services provides a description of the problem.

Data Services also provides three menu options for errors. Right-click an error to use these menu options:

View: The *View* option allows you to view the error text in a smaller, separate window for easy reading.

Go To Error: The *Go to Error* option places an error icon near the line that caused the error. You can also double-click the error to place this icon. This option not available for all errors, however.

Copy: The *Copy* option copies the error text on to the clipboard so you can place it elsewhere.

When you execute a job, you may still encounter errors in an expression that are returned from the operating system or the DBMS. When executing a job, Data Services sends as many operations as possible to the DBMS to evaluate. The DBMS may evaluate part of the expression and return a value that contributes to evaluating the rest of the expression.

3.7.2.10 Keywords

The following sections describe the keywords in the scripting language.

Keywords are listed in the selection list of the smart editor filtered by the context from which the smart editor is opened.

Related Information

About Reserved Words [page 1847]

3.7.2.10.1 BEGIN

Indicates the beginning of the code that becomes the function, script, or other construct. BEGIN and END statements are added automatically to function, transform, and script definitions.

3.7.2.10.2 CATCH

Indicates a catch for a try/catch block. If an error occurs while executing any of the statements between the TRY and the CATCH statements, Data Services executes the statements defined by the CATCH. Use the CATCH keyword as shown in the following script, or use `CATCH(ALL)`.

```
BEGIN
TRY
    BEGIN
        <script_step>;
        <script_step>;
    END
CATCH (<exception_number>)
    BEGIN
        <catch_step>;
        <catch_step>;
    END
CATCH (<exception_number>)
    BEGIN
        <catch_step>;
        <catch_step>;
    END
END
```

3.7.2.10.3 ELSE

Defines the second branch for an IF statement. If no ELSE follows the IF, no action is taken if the condition is not met.

3.7.2.10.4 END

Indicates the end of the code that becomes the function, script, or other construct. BEGIN and END statements are added automatically to function, transform, and script definitions.

3.7.2.10.5 IF

Indicates a conditional step in the code. An IF statement can be constructed with or without an ELSE step. Use the IF keyword as follows:

```
IF (<condition>) <script_step>; ELSE <script_step>;
```

or

```
IF (<condition>) <script_step>;
```

where `<condition>` is an expression that evaluates to True or False. `<script_step>` indicates the set of instructions to execute based on the value of `<condition>` . If `<script_step>` contains more than one statement, enclose these statements in BEGIN and END statements.

Related Information

RepeatString function [page 1720]

3.7.2.10.6 RETURN

Indicates the value to be returned by a function. Use the RETURN keyword as follows:

```
RETURN (<expression>);
```

where `<expression>` defines the value to be returned.

3.7.2.10.7 TRY

Indicates the start of a try/catch block.

Related Information

CATCH [page 1718]

3.7.2.10.8 WHILE

Defines a set of statements to execute until a condition evaluates to FALSE. Use the WHILE keyword as follows:

```
WHILE (<condition>) <script_step>;
```

where **<condition>** is an expression that evaluates to True or False. **<script_step>** indicates the set of instructions to execute based on the value of **<condition>** . If **<script_step>** contains more than one statement, enclose each statement in BEGIN and END statements.

3.7.3 Sample scripts

The following examples show how a script would be formatted for the Square and Repeat String functions.

3.7.3.1 Square function

This function accepts an integer and returns the square of the input value. To define this script, supply the following values to Data Services:

Description	Value	Arguments
Function name	Square	
Return value	Return	int
Input value	input_int	int, input

The text of the function script is as follows:

```
RETURN($input_int * $input_int);
```

3.7.3.2 RepeatString function

This function accepts a one-character string and an integer indicating the number of times to repeat the input character. It outputs the created string or, if the input character or repeat number is NULL, it outputs a NULL value. It uses a variable to keep track of the string components as it is being generated.

To define this script, supply the following values to Data Services:

Description	Value	Arguments
Function name	RepeatString	
Return value	Return	VARCHAR (255),allow NULL
Input string	InputCharacter	VARCHAR (1), input, allow NULL
Input integer	RepeatNumber	INT, input, allow NULL
Internal variable	Partial	VARCHAR (255), allow NULL

The text of the function is as follows:

```
IF ($InputCharacter = NULL)
    BEGIN
    $Partial = NULL;
    RETURN NULL;
    END
IF ($RepeatNumber = NULL)
    RETURN NULL;
IF ($RepeatNumber > 255)
    $RepeatNumber = 255;
IF ($RepeatNumber < 0)
    $RepeatNumber = 0;
    BEGIN
    WHILE ($RepeatNumber != 0)
        BEGIN
        $Partial = ($Partial || $InputCharacter);
        $RepeatNumber = ($RepeatNumber - 1);
        END
    RETURN $Partial;
    END
```

3.8 Metadata in Repository Tables and Views

Data Services provides full access to the repository metadata used by the applications you create. To access this metadata for application analysis, either manually enter SQL SELECT statements or open the metadata reporting tool.

This section describes the tables and views in the repository that are useful for metadata analysis. This section also provides sample SQL SELECT statements for creating reports using a SQL editor.

For more information, see the *Management Console Guide*.

3.8.1 Auditing metadata

This set of tables in the Data Services repository stores the statistics that the audit feature collects.

- *AL_AUDIT* [page 1722]
- *AL_AUDIT_INFO* [page 1722]

3.8.1.1 AL_AUDIT

This table contains audit information about each data flow execution. The column OBJECT_KEY uniquely identifies a data flow execution.

Column Name	Data Type	Description
OBJECT_KEY	INTEGER	Identifies the audit event.
HISTORY_KEY	INTEGER	Refers to the OBJECT_KEY column in the AL_HISTORY table. Use this referential relationship to obtain history information about operational statistics for the data flow.
DF_LANG_KEY	INTEGER	Refers to the OBJECT_KEY column in the AL_LANG table. Use this referential relationship to obtain the definition for the data flow.
STATUS	INTEGER	Audit status can be one of the following values: ● 0 — Not audited ● 1 — Audit rule succeeded ● 2 — Audit information collected. This status occurs when you define audit labels to collect statistics but do not define audit rules. ● 3 — Audit rule failed
RULEINFO	VARCHAR(255)	The audit rule that failed and the values of the left-hand-side (LHS) and right-hand-side (RHS) of the Boolean expression.

Example

The following query returns the names of data flows that failed an audit and the audit rules that failed.

```
SELECT L.NAME, RULEINFO
    FROM AL_AUDIT A, AL_LANG L
    WHERE A.STATUS = 3
        AND A.DF_LANG_KEY = L.OBJECT_KEY
```

3.8.1.2 AL_AUDIT_INFO

This table contains information about the audit statistics.

Column Name	Data Type	Description
AUDIT_KEY	INTEGER	Refers to the OBJECT_KEY column in the AL_AUDIT table. Use this referential relationship to obtain audit information for the data flow.
LABEL	VARCHAR(255)	Refers to the OBJECT_KEY column in the AL_HISTORY table. Use this referential relationship to obtain history information for the data flow.
VALUE	VARCHAR(255)	Value of the label. This value can be one of the following: ● Number of rows in a table or whole row set

Column Name	Data Type	Description
		- Sum of the values in a column - Average of the values in a column - Checksum of the values in a column

Example

The following query returns the values of the labels of audit points that failed.

```
SELECT L.NAME DF_NAME, B.LABEL, B.VALUE AUDIT_VALUE
    FROM AL_AUDIT A, AL_AUDIT_INFO B, AL_LANG L
    WHERE A.OBJECT_KEY = B.AUDIT_KEY
        AND A.STATUS = 3
        AND A.DF_LANG_KEY = L.OBJECT_KEY;
```

If you want to see values of audit labels for a specific data flow, use a query similar to the following:

```
SELECT L.NAME DF_NAME, B.LABEL, B.VALUE AUDIT_VALUE
    FROM AL_AUDIT A, AL_AUDIT_INFO B, AL_LANG L
        WHERE A.OBJECT_KEY = B.AUDIT_KEY
            AND A.STATUS = 3
            AND A.DF_LANG_KEY = L.OBJECT_KEY
            AND L.NAME = 'Validation_DF';
```

3.8.2 Imported metadata

This set of tables (prefixed by AL_) and views (prefixed by ALVW_) capture information about the metadata imported into SAP Data Services from external databases and applications (such as Oracle, PeopleSoft, and SAP Applications).

- *AL_INDEX* [page 1723]
- *AL_PCOLUMN* [page 1724]
- *AL_PKEY* [page 1724]
- *ALVW_COLUMNATTR* [page 1725]
- *ALVW_COLUMNINFO* [page 1726]
- *ALVW_FKREL* [page 1727]
- *ALVW_MAPPING* [page 1727]
- *ALVW_TABLEATTR* [page 1733]
- *ALVW_TABLEINFO* [page 1734]

3.8.2.1 AL_INDEX

This table contains index information for tables.

Column Name	Description
TABLEKEY	The table ID associated with the index. The TABLEKEY relates to table information in ALVW_TABLEINFO.
NAME	The index name.
COLNAME	The name of the table's index column.
COLPOSITION	Position of the column in the index.

Example

The following query returns the index information associated with a table EMPLOYEE in datastore ORA_DS:

```
SELECT NAME, COLNAME, COLPOSITION
    FROM AL_INDEX, ALVW_TABLEINFO
    WHERE AL_INDEX.TABLEKEY =
            ALVW_TABLEINFO.TABLE_ID
        AND TABLE_NAME = 'EMPLOYEE'
        AND DATASTORE = 'ORA_DS'
```

3.8.2.2 AL_PCOLUMN

This table contains partition information for tables.

Column Name	Description
TABLEKEY	The partitioned table ID. The TABLEKEY relates to table information in ALVW_TABLEINFO.
COLNAME	The name of the table's partition column.
COLPOSITION	Position of the column in the partition.

3.8.2.3 AL_PKEY

This table contains primary key information for tables.

Column Name	Description
TABLEKEY	The table ID associated with a primary key. The TABLEKEY relates to table information in ALVW_TABLEINFO.
COLNAME	Name of the table's primary key column.

Column Name	Description
COLPOSITION	Position of the primary key column.

Example

The following query returns the primary key associated with a table EMPLOYEE in datastore ORA_DS:

```
SELECT COLNAME, COLPOSITION
    FROM AL_PKEY, ALVW_TABLEINFO
    WHERE AL_PKEY.TABLEKEY =
            ALVW_TABLEINFO.TABLE_ID
        AND TABLE_NAME = 'EMPLOYEE'
        AND DATASTORE = 'ORA_DS'
```

3.8.2.4 ALVW_COLUMNATTR

This view contains information about column attributes.

Column Name	Data type	Description
TABLE_NAME	Varchar(256)	Name of the table.
TABLE_OWNER	Varchar(256)	Owner of the table.
DATASTORE	Varchar(256)	The datastore to which this table belongs.
COLUMN_NAME	Varchar(256)	Name of the column.
COLUMN_ATTR	Varchar(64)	Name of the attribute (property of this table). The name of the attribute will be the same as seen when viewing the attributes of a table in the Designer's interface. Examples: Description, Business_Name, Date_last_loaded, Date_created, Total_Number_Of_Rows_Processed.
COLUMN_ATTR_VALUE	Varchar(255)	Value of this attribute.

Example

The following query returns all columns and their descriptions for table EMP in datastore HR:

```
SELECT COLUMN_NAME, COLUMN_ATTR_VALUE
    FROM ALVW_COLUMNATTR
    WHERE TABLE_NAME = 'EMP'
```

```
        AND COLUMN_ATTR = 'Description'
        AND DATASTORE = 'HR'
```

3.8.2.5 ALVW_COLUMNINFO

This view contains information about the columns in a table.

Column Name	Data type	Description
TABLE_NAME	Varchar(256)	Name of the table.
TABLE_OWNER	Varchar(256)	Owner of the table.
DATASTORE	Varchar(256)	The datastore to which this table belongs.
COLUMN_NAME	Varchar(256)	Name of the column.
COLUMN_DATATYPE	Varchar(20)	Data type of this column. Examples: `integer`, `datetime`, `decimal`, `real`.
COLUMN_LENGTH	Int	Length of this column in bytes.
COLUMN_PRECISION	Int	Precision of this column (applies only to columns with the data type `decimal`).
COLUMN_SCALE	Int	Scale for this column (applies only to columns with the data type `decimal`).
COLUMN_IS_NULLABLE	Int	One (`1`) indicates this column will accept NULL values, `0` indicates not.
COLUMN_ID	Int	The ID for this column within the repository. It can be used to join with other tables containing additional column information.

Example

The following query returns all columns in table `EMP` in datastore `HR`:

```
SELECT COLUMN_NAME
    FROM ALVW_COLUMNINFO
    WHERE TABLE_NAME = 'EMP'
        AND DATASTORE = 'HR'
```

3.8.2.6 ALVW_FKREL

This view contains information about the primary and foreign key relationships among tables.

Column Name	Description
TABLEKEY	The table ID.
PKCOLUMN	Primary key column in this table.
FKTABLE	The table where this column is referenced.
FKCOLUMN	The column in the 'foreign' table which is the same as the primary column.

Example

The following query returns the primary and foreign key information associated with table **<EMPLOYEE>** in datastore **<ORA_DS>**.

```
SELECT FKTABLE, FKCOLUMN, PKCOLUMN
    FROM ALVW_FKREL, ALVW_TABLEINFO
    WHERE ALVW_FKREL.TABLEKEY =
            ALVW_TABLEINFO.TABLE_ID
        AND TABLE_NAME='EMPLOYEE'
        AND DATASTORE='ORA_DS'
```

3.8.2.7 ALVW_MAPPING

The ALVW_MAPPING view joins the AL_COLMAP and the AL_COLMAP_TEXT tables. These tables contain information about target tables and columns, the sources used to populate target columns, and the transforms Data Services applies to sources before applying them to targets. Data Services uses the ALVW_MAPPING view for impact analysis in Metadata Reports.

The column mapping calculation generates the following information for target columns:

- The source column(s) from which the target column is mapped.
- The expressions used to populate target columns.

Data Services stores column mappings of nested source and target data in data flows using both the ALVW_MAPPING view and the AL_COLMAP_NAMES table.

Note

For those column names with varchar(256), the maximum length depends on the Data Services repository type. For most repository types the maximum length is 256, for MySQL the length is 64, and for MS SQL server the length is 128.

Table 176: ALVW_MAPPING view

Column Name	Data type	Description
DF_NAME	varchar(256)	Data flow that populates the target table.
TRG_TAB_NAME	varchar(256)	Name of the target table.
TRG_TAB_ID	int	ID for this table within the repository.
TRG_TAB_DESC	varchar(100)	Description of the target table.
TRG_OWNER	varchar(256)	Owner of the target table.
TRG_DS	varchar(256)	Datastore of the target table.
TRG_TYPE	varchar(64)	Type of target. Examples: table, BW transfer structure.
TRG_USAGE	varchar(65)	Usage of the target table. Examples: fact, dimension, lookup. Currently set to NULL.
TRG_COL_NAME	varchar(256)	Column name in the target.
TRG_COL_ID	int	ID for this column in the repository.
TRG_COL_DESC	varchar(100)	Description of this column.
SRC_TAB_NAME	varchar(256)	Name of the source table used to populate the target.
SRC_TAB_ID	int	ID for this table within the repository.
SRC_TAB_DESC	varchar(100)	Description of the source table.
SRC_OWNER	varchar(256)	Owner of the source table.
SRC_DS	varchar(256)	Datastore of the source table.
SRC_TYPE	varchar(64)	Type of source. Examples: table, file.
SRC_COL_NAME	varchar(256)	Name of the source column.
SRC_COL_ID	int	ID for this column in the repository.
SRC_COL_DESC	varchar(100)	Description of this column.
MAPPING_TYPE	varchar(65)	Types of source to target mapping. Examples: direct, computed, lookup.
MAPPING_TEXT	varchar(255)	The expression used to map the source to the target column.

Related Information

Storing nested column-mapping data [page 1731]

3.8.2.7.1 Example use case

The following query returns target tables and columns populated from the column EMPID in table EMP (in datastore HR):

```
SELECT TRG_TAB_NAME, TRG_COL_NAME
    FROM ALVW_MAPPING
    WHERE SRC_TAB_NAME = 'EMP'
        AND SRC_COL_NAME = 'EMPID'
        AND SRC_DS = 'HR'
```

3.8.2.7.2 Mapping types

The AL_COLMAP_TEXT table contains information qualifying the mapping relationships. This information, stored in the MAPPING_TYPE column, can have the following values:

Mapping Type	Description
Direct	The target column is mapped directly from a source column with no expression to transform it. For example, EMPID (employee ID) mapped directly from source to target.
Computed	There is an expression associated with the target column. For example, NAME is LAST_NAME||','|| FIRST_NAME.
Generated	There is no source column associated with the target column. For example, the target table is mapped to a constant or a function, such as sysdate, or is obtained from a transform, such as Date_Generation.
LookedUp	A lookup function is used in the expression.
Merged	Two data streams are merged to populate the target table. The two expressions mapped to the target table are separated by AND.
Not mapped	The column in the target table is not being populated by the data flow.
Unknown	Data Services is unable to identify the expression used to map the target column. This happens only under unusual error conditions.

3.8.2.7.3 How mappings are computed

When a data flow processes information, it performs potentially complex transformations on data in preparation for loading it into one or more target tables. Typical operations include:

- Reading data from the appropriate sources.
- Processing data using Query transforms or other transforms.
- Splitting the data stream and then merging it again.

Consider the following example, where two transformations operate against a value from one column of a source table.

The information is captured in AL_COLMAP_TEXT as follows:

Target column	Source column	Mapping expression
Total_value	Price	`((Price x 1.17) x 112)`

This kind of information becomes more valuable as transformation complexity increases. Consider the following example:

- Data flow DF_1 reads three columns (a, b, c) from source table S.
- Table S is connected to a Query transform Q1.
- The Query transform output has four columns (Qa, Qb, Qc, and Qd) whose mapping expressions are S.a, S.b, S.c and S.a – S.b.
- The output of Q1 is connected to Query transform Q2, which has two columns Q2y and Q2z whose expressions are Qa – Qb and Qc – Qd.
- The output of Q2 is loaded into target table T, which has two columns: T1 and T2.

The mapping expressions for target columns T1 and T2 are computed by starting from the end point (the target object) and "walked" back through the list of transforms, with columns of a transform written in terms of expressions from the previous transform.

When processing is started on data flow DF_1, it starts with column T1 of target table T.

The expression for T1 is Q2y, which in turn is A – dB, which can be written as S.a – S.b. Therefore the mapping expression is S.a – S.b and column T1 has two source columns—it is mapped from S.a and S.b. The AL_COLMAP table contains two rows for the target column to describe the two source columns.

In the case of T2, it is mapped from DC – JD, which can be written as S.c – (S.a – S.b). In this case, there are three rows for this target column in the AL_COLMAP table, one for each source column.

3.8.2.7.4 Mapping complexities

If a data flow calls another data flow and then loads a target table, the mappings are expressed in terms of the tables and columns used within the other data flow. Information is generated by "drilling down" into the other data flow to continue the mapping process.

The situation in which the Merge transform is used within a data flow is a bit more complex, because when two data streams are merged, there are two ways to populate a target table. This possibility is captured by separating the mapping expressions with the keyword `AND`. For example, a target column could be populated from `S.a AND R.a`.

Transforms like Hierarchy_Flattening and Pivot also introduce column mapping complexities.

It is also possible that some target columns are mapped by constants or expressions that do not use source columns. In this case there will be no rows in the AL_COLMAP table for the target column. The mapping expression in the AL_COLMAP_TEXT table will reflect this.

If a target column is populated with a call to the lookup function, then its source columns are both the looked up column and the key used to do the lookup.

3.8.2.7.5 Storing nested column-mapping data

SAP Data Services calculates column mappings (identifies the source column(s) and expressions in use to map the target column) for all data flows including those that use nested data.

The following objects and conditions are supported:

- XML files or messages
- IDOC files or messages
- Custom and adapter functions
- SAP Applications and PeopleSoft hierarchies
- Column mappings that perform nesting or un-nesting (target columns mapped from a nested or un-nested data set)
- Nested columns used as parameters in custom or adapter functions (including SAP Application RFC output parameters, BAPI function calls, and database stored procedures)
- Embedded data flows
- ABAP data flows
- Correlated columns
  You can map a column in a nested schema from a column in the input schema of the nested schema, or from a column in the input schema of the parent (or any ancestor) of the nested schema. If you map a column from an ancestor, the column is correlated.

Transforms support nested column-mapping data as follows:

- Query transforms process nested data and mappings are stored in repository tables and views.
- The software allows nested column mappings to pass through the Merge, Case, and Map_Operation transforms.
- Other transforms do not process nested data.

Nested (NRDM) notations that represent column names are longer than those used for a flat schema column.

- A column in a flat schema is represented by Table. Column, for example, "mats_emp.empno". Note that Table may represent a database table, a file, an XML message or file, an IDOC message or file, and so on.
- A column in a nested schema is represented by

  ```
  Table.Subschema1…SubschemaN.Column
  ```

For example, "personnel.name.given" represents a column of a nested schema which has three components. The first component is the Table. The last component is the Column. The middle components identify the nested levels in the Table.

Because the TRG_COL_NAME and SRC_COL_NAME columns in the ALVW_MAPPING view of the repository are VARCHAR(64) (MySQL only) and not big enough to store long NRDM column names, the software uses the AL_COLMAP_NAMES table to support nested data.

Table 177: AL_COLMAP_NAMES table

Column Name	Data type	Description
DF_NAME	varchar(256)	Data flow with that populates a target table.
COL_ID	varchar(65)	The software generates this value using the following format when a nested column is encountered. `"__DI_NESTED_COLNAME_n"` where n is an integer that starts from 1
COL_NAME	varchar(256)	If the software generates a COL_ID value, this column stores the original nested column name.
SEQNUM	int	The software generates this value if more than one set of 256 characters is required to store data in the COL_NAME column. For each set of 256 characters, it generates a new row and a sequence number.

The AL_COLMAP_NAMES table uses the DF_NAME, COL_ID, SEQNUM columns as primary keys. The DF_NAME and COL_ID columns are keyed to the following columns in the ALVW_MAPPINGS view.

- DF_Name is keyed to DF_Name.
- COL_ID is keyed to SRC_COL_NAME and TRG_COL_NAME

The AL_COLMAP_NAMES table also provides an internal mapping mechanism from COL_ID column to COL_NAME.

For example, if a source column BOOKS.AUTHOR.FIRST_NAME is mapped into a target column BOOK.AUTHOR_NAME (an un-nesting is probably in place), you can create a report to query the following column values in the repository:

ALVW_MAPPING view	Column value
TRG_TAB_NAME	BOOK
TRG_COL_NAME	AUTHOR_NAME
SRC_TAB_NAME	BOOKS
SRC_COL_NAME	__DI_NESTED_COLNAME_1
MAPPING_TEXT	BOOKS.AUTHOR.FIRST_NAME

AL_COLMAP_NAMES table	Column value
COL_ID	__DI_NESTED_COLNAME_1

AL_COLMAP_NAMES table	Column value
COL_NAME	AUTHOR.FIRST_NAME

The TRG_COL_NAME or SRC_COL_NAME columns in the ALVW_MAPPING view store the COL_ID, if the target or source column is nested. To get the actual column name, lookup the AL_COLMAP_NAMES table using the DF_Name, COL_ID, and COL_NAME.

Flat or un-nested target or source column names are stored using the format Column in TRG_COL_NAME and SRC_COL_NAME. For example, of the three source columns shown below, only the second one is nested:

SRC_COL_NAME
EMPNO
_DI_Nested_Names_1
ENAME

The second value is the only one for which the software generates a column ID. To find this source column's real name, create a report that looks up its COL_NAME from the AL_COLMAP_NAMES table.

3.8.2.8 ALVW_TABLEATTR

This view contains information about the attributes in a table.

Column Name	Data type	Description
TABLE_NAME	Varchar(256)	Name of the table.
TABLE_OWNER	Varchar(256)	Owner of the table. For SAP applications, the value is NULL.
DATASTORE	Varchar(256)	The datastore to which this table belongs.
TABLE_ATTR	Varchar(64)	Name of the attribute (property of this table). The name of the attribute will be the same as seen when viewing the attributes of a table in the Designer's interface. Examples: Description, Business_Name, Date_last_loaded, Date_created, Total_Number_Of_Rows_Processed.
TABLE_ATTR_VALUE	Varchar(255)	Value of this attribute.

Example

The following query returns when table EMP in datastore HR was last loaded:

```
SELECT TABLE_ATTR_VALUE
    FROM ALVW_TABLE_ATTR
    WHERE TABLE_NAME = 'EMP'
        AND TABLE_ATTR = 'Date_last_loaded'
        AND DATASTORE = 'HR'
```

3.8.2.9 ALVW_TABLEINFO

This view contains the list of tables imported into the repository.

Column Name	Data type	Description
TABLE_NAME	Varchar(256)	Name of the table.
TABLE_OWNER	Varchar(256)	Owner of the table. For SAP applications, this table is NULL.
DATASTORE	Varchar(256)	The datastore to which this table belongs.
TABLE_ID	int	Internal ID of the table within the repository.

3.8.3 Internal metadata

This set of tables and views capture information about built-in metadata objects used by Data Services and the relationships between those objects.

- *AL_LANG* [page 1734]
- *AL_LANGXMLTEXT* [page 1735]
- *AL_ATTR* [page 1736]
- *AL_USAGE* [page 1737]
- *ALVW_FUNCINFO* [page 1740]
- *ALVW_PARENT_CHILD* [page 1741]

3.8.3.1 AL_LANG

This table contains various Data Services objects. These objects are also displayed in Data Services' object library.

Column Name	Description
OBJECT_KEY	Internal ID of the object.
OBJECT_TYPE	Type of object (an integer). Query the AL_REPO-TYPE_NAMES table to find the corresponding name for this type. Examples: data flow, table, datastore.
NAME	Name of the object.
VERSION	Indicates the number of times this object has been updated.
TYPE	Subtype of the object.
OWNER	For table objects, the owner.
DATASTORE	For table objects, the datastore to which they belong.
NORMNAME	Unique name for this object in this table.

Example

The following query returns all the data flows in the repository:

```
SELECT OBJECT_KEY, NAME
    FROM AL_LANG A
    WHERE OBJECT_TYPE = 1
        AND VERSION =
            (SELECT MAX(VERSION) FROM AL_LANG B
            WHERE A.NORMNAME = B.NORMNAME)
```

3.8.3.2 AL_LANGXMLTEXT

This table contains various Data Services objects. These objects are also displayed in Data Services' object library.

Column Name	Description
OBJECT_KEY	Internal ID of the object.
DATE_MODIFIED	Date the object was last modified.
OBJECT_TYPE	Type of object (an integer). Query the AL_REPO-TYPE_NAMES table to find the corresponding name for this type. Examples: data flow, table, datastore.

Column Name	Description
OBJECT_SUBTYPE	Subtype of the object.
OBJECT_NORMNAME	Unique name for this object in this table.
SEQNUM	Used reorder XML segments.
TEXT_VALUE	Contains the XML representation of the object.

3.8.3.3 AL_ATTR

This table contains attributes of repository objects provided by Data Services. For example, a description is an object attribute.

Column Name	Description
PARENT_OBJID	The internal ID of an object.
PARENT_OBJ_TYPE	Type of the object (integer).
ATTR_NAME	The attribute name for this object.
ATTR_VALUE	Value of the attribute.

Example

The following query returns all the data flows and their descriptions in the repository:

```
SELECT OBJECT_KEY, NAME, ATTR_VALUE
    FROM AL_LANG O, AL_ATTR A
    WHERE O.OBJECT_TYPE = 1
        AND O.OBJECT_KEY = A.PARENT_OBJID
        AND ATTR_NAME = 'Description'
        AND O.VERSION =
            (SELECT MAX(VERSION) FROM AL_LANG B
            WHERE O.NORMNAME = B.NORMNAME)
```

3.8.3.4 AL_SETOPTIONS

This table includes option settings for all objects.

Column Name	Data type	Description
PARENT_OBJ_ID	numeric(38)	ID of the parent object to which this option belongs.
PARENT_OBJ_TYPE	numeric(38)	Type of the parent object. Examples: batch job or data flow.
CALL_OBJID	varchar(100)	ID of the calling object. (Future use)
CALL_OBJTYPE	varchar(255)	Type of the calling object. (Future use)
OPTION_NAME	varchar(100)	Name of the option.
OPTION_VALUE	varchar(255)	Value of the option.
OVERFLOW_KEY	numeric(38)	KEY value pointing to a row in the AL_OVERFLOW_ATTR table. When an OPTION_VALUE exceeds 255 characters, Data Services adds the remaining characters to AL_OVERFLOW_ATTR and stores the row ID as OVERFLOW_KEY in the AL_SETOPTIONS table.

3.8.3.5 AL_USAGE

This table is identical to ALVW_PARENT_CHILD except it captures the entire call hierarchy. For example, if a table is used in a data flow which is called from a work flow, then rows appear in this table that associate the work flow (parent) to the table (descendent). The Depth column is unique to this table.

Note

You need to populate this table explicitly by using the *Calculate Usage Dependencies* command.

To query this table, use the following *Example use cases* [page 1738].

Column Name	Data type	Description
PARENT_OBJ	varchar(64)	Name of the calling object.
PARENT_OBJ_TYPE	varchar(64)	Type of the object. Examples: batch job or data flow.
PARENT_OBJ_DESC	varchar(255)	The description associated with this object.
PARENT_OBJ_KEY	int(4)	Key in the AL_LANG table of the parent object.
DESCEN_OBJ	varchar(64)	Name of the descendant object.

Column Name	Data type	Description
		For transforms, the name of the output schema of the transform call (if the name of the transform is unique). If it is not unique, Data Services generates a unique numeric suffix and appends that to the given name.
DESCEN_OBJ_TYPE	varchar(64)	Type of the called object. Examples: data flow, table, function, file.
DESCEN_OBJ_DESC	varchar(255)	Description associated with the called object.
DESCEN_OBJ_USAGE	varchar(20)	Applies only to tables and files. How the child is used. Examples: source, target, lookup table.
DESCEN_OBJ_KEY	int(4)	Key in AL_LANG of the descendant object.
DESCEN_OBJ_DS	varchar(64)	Applies only to tables and files. The datastore of the child object.
DESCEN_OBJ_OWNER	varchar(256)	Owner of the child table.
DEPTH	int	Indicates the number of levels between objects in a parent/descendent relationship.

3.8.3.5.1 Example use cases

You can query the AL_USAGE table using SQL statements. For example, the following report shows a few columns and rows from AL_USAGE listing the objects that are related to the SALES_ORDER target table:

Parent_Obj	Parent_Obj_Type	Descen_Obj	Descen_Obj_Type	Descen_Obj_Desc	Descen_Obj_Usage
Build_Fact	data flow	SALES_ORDER	Table	Sales order target fact table	Target
Daily_Job	work flow	SALES_ORDER	Table	Sales order target fact table	Target
DF_NewOrders	Job	SALES_ORDER	Table	Sales order target fact table	Target
Get_IDoc	data flow	SALES_ORDER	Table	Sales order target fact table	Target
IDoc_job	data flow	SALES_ORDER	Table	Sales order target fact table	Target
initial_Job	Job	SALES_ORDER	Table	Sales order target fact table	Target

Example

To find out which jobs load a table

The following query returns which jobs load a particular target:

```
SELECT PARENT_OBJ
    FROM AL_USAGE
    WHERE PARENT_OBJ_TYPE = 'Job'
        AND DESCEN_OBJ_TYPE = 'Table'
        AND DESCEN_OBJ_USAGE = 'Target'
        AND DESCEN_OBJ = '<targetTable>'
```

Example

To find out which objects depend on a source

The following query returns which objects would be affected if you drop a source table:

```
SELECT PARENT_OBJ, PARENT_OBJ_TYPE
    FROM AL_USAGE
    WHERE DESCEN_OBJ_TYPE = 'Table'
        AND DESCEN_OBJ = '<targetTable>'
```

Example

To produce a "where used" report for an object

The following query returns what objects call a given object. The given object in this case is the target table SALES_ORDER.

```
SELECT
            AL_USAGE.PARENT_OBJ,
            AL_USAGE.PARENT_OBJ_TYPE,
            AL_USAGE.DESCEN_OBJ,
            AL_USAGE.DESCEN_OBJ_DESC,
            AL_USAGE.DESCEN_OBJ_TYPE,
            AL_USAGE.DESCEN_OBJ_USAGE
    FROM AL_USAGE
    WHERE (AL_USAGE.DESCEN_OBJ_TYPE = 'Table'
            AND AL_USAGE.DESCEN_OBJ='SALES_ORDER')
```

The following table shows the result for an example repository:

Parent_Obj	Parent_Obj_Type	Descen_Obj	Descen_Obj_Type	Descen_Obj_Desc	Descen_Obj_Usage
Build_Fact	data flow	SALES_ORDER	Table	Sales order target fact table	Target
Daily_Job	work flow	SALES_ORDER	Table	Sales order target fact table	Target
DF_NewOrders	Job	SALES_ORDER	Table	Sales order target fact table	Target
Get_IDoc	data flow	SALES_ORDER	Table	Sales order target fact table	Target

Parent_Obj	Parent_Obj_Type	Descen_Obj	Descen_Obj_Type	Descen_Obj_Desc	Descen_Obj_Usage
IDoc_job	data flow	SALES_ORDER	Table	Sales order target fact table	Target
initial_Job	Job	SALES_ORDER	Table	Sales order target fact table	Target

Example

To show which jobs load what targets

The following query returns all of the jobs in the repository and what targets they load:

```
SELECT
    AL_USAGE.PARENT_OBJ,
    AL_USAGE.PARENT_OBJ_TYPE,
    AL_USAGE.DESCEN_OBJ,
    AL_USAGE.DESCEN_OBJ_DESC,
    AL_USAGE.DESCEN_OBJ_TYPE,
    AL_USAGE.DESCEN_OBJ_USAGE
    FROM AL_USAGE
    WHERE (AL_USAGE.PARENT_OBJ_TYPE = 'Job'
        AND AL_USAGE.DESCEN_OBJ_TYPE = 'Table'
        AND AL_USAGE.DESCEN_OBJ_USAGE = 'Target')
```

This table shows the results for an example repository:

Parent_Obj	Parent_Obj_Type	Descen_Obj	Descen_Obj_Type	Descen_Obj_Desc	Descen_Obj_Usage
Daily_Job	Job	SALES_ORDER	Table	Sales order target fact table	Target
IDoc_job	Job	SALES_ORDER	Table	Sales order target fact table	Target
initial_Job	Job	SALES_ORDER	Table	Sales order target fact table	Target

3.8.3.6 ALVW_FUNCINFO

This view contains a list of functions you defined in Data Services and those you imported into its repository.

Column Name	Description
FUNC_KEY	Internal ID for the function within the repository.
FUNC_NAME	The function name.
FUNC_OWNER	Applies only to imported functions. Owner of the function.

Column Name	Description
DATASTORE	Applies only to imported functions. Datastore to which the function belongs.

3.8.3.7 ALVW_PARENT_CHILD

This view contains information about objects (parents) that contain (or call) other objects (children).

Column Name	Description
PARENT_OBJ	Name of the calling object.
PARENT_OBJ_TYPE	Type of the object. Examples: batch job, real-time job, data flow.
PARENT_OBJ_DESC	The description associated with this object.
DESCEN_OBJ	Name of the called object.
DESCEN_OBJ_TYPE	Type of the called object. Examples: data flow, table, function, file.
DESCEN_OBJ_DESC	Description associated with the called object.
DESCEN_OBJ_USAGE	Applies only to tables and files. How the child is used. Examples: source, target, lookup table.
DESCEN_OBJ_DS	Applies only to tables and files. The datastore of the child object.
DESCEN_OBJ_OWNER	Owner of the child table.

Example

You can query this table to:

- View which data flows load table EMP

```
SELECT PARENT_OBJ
    FROM ALVW_PARENT_CHILD
    WHERE DESCEN_OBJ_TYPE = 'Table'
        AND DESCEN_OBJ = 'EMP'
        AND DESCEN_OBJ_USAGE = 'Target'
```

- View the data flows called by job HR_INITIAL_LOAD

  ```
  SELECT DESCEN_OBJ
      FROM ALVW_PARENT_CHILD
      WHERE PARENT_OBJ_TYPE = 'Job'
          AND PARENT_OBJ = 'HR_INITIAL_LOAD'
          AND DESCEN_OBJ_TYPE = 'Dataflow'
  ```

3.8.4 Operational metadata

These tables and views contain information about the run-time statistics of Data Services jobs and data flows.

- *AL_HISTORY* [page 1742]
- *ALVW_FLOW_STAT* [page 1743]

3.8.4.1 AL_HISTORY

This table contains information about the execution statistics of jobs.

Column Name	Description
OBJECT_KEY	Internal ID of the job within the repository.
INST_MACHINE	Computer on which the job was executed.
TYPE	Batch job or a real-time job.
SERVICE	Name of the job.
START_TIME	Time when the job was launched.
END_TIME	Time when the job completed.
EXECUTION_TIME	Difference between start time and end time in seconds.
STATUS	Status of the job upon completion. Examples: Error (E), Success (S).
HAS_ERROR	Displays a zero if there are no errors.

Example

The following query returns the run statistics of all successfully executed jobs:

```
SELECT SERVICE, INST_MACHINE, START_TIME, END_TIME, EXECUTION_TIME
    FROM AL_HISTORY A
    WHERE HAS_ERROR = 0
        AND SERVICE NOT IN ('di_job_al_mach_info', 'CD_JOB_d0cafae2')
```

```
        AND OBJECT_KEY = (SELECT MAX(OBJECT_KEY) FROM AL_HISTORY b WHERE
A.SERVICE = B.SERVICE)
```

3.8.4.2 ALVW_FLOW_STAT

This view contains information about the execution statistics of transforms within data flows.

Column Name	Description
DATAFLOW_NAME	Name of the data flow.
JOB_NAME	Name of the executed job.
JOB_KEY	Identifier that represents a job run. Whenever a job is executed, a new ID is given.
JOB_RUNID	Identifier that represents a single job over its duration. For example, if a job is set to recover from a failed execution and then the job fails, it would restart with the same JOB_RUNID.
RUN_SEQ	Unique identifier for a particular sequence of an execution.
PATH	Position of the transform in the data flow.
OBJECT_NAME	Name of the transform.
OBJECT_TYPE	Type of the transform.
ROW_COUNT	Number of rows processed by this transform.
START_TIME	Time when transform started executing.
END_TIME	Time when transform stopped.
EXECUTION_TIME	The difference between start and end time.

3.9 Data Quality repository statistics tables

3.9.1 Data Quality repository statistics tables

Repository tables hold job processing statistics. There is a table for each aspect of job processing, and the tables contain columns that hold job statistics. There is a set of tables for each of the following Data Quality transforms:

- DSF2 Walk Sequencer
- Geocoder
- Global Address Cleanse
- Match
- USA Regulatory Address Cleanse

Enable statistics in the Data Quality transform settings. Then the software populates applicable repository tables with statistics when you run your job.

Enable reports in the Data Quality transform to obtain specific reports from the job. The software generates reports based on the availability of statistics in the tables. These reports may be regulatory, like the AMAS form for Australia address matching processing, or informative, like the U.S. Addressing Report. You can also create customized reports comprised of the statistics in the repository tables.

Repository tables and related reports

The table below lists the established reports, the corresponding repository table name, and the applicable transforms.

> i Note
>
> There are additional tables that contain data, but they are not related to a specific report.

Report	Repository table	Transform(s)
US CASS report: USPS Form 3553	PSFORM3553DATA	USA Regulatory Address Cleanse
NCOALink Processing Summary report	NCOALINKSUMMARY MEDSTATS NCOACERTIFICATIONDATA	USA Regulatory Address Cleanse
Customer Service Log	CSLSTATS	USA Regulatory Address Cleanse
Broker and List Administrator file	PAFBALASTATS	USA Regulatory Address Cleanse
Delivery Sequence Invoice report	DSFSEQUENCESTATS	DSF2 Walk Sequencer
US Addressing Report	DPVLACSLINKSUMMARY	USA Regulatory Address Cleanse
US Regulatory Locking Report	USREGULATORYLOCKING	USA Regulatory Address Cleanse
Canada SERP report: Statement of Address Accuracy	SERPADDRACCURACY	Global Address Cleanse
Australia AMAS report: Address Matching Processing Summary	AMASADRPROCSUMMARY	Global Address Cleanse
Address Information Code Sample report	ADDRINFOCODEDATA	Global Address Cleanse USA Regulatory Address Cleanse
Address Information Code Summary report	ADDRINFOCODESUMMARY ADDRSTATUSCODEDATA	Global Address Cleanse USA Regulatory Address Cleanse
Address Validation Summary report	ADDRVALIDATESUMMARY	Global Address Cleanse USA Regulatory Address Cleanse
Address Type Summary report	ADDRTYPESUMMARY	Global Address Cleanse USA Regulatory Address Cleanse
Address Standardization Sample	ADDRINFOCODEDATA	Global Address Cleanse

Report	Repository table	Transform(s)
		USA Regulatory Address Cleanse
Geocoder Summary Report (part of the US Addressing report)	GEO_ASSIGN_LEVEL GEO_INFO_CODE	Geocoder transform USA Regulatory Address Cleanse
Address Quality Code Summary	ADDRINFOCODESUMMARY	Global Address Cleanse
Best Record Summary	MTBRINFO MTBRACTION	Match
Match Contribution Report	MTRULESRES MTBRKGRPINFO MTBRKGRP	Match
Match Criteria Summary report	MTCRITINFO MTCRITDEF MTKEYDEF MTCMPCRIT	Match
Match Source Stats Summary report	MTGSSRCSTS MTGSSRCBYSRCSTS	Match
Match Duplicate Sample report	MTDUPESDATA	Match
Match Input Source Output Select Report	MTINSRCINFO	Match
Match Multi-Source Frequency Report	Match statistics tables	Match
New Zealand SOA	SENDRIGHTADDRACCURACY	Global Address Cleanse

Related Information

Match repository statistics tables [page 1772]

3.9.2 Repository tables common columns

There are two columns that are present in most of the repository tables: OBJECT_KEY and OBJECT_ID. These columns contain platform-generated data. These columns are not listed in the descriptions of specific repository tables, but each table contains these columns unless indicated in the individual description.

Column	Data type definition	Description
🔑 OBJECT_KEY	INT	Identification for a specific run (also called Run ID). May not appear in each table.
🔑 OBJECT_ID	NVARCHAR (255)	GUID (globally unique identifier) assigned to a transform. Appears in each table.

3.9.3 Repository tables for USA and Global address cleanse

The table below contains a list of repository tables used for report and statistical information for the USA Regulatory Address Cleanse, Global Address Cleanse, and Geocoder transforms. The sections following this chart contain a topic for each table with descriptions for the fields (columns) in the table.

Repository table name	Description	Transform
ADDRINFOCODEDATA	Contains statistics about each record that generated an address information code during processing. Used for the Address Information Code Sample report.	Global Address Cleanse USA Regulatory Address Cleanse
ADDRINFOCODESUMMARY	Contains statistics about each information code found during processing. Used for the Address Information Code Summary and the Address Quality Code Summary reports.	Global Address Cleanse USA Regulatory Address Cleanse
ADDRSTATUSCODEDATA	Contains status codes found by the transform and their descriptions. Used for the Address Information Code Sample Report.	Global Address Cleanse USA Regulatory Address Cleanse
ADDRTYPESUMMARY	Contains statistics about address types found during processing. Used for the Address Type Summary.	Global Address Cleanse USA Regulatory Address Cleanse
ADDRVALIDATESUMMARY	Contains record validation statistics found by the transform. Used for the Address Validation Summary.	Global Address Cleanse USA Regulatory Address Cleanse
AMASADRPROCSUMMARY	Contains summary statistics for address processing. Used for the AMAS (Australia Matching Approval System) Address Matching Processing Summary.	Global Address Cleanse

Repository table name	Description	Transform
CSLSTATS	Contains statistics from NCOALink processing. Used for the NCOALink CSL (Customer Service Log).	USA Regulatory Address Cleanse
DPVLACSLINKSUMMARY	Contains statistics about the DPV, DSF2, SuiteLink, and LACSLink processing. Used for the U.S. Addressing Report.	USA Regulatory Address Cleanse
DSFAUGMENTSTATS	Contains a detailed record plus the DSF2 licensee name and processing date. Used in the DSF2 Augment Statistics Log File.	USA Regulatory Address Cleanse
DSFSEQUENCESTATS	Contains DSF2 sequence statistics per postcode/sortcode combination. Used in the Delivery Sequence Invoice Report.	USA Regulatory Address Cleanse
MEDSTATS	Contains statistics for NCOALink move effective dates. Used for the NCOALink Report.	USA Regulatory Address Cleanse
NCOALCERTIFICATIONDATA	Contains statistics required for NCOALink processing. Used for the NCOALink Processing Summary Report.	USA Regulatory Address Cleanse
NCOALINKSUMMARY	Contains summary statistics required for NCOALink processing. Used for the NCOALink Processing Summary Report.	USA Regulatory Address Cleanse
PAFBALASTATS	Contains statistics for NCOALink processing. Used for the Processing Acknowledgement Form and the Broker and List Administrator file.	USA Regulatory Address Cleanse
PSFORM3553DATA	Contains data for the USPS Form 3553 report that is submitted with all CASS-certified mailings.	USA Regulatory Address Cleanse
SERPADDRACCURACY	Contains statistics about the accuracy of the addresses in the list. Used for the Statement of Address Accuracy report (Canada).	Global Address Cleanse
SENDRIGHTADDRACCURACY	Contains summary statistics for New Zealand address processing.	Global Address Cleanse

Repository table name	Description	Transform
	Used for the SendRight New Zealand Statement of Accuracy (SOA) report.	
USREGULATORY-LOCKING	Contains information about the record that caused the lock. Used for the US Regulatory Locking Report.	USA Regulatory Address Cleanse

3.9.3.1 ADDRINFOCODEDATA

This table contains statistics about each record that generated an address information code during processing. The information is used for the Address Information Code Sample report. It applies to the Global Address Cleanse and USA Regulatory Address Cleanse transforms.

Column	Data type definition	Description
🔑 RECNUM	INT	Record number that generated the information code.
🔑 NAME	VARCHAR (128)	Name of the field that generated the information code. For example, COUNTRY_CODE, ENGINE_NAME and so on.
VALUE	VARCHAR (256)	Information contained in the field identified under NAME. For example, “US” (COUNTRY_CODE) or “USA” (ENGINE_NAME).

> **Note**
>
> The OBJECT_KEY column is included in this table but it is not listed. it is a primary key common to most tables. The OBJECT_ID column does not apply to this table.

Related Information

Repository tables common columns [page 1745]

3.9.3.2 ADDRINFOCODESUMMARY

This table contains statistics about each information code found during processing. The information is used for the Address Information Code Summary report (USA Regulatory Address Cleanse transform) and the Address Quality Code Summary (Global Address Cleanse transform).

Column	Data type definition	Description
🔑 COUNTRYID	VARCHAR (2)	Country code applicable to the listed INFOCODE.
🔑 INFOCODE	VARCHAR (4)	Information code.
INFOCOUNT	INT	Total number of records in the list that received the listed INFOCODE.
🔑 ENGINENAME	CHAR (50)	Name of the engine applicable to the listed INFOCODE. For the Global Address Cleanse transform, it is the name of the engine that processed the data (USA, CANADA, GLOBAL_ADDRESS, or GLOBAL_ADDRESS_CJK). For the USA Regulatory Address Cleanse transform, it is always USA.
🔑 DATA_SOURCE_ID	VARCHAR (80)	Code that uniquely identifies the list that contains the listed INFOCODE.

ℹ Note

The OBJECT_KEY and OBJECT_ID columns are included in this table but they are not listed. They are primary keys common to most tables.

Related Information

Repository tables common columns [page 1745]

3.9.3.3 ADDRSTATUSCODEDATA

This table contains status codes and descriptions. The information is used for the Status Code Sample Report. It is applicable for Global Address Cleanse and USA Regulatory Address Cleanse transforms.

Column	Data type definition	Description
🔑 RECNUM	INT	Record number that generated the information code.
🔑 NAME	VARCHAR (128)	Name of the field that generated the information code. For example, COUNTRY_CODE, ENGINE_NAME.

Column	Data type definition	Description
VALUE	VARCHAR (256)	Information contained in the field identified under NAME. For example, “US” (COUNTRY_CODE) or “USA” (ENGINE_NAME).

ℹ Note

The OBJECT_KEY column is included in this table but it is not listed. it is a primary key common to most tables. The OBJECT_ID column is not applicable to this table.

Related Information

Repository tables common columns [page 1745]

3.9.3.4 ADDRTYPESUMMARY

This table contains statistics about address types found during processing for the Address Type Summary. The Address Type Summary contains the record count for each Assignment_Type field value (Global Address Cleanse transform) or Address_Type field value (USA Regulatory Address Cleanse transform).

Column	Data type definition	Description
🔑 ENGINENAME	CHAR (50)	Name of the engine used to process the list. For the Global Address Cleanse transform, it is the name of the engine that processed the data (USA, CANADA, GLOBAL_ADDRESS, and GLOBAL_ADDRESS_CJK). For the USA Regulatory Address Cleanse transform, it is always USA.
🔑 COUNTRYID	CHAR (2)	Country code applicable to the listed address type.
BLDNAMERECS	INT	Number of records that were determined to be building name addresses (Global Address Cleanse transform).
FIRMNAMERECS	INT	Number of records that were determined to be firm addresses.
GENDELIVERYRECS	INT	Number of records that were determined to be general delivery addresses.

Column	Data type definition	Description
UNIQSUBURBANRECS	INT	Number of records that were determined to be unique suburban addresses.
MOBILEROUTERECS	INT	Number of records that were determined to be mobile route addresses (Canadian addresses, Global Address Cleanse transform).
HIGHRISERECS	INT	Number of records that were determined to be highrise addresses.
MILITARYRECS	INT	Number of records that were determined to be military addresses.
POSTALRECS	INT	Number of records that were determined to be post office box addresses.
RURALRECS	INT	Number of records that were determined to be rural route addresses.
STREETRECS	INT	Number of records that were determined to be street addresses.
UNDERTERMINDRECS	INT, NULL	Number of records that were determined to be non US records (USA Regulatory Address Cleanse transform).
PROCESSEDRECS	INT	Number of records processed by the transform.
🔑 SUITEL_TYPE	INT	Pre-SuiteLink or post-SuiteLink processing. Values include: 1 (Post-SuiteLink processing) -1 (Pre-SuiteLink processing)
🔑 DATA_SOURCE_ID	NVARCHAR (80)	Unique identification code assigned to the list.

Note

The OBJECT_KEY and OBJECT_ID columns are included in this table but they are not listed. They are primary keys common to most tables.

Related Information

Repository tables common columns [page 1745]

3.9.3.5 ADDRVALIDATESUMMARY

This table contains record validation statistics. The information is used for the Address Validation Summary. It is applicable for Global Address Cleanse and USA Regulatory Address Cleanse transforms.

Column	Data type definition	Description
🔑 ENGINENAME	CHAR (50)	Name of the engine applicable to the COMPONENTNAME column. For the Global Address Cleanse transform, it is the name of the engine that processed the data (USA, CANADA, GLOBAL_ADDRESS, and GLOBAL_ADDRESS_CJK). For the USA Regulatory Address Cleanse transform, it is always USA.
🔑 COUNTRYID	CHAR (2)	Country code applicable to the COMPONENTNAME column.
🔑 COMPONENTNAME	NVARCHAR (64)	Address component (ADDRESS1, LOCALITY1, and so on) to which the counts and percentages apply.
ADDEDRECS	INT	Number of records processed by the transform.
DELETEDRECS	INT	Number of records that were deleted during processing for the applicable COMPONENTNAME.
CORRECTEDRECS	INT	Number of records that were corrected during processing for the applicable COMPONENTNAME.
UNCHANGEDRECS	INT	Number of records that remained unchanged for the applicable COMPONENTNAME.
🔑 SUITEL_TYPE	INT	Indicates whether the count information applies to pre-SuiteLink or post-SuiteLink processing, or pre-NCOALink or post-NCOALink processing. Values include: 1 (post-SuiteLink/NCOALink processing) -1 (pre-SuiteLink/NCOALink processing)
🔑 DATA_SOURCE_ID	NVARCHAR (80)	Unique identification code assigned to the list.

Note

The OBJECT_KEY and OBJECT_ID columns are included in this table but they are not listed. They are primary keys common to most tables.

Related Information

Repository tables common columns [page 1745]

3.9.3.6 CSLSTATS

This table contains statistics for NCOALink processing for the Customer Service Log. It is applicable for the USA Regulatory Address Cleanse transform.

Column	Data type definition	Description
🔑 LICENSEEID	NVARCHAR (4)	NCOALink licensee's identification number assigned by the USPS.
🔑 SEQNUM	INT	DSF2 sequence number assigned to the address.
DTLRECORD	NVARCHAR (1000)	String of Customer Service Log field values.
LICENSEETYPE	NVARCHAR (1)	Type of service provider. Values are: E (End user) F (Full service provider) L (Limited service provider)
PROCESSINGDATE	DATETIME	Date and time the job was processed through the software in YYYY-MM-DD HR:MIN:SEC format.
RESERVED_COUNT1	INT	Reserved for future record counts.
RESERVED_COUNT2	INT	Reserved for future record counts.
RESERVED_COUNT3	INT	Reserved for future record counts.
RESERVED_STRING1	NVARCHAR (100)	Reserved for future strings.
RESERVED_STRING2	NVARCHAR (100)	Reserved for future strings.
RESERVED_STRING3	NVARCHAR (100)	Reserved for future strings.
🔑 DATA_SOURCE_ID	NVARCHAR (80)	Unique identification code assigned to the list.

Note

The OBJECT_KEY and OBJECT_ID columns are included in this table but they are not listed. They are primary keys common to most tables.

Related Information

Repository tables common columns [page 1745]

3.9.3.7 DPVLACSLINKSUMMARY

This table contains statistics about the DPV, DSF2, LACSLink, and SuiteLink processing. The information is used in the US Addressing Report. It is applicable for the USA Regulatory Address Cleanse transform.

Column	Data type definition	Description
LACSCONVERTED_A	INT	Number of LACSLink records that were converted by the transform (return code A).
LACSCONVERTED_92	INT	Number of LACSLink records that matched after dropping the secondary number from the input address (return code 92).
LACSNOTCONVERTED_09	INT	Number of LACSLink records that matched an input address to an old address, and the old address is a high-rise default address. No new addresses provided (return code 09).
LACSNOTCONVERTED_00	INT	Number of records that had no match to LACSLink and, therefore, no addresses converted (return code 00).
LACSNOTCONVERTED_14	INT	Number of LACSLink records that matched to LACSLink, but couldn't be converted to a deliverable address (return code 14).
DPVVALIDATED_Y	INT	Number of records that were validated for DPV (status of Y, primary and secondary range is valid).
DPVVALIDATED_S	INT	Number of records that contained an invalid secondary range (DPV status of S, secondary range not present).
DPVVALIDATED_D	INT	Number of records that did not have a secondary range (DPV status of D, secondary range not present).
DPVVALIDATED_CMRA	INT	Number of records that were validated as a CMRA (Commercial Mail Receiving Agency).
DPVNOTVALIDATED	INT	Number of records that were not validated for DPV.

Column	Data type definition	Description
🔑 SUITEL_TYPE	INT	Indicates whether the information is from pre-SuiteLink or post-SuiteLink processing. 1 (Pre-SuiteLink processing) -1 (Post-SuiteLink processing) 0 (NCOALink is not enabled so there is no pre-NCOALink or post-NCOALink processing sections)
SUITEL_MATCH_A	INT	Number of records that matched to SuiteLink and had secondary information added.
SUITEL_NOMATCH_00	INT	Number of records that did not match to SuiteLink.
DPVVALIDATED_VACANT	INT	Number of records with DPV status of vacant.
DPVVALIDATE_NOSTATS	INT	Number of records with DPV status of nostats.
DSF2_DROP	INT	Number of records that are dropped at a delivery point that serves businesses or families (for example, a CMRA).
DSF2_BUSINESS	INT	Number of records that have a business address.
DSF2_THROWBACK	INT	Number of records that are throwbacks (customer wants delivery at PO Box instead of street address).
DSF2_SEASONAL	INT	Number of records that are seasonally occupied.
DSF2_EDUCATIONAL	INT	Number of records that are educational institutions.
DSF2_CURB	INT	Number of records that have a curb-side delivery indicator.
DSF2_CENTRAL	INT	Number of records that have a central delivery indicator.
DSF2_DOOR	INT	Number of records that have a door-slot delivery indicator.
DSF2_NDCBU	INT	Number of records that have an NDCBU (Neighborhood Delivery Centralized Box Unit) delivery indicator.
🔑 DATA_SOURCE_ID	NVARCHAR (80)	A unique identification for a list.

Note

The OBJECT_KEY and OBJECT_ID columns are included in this table but they are not listed. They are primary keys common to most tables.

Related Information

Repository tables common columns [page 1745]

3.9.3.8 DSFAUGMENTSTATS

This table contains information used in the DSF2 Augment Statistics Log file. It is applicable for the USA Regulatory Address Cleanse transform.

Column	Data type definition	Description
🔑 LICENSEE_NUMBER	NVARCHAR (4)	DSF2 licensee number.
🔑 SEQNUM	INT	Sequence number from 0000 to 9999. ● If the Postcode2 field is blank, this column is blank. ● If the Postcode2 field is not blank and the DPV_Status is not Y, then the column contains “0000”.
LICENSEE_NAME	NVARCHAR (40)	DSF2 licensee name.
PROCESSING_DATE	DATETIME	Date and time the job was processed through the software in YYYY-MM-DD HR:MIN:SEC format.
DTLRECORD	NVARCHAR (1000)	String of log file field values for DSF2 Augment Statistics.
🔑 DATA_SOURCE_ID	NVARCHAR (80)	Unique identification code assigned to the list.

Note

The OBJECT_KEY and OBJECT_ID columns are included in this table but they are not listed. They are primary keys common to most tables.

Related Information

Repository tables common columns [page 1745]

3.9.3.9 DSFSEQUENCESTATS

This table contains information for the Delivery Sequence Invoice Report. It is applicable for the USA Regulatory Address Cleanse transforms.

Column	Data type definition	Description
🔑 POSTCODE1	NVARCHAR (5)	Postcode (ZIP Code) for the records being processed.
🔑 SORTCODE_ROUTE	NVARCHAR (4)	Sortcode route (carrier route) for the records being processed.
🔑 LICENSEE_NAME	NVARCHAR (40)	DSF2 licensee name.
TOTAL_DELIVERY_POINTS	INT	Number of deliveries within the specified postcode/sortcode combination.
TOTAL_RESIDENCES	INT	Number of residences within the specified postcode/sortcode combination.
TOTAL_DELIVERY_POINTS_SEQ	INT	Number of delivery points sequenced by the transform for the specific postcode/ sortcode combination.
TOTAL_RESIDENCES_SEQ	INT	Number of residences sequenced for the specific postcode/sortcode combination.
SITE_LOCATION	NVARCHAR (20)	Location of the site where the DSF2 walk sequence processing occurred.
LIST_ID	NVARCHAR (6)	Unique ID assigned by the licensee to identify the list.
PROCESSING_DATE	DATETIME	Date and time the job was processed through the software in YYYY-MM-DD HR:MIN:SEC format.

Note

The OBJECT_KEY and OBJECT_ID columns are included in this table but they are not listed. They are primary keys common to most tables.

Related Information

Repository tables common columns [page 1745]

3.9.3.10 MEDSTATS

This table contains statistics for NCOALink move effective dates. The information is used for the NCOALink Report. It is applicable for the USA Regulatory Address Cleanse transform.

Column	Data type definition	Description

🔑 CATEGORY	NVARCHAR (1)	Return code category:
		A = Return codes A, 91, 92
		B = Return codes 01, 02, 03
		C - Return codes 05, 14, 19

🔑 PERIOD	NVARCHAR (2)	Time period for the number of records for each return code category. Values include the following: 1 = Months 0-3 2 = Months 4-6 3 = Months 7-12 4 = Months 13-18 5 = Months 19+
MEDCOUNT	INT	Number of moves in the specified period.
🔑 DATA_SOURCE_ID	NVARCHAR (80)	Unique identification for a list.

ℹ Note

The OBJECT_KEY and OBJECT_ID columns are included in this table but they are not listed. They are primary keys common to most tables.

Related Information

Repository tables common columns [page 1745]

3.9.3.11 NCOALCERTIFICATIONDATA

This table contains statistics from NCOALink processing and is used for the NCOALink Reports. It is applicable for the USA Regulatory Address Cleanse transform.

Column	Data type definition	Description
MAILER_PAF_ID	VARCHAR (40)	Combination of the following information: • USPS-assigned license ID (first 4 characters) • List Owner NAICS Code (next 5 characters) • Frequency of processing (next 2 characters) • Licensee-assigned List ID (last 6 characters)
MAILER_COMPANY	VARCHAR (30)	Name of the customer that requested NCOALink processing.
PROCESSES_USED	VARCHAR (768)	All USPS processes used to obtain the final data results.
DATA_RETURNED	VARCHAR (1)	Purpose for NCOALink processing. C (Change of address) F (Return codes) S (Statistics)
PRE_PROCESSES	VARCHAR (1)	Indicates that the list was pre processed and what data modifications ocurred. Values are: N (None) Y (Yes, but with no data modifications). D (Yes, data modifications from sources other than postal data). P (Yes, data modifications from postal data only. For example, ZIP+4 or DPV) B (Yes, data modifications from postal and other sources)
POST_PROCESSES	VARCHAR (1)	Indicates that the list was post processed and what data modifications ocurred. Values are: N (None). Y (Yes, but with no data modifications). D (Yes, data modifications from sources other than postal data). P (Yes, data modifications from postal data only. For example, LACSLink).

<table>
<tr><th>Column</th><th>Data type definition</th><th>Description</th></tr>
<tr><td></td><td></td><td>B (Yes, data modifications from postal and other sources).</td></tr>
<tr><td>CONCURRENT_PROCESSES</td><td>VARCHAR (1)</td><td>Indicates that the list was concurrently processed and the data modifications that ocurred. Values are:
N (None).
Y (Yes, but with no data modifications).
D (Yes, data modifications from sources other than postal data).
P (Yes, data modifications from postal data only. For example, ZIP+4 or DPV).
B (Yes, data modifications from postal and other sources).</td></tr>
<tr><td>LIST_NAME</td><td>VARCHAR (30)</td><td>Name of the list being processed.</td></tr>
<tr><td>LICENSEE_ID</td><td>VARCHAR (4)</td><td>Unique ID for the broker or list administrator.</td></tr>
<tr><td>LICENSEE_COMPANY</td><td>VARCHAR (50)</td><td>Broker or list administrator name.</td></tr>
<tr><td>PROCESSING_CATEGORY</td><td>VARCHAR (20)</td><td>Reason for the NCOALink processing. Values are:
<table>
<tr><th>Option</th><th>Printed on report</th></tr>
<tr><td>Marketing</td><td>MKTG TEST</td></tr>
<tr><td>Normal</td><td>NORMAL</td></tr>
<tr><td>Stage I</td><td>STAGE I</td></tr>
<tr><td>Stage II</td><td>STAGE II</td></tr>
<tr><td>System testing</td><td>SYS TEST</td></tr>
</table></td></tr>
<tr><td>SERVICE_PROVIDER</td><td>VARCHAR (1)</td><td>NCOALink list processor's provider level. Values are:
0 End user
1 Limited service provider
2 Full service provider</td></tr>
<tr><td>NCOAL_PROCESS_DATE</td><td>VARCHAR (10)</td><td>Date based on the time that the list was processed. Automatically generated by the software, and included in reports.</td></tr>
<tr><td>LIST_RETURN_DATE</td><td>VARCHAR (10)</td><td>Date obtained from the <i>List returned date</i> option in the USPS License Information group.</td></tr>
</table>

Column	Data type definition	Description
DPV_ENABLED	VARCHAR (1)	DPV is enabled in the transform (Y/N indicator in reports).
LACSL_ENABLED	VARCHAR (1)	LACSLink is enabled in the transform (Y/N indicator in reports).
SUITEL_ENABLED	VARCHAR (1)	SuiteLink is enabled in the transform (Y/N indicator in reports).
ANK_ENABLED	VARCHAR (1)	ANKLink is enabled in the transform (Y/N indicator in reports).
USE_BUSINESS_MOVES	VARCHAR (1)	Business moves were included in processing (Y/N indicator in reports).
USE_INDIVIDUAL_MOVES	VARCHAR (1)	Individual moves were included in processing (Y/N indicator in reports).
USE_FAMILY_MOVES	VARCHAR (1)	Family moves were included in processing (Y/N indicator in reports).
MAIL_CLASS	VARCHAR (1)	Mail class that was processed.
MATCH_LOGIC	VARCHAR (1)	Move types that were processed. Values are: S (Standard move types such as business, individual, and family matches). I (Individual only). B (Business only). C (Individual and business only).
STD_OUTPUT_RETURNED	VARCHAR (1)	Transform-generated value that indicates whether the standard output was returned. Values are: Y (All NCOALink-required output returned to client). N (Post processes modified return information. For example updates applied to list). B (Post processes modified return information. However, a separate file containing all required output data was also returned).
PROCESS_PERIODICAL	VARCHAR (1)	Periodicals mail was processed by the transform. (Y/N indicator in reports.)
PROCESS_FIRST	VARCHAR (1)	First Class mail was processed by the transform. (Y/N indicator in reports.)

Column	Data type definition	Description
PROCESS_STD	VARCHAR (1)	Standard mail was processed by the transform. (Y/N indicator in reports.)
PROCESS_PACKAGE	VARCHAR (1)	Package Services mail was processed by the transform. (Y/N indicator in reports.)
TOTAL_RECORDS	INT	Number of records processed by the transform.
NCOAL_MATCHES	INT	Number of NCOALink matches found in the list.
ANK_MATCHES	INT	Number of ANKLink matches found in the list.
ZIP4_MATCHES	INT	Number of ZIP+4 matches found in the list.
DPV_MATCHES	INT	Number of DPV matches found in the list.
LACSL_MATCHES	INT	Number of LACSLink matches found in the list.
SUITEL_MATCHES	INT	Number of SuiteLink matches found in the list.
INDIVIDUAL_RECORDS	INT	Number of individual type records found in the list.
FAMILY_RECORDS	INT	Number of family type records found in the list.
BUSINESS_RECORDS	INT	Number of business type records found in the list.
NCOAL_NAME	VARCHAR (16)	Name of the NCOALink-certified software.
NCOAL_VERSION	VARCHAR (16)	Version of the NCOALink-certified software.
RESERVED_COUNT1	INT	Extra field for additional counts.
RESERVED_COUNT2	INT	Extra field for additional counts.
RESERVED_COUNT3	INT	Extra field for additional counts.
RESERVED_STRING1	VARCHAR (100)	Extra field for additional string.
RESERVED_STRING2	VARCHAR (100)	Extra field for additional string.
RESERVED_STRING3	VARCHAR (100)	Extra field for additional string.
🔑 DATA_SOURCE_ID	VARCHAR (80)	Unique identification code assigned to the list.

Note

The OBJECT_KEY and OBJECT_ID columns are included in this table but they are not listed. They are primary keys common to most tables.

Related Information

3.9.3.12 NCOALINKSUMMARY

This table contains summary statistics required for NCOALink processing. The information is used for the NCOALink Summary Report. It is applicable for the USA Regulatory Address Cleanse transform.

Column	Data type definition	Description
🔑 CODE	NVARCHAR (5)	Return code.
CODEGROUP	NVARCHAR (1)	Group in which the code applies. 1 = New address provided by NCOALink 2 = Found COA 3 = Cannot match COA 4 = From the daily delete process
CODEDESC	NVARCHAR (50)	Description for the return code listed.
RECCOUNT	INT	Number of list records found for the code listed.
ADDRESS_PROVIDED	NVARCHAR (1)	Indicates whether an address was provided (Y/N).

ADDRESS_SOURCE	NVARCHAR (1)	D = Derived by data
		S = Derived from software

DETAILED_DESC	VARCHAR (1)	Provides a more detailed description of the listed code.
🔑 DATA_SOURCE_ID	NVARCHAR (80)	Unique identification code assigned to a list.

Note

The OBJECT_KEY and OBJECT_ID columns are included in this table but they are not listed. They are primary keys common to most tables.

Related Information

Repository tables common columns [page 1745]

3.9.3.13 PAFBALASTATS

This table contains statistics for NCOALink processing. The information is used for the Processing Acknowledgement Form and the Broker and List Administrator file. It is applicable for the USA Regulatory Address Cleanse transform.

Column	Data type definition	Description
🔑 LICENSEEID	NVARCHAR (4)	Service provider's NCOALink license ID.
DTLRECORD	NVARCHAR (700)	All field values per list.

🔑 LOGTYPE	NVARCHAR (1)	The type of log file:
		P = PAF
		B = BALA

🔑 SEQNUM	INT	DSF2 sequence number assigned to the address.
RESERVED_COUNT1	INT	Reserved for future record counts.
RESERVED_COUNT2	INT	Reserved for future record counts.
RESERVED_COUNT3	INT	Reserved for future record counts.
RESERVED_STRING1	NVARCHAR (255)	Reserved for future text.
RESERVED_STRING2	NVARCHAR (255)	Reserved for future text.
RESERVED_STRING3	NVARCHAR (255)	Reserved for future text.
🔑 DATA_SOURCE_ID	NVARCHAR (80)	Unique identification for a list.

ℹ Note

The OBJECT_KEY and OBJECT_ID columns are included in this table but they are not listed. They are primary keys common to most tables.

Related Information

3.9.3.14 PSFORM3553DATA

This table contains data for the USPS Form 3553 report that is submitted with all CASS-certified mailings.

Column	Data type definition	Description
CASSCOMPANYNAME	NVARCHAR (50)	Name of the company that is CASS-certified.

Column	Data type definition	Description
CASSCONFIGURATION	NVARCHAR (10)	Software configuration settings as they appear on the CASS certificate.
CASSSOFTWARE	NVARCHAR (60)	Name and version of the software that is CASS certified.
Z4COMPANYNAME	NVARCHAR (40)	Name of the company that is Z4Change certified.
Z4CONFIGURATION	NVARCHAR (10)	Software configuration settings for Z4Change.
Z4SOFTWARE	NVARCHAR (60)	Name and version of the software that is certified for Z4Change processing.
eLOTCOMPANYNAME	NVARCHAR (40)	Name of the company that is certified for eLOT processing.
eLOTCONFIGURATION	NVARCHAR (10)	Software configuration settings for eLOT.
eLOTSOFTWARE	NVARCHAR (60)	Name and version of the software that is certified for eLOT processing.
MASSCOMPANYNAME	NVARCHAR (40)	Not populated from the software.
MASSCONFIGURATION	NVARCHAR (10)	Not populated from the software.
MASSSOFTWARE	NVARCHAR (60)	Not populated from the software.
MLOCRSERIALNUMBER	NVARCHAR (20)	Not populated from the software.
LISTPROCESSOR	NVARCHAR (35)	MASS list processor. Not populated from the software.
ZIP4DBDATE	VARCHAR (15)	ZIP4 directory date.
Z4CHANGEDATE	VARCHAR (15)	Not populated from the software.
Z4CHANGEDBDATE	VARCHAR (15)	Z4Change directory date.
eLOTDATE	VARCHAR (15)	Not populated from the software.
eLOTDBDATE	VARCHAR (15)	eLOT directory date.
CRISDATE	VARCHAR (15)	Not populated from the software.
CRISDBDATE	VARCHAR (15)	Not populated from the software.
ADDRESSLISTNAME	NVARCHAR (20)	Name of the address list processed. (Entered in *CASS Report Options* > *List Name*.)
NUMBEROFLISTS	INT	Not populated from the software.
TOTALRECPROCESSED	INT	Number of records processed in the job.
ZIP4RECORDSCODED	INT	Number of ZIP+4 records that were DPV confirmed.
Z4CHGRECORDSCODED	INT	Number of records that were Z4Change coded.

Column	Data type definition	Description
DPBRECORDSCODED	INT	Number of records with delivery point bar codes.
DPBCDATEFROM	VARCHAR (15)	Not populated from the software.
FIVEDIGITRECCODED	INT	Number of records that were assigned 5-digit ZIP Codes.
FIVEDIGITDATEFROM	VARCHAR (15)	Not populated from the software.
CRRTRECORDSCODED	INT	Number of records that were assigned carrier route codes.
CRRDATEFROM	VARCHAR (15)	Not populated from the software.
eLOTRECORDSCODED	INT	Number of records that were assigned eLOT codes.
eLOTDATEFROM	VARCHAR (15)	Not populated from the software.
MAILERINFO1	NVARCHAR (50)	Information entered in the USA Regulatory Address Cleanse transform in the CASS report options group.
MAILERINFO2	NVARCHAR (50)	Information entered in the USA Regulatory Address Cleanse transform in the CASS report options group.
MAILERINFO3	NVARCHAR (50)	Information entered in the USA Regulatory Address Cleanse transform in the CASS report options group.
MAILERINFO4	NVARCHAR (50)	Information entered in the USA Regulatory Address Cleanse transform in the CASS report options group.
HIGHRISEDEFAULT	INT	Number of records that were assigned as highrise defaults.
HIGHRISEEXACT	INT	Number of records that were assigned as highrise exact matches.
RURALROUTEDEFAULT	INT	Number of records that were assigned as rural route default matches.
RURALROUTEEXACT	INT	Number of records that were assigned as rural route exact matches.
LACS	INT	Number of addresses that were converted through the LACSLink process.
EWS	INT	Number of records that were assigned as EWS addresses (and, therefore, are not listed in the current U.S. Postal Service® ZIP + 4 File).
DPV	INT	Number of records that were confirmed as ZIP + 4/DPV that matched to a highrise default, and the SuiteLink process returned the appropriate suite number.

Column	Data type definition	Description
RDI	INT	Not populated from the software (always zero).
RESERVED_COUNT1	INT	Reserved for future record counts.
RESERVED_COUNT2	INT	Reserved for future record counts.
RESERVED_COUNT3	INT	Reserved for future record counts.
RESERVED_STRING1	NVARCHAR (100)	Reserved for future strings.
RESERVED_STRING2	NVARCHAR (100)	Reserved for future strings.
RESERVED_STRING3	NVARCHAR (100)	Reserved for future strings.
🔑 DATA_SOURCE_ID	NVARCHAR (80)	Unique identification assigned to the list.

ℹ Note

The OBJECT_KEY and OBJECT_ID columns are included in this table but they are not listed. They are primary keys common to most tables.

3.9.3.15 SENDRIGHTADDRACCURACY

This table contains summary statistics about the address processing for the Global Address Cleanse SendRight certification report. The information is used for the SendRight Address Accuracy report (for New Zealand). These statistics are generated by the Global Address Cleanse transform.

Column	Data type definition	Description
CERTCOMPANYNAME	VARCHAR 40	Name of the company that is SendRight certified. This value will be SAP Business Objects.
CERTPRODNAME	VARCHAR 40	Name of the product that is SendRight certified. This value will be Data Services.
CERTPRODVER	VARCHAR 20	Version of the SendRight-certified software.
PAFVERSION	VARCHAR 20	Version of the current (most recent) PAF.

Column	Data type definition	Description
		PAF refers to the version number supplied by New Zealand post.
SOAUNIQUEID	VARCHAR 20	Unique ID generated by the certified engine to guarantee a unique report for each Global Address Cleanse transform within a data flow.
CUSTOMERNAME	VARCHAR 40	Name of the list owner or list processor.
MAILERADDR1–6	VARCHAR 60	Name and address of the person or organization for whom you are preparing the mailing. (6 columns, 60 varchars each).
FILENAME	VARCHAR 40	Input file name.
TOTALRECPROC	INT	Number of records processed.
UNIQUEMATCHES	INT	Number of unambiguous matches between the input addresses and one address record in the PAF.
BASEMATCHES	INT	Number of unambiguous matches between the input addresses and one base address.
DATEISSUED	DATETIME	Date that this report was generated.
DATEEXPIRED	DATETIME	Date that this report will expire. (Always exactly 1 year after generation date.)
TOTALVALIDATED	INT	Number of records validated.
ADDRESSACCURACY	VARCHAR 8	Percentage of the total records validated from the total number of records processed.
RESERVED_COUNT1–3	INT	Reserved for future use.
RESERVED_STRING1–3	VARCHAR 255	Reserved for future use.

3.9.3.16 SERPADDRACCURACY

This table contains statistics about the accuracy of the addresses in the list. The information is used for the SERP (Statement of Address Accuracy) report (Canada). These statistics are generated by the Global Address Cleanse transform.

Column	Data type definition	Description
VENDORNAME	VARCHAR (40)	Name of the Address Accuracy vendor. This value will be SAP Business Objects.
VENDORADDR1-2	VARCHAR (40)	Address of the Address Accuracy vendor. This will be the current SAP Business Objects address. (Two columns, 40 varchars each.)
PRODNAMEVER	VARCHAR (36)	Name of the Address Accuracy software product and version. This is hardcoded to the current product and version.
SREXPIRYDATE	VARCHAR (11)	Expiration date of the software's SERP certification.
CUSTOMERNAME	VARCHAR (40)	Company name of the organization for whom the mailing is being prepared.
CUSTOMERADDR1-4	VARCHAR (40)	Name and address of the person or organization for whom the mailing is being prepared. (Four columns, 40 varchars each.)
CUSTOMERCPCNUM	VARCHAR (15)	Date of the postalcode file.
CPCMASTERFILEVER	VARCHAR (11)	Customer's CPC number that is located in the Canada Post Contract.
TOTALRECPROC	INT	Number of urban and rural records processed.
RECASSIGNED	INT	Number of records assigned.
QUEST_RECS_RURAL	INT	Number of questionable rural records.
QUEST_RECS_APPT	INT	Number of questionable apartment records.
RESERVED_COUNT1–3	INT	Reserved for future record counts.
RESERVED_STRING1–3	NVARCHAR (255)	Reserved for future strings.

Note

The OBJECT_KEY and OBJECT_ID columns are included in this table but they are not listed. They are primary keys common to most tables.

Related Information

Repository tables common columns [page 1745]

3.9.3.17 USREGULATORYLOCKING

This table contains information about the record that caused DPV or LACSLink locking. The information is used for the USA Regulatory Locking Report.

Column	Data type definition	Description
🔑 LOCKMODE	INT	Whether the lock was for DPV (1) or LACSLink (2).
LOCK_CODE	VARCHAR (81)	Lock code issued by the software and found in the Alert area of the report.
POSTCODE	VARCHAR (81)	Input postalcode from the address that caused the lock.
PRIMARY_NUMBER	VARCHAR (81)	Input primary range from the address that caused the lock.
PRIMARY_NAME	VARCHAR (81)	Primary name from the address that caused the lock.
UNIT_NUMBER	VARCHAR (81)	Secondary range for the address that caused the lock.
UNIT_DESCRIPTION	VARCHAR (81)	Unit designator for the address that caused the lock.
PRIMARY_PREFIX	VARCHAR (81)	Predirectional for the address that caused the lock.
ADDRESS_TYPE	VARCHAR (81)	Suffix for the address that caused the lock.
PRIMARY_POSTFIX	VARCHAR (81)	Postdirectional for the address that caused the lock.
RESERVED_COUNT1	INT	Reserved for future record counts.
RESERVED_COUNT2	INT	Reserved for future record counts.
RESERVED_COUNT3	INT	Reserved for future record counts.
RESERVED_STRING1	NVARCHAR (255)	Reserved for future strings.
RESERVED_STRING2	NVARCHAR (255)	Reserved for future strings.
RESERVED_STRING3	NVARCHAR (255)	Reserved for future strings.
🔑 DATA_SOURCE_ID	NVARCHAR (80)	Unique identifier for the list.

ℹ Note

The OBJECT_KEY and OBJECT_ID columns are included in this table but they are not listed. They are primary keys common to most tables.

3.9.4 Geocoder repository statistics tables

The table below contains a list of repository tables used for report and statistical information for the Geocoder transform. The sections following this chart contain a topic for each table with descriptions for the fields (columns) in the table.

Repository table name	Description	Transform
GEO_ASSIGN_LEVEL	Contains Geo statistics per assignment level. Used in the Geocoder Summary Report, a subsection of the US Addressing Report.	Geocoder
GEO_INFO_CODE	Contains Geocoder information codes and record counts per code. Used in the US Addressing Report.	Geocoder

3.9.4.1 GEO_ASSIGN_LEVEL

Statistics generated in this repository table are found in the Geocoder Summary Report. The Geocoder transform is used in conjunction with the Global Address Cleanse transform or the USA Regulatory Address Cleanse transform.

Column	Data type definition	Description
🔑 COUNTRY	CHAR (2)	Three-character ISO country code.
🔑 CODE	NVARCHAR (4)	Code that provides information about the geocoding results. Values are: PRE (Primary number exact) PRI (Primary number interpolated) PF (Postcode full) P2P (Postcode2 partial) P1 (Postcode1) L4 (Locality4) L3 (Locality3) L2 (Locality2) L1 (Locality1)
ASSIGN_COUNT	INT	Number of records for the assignment level listed.

Note

The OBJECT_KEY and OBJECT_ID columns are included in this table but they are not listed. They are primary keys common to most tables.

Related Information

Repository tables common columns [page 1745]

3.9.4.2 GEO_INFO_CODE

The table below contains statistics about information code found during processing for the Geocoder transform. The Geocoder transform that is used in conjunction with the Global Address Cleanse transform or the USA Regulatory Address Cleanse transform.

Column	Data type definition	Description
🔑 INFOCODE	NVARCHAR (4)	A three-character code that provides information about the geocoding results. The status for address and point-of-interest geocoding assignment is indicated in the third character. The status for reverse geocoding assignment is indicated in the second and third characters. If assigned to the best level, the Info_Code field is blank. The first character is not used at this time.
INFO_COUNT	INT	Number of records for the listed INFOCODE.

ℹ Note

The OBJECT_KEY and OBJECT_ID columns are included in this table but they are not listed. They are primary keys common to most tables.

3.9.5 Match repository statistics tables

There are many Match statistics that appear in various reports. These statistics are stored in statistics tables in the repository. The Match repository statistics tables are listed alphabetically below with a brief description for each table. Later, each table is described including the field names, data-type definitions, and descriptions.

Table	Description
MTBRACTION	Information about the best record action. Related report: Best Record Summary report.
MTBRINFO	Best record information. Related report: Best Record Summary report.
MTBRKGRP	Break group information. Related report: Break Group Contribution section of the Match Contribution report.
MTBRKGRPINFO	Information about the top and bottom ten break group strings and counts. Related report: Match Contribution report.
MTCMPCRIT	Match level option setting information for each match set. Related report: Match Level Options section of the Match Criteria Summary report.
MTCRITDEF	Match criteria information for each match set. Related report: Match Input Fields and Detailed Criteria Definition sections of the Match Criteria Summary report.
MTDUPESDATA	Information about match records as a sample of the match results. Related report: Duplicate Sample report.
MTGSSRCBYSRCSTS	Inter and intra-source match counts. Related report: Match Source Statistics Summary report.
MTGSSRCSTS	Information about the distribution of the matches found in various input source records including how the matches were distributed as master records and subordinate records. Related report: Match Source Statistics report.
MTINFO	Name of the match set. Related reports: All of the Match reports except the Best Record Summary report.
MTINSRCBYSRC	Information about how often each input source matched the other input sources.
MTINSRCGRPINFO	Input source group information. The table is populated once per transform if statistics are enabled and the source groups section of the input source object is defined.
MTINSRCINFO	Input source information. The table is populated once per transform if statistics are enabled and the input source object is defined.
MTINSRCMSRC	Multi-source statistics of each input source and each source group. The table is populated once per input source group statistics object if statistics are enabled.

Table	Description
MTINSRCSELECT	Input source group information. The table is populated once per input source select record object if statistics are enabled.
MTINSRCSTATS	Statistics of each input source and each source group. The table is populated once per input source group statistics object if statistics are enabled.
MTKEYDEF	Preprocessing criteria information for each key field. Related report: Match Input Fields section of the Match Criteria Summary report.
MTPROCESS	Information about match processing. Related reports: All Match reports except the Best Record Summary report.
MTRULESRES	Information about the effect of the criteria on the total matching process. Related report: Match Contribution report (Criteria Information sub report).

3.9.5.1 MTBRACTION

This table contains best record information and is applicable to the Match transform. The information is used for the Best Record Summary report.

> Note
>
> This table is populated only if the Best Record functionality is enabled in your job.

Column	Data type definition	Description
🔑 PROCID	INT	Sequential number that identifies a match level or an association.
🔑 ACTIONID	INT	Sequential number that identifies a Best Record Action section.
BRNAME	NVARCHAR (15)	Name of the Best Record operation you specified in the Match Editor.
SRCFLD	NVCHAR (256)	Source field used in the Best Record Action section. Note This column is blank if a source expression is completed instead of a source field.
DSTFLD	NVCHAR (256)	Destination field used in the Best Record Action section.

ℹ Note

The OBJECT_KEY and OBJECT_ID columns are included in this table but they are not listed. They are primary keys common to most tables.

Related Information

Repository tables common columns [page 1745]

3.9.5.2 MTBRINFO

This table contains best record information and is applicable to the Match transform. The information is used for the Best Record Summary report.

ℹ Note

This table is populated only if the Best Record functionality is enabled in your job.

Column	Data Type Definition	Description
🔑 PROCID	INT	Sequential number that identifies a match level or an association.
🔑 BRNAME	NVARCHAR (255)	Name of the best record object.
POSTDEST	CHAR (1)	Destination for the post. Values are A (all), M (master only), or S (subs only).
POSTOPD	CHAR (1)	More than one posting per destination will be attempted or not for each record (Y/N).
PROTECTDROPS	INT	Number of post operations that were canceled because the destination record was protected.
DSTFLDDROPS	INT	Number of post operations that were canceled because the destination record had already been posted to once, and POSTOPD was set to Y.
FILTERDROPS	INT	Number of post operations that were canceled because the Best Record filter returned F (false).
POSTCOMPLETS	INT	Number of post operations that were successfully completed.

ℹ Note

The OBJECT_KEY and OBJECT_ID columns are included in this table but they are not listed. They are primary keys common to most tables.

Related Information

Repository tables common columns [page 1745]

3.9.5.3 MTBRKGRP

This table contains information about match break groups and is applicable to the Match transform. The information is used in the Match Contribution Report. This table is generated if matching is performed (not associating).

ℹ Note

If breaking is not defined in the job setup, then all records are included in one break group.

Column	Data type definition	Description
NUMRECS	INT	Number of records processed in all of the break groups.
ELAPSEDTIME	INT	Elapsed time to process the break groups (in seconds).
CMPBUFMAXRECS	INT	Maximum number of records that can fit into the compare buffer at one time.
NOBRKCOMPARES	FLOAT	Number of comparisons that would be made without using any break group strategy (or putting all records in a single break group).
BRKGRPCOUNT	INT	Number of break groups formed based on the break group strategy.
BRKGRPLARGEST	INT	Largest break group processed.
BRKGRPCOMPARES	FLOAT	Number of comparisons made in all the break groups.

ℹ Note

The OBJECT_KEY and OBJECT_ID columns are included in this table but they are not listed. They are primary keys common to most tables.

Related Information

Repository tables common columns [page 1745]

3.9.5.4 MTBRKGRPINFO

This table contains information about the top and bottom ten break group strings and counts and is applicable to the Match transform. The information is used in the Break Group Contribution section of the Match Contribution Report.

> **Note**
>
> This table is populated only if the software performs matching and breaking.

Column	Data type definition	Description
🔑 BRKID	INT	Identification number for the break group.
BRKSTR	NVARCHAR (256)	Break string from the break group.
NUMRECS	INT	Number of records in the break group.

> **Note**
>
> The OBJECT_KEY and OBJECT_ID columns are included in this table but they are not listed. They are primary keys common to most tables.

Related Information

Repository tables common columns [page 1745]

3.9.5.5 MTCMPCRIT

This table contains match level option setting information for each match set and is applicable to the Match transform. This information is in the Match Level Options section of the Match Criteria Summary report.

Column	Data type definition	Description
🔑 CMPCRITID	INT	Sequential number that identifies the criteria of a match level.
NAME	NVARCHAR (256)	Match level name.

Column	Data type definition	Description
WTMTSCORE	INT	Minimum weighted match score needed to make a match decision.
NUMNAMEMUSTMT	CHAR (1)	Number of names that must match. Values are O (one name) or A (all names).
CMPFTOMNAME	CHAR (1)	Specifies the setting for the *Compare Given Name1 to Given Name2* option. (Y/N)
MTONHYPLNAME	CHAR (1)	Specifies the setting for the *Match on hyphenated family name* option. (Y/N)
TRNONMAIDENADJ	CHAR (1)	Specifies the setting for the *Ignore family name when female* option. (Y/N)
IGNFIRMIFNAME	CHAR (1)	Specifies the setting for the *Ignore Firm if Name matches* option. (Y/N)
IGNORESTIFBOX	CHAR (1)	Specifies the setting for the *Match on Street and RR, or on Box* option. (Y/N)
ADDRBLMIFFIRM	CHAR (1)	Specifies the setting for the *Address matches blank if Firms match* option. (Y/N)
UNIQRESRRNOBOX	CHAR (1)	Specifies the setting for the *Unique on resident if RR, but no Box* option. (Y/N)

Note

The OBJECT_KEY and OBJECT_ID columns are included in this table but they are not listed. They are primary keys common to most tables.

Related Information

Repository tables common columns [page 1745]

3.9.5.6 MTCRITDEF

This table contains match criteria information for each match set and is applicable to the Match transform. The information is used in the Match Input Fields and Detailed Criteria Definition sections of the Match Criteria Summary.

Column	Data type definition	Description
🔑 CMPCRITID	INT	Sequential number that identifies the criteria of a match level.
🔑 CRITID	INT	Sequential number that identifies an individual criteria.
CRITNAME	NVARCHAR (256)	Name given to the match criteria when it was created.
KEYID	INT	Sequential number that identifies the type of a key field.
MTSCORE	INT	Threshold for similarity scores. Similarity scores at or above this setting are considered a match.
NOMTSCORE	INT	Threshold for similarity scores. Similarity scores at or below this setting are not considered a match.
ONEFLDBLNKOP	CHAR (1)	Setting for the One Field Blank operation. Values are E (evaluate) and I (ignore).
ONEFLDBLNKSCORE	INT	Score given to the criteria when one of the two fields compared is blank.
BTFLDBLNKOP	CHAR (1)	Setting for the Both Fields Blank operation. Values are E (evaluate) and I (ignore).
BTFLDBLNKSCORE	INT	Score given to the criteria when both fields compared are blank.
CNTRBTOWTSCORE	INT	Weight percentage given to the match criteria's contribution to the weighted score.
USEINWTSCOREIFGT	INT	Minimum similarity score needed to qualify the match criteria for use in determining the weighted match score.
ZWTSCOREIFLTOREQ	INT	Minimum similarity score needed for the match criteria to qualify for contributing a value other than zero to the weighted match score.
CMPALGO	CHAR (1)	String comparison algorithm that was used. Values are F for field or W for word.
CHKTRANSPSLET	CHAR (1)	Indicates whether to check for transposed letters (Y/N).
INITADJSCORE	INT	Adjustment score given when fields with whole words match to fields with initials.
SUBSTRADJSCORE	INT	Adjustment score given when fields with longer strings of words match to fields with shorter strings of words (the

Column	Data type definition	Description
		shorter string must match the first part of the longer string).
APPRSUBADJSCORE	INT	Adjustment score given when fields with longer strings of words do not match to fields with shorter strings of words (the shorter string does not match the first part of the longer string).
ABBRADJSCORE	INT	Adjustment score given to the abbreviation substring adjustment score when the first letter of the shorter word matches the first letter of the longer word, and all remaining letters of the shorter word appear in the longer word in the same order as in the shorter word.
EXTABBRADJSCORE	INT	Adjustment score given when two fields match based on a combination of the abbreviation adjustment score. Keep in mind the following requirements for the extended abbreviation adjustment: ● The first letter of the short word must match the first letter of the first word in the multiple-word string. The remaining letters of the short word must be found in order in the multiple-word string. ● Letters that match are given a score of 100. The remaining letters are given the score that you specify. ● The two scores are proportionally combined to render the overall score.
NUMWDMTEXTOPT	CHAR (1)	Numeric word setting. Values include N (none), A (any position), S (same position), P (any position consider punctuation), or Y (any position ignore punctuation).

Note

The OBJECT_KEY and OBJECT_ID columns are included in this table but they are not listed. They are primary keys common to most tables.

Related Information

Repository tables common columns [page 1745]

3.9.5.7 MTDUPESDATA

This table contains information about duplicate records as a sample of the match results and is applicable to the Match transform. The information is used for the Match Duplicate Sample Report.

Columns	Data type definition	Description
🔑 RECNUM	INT	Sequential number assigned to each sample record output.
🔑 NAME	NVARCHAR (128)	Name of the field listed.
VALUE	NVARCHAR (256)	Value in the field listed.

> ℹ Note
>
> The OBJECT_KEY column is included in this table but it is not listed. It is a primary key common to most tables. The OBJECT_ID column is not in this table.

Related Information

Repository tables common columns [page 1745]

3.9.5.8 MTGSSRCBYSRCSTS

This table contains the inter-match and intra-match source counts for the *Source by Source Statistics* section of the Match Source Stats Summary report. This table is applicable to the Match transform.

Column	Data type definition	Description
🔑 SRCID	INT	Sequential number that identifies a source.
🔑 PROCID	INT	Sequential number that identifies a match level or an association.
GSNAME	NVARCHAR (15)	Group statistics name.
SRCNAME	NVARCHAR (256)	Source name.
OTHERSRCNAME	NVARCHAR (256)	Other source name.
TOTDUPES	INT	Total matches between the source and the other source.

> ℹ Note
>
> The OBJECT_KEY and OBJECT_ID columns are included in this table but they are not listed. They are primary keys common to most tables.

Related Information

Repository tables common columns [page 1745]

3.9.5.9 MTGSSRCSTS

This table contains information about the distribution of the duplicates found in various input source records and is applicable to the Match transform. It includes information about how the duplicates were distributed as master records and subordinate records. The information is used for the Match Source Statistics Report.

Column	Data type definition	Description
🔑 SRCID	INT	Sequential number that identifies a source.
🔑 PROCID	INT	Sequential number that identifies a match level or an association.
GSNAME	NVARCHAR (15)	Group statistics name.
SRCNAME	NVARCHAR (256)	Source name.
SSSUB	INT	Single source subordinate record count for this source.
MSSUB	INT	Multiple source subordinate record count for this source.
SSMASTS	INT	Single source master record count for this source.
MSMASTS	INT	Multiple source master record count for this source.
NUMRECS	INT	Record count for this source.

> ℹ Note
>
> The OBJECT_KEY and OBJECT_ID columns are included in this table but they are not listed. They are primary keys common to most tables.

Related Information

Repository tables common columns [page 1745]

3.9.5.10 MTINFO

This table contains the match set name and is applicable to the Match transform. The information is used in all of the Match reports except the Best Record Summary report.

Column	Data type definition	Description
MTSET	NVARCHAR (256)	Name of the match set.

> **Note**
>
> The OBJECT_KEY and OBJECT_ID columns are included in this table but they are not listed. They are primary keys common to most tables.

Related Information

Repository tables common columns [page 1745]

3.9.5.11 MTINSRCBYSRC

This table contains information about how often each input source matched the other input sources, and these statistics are generated by the Match transform. This table is populated once per input source group statistics object if statistics are enabled. This table is similar to the MTGSSRCBYSRCSTS table. To obtain the numbers for the source groups, the rows with the same INSRCGRPID and the same INSRCGRPID_OTHER must be added.

Column	Data type definition	Description
🔑 PROCID	INT	Sequential number used to identify a match level or an association.
🔑 INSRCID	INT	Sequential number used to identify an input source.
🔑 INSRCID_OTHER	INT	Sequential number used to identify an input source that had one or more records that matched one or more records in INSRCID.
🔑 INSRCGRPID	INT	Sequential number used to identify an input source group. A value of zero implies records that do not belong to an input source group.
🔑 INSRCGRPID_OTHER	INT	Sequential number used to identify the input source group of INSRCID_OTHER. A value of zero implies that INSRCID_OTHER does not belong to an input source group.
🔑 OBJNAME	NVARCHAR (15)	Name of the input source group statistics object.
MATCHES	INT	Sequential number used to identify the input source group of INSRCID. A value of zero indicates that INSRCID does not belong to an input source group.

Note

The OBJECT_KEY and OBJECT_ID columns are included in this table but they are not listed. They are primary keys common to most tables.

Related Information

Repository tables common columns [page 1745]

3.9.5.12 MTINSRCGRPINFO

This table contains input source group information and is applicable to the Match transform. It is populated once per transform when statistics are enabled and the source groups section of the input source object is defined.

Column	Data type definition	Description
🔑 INSRCGRPID	INT	Sequential number that identifies an input source group.
INSRCGRPNAME	NVARCHAR (255)	Name of an input source group.
MATCHED_COUNT	INT	Number of input records that belong to this input source group because they matched a specified input source.
DEFAULT_COUNT	INT	Number of input records that belong to this input source group because it is the default input source group.

If an input source exists that does not belong to a super source, that input source is assigned a super source ID of zero. A corresponding entry is made into the MTINSRCGRPINFO table in the following fields:

- INSPRSRCID
- INSPRSRCNAME
- MATCHED_COUNT
- DEFAULT_COUNT

All of these fields are set to zero. This allows the report code to successfully perform join operations.

Note

The OBJECT_KEY and OBJECT_ID columns are included in this table but they are not listed. They are primary keys common to most tables.

Related Information

Repository tables common columns [page 1745]

3.9.5.13 MTINSRCINFO

This table contains input source information and is applicable to the Match transform. It is populated once per transform if statistics are enabled and the input source object is defined.

Column	Data type definition	Description
🔑 INSRCID	INT	Sequential number used to identify the input source.
🔑 INSRCGRPID	INT	Sequential number used to identify the input source group. The number is zero if this input source does not belong to a source group.
INSRCNAME	NVARCHAR (255)	Name of the input source.
INSRCVALUE	NVARCHAR (255)	Value of the input source.
INSRCTYPE	NVARCHAR (8)	Input source type. Valid values are NORMAL, SUPPRESS, and SPECIAL.
MATCHED_COUNT	INT	Number of input records that belong to this input source because their input source value matched the value of this source.
DEFAULT_COUNT	INT	Number of records that belong to this input source because it is the defaut input source.

ℹ Note

The OBJECT_KEY and OBJECT_ID columns are included in this table but they are not listed. They are primary keys common to most tables.

Related Information

Repository tables common columns [page 1745]

3.9.5.14 MTINSRCMSRC

This table contains the multi-source statistics of each input source and each source group and is applicable to the Match transform. The table is populated once per input source group statistics object if statistics are enabled. To get the numbers for the source groups, the rows with the same INSRCGRPID must be added.

Column	Data type definition	Description
🔑 PROCID	INT	Sequential number that identifies a match level or an association.

Column	Data type definition	Description
🔑 INSRCID	INT	Sequential number that identifies an input source.
🔑 INSRCGRPID	INT	Sequential number that identifies an input source group. When INSRCGRPID is zero, the record does not belong to a source group.
🔑 OBJNAME	NVARCHAR (15)	Name of the input source group statistics object.
SRC2	INT	Number of records in INSRCID that are masters in match groups with a source count of 2.
SRC3	INT	Number of records in INSRCID that are masters in match groups with a source count of 3.
SRC4	INT	Number of records in INSRCID that are masters in match groups with a source count of 4.
SRC5	INT	Number of records in INSRCID that are masters in match groups with a source count of 5.
SRC6	INT	Number of records in INSRCID that are masters in match groups with a source count of 6.
SRC7	INT	Number of records in INSRCID that are masters in match groups with a source count of 7.
SRC8	INT	Number of records in INSRCID that are masters in match groups with a source count of 8.
SRC9	INT	Number of records in INSRCID that are masters in match groups with a source count of 9.
SRC10	INT	Number of records in INSRCID that are masters in match groups with a source count of 10.

ℹ Note

The OBJECT_KEY and OBJECT_ID columns are included in this table but they are not listed. They are primary keys common to most tables.

Related Information

Repository tables common columns [page 1745]

3.9.5.15 MTINSRCSELECT

This table contains input source group information and is applicable to the Match transform. This table is populated once per input source select record object if statistics are enabled. To obtain the numbers for the source groups, the rows with the same INSRCGRPID must be added. Refer to the *Reference Guide, Output flag selection options* section for more information.

Column	Data type definition	Description
🔑 PROCID	INT	Sequential number that identifies the match level or an association.
🔑 INSRCID	INT	Sequential number that identifies an input source.
🔑 INSRCGRPID	INT	Sequential number that identifies an input source group. When INSRCGRPID is zero, the record does not belong to a source group.
🔑 SECSRCID	INT	Currently not used.
🔑 OBJNAME	NVARNVARCHAR (15)	Name of the input source group statistics object.
SECSRCNAME	NVARNVARCHAR (255)	Currently not used.
SSMASTERS_SEL	NVARNVARCHAR (1)	Indicates whether the *Single source masters* option is selected (Y/N).
SSMASTERS_KEEP	INT	Number of single source master records in INSRCID that are flagged for selection. Depending on the input source type, these are either normal or special records.
SSMASTERS_DROP	INT	Number of single source master records in INSRCID that are not flagged for selection. Depending on the input source type, these are either normal or special records.
MSMASTERS_SEL	NVARCHAR (1)	Indicates whether the *Multiple source masters* option is selected (Y/N).
MSMASTERS_KEEP	INT	Number of multi-source master records in INSRCID that are flagged for selection. Depending on the input source type, these are either normal or special records.
MSMASTERS_DROP	INT	Number of multi-source master records in INSRCID that are not flagged for selection. Depending on the input source type, these are either normal or special records.
SSSUBS_SEL	NVARCHAR (1)	Indicates whether the *Single source subordinates* option is selected (Y/N).

Column	Data type definition	Description
SSSUBS_KEEP	INT	Number of single source subordinate records in INSRCID that are flagged for selection. Depending on the input source type, these are either normal or special records.
SSSUBS_DROP	INT	Number of single source subordinate records in INSRCID that are not flagged for selection. Depending on the input source type, these are either normal or special records.
MSSUBS_SEL	NVARCHAR (1)	Indicates whether the *Multiple source subordinates* option is selected (Y/N).
MSSUBS_KEEP	INT	Number of multi-source subordinate records in INSRCID that are flagged for selection. Depending on the input source type, these are either normal or special records.
MSSUBS_DROP	INT	Number of multi-source subordinate records in INSRCID that are not flagged for selection. Depending on the input source type, these are either normal or special records.
SUPSUBS_SEL	NVARCHAR (1)	Indicates whether the *Suppression subordinates* option is selected (Y/N).
SUPSUBS_KEEP	INT	Number of suppress subordinate records in INSRCID that are flagged for selection.
SUPSUBS_DROP	INT	Number of suppress subordinate records in INSRCID that are not flagged for selection.
UNIQUES_SEL	NVARCHAR (1)	Indicates whether the *Unique* option is selected (Y/N).
UNIQUES_KEEP	INT	Number of unique records in INSRCID that are flagged for selection. Depending on the input source type, these are either normal or special records.
UNIQUES_DROP	INT	Number of unique records in INSRCID that are not flagged for selection. Depending on the input source type, these are either normal or special records.
SUPMASTERS_SEL	NVARCHAR (1)	Indicates whether the *Suppression masters* option is selected (Y/N).
SUPMASTERS_KEEP	INT	Number of suppress master records in INSRCID that are flagged for selection.

Column	Data type definition	Description
SUPMASTERS_DROP	INT	Number of suppress master records in INSRCID that are not flagged for selection.
SUPMATCHES_SEL	NVARCHAR (1)	Indicates whether the *Suppression matches* (normal and special records that follow a suppress record in a match group) option is selected (Y/N).
SUPMATCHES_KEEP	INT	Number of suppress match records in INSRCID that are flagged for selection.
SUPMATCHES_DROP	INT	Number of suppress match records in INSRCID that are not flagged for selection.
SUPUNIQUES_SEL	NVARCHAR (1)	Indicates whether the *Suppression uniques* option is selected (Y/N).
SUPUNIQUES_KEEP	INT	Number of unique suppress records in INSRCID that are flagged for selection.
SUPUNIQUES_DROP	INT	Number of unique suppress records in INSRCID that are not flagged for selection.

Note

The OBJECT_KEY and OBJECT_ID columns are included in this table but they are not listed. They are primary keys common to most tables.

Repository tables common columns [page 1745]

3.9.5.16 MTINSRCSTATS

This table contains the statistics of each input source and each source group and is applicable to the Match transform. It is populated once per input source group statistics object if statistics are enabled.

Note

To obtain the numbers for the source groups, the rows with the same INSRCGRPID must be added.

Column	Data type definition	Description
🔑 PROCID	INT	Sequential number that identifies a match level or an association.

Column	Data type definition	Description
🔑 INSRCID	INT	Sequential number that identifies an input source.
🔑 INSRCGRPID	INT	Sequential number that identifies an input source group. When the INSRCGRPID value is zero, the record does not belong to a source group.
🔑 OBJNAME	NVARCHAR (15)	Name of the input source group statistics object.
SSMASTERS	INT	Number of records in INSRCID that are single source masters. Depending on the input source type, these could be normal or special records.
MSMASTERS	INT	Number of records in INSRCID that are multi source masters. Depending on the input source type, these could be normal or special records.
SSSUBS	INT	Number of records in INSRCID that are single source subordinates. Depending on the input source type, these could be normal or special records.
MSSUBS	INT	Number of records in INSRCID that are multi source subordinates. Depending on the input source type, these could be normal or special records.
SUPSUBS	INT	Number of records in INSRCID that are suppress subordinates.
UNIQUES	INT	Number of records in INSRCID that are unique. Depending on the input source type, these could be normal or special records.
SUPMASTERS	INT	Number of records in INSRCID that are suppress master records.
SUPMATCHES	INT	Number of records in INSRCID that are suppress matches (normal and special records that follow a suppress record in a match group).
SUPUNIQUES	INT	Number of suppress records in INSRCID that are unique.

Note

The OBJECT_KEY and OBJECT_ID columns are included in this table but they are not listed. They are primary keys common to most tables.

Related Information

Repository tables common columns [page 1745]

3.9.5.17 MTKEYDEF

This table contains match criteria information for each match set and is applicable to the Match transform. The information is used in the Match Criteria Summary report.

Column	Data type definition	Description
🔑 KEYID	INT	Number that represents the field type of the key field.
🔑 KEYFLDNUM	INT	Number that indicates which occurrence of the key field this is. The first occurrence will have a value of 1, the second will have a value of 2, and so on. An example of a key field that supports multiple occurrences is the Given Name field, where each occurrence is a different person.
🔑 KEYFLDALTNUM	INT	Number that indicates which alternate (match standard) of the key field this is. The original data will have a value of 0, the first alternate will have a value of 1, the second alternate will have a value of 2, and so on.
KEYNAME	NVARCHAR (256)	Name assigned to the key field when it was created in the job.
KEYLEN	INT	Number of characters in the database field that are used in creating the key field.
DATARECFLDNAME	NVARCHAR (256)	Field's input mapped name.
RMVPUNCT	CHAR (1)	Indicates whether the field was preprocessed by removing punctuation (Y/N).
CONVTOUPPER	CHAR (1)	Indicates whether the field was preprocessed by converting text to upper case (Y/N).
STDDIACHRS	CHAR (1)	Indicates whether the field was preprocessed by converting diacritical characters (Y/N).
CONVTXTTONUM	CHAR (1)	Indicates whether the field was preprocessed by converting numbers represented by text to numerals (Y/N).

Note

The OBJECT_KEY and OBJECT_ID columns are included in this table but they are not listed. They are primary keys common to most tables.

Related Information

Repository tables common columns [page 1745]

3.9.5.18 MTPROCESS

This table contains information about the Match transform processing and is applicable to the Match transform. The information is used in all of the Match reports except the Best Record Summary report.

Column	Data type definition	Description
🔑 PROCID	INT	Sequential number that identifies a match level or an association.
PROCTYPE	CHAR (1)	Process type. Valid values are B (Break Group Process), M (Match Level Process), or A (Association Process).
PROCNAME	NVARCHAR (15)	Process name.

Note

The OBJECT_KEY and OBJECT_ID columns are included in this table but they are not listed. They are primary keys common to most tables.

Related Information

Repository tables common columns [page 1745]

3.9.5.19 MTRULESRES

This table contains information about the effect of the criteria on the total matching process and is applicable to the Match transform. The information is used in the Match Contribution Report (Criteria Information subreport).

Columns	Data type definition	Description
🔑 PROCID	INT	Sequential number that identifies a match level or an association.
🔑 CMPCRITID	INT	Sequential number that identifies the criteria of a match level.
🔑 CRITID	INT	Sequential number that identifies an individual criteria. A value of 999 is used for the weighted results.
MTDECS	INT	Number of match decisions made by this criteria.
NOMTDECS	INT	Number of no match decisions made by this criteria.
CTDECS	INT	Number of records that were allowed to continue with the match process after a no match decision was made.

i Note

The OBJECT_KEY and OBJECT_ID columns are included in this table but they are not listed. They are primary keys common to most tables.

3.10 Locales and Multi-byte Functionality

Data Services supports the use of different locales in sources, the Job Server, and targets. It also supports single and multi-byte code pages. By combining these settings, you can control processing across different languages and allow for differences in capitalization, time and date formats, and character sets.

Related Information

Definitions [page 1808]
Supported locales and encodings [page 1810]

3.10.1 Language packs

Language packs are available for installation, and provide you with locales, other than English (the default locale), for viewing the Data Services user interface and any text that the user interface generaties in other languages.

There is no need to reinstall Data Services to acquire a language pack; they can be installed over an existing Data Services installation.

After a language pack is installed, you will be able to select the locale for both the user interface and the displayed data.

- *Product locale:* Specifies the user interface language and all product messages.
- *Preferred viewing locale:* Specifies the locale that the user data should be presented in. For example, date formatting should be presented in the preferred viewing locale.

There are two locations for setting these options: the Locale Selector and the *Tools* > *Options* window in the Designer.

Where you make your selections depends on your installation configuration.

3.10.1.1 To set locales in the Designer

If you are including the Designer in your installation, you can set your locales in the Designer itself.

> i Note
>
> Changing the locale settings in the Designer's *Options* window will automatically change the locale settings in the Locale Selector.

1. In the Designer, choose *Tools* > *Options* .
   The *Options* window opens.
2. Expand the *Designer* category, and select *Language*.
3. Select a value for the *Product Locale* and the *Preferred Viewing Locale* options.

3.10.1.2 To set locales in the Locale Selector

Perform this task if you are installing the engine but not the Designer.

> i Note
>
> Changing the locale settings in the Locale Selector will automatically change the locale settings in the Designer's *Options* window.

1. Access the Locale Selector.
   ○ Windows: Choose *Start* > *Programs* > *SAP Data Services* `<x.x>` > *Data Services Locale Selector*

- UNIX/Linux: From the command line, type `./start LocaleSelector.sh`

The Locale Selector window opens.

2. Select the locales for the *Product locale* and the *Viewing locale* options.
3. Select the locale for the *Server Log Locale*.
4. To specify the Language, territory, and code page to use for the repository connection and for processing data:
   - To use the default locale, select *Use default database locale*
   - Select the locales for the *Language and Territory* and *Code Page* options.

> **Note**
>
> utf-16 is supported as a code page but cannot be selected in locale selector code page dropdown list.

3.10.1.3 To set locales in UNIX or Linux

Use this procedure to modify the product locales on a UNIX or Linux system.

1. Locate and open your `DSConfig.txt` file. (The default directory is **`<$LINK_DIR>`**`/conf/`.)
2. In the `[Locales]` section, change the `ProductLocale` options to the locale you want.
3. Save and close the `DSConfig.txt` file.

3.10.1.4 Impact of locale settings on Data Services components

The locale settings you choose impact Data Services components differently. Here is a list of those impacts:

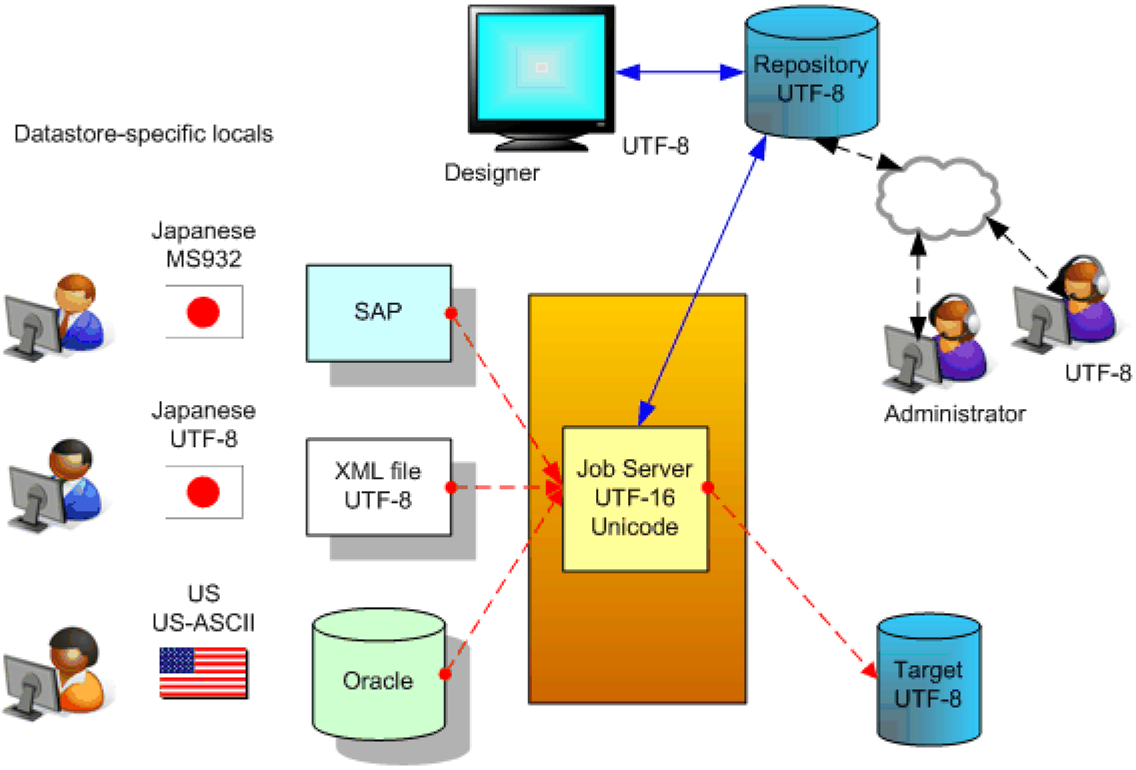
Component	Description
License Manager	License Manager always displays in English.
Management Console	The Management Console's locales are controlled in your internet browser's locale setting.
Documentation	Documentation that is accessed from the Designer will display in the same language as the Designer's *Options* window *Product locale* setting.
Log files	Messages written to a log file will be in the language set in the *Server Logs locale* option in the Locale Selector. This affects only the text of the log files. The date and timestamps remain the same.

3.10.2 Locale support

By supporting different locales Data Services allows you to configure an enterprise environment in which components process data in different human languages and then load the data to a target data code page.

For example, you can configure locales for the following sources:

Language	Territory	Code page
Japanese	Japan	shift_jis
Japanese	Japan	UTF-8
English	United States	US-ASCII



To use Data Services' locale support, set locales within each of the following:

- Database (source, target, and repository) or application (SAP, SAP Master Data Services, PeopleSoft, Oracle, Siebel, JDE).
- Database client.
- Datastore connection to a database or application.
  Datastore locales must match the locales of source and target database clients. This allows the datastore to move data between Data Services and each database without possible data corruption. If the database locale differs from its database client locale, it is your responsibility to ensure that the database transcodes the data before it reaches or after it leaves Data Services.

i Note

To avoid the necessity of setting locales for a database client and a Data Services datastore, you can process with or without UTF-16 Unicode.

i Note

All adapter datastores are automatically set by Data Services to the code page UTF-8. They are handled the same way as XML message sources and targets.

- File format (flat file, XML Schema, and DTD): Match the file format locale to that of each source or target file.
- Job Server: Data Services uses the Job Server's locale for the engines it spawns. The Designer also uses the Job Server's locale as its repository connection locale. To avoid possible data corruption, in case the SAP Sybase repository or DB2 repository database codepage is not UTF-8, use the same locale settings for the repository, its client, and the Job Server.

Related Information

Processing with and without UTF-16 Unicode [page 1799]

File format locales [page 1803]

3.10.2.1 Locale selection

Data Services automatically sets the locale for the following components:

Job Server

After installation, the locale of the Job Server is set to `<default>` which enables Data Services to automatically set the locale for the repository connection (for the Designer) and to process job data (for the Job Server) according to the locale of the datastore or operating system. This capability enables Data Services to automatically change the locale for better performance (for example, set the locale to non-UTF-8 if the datastore is non-unicode data).

The following table shows different datastores and Job Server locale settings and the locale that Data Services automatically sets for the data flow. In this table, the Job Server locale is set to `<default>` and derives its value from the operating system.

Datastore 1 locale	Datastore 2 locale	Job Server locale	Data flow locale
Single-byte code page	Multi-byte code page	Single-byte or Multi-byte code page	Unicode
Multi-byte code page	Multi-byte code page	Single-byte code page	Unicode
Multi-byte code page	Multi-byte code page	Multi-byte code page	Unicode

Datastore 1 locale	Datastore 2 locale	Job Server locale	Data flow locale
Single-byte code page 1	Single-byte code page 2	Single-byte code page 3	Unicode
Single-byte code page 1	Single-byte code page 2	Multi-byte code page	Unicode
Single-byte code page 3	Single-byte code page 3	Multi-byte code page	Unicode
Single-byte code page 3	Single-byte code page 3	Single-byte code page 1	Single-byte code page 3

The following table summarizes the locale that Data Services now sets for each data flow when the locale of the Job Server is set to `<default>`. Different data flows in the same job can run in either single-byte or Unicode.

Locale of datastores in data flow	Job Server locale	Locale that Data Services sets
One datastore has multi-byte locale	Single-byte or multi-byte	Unicode
Different single-byte locales	Single-byte or multi-byte	Unicode
Same single-byte locale	Multi-byte	Unicode
Same single-byte locale	Single-byte	Single-byte

Designer

The Designer uses the Job Server locale to move data between the Designer and the repository.

The Designer expects to receive data from the repository in the Job Server's locale. Objects you create in the Designer are represented internally using a textural language (ATL) that is sent to and received from the repository's database client in the form of SQL statements. Use the same locale when installing the Job Server as you set for your repository and its client to support Data Services' internal language.

The Designer also has its own locale which is automatically set to that of its Microsoft Windows operating system locale. The Designer automatically transcodes input data from its locale to the Job Server locale when it interacts with the repository.

Management Console

The Management Console's locale is automatically set to UTF-8. By using UTF-8 (a Unicode encoding that supports all languages), Data Services ensures data integrity in the Management Console. All Data Services logs (error, trace, and monitor) are generated by the engine in UTF-8. When the Designer reads logs, it transcodes their content from UTF-8 to the Designer locale.

3.10.2.1.1 To override the default Job Server locale

You can override the default locale for the Job Server by using the Data Services Locale Selector utility.

Choose *Start* > *Programs* > *SAP Data Services* **`<x.x>`** > *Data Services Locale Selector*.

For more information, see “Guidelines for setting locales”.

3.10.2.2 Code page support

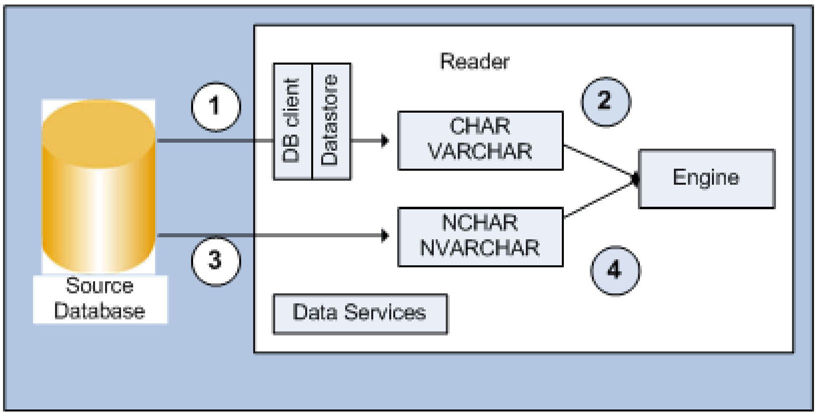
The code page you select in each locale used by a job determines whether transcoding occurs during job processing. Data Services automatically transcodes between different code pages when necessary to support complex, multi-language data management in a single job.

However, it is your responsibility to set up the connections between Data Services and its repository, sources, and targets to avoid data corruption due to mismatched locale settings between Data Services and its connections to external systems. Therefore, ensure you use the same code page as the database middleware to which you are connecting.

3.10.2.2.1 Processing with and without UTF-16 Unicode

The Job Server supports reading and loading national character-set data types (`nchar`, `nvarchar`, `nvarchar2`, `graphic` and `var-graphic`). Data Services automatically handles these data types using UTF-16. If extracting or loading data that uses only these data types, you do not have to set locales for a database client and its datastore. If the data is multi-byte, the Job Server locale should be set to a multi-byte code page, such as `UTF-8` or `shift_jis`.

For example, here is the path that your data takes from a source database to a Data Services engine when data is read during a job run.



The upper arrow shows a normal job run and the locales the job uses to support data integrity.

1. Data Services assumes the database transcodes data into the database client code page, as needed, before it uses its datastore code page to read data from the database. The client and datastore code pages must match otherwise Data Services cannot recognize the format of the data. Note that the data types are not national character-set data types.
2. If the datastore code page is different from the Job Server code page, Data Services transcodes it then processes the job. Note that the client and datastore are not in the path.
   The lower arrow shows a national character-set data type job run:
3. Data Services reads the data formatted for national character-set data types using a UTF-16 code page without using client and datastore code pages.
4. The engine transcodes the data from UTF-16 to the Job Server's code page before it is processed.

When data continues to a target database, the processes are reversed. Data Services automatically transcodes the data in the national character-set data type path back into UTF-16 before loading it into a target. In a normal job run path, if the datastore code page differs from the Job Server code page, the engine transcodes the data to the target's code page before it is passed on to the database client. The datastore locale and the database client locale must match so that data is accurately sent into the database where it might again need to be transcoded into a different locale for storage.

Data Services support of national character-set data types is restricted to the specific source and target databases. For example:

- Oracle with `nchar` or `nvarchar2`
- Microsoft SQL Server with `nchar` or `nvarchar`
- DB2 with `graphic` or `vargraphic`

Data Services can also extract, transform, and load a single table with both national character-set data types and other data types. In this case, the data in the columns with the national character-set data types uses the UTF-16 path and the other data uses the datastore path through Data Services.

In the Designer, you can also assign Unicode as a code page by creating a Microsoft SQL Server datastore connection and selecting *UTF16* or *UTF8* as its code page.

National character-set data types help you avoid having to set locales for connections to database and application sources and targets. However, you still must set locales for the Job Server and for file formats (if you use files in your job).

Also, when Data Services imports a table with columns using any character data type (`nchar`, `nvarchar`, `varchar, char`, and so on), it imports the column size in number of characters (not bytes). Similarly, while creating a new column in Query objects, Data Services assumes the column size is in number of characters. As the number of bytes per character varies from code page to code page, at runtime, the Data Services engine allocates memory based on the Job Server's code page.

Related Information

Column sizing [page 1808]

3.10.2.2.2 Minimizing transcoding

As a rule, transcoding impacts job performance.

- Use the same locale for all components and use a single-byte code page if possible.
- If a datastore or file format and the Job Server use a different locale, Data Services automatically transcodes the data, which supports a multi-language enterprise environment.

Data Services minimizes the impact of transcoding for equivalent code sets such that transcoding between the following code page pairs does not impact performance.

Superset	Subset
cp1252	ISO88591 (LATIN1)
cp1250	ISO88592
cp1251	ISO88595
cp1253	ISO88597
cp1254	ISO88599
cp1255	ISO88598
cp1256	ISO88596
cp1257	ISO88594

Related Information

Supported locales and encodings [page 1810]

3.10.2.3 Guidelines for setting locales

3.10.2.3.1 Job Server locale

The Job Server locale is used by the engines it spawns as well as the Designer's repository connection locale.

If the locale of the Job Server is set to `<default>` after installation, the Job Server takes its locale from the operating system of the host computer where it is installed. If you process multi-byte data with the operating system locale set to single-byte, set the Job Server's locale to the same code page or a superset of the data code page to avoid data corruption. For more information, see Example 3 in the “Example locale settings” section.

If your jobs will run in a multi-language environment, Data Services automatically sets the Job Server's locale to a superset of all datastore and file format locales.

If you do not have a multi-language environment, use a single-byte code page and use the same settings for all locale values or use only locales with code pages that minimize transcoding. This strategy ensures the best performance.

You can override the default locale for the Job Server by using the Data Services Locale Selector utility. Choose *Start* > *Programs* > *SAP Data Services* **<x.x>** > *Data Services Locale Selector*.

Also make sure that the locale of the repository's database client (installed on the Designer's computer) matches the Job Server locale. The Designer uses the Job Server's locale to ensure that it passes accurate data to the repository.

Related Information

Minimizing transcoding [page 1801]
Supported locales and encodings [page 1810]
Example locale settings [page 1805]

3.10.2.3.2 Database, database client, and datastore locales

Set a database and its database client locales using your database software.

Set a Data Services datastore to the same locale as the application or database client to which it connects. Data Services automatically sets each datastore locale to `<default>` in order to match that of the Job Server. However, if your sources or targets use different locales, manually modify the *Language* and *Code page* options under the *Advanced* button in the Datastore Editor.

When you view table data with the View Data feature of the Designer, Data Services formats the values of numeric data type columns according to the number format of its locale territory. For example, suppose a datastore that is connected to an Oracle database with a datastore locale of `deu_de.cp1252`. With the Data Services locale set to `eng_us.cp1252`, View Data will display numeric values with a dot (.) as the decimal separator.

When reading and loading numeric data from databases, Data Services automatically determines the number format appropriate for each database, which does not depend on the Job Server locale territory. However, if the datastore table contains numeric values in string data type columns and an implicit conversion from string to numeric data type is required, Data Services expects that the number format matches the format of its locale territory.

If the format of numeric values in string data type columns does not match the Job Server locale territory, use the `to_decimal_ext` function or the `to_decimal` function to convert the string to a numeric data type by specifying the correct thousand and decimal separators. Similarly, when loading numeric values to string-type columns in a datastore, Data Services formats numbers according to the Job Server locale territory format. If you need to convert the data to a number format used by a different territory, use the `to_char` function.

Locales apply for all profiles created from each datastore.

All adapter datastores are automatically set by Data Services to the code page UTF-8. They are handled the same way as XML message sources and targets.

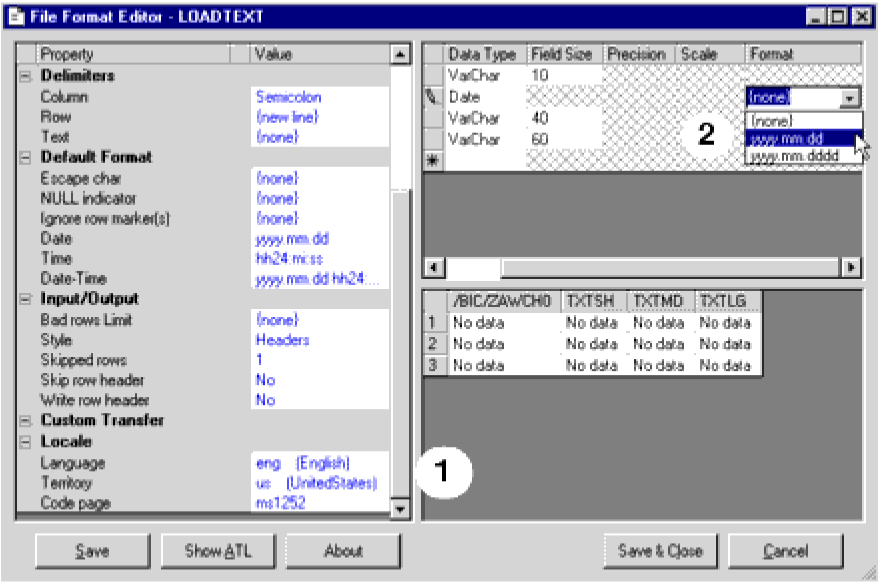
Related Information

Datastore [page 860]
XML encodings [page 1804]
to_char [page 1676]
to_decimal [page 1679]
to_decimal_ext [page 1680]

3.10.2.3.3 File format locales

For flat files, the `<default>` locale is automatically set to match that of the Job Server. However, you can use the *Locale* section on the file format editor to specify the language and code page that corresponds to the file data.

Refer to the following image:



File Format Editor - LOADTEXT

Property	Value
Delimiters	
Column	Semicolon
Row	{new line}
Text	{none}
Default Format	
Escape char	{none}
NULL indicator	{none}
Ignore row marker(s)	{none}
Date	yyyy.mm.dd
Time	hh24:mi:ss
Date-Time	yyyy.mm.dd hh24:...
Input/Output	
Bad rows Limit	{none}
Style	Headers
Skipped rows	1
Skip row header	No
Write row header	No
Custom Transfer	
Locale	
Language	eng {English}
Territory	us {UnitedStates}
Code page	ms1252

Data Type	Field Size	Precision	Scale	Format
VarChar	10			
Date				{none}
VarChar	40			
VarChar	60			

	/BIC/ZAWCH0	TXTSH	TXTMD	TXTLG
1	No data	No data	No data	No data
2	No data	No data	No data	No data
3	No data	No data	No data	No data

1. As in datastore locales, the *Territory* option for a flat file's locale is not active in Data Services.
2. However, you can change the data type for a flat file column and then enter the format that you want to use for a `date` or any numeric data type using the *Column Attributes* work area.

Related Information

File format [page 920]
Designer Guide: File Formats, Number formats [page 264]

3.10.2.3.4 XML encodings

For XML Schemas or DTDs used as sources, the default encoding (code page) for messages is assumed by Data Services to be UTF-8. Header information is ignored. Data Services transcodes inbound data to the Job Server code page (if necessary) before processing it. For XML files Data Services reads header information at run-time. If encoding information is not specified, Data Services assumes it is UTF-8. To edit the encoding for XML file sources, do so in the original file then rerun the job.

For XML Schemas or DTDs used as targets, the default encoding is automatically set to UTF-8.

- If you use an XML Schema or DTD as a file, you can change the encoding using the target editor.
- If you use an XML Schema or DTD as a message, the encoding cannot be changed. Data Services transcodes out-bound message configuration information (like global variable data) into UTF-8.

Related Information

Target XML files, messages, and templates [page 994]

3.10.2.3.5 Overriding the database client locale

By default, most database clients set their locale to the same locale used by the operating system. However, you can override the default setting by using either an environment variable or client configuration tool. We recommend using the methods below to override the client locale for different database types.

Database	Default setting	Environment variable	Driver setting
DB2	OS Locale	DB2CODEPAGE	N/A
Informix	OS Locale	CLIENT_LOCALE	Client Locale field
MySQL	Latin1	N/A	Character Set field
Netezza	N/A	N/A	ASCII (8-bit driver) UTF16 (Unicode driver)
Oracle	OS Locale	NLS_LANG	NLS_LANG
SAP Sybase ASE	OS Locale	LC_ALL	N/A
SAP Sybase IQ	OS Locale	N/A	Character Set field
Teradata	ASCII	N/A	Session Character Set field

> i Note
>
> For Microsoft SQL Server and NeoView databases, the only way to change the database client locale is to change the operating system locale. For generic ODBC databases, see your ODBC driver configuration documentation.

3.10.2.3.6 Example locale settings

Example 1

Suppose you are running Data Services on a Windows system that is set to Japanese and want to process Japanese data, with the Data Services code page set to default, `<default>_<default>.<default>`. All datastore and file formats are also set to the `<default>` code page.

In this situation, the Job Server takes its locale from the server's system locale, `jpn_jp.shift_jis`. All datastore and file formats get the `shift_jis` codepage.

To access the data correctly, the database client must also be configured for a locale equivalent to `jpn_jp.shift_jis`. Refer to the database client documentation for information on how to obtain and configure the correct locale name.

Example 2

Suppose you are running Data Services on a Windows system and want to extract data from multiple databases using different character sets, such as `shift_jis`, `latin1`, and `latin9`, and then load that data to a single UTF-8 target database.

To support this scenario, set the Data Services code page to `eng_US.utf8`, and configure each datastore locale to match the locale of the linked database.

⚠ Restriction

Because the database client code page must match the database server code page, there can be only one client character set per system. This restriction does not apply to databases that allow you to configure the character set via an ODBC driver setting.

Example 3

Suppose you are running Data Services on a Windows system that is set to English (`ms1252`) and want to process Japanese data with the datastore code page set to the `<default>` code page. You must set the Job Server's code page to Japanese (`shift_jis`) to avoid data corruption.

3.10.3 Multi-byte support

Data Services supports various multi-byte code pages that are typically specific to each language. Data Services also provides support for two Unicode encodings: UTF-8 and UTF-16. These are multi-byte code pages that support most of the world's languages.

3.10.3.1 Multi-byte string functions

All Data Services string functions support multi-byte data.

For example, when using the functions INDEX, LENGTH, RPAD, and SUBSTR, the sizes and offsets used as arguments or return values are expressed as number of characters, not number of bytes. You can also see this logical, intuitive behavior when these functions are pushed down and evaluated by the database. Similarly, when Data Services evaluates the SQL predicate `LIKE`, the single-character wildcard "_" matches exactly one character, not one byte.

3.10.3.2 Numeric data types: assigning constant values

Use care when assigning a constant to a numeric variable or column in Data Services.

Assigning a value as a numeric directly

If a numeric value is not within quotes—for example, `$comm = 123.45`—then Data Services stores the value as a numeric. If the value is stored as numeric, then dot (".") is the only recognized decimal separator in the Designer, regardless of the locale. While executing the job, however, the Data Services engine automatically converts the value to appropriate decimal separator for the locale.

Syntax	Comment
`$VALUE = 123.45`	Correct syntax.
`$VALUE = 123,45`	Wrong syntax. Use a comma "," as a decimal separator inside Data Services only if the opertating system's decimal separator is a comma "," and the value is within quotes.

Assigning a value in string format

If a numeric value is stored within quotes—for example, `$comm = '123,45'`—then the Designer stores the value in a string format and while executing the job, the Data Services engine automatically converts the value from the string to the appropriate numeric data type. When the Data Services engine converts a string to a numeric format, it uses the decimal separator for the specified Job Server locale.

For example, if the Job Server locale is set to German regional settings (`deu_de.cp1252`), then Data Services uses a comma (",") as the decimal separator when converting a value from a string to appropriate numeric data type.

Syntax	Comment
`$VALUE = '123,45'`	Correct syntax.

Syntax	Comment
`$VALUE = '123.45'`	Wrong syntax. If the operating system's decimal separator is a comma "," and the value is within quotes, then Data Services tries to process a dot "." as a thousands separator.

If the Job Server locale is set to English regional settings (`eng_us.cp1252`), then Data Services uses a dot (".") as the decimal separator when converting a value from a string to an appropriate numeric data type.

Syntax	Comment
`$VALUE = '123.45'`	Correct syntax.
`$VALUE = '123,45'`	Wrong syntax. If the operating system's decimal separator is a dot "." and the value is within quotes, then Data Services tries to process a comma "," as a thousands separator.

i Note

Using the incorrect decimal separator can generate incorrect results. Similarly, having a thousands separator can generate incorrect results. It is recommended that you do not use a thousands separators when converting a value from string to numeric.

3.10.3.3 Byte Order Mark characters

The Unicode standard includes the use of Byte Order Mark (BOM) characters as a signature for file data.

Data Services supports BOM characters. When it reads data from a file, the Data Services engine trims BOM characters. Data Services supports the following BOM characters and their corresponding encodings:

BOM Characters (Bytes)	Encoding Form
`FE FF`	UTF-16 big-endian
`FF FE`	UTF-16 little-endian
`EF BB BF`	UTF-8

3.10.3.4 Round-trip conversion

While transcoding, if Data Services encounters round-trip conversion conflicts, it transcodes to the first code point match (ascending order of the hexadecimal values) in the target code page. For example, consider two different Japanese characters that are mapped to different hexadecimal code points in the shift_jis code page (`EEFA` and `FFE4`) but then are mapped to the same UTF-16 code point (`FFE4`). In this case, when transcoding back from UTF-16 to shift_jis, Data Services converts them both to code point `EEFA`.

3.10.3.5 Column sizing

The number of bytes per character can vary from one code page to another. For example, the "£Á" which represents a special "A" in the Korean ksc-5601 code page, needs 2 bytes to represent the character, while the UTF-8 code page needs 3 bytes to represent the same character.

Code page	Value	Hex values	Bytes
ksc-5601	special A	`A3 C1`	2
UTF-8	special A	`EF BC A1`	3

Data Services represents sizes in number of characters. Internally, Data Services allocates enough memory to store multi-byte characters.

If the datastore code page is different from the Job Server code page, then transcoding must occur, which may result in the need for extra space allocation.

3.10.4 Limitations of multi-byte support

There are several limitations to SAP Data Services' support for multi-byte characters:

- The software supports a variety of single- and multi-byte code pages, but it does not support UCS-4, or SAP application blended code pages. In addition, the software does not support Surrogate Pairs. EBCIDIC is supported for COBOL files only.
  The software does not support EBCDIC code pages for datastores as they are not ASCII- or UTF-8 -compatible. This is not a problem for users targeting or sourcing data from IBM systems if the engine is running on a non-IBM platform. The IBM system will transparently convert its data to/from EBCDIC when communicating with a foreign architecture.
- Each data flow can process in different locales. However, if you need to change the default locale setting, you need to use a different installation of the Job Server on a different computer, because the automatic locale setting will be disabled.
- The software does not yet fully address all formatting issues. For instance, it supports the "dot" and "comma" currency formats used for most European currencies, but does not support the "tick" and "space" currency format used in Switzerland.

3.10.5 Definitions

With regard to locales and multi-byte functionality associated with Data Services, refer to the following terms:

Locale

Consists of three values related to world regions that control the format of data when it is stored, processed, or displayed. To specify a locale for the Job Server, you must select a Language, Territory, and Code page value.

Datastore and file format locales do not require that you set the Territory value for a locale.

Database sources and targets might not need locale values specified.

Language

Specifies the locale value for a human language.

Territory

Specifies the locale value for a geographical location (usually the country) where a locale language is used. The paring of a language with a territory determines factors such as date format, time format, decimal separator, currency format, and so on. Data Services uses territory values to process the following data types:

- date
- datetime
- decimal
- double
- int
- interval
- numeric
- real
- time
- timestamp

Code page

A table of characters that associates each character with a numeric index (code point value). Data Services uses a code page value to transcode varchar data types. Most languages require their own code pages, although some code pages can represent multiple languages. Most code pages are compatible with `US-ASCII` for code points below 128.

This means for example, that the Japanese code page shift_jis also partially supports other languages such as English. However, use `Japanese` as the Language value, `Japan` as the Territory value, and `shift_jis` as the Code page to avoid possible data corruption in a Japanese locale. It is your responsibility to select corresponding values for locales. While Data Services validates that locale values are entered, it does not validate that they are realistic.

Single-byte

An encoding or code page in which each character is represented by one byte.

Multi-byte

An encoding or code page in which each character is represented by one or more bytes. Some languages, like Korean and Chinese, can only be represented by multi-byte characters. Use multi-byte code pages to process characters for those languages.

Encoding

The process of representing a code page character as one byte (single-byte encoding) or a sequence of bytes (multi-byte encoding).

Transcode

Converts data from one code page to another.

To support ETL environments in which sources with different locales are processed in the same job, Data Services supports transcoding. Note that transcoding can impact performance.

Unicode

Provides a unique number for every character and a method to implement ISO/ISE 10646. Data Services supports UTF-8 and UTF-16 Unicode transformation formats.

UTF-8

Serializes a Unicode code point as a sequence of one to four bytes depending on the complexity of the character (single-byte characters use one byte and multi-byte characters use up to four). Data Services allows you to select UTF-8 as a code page for the Job Server and connections to sources and targets.

UTF-16

In Data Services, standardizes each Unicode code point at two bytes for each character. Allows access to 63k characters as 16-bit units.

Data Services supports UTF-16 for:

- A Microsoft SQL Server database when its datastore code page is set to utf8 or utf16
- National character-set data types in the following databases:
  - Oracle with nchar or nvarchar2
  - Microsoft SQL Server with nchar or nvarchar
  - DB2 with graphic or vargraphic

When using UTF-16 support, you do not have to set locales for connections to database sources and targets.

3.10.6 Supported locales and encodings

For a language, territory, code page or encoding you can also select <default>. For a Job Server locale, this means that the value is read from the operating system's locale. For example, you log in to your Windows session as Davis with a user locale of eng_gb.cp1252. When you install a Job Server, it picks up the same locale and displays it as the default (eng_gb.cp1252). At this point you can:

- Accept these values. The Job Server will always use the eng_gb.cp1252 locale.
- Use default for one or all values, for example by entering <default>_<default>.<default>. The Job Server's locale will always match the operating system's locale.
- Edit this locale to, for example eng_us.cp1252. The Job Server will always use the eng_us.cp1252 locale.

Your choice will depend on how you want to set up your system.

Note

The combination of language code zho and territory cn maps to Simplified Chinese, while the combination of zho and tw maps to Traditional Chinese.

Supported languages

SAP Data Services supports all three-letter language abbreviations specified in the ISO 639-2/T standard.

Supported territories

SAP Data Services supports all two-letter territory abbreviations specified in the ISO 3166-1 standard.

Supported code pages

SAP Data Services supports the following code pages:

Code page	Description			
	XML Encoding	Multi-byte	Vendor	Unicode Ver.
big5	Traditional Chinese Big 5 plus Microsoft extensions. User-defined range added to match Windows 2000 SP4.			
	big5	Yes	Microsoft code page 950	3.0
big5-hkscs	Traditional Chinese Big 5 plus Hong Kong Supplementary Character Set.			
	big5-hkscs	Yes	Microsoft code page 950	3.0
cp1250	Latin-2 (Central Europe)			
	WINDOWS-1250		Microsoft code page 1250	2.1
cp1251	Cyrillic (Slavic)			
	WINDOWS-1251		Microsoft code page 1251	2.1

	UTF-16	Yes		2.1
utf-16be	UTF-16be (big endian) encoding of Unicode			
	UTF-16be	Yes		2.1
utf-16le	UTF-16le (little endian) encoding of Unicode			
	UTF-16le	Yes		2.1
utf-8	UTF-8 encoding of Unicode			
	UTF-8	Yes		2.1

3.11 Python

3.11.1 Python

SAP Data Services supports the Python programming language for writing expressions with the User-Defined and Match transforms. In this section, you can find explanations of Python methods and some examples.

If you want more information about the Python language, see the Python help file, which is installed with the software. By default, it is located at **`<LINK_DIR>`**`\DataQuality\python\doc\python25.chm`. The Python web site, at *www.python.org* , also contains valuable information.

3.11.1.1 About Python

Python is an open-source, object-oriented scripting language. Python is installed with your SAP Data Services installation; therefore, you are equipped with everything you need to begin coding. The software even has its own Python Expression editor, which is accessed from the Match and User-Defined transforms.

By using Python with the software, you can customize transforms to meet your specific needs during processing.

Python module

The software has its own Python module that contains five classes:

- FLDataCollection class
- FLDataManager class
- FLDataRecord class
- FLProperties class
- FLPythonString class

Each of these classes has one or more methods.

Supported transforms

You can use the Python module with these transforms:

- Match
- User-Defined

Third-party Python libraries

To ensure that your Python expressions run correctly, make sure that all third-party python libraries are in the appropriate dynamic library path for your operating system so that the dependencies are resolved. If you find that a Python library is not working correctly, update the library path (LD_LIBRARY_PATH for Solaris and Linux, LIBPATH for AIX, and SHLIB_PATH for HP) in the environment where the AL_JobService is installed, and restart the job service.

Processing mode

The User-Defined transform can run in two processing modes. You specify the mode in the User-Defined Editor. The processing mode determines how the Python expression is applied:

- *Per Record:* Applies the expression to each record. This method is useful for formatting your data, such as making the data all uppercase. You cannot add new records into the data flow with this option.

- *Per Collection:* Applies the expression to the entire data collection. For example, the software could go through each record in a collection to decide if a certain statement is true and then take an action on the entire collection. Use this option when adding or deleting new or duplicate records.

Internal coding

For use with Per Record processing mode, much of the Python coding is done internally, so that you don't need to worry about properly importing the Python module. Most of the examples in this section do not include any import syntax.

Unicode in Python

The software is Unicode-enabled. Therefore, all Python methods require Unicode input and all return values are in Unicode. In Python syntax, you must alert Python that you are processing Unicode data, for example (where "u" indicates Unicode):

```
record.SetField(u'NAME', u'value')
```

⚠ Caution

Make sure to use a "u" to indicate Unicode every time you use a Unicode string to look up field names; for example, in a GetField, SetField, or SendToPipe method. If you do not, an error or crash may occur.

Clean up new memory references

Some of the Python methods return new objects when you call the method. You can see which methods return new objects by reviewing the “Return value” heading under each method's section in this document. Any method with a return value returns new objects.

Whenever you create a new object (such as a variable) that refers to one of these methods, you are also creating a new memory reference.

⚠ Caution

Be sure to clean new memory references. If you don't clean up these references in your scripts, you may notice a memory leak after running projects where your script is present.

For example, assume that you want to retrieve the value of a field using the GetField() method, and save that value as a variable. Because that method returns a value, you must clean up that reference by deleting the variable at the end of the script. For example:

```
Master = SRC.GetField(u'input.code')
del Master
```

However, if you use the NewDataRecord() method and do not use Collection.AddRecord(newRec), use the DeleteDataRecord() method before you use the del command. Otherwise, the memory allocation remains. For example:

```
newRec = DataManager.NewDataRecord(1)
DataManager.DeleteDataRecord(newRec)
del newRec
```

If you use Collection.AddRecord(newRec), you do not need to use the DeleteDataRecord() method before you use the del command, because you do not own the record. For example:

```
Collection.AddRecord(newRec)
del newRec
```

The following example gets the first record from a collection and deletes it.

```
newRec = DataManager.NewDataRecord(0)
Collection.GetRecord(newRec, 1)
Collection.DeleteRecord(newRec)
del newRec
```

Using Mapped_Name

When you set up fields for the transforms that use Python scripts in Per Record mode, you can specify the Mapped_Name. The value of this option indicates an “alias” so that you can refer to your field easily in your Python code.

In some transforms, you can specify a Mapped_Name for fields on both input and output. In this case, be sure to use unique values for these options. If you use the same value on both input and output, you will receive an error.

When you use the GetField and SetField methods, make sure the you enter the Mapped_Name correctly in the Python code and map the input field in the transform. If the Mapped_Name is not used correctly and mapped, you may encounter the following error:

FlDataRecord::GetField() error: Invalid field name MAPPED_RECNO.

Using paths with substitution parameters and custom options

Be cautious when writing any sort of expression that might reference a path. The backslash (\) symbol is used in Python to indicate an escaped character. For example, “\u” indicates Unicode. Therefore, if you use certain paths in your expression, it won't be read properly because the escaped character will be recognized as such. For example:

c:*\u*serdata\myfolder

In this specific instance, you would likely receive the following error when you run the project that contains this User-Defined transform: “UnicodeError: Unicode-Escape decoding error: truncated \uXXXX escape”.

It is also important to consider this when using substitution parameters or custom option in your expression. If your substitution parameter refers to a path, it may encounter the same issue.

You can avoid this issue in several different ways:

- Use forward slashes.

```
u"c:/userdata/myfolder/test_file.txt"
```

- Use a double backslash in the path.

```
u"c:\\userdata\\myfolder\\test_file.txt"
```

- Enclose the substitution value with an “r”, which indicates a raw string.

```
r'[$$TEST]'
```

3.11.1.2 Create an expression with the Python Expression editor

The Python Expression editor, which is similar to the Smart editor, helps you create your Python expressions. The editor provides basic programming features such as keyword highlighting, auto-completion, auto-indentation, and code tool tips.

Related Information

Smart editor [page 1021]
To open the Python Expression editor from the User-Defined transform [page 1818]
Write Python code [page 1818]
Validate syntax [page 1820]
Fix syntax [page 1820]
Find and Replace [page 1820]

3.11.1.2.1 To open the Python Expression editor from the User-Defined transform

Before you use the Python Expression editor, define your input and output fields for the User-Defined transform in the transform editor.

1. In the User-Defined transform editor *Options* tab, click the *Edit Options* button to open the User-Defined Editor.

   You can also select the User-Defined transform in the data flow and choose ▶ *Tools* ▸ *User-Defined Editor* ◀.
2. Decide which processing mode you want to use and select Per Record or Per Collection mode.
3. Select Python Expression Editor in the Option Editor pane, and click the *Launch Python Editor* button.

Related Information

Smart editor [page 1021]

3.11.1.2.2 To open the Python Expression editor from the Match transform

Before you use the Python Expression editor, define your input and output fields for the Match transform in the transform editor.

1. In the Match transform editor *Options* tab, click the *Edit Options* button to open the Match Editor.

   You can also select the Match transform in the data flow and choose ▶ *Tools* ▸ *Match Editor* ◀.
2. Add a best record operation to your Match transform and select the appropriate option values.
3. To customize the Python code, make sure that you select *Yes* in the Custom column of the Best Record Action Fields table. Otherwise, the Python code is not editable.
4. Click the *View/Edit Python* button.

Related Information

Smart editor [page 1021]

3.11.1.2.3 Write Python code

In the Python Expression editor, create and edit Python code in the editor pane of the window. The Python expression that you create here depends on what you need to do with the Match or User-Defined transform.

The Python Expression editor includes keyword highlighting, auto-completion, auto-indentation, and code tool tips. As you type, the Python Expression editor highlights the correct Python syntax. It also auto-completes:

- The Python objects, functions, classes, and methods
- The SAP Data Services generated variables

Python API

The Python API tab lists the objects, functions, classes, and methods that are available for the specific transform and processing mode. When you select an item in the tab, information about it appears in the help area.

Input and output fields

The I/O Fields tab displays the input fields and output fields that have been mapped in the User-Defined transform. You can also add, delete, and edit the properties of user-defined input and output fields from this tab by right-clicking *Input Fields* or *Output Fields* and selecting *Insert*, *Delete*, or *Properties*.

The field variable name is the Mapped_Name option. For example, in a transform you may have an input field as follows:

- *Mapped_Name:* BEST_PRIMNAME1_IN

You could also have an output field as follows:

- *Mapped_Name:* BEST_PRIMNAME1_OUT

The Python Expression editor works in this way for both Per Record and Per Collection processing modes.

Custom options

For the User-Defined transform, you can create custom options that are used as variables within the transform (for example, a file path). You create the custom option in the User-Defined editor, and it is then displayed in the Variables tab of the Python Expression editor. Like substitution parameters, custom options are assigned $$ as a prefix and are enclosed in brackets (for example, [$$PATH]).

If you have both custom options and substitution parameters in your data flow, substitution parameters take precedence over custom options.

Related Information

Smart editor [page 1021]

Python examples [page 1836]

3.11.1.2.4 Validate syntax

When you click the Validate button in the Python Expression editor, the syntax checker makes sure that the Python code has:

- All required colon (:) characters
- All string literal closing characters (either double quotes or single quotes)
- Correct indentation

Validating the Python syntax cannot prevent all runtime errors from occurring. Even if the code is syntactically correct, it might not execute correctly, in which case errors are generated during execution. The syntax checker cannot look for the incorrect usage of:

- Variable names
- Arguments to a function
- Method name on an object

3.11.1.2.5 Fix syntax

If a syntax error is found, a message appears in the bottom section of the edit pane. The message points out the line and character number of the error.

To fix the syntax:

1. Double-click the error message. The Python Expression editor puts the focus on the specified line in the Python code.
2. After you fix an error, click the *Validate* button again. Messages are displayed one at a time; you may have additional syntax errors to fix.
3. Repeat steps 1 and 2 until all of the syntax is correct.

3.11.1.2.6 Find and Replace

Instead of browsing through lines of code, click the *Find* and *Replace* buttons to search for specific text and, if you want, replace it with other text. If the text is found, it is highlighted in the script.

Select the options *Match case* or *Match whole word only* to customize your search.

3.11.1.3 Built-in objects

Data Services includes internally-coded objects that you can use when writing expressions. Make sure to use the exact capitalization as you see it in this documentation. Python is case-sensitive.

The User-Defined transform supports two processing modes:

- Per Record

- Per Collection

Class	Object	Description	User-Defined Record Mode	User-Defined Collection Mode	Best Record (Match transform)
FLData Collection	Collection	Reference to each collection being processed.		Yes	
FlData Record	DST	Reference to destination record in a group posting operation.			Yes
	record	Reference to each record being processed by the data flow.	Yes		
	SRC	Reference to source record in a group posting operation.			Yes
FLData Manager	DataManager	Reference to the data manager for the data flow.		Yes	
FL Properties	Properties	Reference to a properties object.	Yes	Yes	Yes
FLPython String	RET	Value you want to post in a group posting operation.			Yes

3.11.1.4 Defined classes and methods

The following table lists every SAP Data Services-defined class and its supported methods in the User-Defined transform and the Best Record operation of the Match transform. The User-Defined transform supports two processing modes:

- Per Record
- Per Collection

Class	Method	User-Defined Record Mode	User-Defined Collection Mode	Best Record (Match transform)
FlData Collection	AddRecord		Yes	
	DeleteRecord		Yes	
	GetRecord		Yes	
	Size		Yes	

Class	Method	User-Defined Record Mode	User-Defined Collection Mode	Best Record (Match transform)
	Truncate		Yes	
FlData Manager	DeleteDataRecord		Yes	
	NewDataRecord		Yes	
FlData Record	GetField	Yes	Yes	Yes
	SetField	Yes	Yes	Yes
FlProperties	GetProperty	Yes	Yes	Yes
FlPython String	GetBuffer			Yes
	Set Buffer			Yes

3.11.1.5 FlDataCollection class

Use FlDataCollection class methods when you want to manipulate entire collections of data or records, and when adding new records to a collection that did not exist before. This can be helpful when matching in a real-time environment.

Related Information

AddRecord [page 1822]
DeleteRecord [page 1824]
GetRecord [page 1824]
Size [page 1825]
Truncate [page 1826]

3.11.1.5.1 AddRecord

Syntax

```
AddRecord(<record>)
```

Description

Adds the record to the new collection.

Note

For every NewDataRecord(), you can call AddRecord() only once.

Note

After you call AddRecord(), do not call DeleteDataRecord().

Parameters

This method has the following parameter.

Parameter	Description
record	Substitute the name of the record you want to add. This parameter is a variable that you must define.

Return value

None.

Example

In this example, the fields are defined for a new record and then the record is added to the collection with this AddRecord() method.

```
aDup = [1, u'brian', u'boyd', u'123 main st', u'83301'], \
[2, u'bryan', u'boyde', u'456 first st', u'83302'], \
[3, u'brina', u'boyle', u'789 last ave', u'83303']

for rec in aDup:
    newrecord = DataManager.NewDataRecord(1)
    newrecord.SetField(u'ID',unicode(rec[0]))
    newrecord.SetField(u'FIRST_NAME',unicode(rec[1]))
    newrecord.SetField(u'LAST_NAME',unicode(rec[2]))
    newrecord.SetField(u'ADDRESS',unicode(rec[3]))
    newrecord.SetField(u'POSTCODE1',unicode(rec[4]))

    Collection.AddRecord(newrecord)
```

3.11.1.5.2 DeleteRecord

Syntax

```
DeleteRecord(<record>)
```

Description

Removes the specified record from the collection.

Parameters

This method has the following parameter.

Parameter	Description
record	Substitute the name of the record you want to delete. This parameter is a variable that you must define.

Return value

None.

Example

In this example, a new record (newRec) is created and then deleted.

```
newRec = DataManager.NewDataRecord()
Collection.DeleteRecord(newRec)
```

3.11.1.5.3 GetRecord

Syntax

```
GetRecord(<record>, <index>)
```

Description

Retrieves the value of a record in a collection in the specified index position.

Parameters

This method has the following parameters.

Parameter	Description
record	Substitute the name of the record object. This parameter is a variable that you must define; for example, `record = DataManager.NewDataRecord().`
index	Substitute the numerical index value of the record in the collection.

Return value

Returns the value from the record at the specified position.

Example

In the following example, a new record (newRec) is created, the value of the record in position one is retrieved, and the record is deleted from the collection.

```
newRec = DataManager.NewDataRecord()
Collection.GetRecord(newRec, 1)
Collection.DeleteRecord(newRec)
```

3.11.1.5.4 Size

Syntax

```
Size()
```

Description

Counts the number of records in the collection.

Parameters

None.

Return value

Returns an integer that refers to the number of records in the collection.

Example

In this example, you're retrieving the number of records in the collection.

```
collectionSize = Collection.Size()
```

3.11.1.5.5 Truncate

Syntax

```
Truncate()
```

Description

Removes all records from a collection, but does not delete the collection.

Parameters

None.

Return value

None.

Example

Use this method to quickly delete all the records from a collection, rather than one by one.

```
Collection.Truncate()
```

3.11.1.6 FIDataManager class

Use FIDataManager class methods when you want to create new records.

Related Information

DeleteDataRecord [page 1827]
NewDataRecord [page 1828]

3.11.1.6.1 DeleteDataRecord

Syntax

```
DeleteDataRecord(<record>)
```

Description

Deletes the memory of a record object allocated using NewDataRecord().

> Note
>
> Do not call DeleteDataRecord() after calling AddRecord().

Parameters

This method has the following parameter.

Parameter	Description
record	Substitute the name of the record object you want to delete.

Return value

None.

Example

In this example, a new record object (newRec) is created. Then, using this method, the memory allocated to the data collection is deleted. You must use this method when you use the NewDataRecord() method, otherwise the Python expression may have a memory leak.

```
newRec = DataManager.NewDataRecord()
DataManager.DeleteDataRecord(newRec)
```

3.11.1.6.2 NewDataRecord

Syntax

```
NewDataRecord()
```

Description

Creates a new record object. Do not use this method in a loop, otherwise the Python expression may experience a memory leak. Depending on the expression, you'll probably want to place this method at the beginning of the expression.

Parameters

This method has none, but see example for an exception.

If you call the record with a parameter of 1, then the new record gets its own memory.

Return value

Returns a new object of type FIDataRecord.

Examples

In the following example, a new record (newRecord) is created and populated in the original collection.

```
newRecord = DataManager.NewDataRecord()

#gets the number of records
numRecords = Collection.Size()

#iterate over the collection
for recordNum in range (1, numRecords + 1)

  #get a record
  Collection.GetRecord(newRecord, recordNum)

  #set a field on the record
  newRecord.SetField(u'NAME', u'test')

DataManager.DeleteDataManager(newRecord)
```

The following example is a little different from the previous one. In this example, records are read from a database and then are added to the original collection. Because of this difference, the NewDataRecord() method then needs a numeric parameter of 1.

```
newRecord = DataManager.NewDataRecord(1)

#get the records from the database (excluded from example)

#populate the record
newRecord.SetField(u'NAME', u'test')

#add record to the collection
Collection.AddRecord(newRecord)

del newRecord
```

⚠ Caution

Make sure that you clean up memory references.

Related Information

About Python [page 1814]

3.11.1.7 FlDataRecord class

Use Data Services-defined FlDataRecord class methods to manipulate existing individual records.

Related Information

GetField [page 1830]
SetField [page 1831]

3.11.1.7.1 GetField

Syntax

```
fieldVal = GetField(u'<fieldName>')
```

Description

Retrieves the contents of the specified input field. This method can be used with defined input fields only.

Parameters

This method has the following parameter:

Parameter	Description
fieldName	In the Python Expression editor, use one of the input field variables. If you use this method with the Best Record operation of the Match transform, this parameter should be replaced with the Mapped Name you want to retrieve.

Return value

Returns a new string with the contents of the specified field.

Example

```
if newRecord.GetField(u'POSTCODE1') == u'54601'...
```

Caution

Make sure to use a "u" to indicate Unicode every time you use a Unicode string to look up field names. If you do not, an error or crash may occur.

3.11.1.7.2 SetField

Syntax

```
SetField(u'<fieldName>', u'value')
```

Description

Stores a value in the specified field.

Parameters

This method has the following parameters:

Parameter	Description
fieldName	In the Python Expression editor, use one of the input or output field variables, which uses the Mapped Name.
value	Specifies the value you want to store in the field.

Return value

None.

Example

For example, you could store "Current Resident" in the field named NAME_SUBSTITUTION.

```
newRecord.SetField(u'NAME_SUBSTITUTION', u'Current Resident')
```

⚠ Caution

Make sure to use a "u" to indicate Unicode every time you use a Unicode string to look up field names. If you do not, an error or crash may occur.

3.11.1.8 FIProperties class

Use the FIProperties class to gain access to various properties of the system that the Python expression is running in. The class can access the following run-time parameters in the Data Services environment variables:

Run-time parameter	Description
APPLICATION_PATH	The directory that contains the application executable.
APPLICATION_VERSION	The version of the framework.
DATAFLOW_NAME	The name of a data flow.
JOB_ID	The run ID of a job.
TRANSFORM_GUID	The globally unique identifier, or GUID, of a transform
TRANSFORM_NAME	The display name of a transform.
REPOSITORY_VERSION	The version of a repository.

Related Information

GetProperty [page 1833]

3.11.1.8.1 GetProperty

Syntax

```
var1 = GetProperty(<PropertyName>)
```

Description

Returns the value of a given property specified as an input parameter.

Parameters

This method has the following parameter:

Parameter	Description
PropertyName	Specifies the environment variable that you want to retrieve.

Return value

Returns the value of the specified property.

Example

The following example shows how to retrieve a value for the JOB_ID parameter.

```
#Retrieve the Property Value for JOB_ID
propValue = Properties.GetProperty(u'JOB_ID')

#Set the Job Id value into JOB_ID_OUT field
record.SetField(u'JOB_ID_OUT',unicode(propValue))

del propValue
```

3.11.1.9 FlPythonString class

Use the FlPythonString methods to customize your data processing. With these methods, you can create a Best Record operation in the Match transform.

Related Information

GetBuffer [page 1834]
SetBuffer [page 1835]

3.11.1.9.1 GetBuffer

Syntax

```
GetBuffer()
```

Description

Returns the specified string.

Parameters

None.

Return value

The Unicode character string.

Example

In the following example, *getstr* would hold the value of the Unicode character string.

```
getstr = STR.GetBuffer()
```

3.11.1.9.2 SetBuffer

Syntax

```
SetBuffer(u'<stringValue>')
```

Description

Sets character buffer to the object.

Parameters

This method has the following parameter:

Parameter	Description
stringValue	Specifies the string that you want to use here.

Return value

None.

Example

This example shows how to post data from a “master” record to its “subordinates” with the Best Record operation of the Match transform. The data is input with the field input.code.

Best Record strategy:

```
# store master and subordinate values
SOURCE = SRC.GetField(u'input.code')
DESTINATION = DST.GetField(u'input.code')

# if the master is not empty and the subordinate is
if len(SOURCE.strip()) != 0 and len(DESTINATION.strip()) == 0:
   RET.SetBuffer(u'T')
else:
   RET.SetBuffer(u'F')

# delete temporary variables
del SOURCE
del DESTINATION
```

Best Record Action:

```
# store master
SOURCE = SRC.GetField(u'input.code')

# return master
RET.SetBuffer(SOURCE)

# delete temporary variables
del SOURCE
```

3.11.1.10 Python examples

The following examples, grouped by the type of action they perform on data, are intended to help you get started writing expressions in Python. You may need to significantly change some of these examples to fit the type of data and names of fields you are using.

Keep in mind that many of these tasks could be also performed with a Query transform.

Formatting data

The following examples of Python code in the User-Defined transform can be used to format data.

Example use	Sample Python code
Data is input without data-source identification. In the User-Defined transform, append a field mapped to the source and populate it with TRC for all records.	`record.SetField(u'SOURCE',u'TRC')`

Data is input with a name field mapped to name. In the User-Defined transform, upper case the name and put it in a new name field that is mapped to uppername.	`name = record.GetField(u'name')`
	`uppername = name.upper()`
	`record.SetField(u'uppername',unicode(uppername))`
	`del name`
	`del uppername`

Data is input with an account type indicator field, mapped to account_type, that contains B or b for business accounts, and I or I for individual accounts. In the User-Defined transform, append two fields mapped to name and firm. If records contain B or b, output the contents of the field mapped to customer_name to the new firm field. If records do not contain B or b, output the contents to the new name field.	`account_type = record.GetField(u'acct_type')`
	`customer_name = record.GetField(u'cust')`
	
	`if account_type.strip().upper() == u'B':`
	`    record.SetField(u'firm',unicode(customer_name))`
	`else:`
	`    record.SetField(u'name',unicode(customer_name))`
	`del account_type`
	`del customer_name`

Example use	Sample Python code

Firm data is input in a field mapped to firm. In the User-Defined transform, populate a two-character field mapped to firm_length that contains the number of characters in the firm name (padded with zeros).	`field = record.GetField(u'firm')`
	`firm_length = field.strip().zfill(2)`
	`record.SetField(u'firm_length',unicode(firm_length))`
	`del field`
	`del firm_length`

Data is input with some records not having a name in the field mapped to name. In the User-Defined transform, complete empty names with Valued Customer, preserving the input name in records that have them. Overwrite the data in the same field.
In this example, name_in is the mapped name for the input name field. In the output field section, name_out is the mapped name for the same field.
	`name_in = record.GetField(u'name')`
	`if len(name_in.strip()) == 0:`
	`    record.SetField(u'name',u'Valued Customer')`
	`del name_in`

Data is input with fields mapped to ZIP Code and street. In the User-Defined transform, append a field mapped to breakgroupid, and populate it with the first three characters of the ZIP Code and the first three characters of the street.	`zip = record.GetField(u'zip')`
	`street = record.GetField(u'street')`
	`breakgroupid = zip[0:3] + street[0:3]`
	`record.SetField(u'breakgroupid',unicode(breakgroupid))`
	`del zip`
	`del street`
	`del breakgroupid`

Data is input with a field mapped to groupnumber. In the User-Defined transform, append a field mapped to groupnumberzeropad, and populate it with the group number, padded with zeros to 10 characters in length.	`groupnumber = record.GetField(u'groupnumber')`
	`groupnumberzeropad = groupnumber.strip().zfill(10)`
	`record.SetField(u'groupnumberzeropad',unicode(groupnumberzeropad))`
	`del groupnumber`
	`del groupnumberzeropad`

In the User-Defined transform, append a field mapped to recordnum, and populate it with the record number.	`dct = locals()`
	`if dct.has_key('COUNTER'):`
	`    dct['COUNTER'] = dct['COUNTER'] + 1`
	`else:`
	`    dct['COUNTER'] = 1`
	`record.SetField(u'recordnum',unicode(dct['COUNTER']))`

In the User-Defined transform, append a field mapped to recordnum, and populate it with the record number, zero padded to 10 characters in length.	`dct = locals()`
	`if dct.has_key('COUNTER'):`
	`    dct['COUNTER'] = dct['COUNTER'] + 1`
	`else:`
	`    dct['COUNTER'] = 1`
	`recordnum = str(dct['COUNTER']).zfill(10)`

Example use	Sample Python code

	`record.SetField(u'recordnum',unicode(recordnum))`
	`del recordnum`

Data is input in user_group and user_code fields. In the User-Defined transform, if the contents of user_code is A, B, C, D, E, F, G, or H, output User-GroupA in the user_group field. If user_code contains I, J, K, L, M, N, O, or P, output UserGroupB in the user_group field. If user_code contains any other value, preserve the input value in the user_group field.	`user_code = record.GetField(u'user_code')`
	`uga = 'A,B,C,D,E,F,G,H'`
	`ugb = 'I,J,K,L,M,N,O,P'`
	`if uga.find(user_code.strip().upper()) > -1:`
	`    record.SetField(u'user_group',u'UserGroupA')`
	`elif ugb.find(user_code.strip().upper()) > -1:`
	`    record.SetField(u'user_group',u'UserGroupB')`
	`del user_code`
	`del uga`
	`del ugb`

Splitting data

The following examples can be used in the User-Defined transform to split your data in a specific way without changing how it is routed.

Example use	Sample Python code

Data is input in an input account field (mapped to account) with contents of name, a slash, and firm, for example "John Smith / SAP". In the User-Defined transform, append two new fields mapped to name and firm, where the contents before the slash are placed in name and the contents after the slash are placed in firm.
In this example, the syntax str specifies the type of split and the syntax 3-part specifies how to split.
	`from flscansplit import ScanSplit`
	`account = record.GetField(u'account')`
	`name = ScanSplit(account, u'str', u'3-part', ['/'])[0]`
	`firm = ScanSplit(account, u'str', u'3-part', ['/'])[2]`
	`record.SetField(u'name',unicode(name))`
	`record.SetField(u'firm',unicode(firm))`
	`del account`
	`del name`
	`del firm`

Data is input in an input.account field (map-	`from flscansplit import ScanSplit`
	`account = record.GetField(u'account')`

Example use	Sample Python code

ped to account) with contents of a person's name followed by a financial suffix, for example "John Smith JTWROS". In the User-Defined transform, append two new fields mapped to account_name and account_type, where the name and type are split.	`type = [u'JT/WROS', u'JT WROS', u'JTWROS', u'JT/TEN', u'JT TEN', u'JTTEN', u'JT/TIC', u'JT TIC', u'JTTIC', u'TEN COM', u'TEN/COM', u'TENCOM']`
	`account_name = ScanSplit(account, u'str', u'before',type)[0]`
	`account_type = ScanSplit(account, u'str', u'before',type)[1]`
	`record.SetField(u'account_name',unicode(account_name))`
	`record.SetField(u'account_type',unicode(account_type))`
	`del account`
	`del type`
	`del account_name`
	`del account_type`

Another option for scan values is to create an external file in a text editor and saved locally, with extension “py”. Import the file prior to the method. Then in the ScanSplit method, use the variable in the file in place of the actual scan values.

For example, to accomplish the same account_name and account_type fields specified in the second example, you may create a file called suffixes.py that has the following contents:

```
type = [u'JT/WROS', u'JT WROS', u'JTWROS', u'JT/TEN', u'JT TEN', u'JTTEN', u'JT/
TIC', u'JT TIC', u'JTTIC', u'TEN COM', u'TEN/COM', u'TENCOM']
```

Then, complete the following expression in the User-Defined transform.

```
from flscansplit import ScanSplit
from suffixes import *
account = record.GetField(u'account')
account_name = ScanSplit(account, u'str', u'before',type)[0]
account_type = ScanSplit(account, u'str', u'before',type)[1]
record.SetField(u'account_name',unicode(account_name))
record.SetField(u'account_type',unicode(account_type))
del account
del account_name
del account_type
```

Best Record

The following example can be used in the Best Record operation in the Match transform. This example shows the use of Unicode.

Example use	Sample Python code

Data is input with a field gen.phone that is populated in some records of a match group and empty in others. Perform the best record action of taking phone data from a populated record and placing it into an empty record.	*Best Record strategy:*
	`Source = SRC.GetField(u'gen.phone')`
	`Destination = DST.GetField(u'gen.phone')`
	`if len(Source.strip()) > 0 and len(Destina-`

Example use	Sample Python code

In this example, the Best Record strategy returns a True when the source is populated and the destination is empty (or else, it returns a False). At the end, the GetField method places the source data into the destination field, provided the Best Record strategy returns a True.	`tion.strip()) == 0:`
	`    RET.SetBuffer(u'T')`
	`else:`
	`    RET.SetBuffer(u'F')`
	
	`del Source`
	`del Destination`
	
	Best Record Action:
	
	`RET.SetBuffer(SRC.GetField(u'gen.phone')`

Assigning source attributes

The following example can be used in the User-Defined transform to assign a source to records in a collection.

Example use	Sample Python code

Data is input with a field mapped to SOURCE_IN. When the source is CRM or LEADS, assign source attributes. When the source is DoNotMarket, assign list attributes.	`SOURCE_IN = SRC.GetField(u'SOURCE_IN')`
	`if SOURCE_IN.strip() == u'CRM':`
	`  SOURCE_TYPE_OUT = u'N'`
	`  DRIVER_ORDER_OUT = u'020'`
	`  BEST_RECORD_PRIORITY_OUT = u'010'`
	`  INCLUDE_IN_SOURCE_COUNT_OUT = u'Y'`
	`  APPLY_BLANK_PENALTY_OUT = u'Y'`
	`  PERFORM_DATA_SALVAGE_OUT = u'N'`
	`  PROTECT_UNIQUE_ID_OUT = u'Y'`
	`elif SOURCE_IN.strip() == u'Leads':`
	`  SOURCE_TYPE_OUT = u'N'`
	`  DRIVER_ORDER_OUT = u'010'`
	`  BEST_RECORD_PRIORITY_OUT = u'020'`
	`  INCLUDE_IN_SOURCE_COUNT_OUT = u'Y'`
	`  APPLY_BLANK_PENALTY_OUT = u'Y'`
	`  PERFORM_DATA_SALVAGE_OUT = u'N'`
	`  PROTECT_UNIQUE_ID_OUT = u'N'`
	`elif SOURCE_IN.strip() == u'DoNotMarket':`
	`  SOURCE_TYPE_OUT = u'S'`
	`  DRIVER_ORDER_OUT = u'000'`
	`  BEST_RECORD_PRIORITY_OUT = u'000'`
	`  INCLUDE_IN_SOURCE_COUNT_OUT = u'Y'`
	`  APPLY_BLANK_PENALTY_OUT = u'N'`
	`  PERFORM_DATA_SALVAGE_OUT = u'N'`
	`  PROTECT_UNIQUE_ID_OUT = u'N'`
	`record.SetField(u'SOURCE_TYPE_OUT',unicode(SOURCE_TYPE_OUT))`
	`record.SetField(u'DRIVER_ORDER_OUT',unicode(DRIVER_ORDER_OUT))`
	`record.SetField(u'BEST_RECORD_PRIORITY_OUT',unicode(BEST_RECORD_PRIORITY_OUT))`
	`record.SetField(u'INCLUDE_IN_SOURCE_COUNT_OUT',unicode(INCLUDE_IN_SOURCE_COUNT_OUT))`
	`record.SetField(u'APPLY_BLANK_PENALTY_OUT',unicode(APPLY_BLANK_PENALTY_OUT))`
	`record.SetField(u'PERFORM_DATA_SALVAGE_OUT',unicode(PERFORM_DATA_SALVAGE_OUT))`

Example use	Sample Python code

	`record.SetField(u'PROTECT_UNIQUE_ID_OUT',unicode(PROTECT_UNIQUE_ID_OUT))`
	`del SOURCE_TYPE_OUT`
	`del DRIVER_ORDER_OUT`
	`del BEST_RECORD_PRIORITY_OUT`
	`del INCLUDE_IN_SOURCE_COUNT_OUT`
	`del APPLY_BLANK_PENALTY_OUT`
	`del PERFORM_DATA_SALVAGE_OUT`
	`del PROTECT_UNIQUE_ID_OUT`

3.12 Hadoop

Data Services can connect to Apache Hadoop frameworks including HDFS and Hive sources and targets. Data Services must be installed on Linux in order to work with Hadoop. Relevant components of Hadoop include:

- Hadoop distributed file system (HDFS): Stores data on nodes, providing very high aggregate bandwidth across the cluster.
- Hive: A data warehouse infrastructure that allows SQL-like ad-hoc querying of data (in any format) stored in Hadoop.
- Pig: A high-level data-flow language and execution framework for parallel computation that is built on top of Hadoop. Data Services uses Pig scripts to read from and write to HDFS including joins and push-down operations.
- Map/Reduce: A computational paradigm where the application is divided into many small fragments of work, each of which may be executed or re-executed on any node in the cluster. Data Services uses map/reduce to do text data processing.

3.12.1 Prerequisites

Before configuring Data Services to connect to Hadoop, verify the following prerequisites:

- The machine where the Data Services Job Server is installed is configured to work with Hadoop and has the Pig client installed, and if using Hive, the Hive client. Verify this by logging on to the node and issuing Pig and Hive commands, which should invoke the respective interfaces. For more information, see the "Common commands for correct setup" section.
- The Data Services Job Server does not have to be part of the Hadoop cluster, but Hadoop must be installed on the same machine as the Data Services Job Server and must be configured with access to the cluster machines.
- To ensure that the environment is set up correctly for interaction with Hadoop, the Job Server should start from an environment that has sourced the Hadoop environment script, as follows:

  ```
  source <$LINK_DIR>/hadoop/bin/hadoop_env.sh -e
  ```

- To enable text data processing, ensure the necessary text data processing components have been copied to the HDFS file system, which enables MapReduce functionality. For more information, see “Configuring Hadoop for text data processing”.

Related Information

Administrator Guide: Server Management, To configure Job Servers (Windows) [page 84]
Designer Guide: Transforms, Text Data Processing transforms [page 318]

3.12.1.1 Common commands for correct setup

Here are some useful commands that you can use to check that everything is set up correctly between Hadoop and Data Services. Output shown for various commands may differ, but the important thing to look for is that you don't get errors when you run the command.

Setting up the environment

To set up the Data Services environment for Hadoop, use the following command:

```
$ cd <DS Install Directory>/bin
$ source ./al_env.sh
$ cd ../hadoop/bin
$ source ./hadoop_env.sh -e
```

Checking components

To make sure that Hadoop, Pig, and Hive are set up correctly on the machine where the Data Services Job Server for Hadoop is configured and installed, use the following command:

```
$ hadoop fs -ls /
```

For Hadoop, you should see output similar to the following:

```
$ hadoop fs -ls /
Found 2 items
drwxr-xr-x   - hadoop supergroup          0 2013-03-21 11:47 /tmp
drwxr-xr-x   - hadoop supergroup          0 2013-03-14 02:50 /user
```

For Pig, you should see output similar to the following:

```
$ pig
INFO  org.apache.pig.Main - Logging error messages to: /hadoop/pig_1363897065467.log
INFO  org.apache.pig.backend.hadoop.executionengine.HExecutionEngine - Connecting
to hadoop file system at: hdfs://machine:9000
INFO  org.apache.pig.backend.hadoop.executionengine.HExecutionEngine - Connecting
to map-reduce job tracker at: machine:9001
grunt> fs -ls /
Found 2 items
drwxr-xr-x   - hadoop supergroup          0 2013-03-21 11:47 /tmp
drwxr-xr-x   - hadoop supergroup          0 2013-03-14 02:50 /user
grunt> quit
```

For Hive, you should see output similar to the following:

```
$ hive
Hive history file=/tmp/hadoop/hive_job_log_hadoop_201303211318_504071234.txt
hive> show databases;
OK
default
Time taken: 1.312 seconds
hive> quit;
```

If all commands pass, use `$LINK_DIR/bin/svrcfg` from within the same shell to set up or restart the Job Server.

By running this command you are giving the Job Server the proper environment from which it can start engines that can call Hadoop, Pig, and Hive.

3.12.1.2 Configuring Hadoop for text data processing

Data Services supports text data processing in the Hadoop framework using a MapReduce form of the Entity Extraction transform. To use text data processing in Hadoop, copy the language modules and other dependent libraries to the Hadoop file system (so they can be distributed during the MapReduce job setup) by running the Hadoop environment script as follows:

```
$LINK_DIR/hadoop/bin/hadoop_env.sh -c
```

You only have to do this file-copying operation once after an installation or update, or when you want to use custom dictionaries or rule files. If you are using the Entity Extraction transform with custom dictionaries or rule files, you must copy these files to the Hadoop file system for distribution. To do so, first copy the files into the languages directory of the Data Services installation, then rerun the Hadoop environment script. For example:

```
cp /myhome/myDictionary.nc $LINK_DIR/TextAnalysis/languages
```

```
$LINK_DIR/hadoop/bin/hadoop_env.sh -c
```

Once this environment is set up, in order to have the Entity Extraction transform operations pushed down and handled by the Hadoop system, it must be connected to a single HDFS Unstructured Text source.

Optimizing text data processing for use in the Hadoop framework

When using text data processing in the Hadoop framework, the amount of data a mapper can handle and consequently the number of mappers a job uses, is controlled by the Hadoop configuration setting, `mapred.max.split.size`.

You can set the value for `mapred.max.split.size` in the Hadoop configuration file (located at `$HADOOP_HOME/conf/core-site.xml` or an alternate configuration location, depending on the flavor of Hadoop you are using).

By default, the value for `mapred.max.split.size` is 0, which means that there is no limit and text data processing would run with only one mapper. You should change this configuration value to the amount of data a mapper can handle.

For example, you might have a Hadoop cluster that contains twenty machines and each machine is set up to run a maximum of ten mappers (20 x 10 = 200 mappers available in the cluster). The input data averages 200 GB. If you want the text data processing job to consume 100 percent of the available mappers (200 GB ÷ 200 mappers = 1 GB per mapper), you would set `mapred.max.split.size` to 1073741824 (1 GB).

```
<property>
  <name>mapred.max.split.size</name>
  <value>1073741824</value>
</property>
```

If you want the text data processing job to consume 50 percent of the available mappers (200 GB ÷ 100 mappers = 2 GB per mapper), you would set `mapred.max.split.size` to 2147483648 (2 GB).

Entity Extraction transform [page 1502]
HDFS file format [page 933]

3.12.2 Connecting to HDFS

To connect to a Hadoop distributed file system (HDFS), you configure an HDFS file format. You then use the file format as a source or target in a data flow.

Related Information

Reference Guide: HDFS file format [page 933]
Reference Guide: File format [page 920]
Designer Guide: File formats [page 254]

3.12.3 Connecting to Hive

The process to connect to Hive, the data-warehousing infrastructure based on Hadoop, is as follows:

1. Enable the Job Server to support adapters. In the Server Manager, open the configuration editor for the Job Server that is installed on the Hadoop node and select the option *Support adapter and message broker SNMP communication*.
2. In the Administrator, add, configure, and start an adapter instance.
3. In the Designer, add and configure a Hive adapter datastore.

3.12.3.1 Adding, configuring, and starting a Hive adapter instance

Enable the Job Server to support adapters. In the Server Manager, open the configuration editor for the Job Server that is installed on the Hadoop node and select the option *Support adapter and message broker communication*.

Use the Data Services Administrator to add and configure an adapter to connect to Hive.

1. Log in to Data Services Management Console and open the Administrator.
2. Expand the *Adapter Instances* node and click the name of the Job Server that is installed on the Hadoop node.
3. Click the *Adapter Configuration* tab and click *Add.*
4. From the list of installed adapters, click *HiveAdapter*.
5. Enter the following adapter instance properties:
    a) Adapter instance name.
    b) For Classpath, the path to the Hive jar files.

    Click *Apply*.
6. Click the *Adapter Instance Status* tab, select the check box for the adapter, and click *Start.*

The adapter has been configured and now will be available in the Designer for adding a Hive datastore.

In the Designer, add and configure the adapter datastore.

Related Information

Administrator Guide: Server Management, To configure Job Servers on Windows [page 84]
Management Console Guide: Administrator, Adapters [page 1938]
Designer Guide: Datastores, Adapter datastores [page 233]

3.12.3.2 Adding and configuring a Hive adapter datastore

Observe the following prerequisites:

- Enable the Job Server to support adapters. In the Server Manager, open the configuration editor for the Job Server that is installed on the Hadoop node and select the option *Support adapter and message broker communication*.
- Add, configure, and start a Hive adapter instance.

Use the Data Services Designer to add and configure a datastore to connect to Hive as follows.

1. Launch the Designer.
2. In the object library, select the *Datastores* tab.
3. Right-click in the blank area of the object library and click *New*.
4. Configure the datastore as follows:

a) Enter a *Datastore name*.

b) For *Datastore type*, select *Adapter*.

c) Select the Job Server associated with this adapter.

d) Select the adapter instance.

e) Click *Advanced* to display the *Adapter Options*.

f) Enter additional adapter information including the following required options: *Host name* (the name of the machine where the Hive service is running), *Port number* (the port number of the machine where the Hive service is running), and *String size* (defaults to 100).

g) Click *OK*.

You can now browse and/or import metadata from the datastore through the adapter.

Then after building a data flow in a job, configure the Hive source and target object options.

Datastore [page 860]
Hadoop Hive Adapter Source [page 950]
Hadoop Hive Adapter Target [page 974]

3.12.3.3 About partitions

Data Services imports Hive partition columns the same way as regular columns. Partition columns display at the end of the table column list. The column attribute *Partition Column* identifies whether the column is partitioned.

When loading to a Hive target, you can select whether or not to use the *Dynamic partition* option on the *Adapter Target* tab of the target table editor. The partitioned data is evaluated dynamically by Hive when scanning the input data. If *Dynamic partition* is not selected, Data Services uses Hive static loading. All rows are loaded to the same partition. The partitioned data comes from the first row that the loader receives.

Hadoop Hive Adapter Target [page 974]

3.13 Reserved Words

3.13.1 About Reserved Words

The following words have special meanings in Data Services and therefore should not be used as names for work flows, data flows, transforms, or other design elements that you create. They should also not be used as user names when you create a Data Services repository. They are reserved with any combination of upper- and lower-case letters.

If you use reserved words you must put double quotation marks around them. For example:

```
"PRIMARY"
```

Reserved words appear in editor text areas in blue.

3.14 Glossary

access server	A real-time, request-reply message broker that collects message requests, routes them to a real-time service, and delivers a message reply within the user-specified time.
adapter	An external Data Services interface that is created using the Software Developer Kit or is prebuilt and purchased from SAP.
Administrator	A browser-based application running on the Data Services Management Console that allows you to schedule, execute, monitor batch jobs, and so on.
after-image	The values in an UPDATE row after the row changes, used for log-based changed-data capture (CDC) jobs.
alias	An alternate form or name.
ANKLink	An NCOALink option that provides additional data about moves that occurred in the previous months 19 through 48.
annotation	A note that you can attach to a workspace diagram to describe or explain job, work flow, or data flow.
application	A software program.
association matching	A method that uses the results of two or more match sets to find matches that could not be found within a single match set.
audit point	The object in a data flow where audit statistics are collected.
batch job	A set of objects that you can schedule and execute together.
batch project	A job that executes at a specific time and ends after all the data in the specific source is processed.
before-image	The values in an UPDATE row before the row changes, used for log-based changed-data capture (CDC) jobs.
best record	A record created by consolidating the most complete, accurate, and up-to-date data elements from matching records.
best record priority	A value used to designate data from a particular source as having more or less importance than other data.
Binary Large Object	A field whose data consists of such objects as bitmap graphics, images, OLE objects, and metafiles. See also blob.
blank penalty	A setting that assigns a lower priority to records in which a particular field is blank.
blob	A field whose data consists of such objects as bitmap graphics, images, OLE objects, and metafiles. See also Binary Large Object.
blueprint	A sample job that has already been set up to handle a common business problem.
break group	A subset of records that are more likely to match, and which consist of driver and passenger records. Fields commonly used for creating break groups are postcodes, account or Social Security numbers, or the first two positions (or characters) of the street name.

break key
A user-defined field used to create a break group.

bulk loading
The moving of large amounts of data into a database to achieve optimal performance.

CASS
A USPS certification that requires software vendors to go through a series of tests to prove that their software correctly codes addresses according to USPS requirements, and produces the required USPS reports. See also Coding Accuracy Support System.

CDC
The process of retrieving changes made to a production data source. This process consolidates units of work, ensures, data is synchronized with the original source, and reduces data volume in a warehouse environment. See also changed-data capture.

CDC checkpoint
A software feature that lets you restrict changed-data capture (CDC) subscription reads.

CDC datastore
A datastore that allows you to limit extracted data to changed data only, and connects a changed-data capture (CDC) table in a source databse to Data Services.

CDC subscription
An option on a source CDC table that defines the start and end of your data set, thereby allowing different data flows to extract data from the same table without corrupting data extracted by other data flows.

central repository
A storage mechanism that contains all information normally found in a local repository (definitions for each object in an application), but is optional and is shared by multiple users, who can check objects in and out of the repository.

changed-data capture
The process of retrieving changes made to a production data source. This process consolidates units of work, ensures, data is synchronized with the original source, and reduces data volume in a warehouse environment. See also CDC.

City directory
A file that is used by the USA Regulatory Address Cleanse transform when processing data from the U.S., and contains a table of city names, states, and ZIP Codes, organized by state and city.

classification
An indicator of the types of situations that apply to a word.

client/server
A distributed technology approach where the processing is divided by function. The server performs shared functions (such as managing communications and providing database services), while the client performs individual user functions.

Coding Accuracy Support System
A USPS certification that requires software vendors to go through a series of tests to prove that their software correctly codes addresses according to USPS requirements, and produces the required USPS reports. See also CASS.

Common Warehouse Model
A specification that enables interchange of data warehouse metadata between tools, platforms, and repositories in distributed heterogeneous environments. See also CWM.

compare buffer
A part of memory reserved for processing break groups (one break group at a time) in the Match or Associate transform. A larger buffer typically helps improve performance.

component
A major piece of the software.

conditional
A single-use object, available in work flows, that allows you to branch the execution logic based on the results of an expression. The conditional takes the form of an if/then/else statement.

connection string
A string version of the initialization properties needed to connect to a database, also known as a "DSN-less" connection. With a connection string you can easily store connection information or pass it between applications.

content type

The type of data in a field in your data source; helps you map your fields when you set up downstream transforms.

contribution value

A value you assign to a match criteria that represents the importance (or weight) you place on that criteria's data.

custom ABAP program

Software that extracts data from an SAP application using custom logic that is not currently supported by Data Services ABAP generation logic, and generates a data set that you use as a source in a data flow or an ABAP data flow.

custom function

A script you create to evaluate or make calculations on input values and produce a return value.

CWM

A specification that enables interchange of data warehouse metadata between tools, platforms, and repositories in distributed heterogeneous environments. See also Common Warehouse Model.

data collection

A collection of information that is sent between transforms.

data flow

A reusable object containing steps to define the transformation of information from source to target.

data record

A row of data that is constructed at run time.

Data Services engine

The core process that reads job information from the Data Services repository and sets up run-time processes that execute the job. The run-time processes extract, transform, and load relational and hierarchical data. The Job Server starts the Data Services engine to execute batch or real-time jobs.

Data Services repository

The database that contains information about a Data Services application. The repository contains information about defined reusable objects, and the metadata for sources and targets, transforms, and functions. The repository also contains the job history and runtime statistics information.

Data Services service

The process that ensures that the Access Server and the Job Server are running.

data set

Rows of data with a defined schema.

data source name

A parameter that provides connectivity for a Windows user to a database through an Open Database Connectivity (ODBC) driver. See also DSN.

data transformation

The phase of the data movement process that occurs between extraction and loading.

data transport

A step in an ABAP data flow that defines a target to store the data set extracted during the flow. You can locate the target file on the SAP Application server or in a location accessible to both the SAP Application server and to Data Services across a network.

data type

The format used to store a value, which can imply a default format for displaying and entering the value.

data validation

The process of defining rules to which correct data should conform. In Data Services you define these rules in the Validation transform.

database link

A communication path from one database server to another.

Database Management System

A software application that builds and maintains database tables. See also DBMS.

DataConnector

An operator instance used to read data files generated by Data Services when performing bulk loading using the Teradata Warehouse Builder.

datastore	A logical channel connecting Data Services to a source or target application.
datastore configuration	The definition of a connection to a particular database from a single datastore.
DBMS	A software application that builds and maintains database tables. See also Database Management System.
debug mode	A state of operation that allows you to diagnose errors while executing a job using the interactive debugging features in the Designer.
degree of parallelism	A property of a data flow that defines how many times each transform defined in the data flow replicates for use on a parallel subset of data. See also DOP.
delimiter	A character sequence used to separate column, row, and text data. To separate columns, a delimiter can be a tab, semicolon, comma, space, or any character sequence. To separate rows of data, a delimiter can be a {new line} or any other character sequence. To denote the start and end of a character string, a delimiter can be single quotation marks ('), double quotation marks ("), or {none}.
Delivery Point Barcode	A form of Postnet barcode, consisting of 62 bars and based on the combination of ZIP Code, ZIP+4, DPBC, and a check digit. See also DPBC.
Delivery Point Validation	A technology that assists you in validating the accuracy of your address information with the USA Regulatory Address Cleanse transform. With DPV you can identify addresses that are undeliverable as addressed and whether an address is a Commercial Mail Receiving Agency (CMRA). See also DPV.
Designer	A graphical user interface that allows you to design and test Data Services jobs.
diacritical character	A character that contains an accent, dieresis (umlaut), tilde, cedilla, or other distinguishing marks (for example, ä or Ç). You can choose to have standardized data with these types of characters. The application uses the Latin-1 code page for assigning these accents.
dictionary	Relational database that contains a lexicon of words and phrases that the data cleansing packages and the Data Cleanse transform use to identify, parse, and standardize data.
directional	A component of the address line that indicates direction, such as North in "211 North 115th St".
disambiguation	The process of resolving ambiguity.
discrete field	Input or output data that has separate fields for each piece of information, such as addresses and names.
discrete line format	Input source format in which pieces of data are parsed down to nearly the most distinct level. For example, a “first name” field would be discrete, whereas a “name” field that could contain first, middle, or last name information would not be discrete.
DOP	A property of a data flow that defines how many times each transform defined in the data flow replicates for use on a parallel subset of data. See also degree of parallelism.
DPBC	A form of Postnet barcode, consisting of 62 bars and based on the combination of ZIP Code, ZIP+4, DPBC, and a check digit. See also Delivery Point Barcode.
DPV	A technology that assists you in validating the accuracy of your address information with the USA Regulatory Address Cleanse transform. With DPV you can identify addresses

that are undeliverable as addressed and whether an address is a Commercial Mail Receiving Agency (CMRA). See also Delivery Point Validation.

drill down
To explore detailed data that was used in creating a summary level of data. How far you drill down depends on the granularity of the data in the warehouse.

driver record
A record that drives the comparison process. Driver records are part of a break group and are compared with passenger records to determine matches.

DSN
A parameter that provides connectivity for a Windows user to a database through an Open Database Connectivity (ODBC) driver. See also data source name.

dual address
A dual address occurs when a record contains two address lines. Two combinations are typical: • PO box and street address: 1000 Main Street, Suite 51 / PO Box 2342 • Rural route or Highway Contract and street address: RR 1 Box 345 / 12784 Old Columbus Road

dual names
Two names included on an address line, such as John and Jane Doe.

Early Warning System
A solution for matching valid delivery points that have been created between updates to the national ZIP+4 directory. EWS uses four months of rolling data found in an intermediate directory that is updated weekly with data from the USPS. See also EWS.

eLOT
A sorting sequence for US mail in which ZIP+4 codes are arranged in the order that they are served by the mail carrier. Compare with Line of Travel (LOT). See also Enhanced Line of Travel.

embedded data flow
A data flow that is called from inside another data flow.

Enhanced Line of Travel
A sorting sequence for US mail in which ZIP+4 codes are arranged in the order that they are served by the mail carrier. Compare with Line of Travel (LOT). See also eLOT.

enterprise application
Software that enables businesses to execute and optimize business and IT strategies in domains like Enterprise Resourcew Planning (ERP), Customer Relationship Management (ERM), or Supply Chain Management (SCM).

enterprise resource planning system
An enterprise application from which Data Services can extract data. See also ERP system.

ERP system
An enterprise application from which Data Services can extract data. See also enterprise resource planning system.

EWS
A solution for matching valid delivery points that have been created between updates to the national ZIP+4 directory. EWS uses four months of rolling data found in an intermediate directory that is updated weekly with data from the USPS. See also Early Warning System.

exception
An error that occurs while executing a job.

expression
A combination of variables, parameters, constants, and functions linked by operation symbols and any required punctuation that describe a rule for calculating a value.

fault code
A numeric value that is assigned to a record after the USA Regulatory Address Cleanse transform validation process that signifies that the particular record was not successfully validated. Each numeric value represent a different type of fault.

file format
A description of how data is or should be organized in a file Data Services reads from or loads to. A file format can be specific to a single file or generic for many files.

Forward Sortation Area	The first three characters of a Canadian alphanumeric postal code, such as K1A in the postal code for Canada Post's Ottawa headquarters, K1A 0B1. See also FSA.
FSA	The first three characters of a Canadian alphanumeric postal code, such as K1A in the postal code for Canada Post's Ottawa headquarters, K1A 0B1. See also Forward Sortation Area.
function	A program that operates on values that are passed to it.
functional area	A virtual group of jobs that relate to the same business function, such as Human Resources or Customers.
gather	To recombine terms, such as alphanumeric terms that you would look up together in the dictionary.
gender	A code that indicates the likelihood of a record being a certain sex. This code is derived from the name and has five possible values: strong male, strong female, weak male, weak female, ambiguous, and unassigned.
generated field	A field that is produced on output by a transform, such as a postcode field generated by the Global Address Cleanse transform.
global suggestion list	A method of completing and populating addresses with minimal data, or offering suggestions for possible matches. This address-entry system is ideal in call center environments or any transactional environment where data cleansing is necessary at the point of entry, and a human being is available to choose one of the suggestions.
host name	A computer's network name (or IP address).
hybrid format	An arrangement for records in which some fields are discrete whereas others are in a multiline format.
impact and lineage analysis	A category of reports on the Management Console that provides end-to-end impact and lineage analysis of Data Services tables and columns and SAP BusinessObjects Enterprise objects such as universes, business views, and reports.
import	The process of acquiring information for the Data Services repository.
input source	The records in a database or file that you want the application to process.
interactive debugger	A Designer feature that allows you to step through the data of a job one row at a time using filters and breakpoints on a line.
interface	A type of interaction with Data Services which is either internal (allows you to create datastore connections to natively- supported applications), or external (allows Data Services to to communicate with information exchange technologies such as Web Services and MQ queries).
intersource match	A match between records of different sources.
job	The unit of work that can be scheduled independently for execution by the Administrator. Jobs are special work flows that can be scheduled for execution, but cannot be called by other work flows or jobs.
Job Server	The Data Services software that receives requests from the Designer and the Administrator to start and stop jobs.
join rank	A value given to or calculated for all data sets in a data flow by which the application determines which source to read first when assembling the data set in a join.

LACS	A database of addresses that have been permanently converted, usually due to 911 emergency system implementation. The changes often consist of conversion from rural-style addressing to standardized, city-style addressing, or renumbering of existing city-style addresses. See also Locatable Address Conversion System.
lastline	The address information that contains components such as the locality, region, postcode, and sometimes country name.
LDU	The last three characters of a Canadian alphanumeric postal code. Compare with Forward Sortation Area (FSA). See also Local Delivery Unit.
legacy system	An information or transaction processing system used to store data such as bank balances, inventories, payroll, and manufacturing parts.
license-controlled feature	A feature that is enabled or disabled depending on the product license.
line	The visual connection between objects in a workspace diagram which shows the left-to-right flow path for data moving between those objects during job execution.
Line of Travel	A sorting sequence for US mail in which ZIP+4 codes are arranged in the order that they are served by the mail carrier. See also LOT.
linked datastores	The datastores in a database link relationship.
Local Delivery Unit	The last three characters of a Canadian alphanumeric postal code. Compare with Forward Sortation Area (FSA). See also LDU.
locale	The identification of a record's world region, which controls the format of data when it is stored, processed, or displayed.
locality	A part of the address line of a record that usually refers to the city or town, but which in some countries, such as the United Kingdom, can extend to include the district.
Locatable Address Conversion System	A database of addresses that have been permanently converted, usually due to 911 emergency system implementation. The changes often consist of conversion from rural-style addressing to standardized, city-style addressing, or renumbering of existing city-style addresses. See also LACS.
lookup table	A table that contains data that other tables can reference with lookup functions that return one or more output columns.
LOT	A sorting sequence for US mail in which ZIP+4 codes are arranged in the order that they are served by the mail carrier. See also Line of Travel.
mail piece unit	A version identifier for printers, representing the unique characteristics of a portion of a mailing.
mapped field	A data-quality-specific field used to tell a data quality transform how to process the data in that field.
master record	The first record in a match group.
match	A pair or group of records that are found to be identical, based on the criteria you set.
match criteria	The options and rules you define for how a match key is used to find records in your data.
match group	A collection of records, consisting of a master and subordinate records, that are found to be matching with each other.

match set	A group of options and rules used to perform comparisons on data.
memory datastore	A datastore connection to an in-memory database.
memory table	An internal table used to store a data set in memory while a job runs.
Meta Integration Model Bridge	A Windows stand-alone utility that converts metadata models among design tool formats. See also MIMB.
metadata	Information acquired and maintained to describe tables in source and target databases.
Metropolitan Statistical Area	An aggregation of counties by the US Office of Management and Budget used for statistical purposes. See also MSA.
MIMB	A Windows stand-alone utility that converts metadata models among design tool formats. See also Meta Integration Model Bridge.
MSA	An aggregation of counties by the US Office of Management and Budget used for statistical purposes. See also Metropolitan Statistical Area.
multiline	A database record format in which address data is not consistently located in the same arrangement in all records.
multiline field	Input or output data that has certain address and name data combined in one field.
NANP	A system for structuring telephone numbers that is shared by 19 North American countries including the United States and Canada. See also North American Numbering Plan.
NCOALink	A USPS product consisting of a secured database of approximately 160 million change of address (COA) records consisting of the names and addresses of individuals, families, and businesses who have filed a change of address with the USPS.
nested data	Information in one table that is related to a single row in another table.
noise word	A word that is meaningless to the matching process.
normal source	An origin of records that the application should consider to be good, eligible records.
North American Numbering Plan	A system for structuring telephone numbers that is shared by 19 North American countries including the United States and Canada. See also NANP.
object	Any item that you create in the Data Services Designer.
object definition	The options that describe the operation of an object, which are viewable in the workspace when you open the object.
object dependent	The state of being associated beneath another object. Any object under the highest level object in the hierarchy is object dependent.
object library	A directory management system that provides access to reusable objects.
object version	An instance of an object. Each time you add or check in an object to the central repository, Data Services creates a new version of the object.
operation code	A flag associated with a row in a data set that indicates the status of the data in the row, such as INSERT, UPDATE, DELETE, and NORMAL.
operational dashboard	A type of report on the Management Console that visually displays the status and performance of job and data flow executions.

Option Editor	A feature in Data Services' Data Quality transform editor through which you can change the value for each option within the transform.
Option Explorer	A pane in the Associate, Match, and User-Defined transform editors which shows a list of the option groups within a transform.
option group	A set of choices that control various business rules for a transform.
other source	In a Match transform, data that should be treated as transparent, such as seed sources, and as such are not counted in determining how to characterize a match group.
parameter	A value passed to a work flow or data flow when that flow is called.
partition	The division of table data into sets based on criteria such as a range or list of values in each row.
passenger record	A row of data in a break group that is compared against the driver record.
pattern file	A plain text file that contains user-defined patterns and is used by the Data Cleanse transform, and can be edited by any text editing program.
PMB	A postal delivery location similar to a post-office box but which is hosted by a private company. See also Private Mail Box.
postal code	A system of letters and/or digits used for sorting mail, such as the numeric ZIP Code used in the U.S. and the alphanumeric FSA LDU system used in Canada.
postcode move	A valid postcode that has been split or moved, so only a portion of the the area that had been covered by the one postcode now has two or more postcodes, including the original one, for the same area.
postcode1	The postal code or five-digit ZIP Code (USA).
postcode2	The secondary part of a postal code, such as the "4051" in the United States postcode "54601-4051".
primary entry	A word or phrase in the dictionary that the data cleansing packages and Data Cleanse transform use to identify, parse, and standardize data.
Private Mail Box	A postal delivery location similar to a post-office box but which is hosted by a private company. See also PMB.
project	The highest-level object in the Designer window, which provides you with a way to organize the other objects you create in Data Services.
projection	An operation within a SELECT statement that the software can push to the database; the subset of columns that you map on the Mapping tag in the query editor.
property	An item of information that describes an object, such as its name, description, or date on which it was created.
query transform	A data transformation object that creates a data set that satisfies conditions you specify.
real-time job	A job that executes on-demand as a "request-response" system.
reference file	A file of address data that Data Services can use to match, assign, standardize, and verify addresses.
relational data	A data set in which data in each column contains a scalar value.

Remote Function Call server
A server that allows third-party programs, including SAP Applications and SAP NetWeaver Business Warehouse, to schedule and initiate Data Services jobs and return the results to Data Services. See also RFC server.

Remote Function Call server interface
The node on the Administrator application of the Data Services Management Console where you configure SAP connections to load data into or read data from an SAP NetWeaver Business Warehouse system. See also RFC server interface.

repository
A set of tables that hold user-created and predefined system objects, source and target metadata, and transformation rules.

request/acknowledge operation
An operation that executes a remote HTTP service in the Request Acknowledge mode, wherein acknowledgement is sent only if the operation is successful.

request/reply operation
An operation that sends a request and then awaits notice of the request's result.

reusable object
An object that can be defined, stored, and reused independent of other objects, and is accessible from the object library.

RFC server
A server that allows third-party programs, including SAP Applications and SAP NetWeaver Business Warehouse, to schedule and initiate Data Services jobs and return the results to Data Services. See also Remote Function Call server.

RFC server interface
The node on the Administrator application of the Data Services Management Console where you configure SAP connections to load data into or read data from an SAP NetWeaver Business Warehouse system. See also Remote Function Call server interface.

rule file
A text file that controls how the application parses data.

rule matching
The process of comparing token classifications against defined rules.

sample size
The number of rows to display in the View Data feature.

sampling rate
The number of rows processed after which Data Services writes information to the monitor log file and updates job events.

sampling rows
The parameter that specifies the frequency with which the Management Console Profiler samples data, beginning with the first row of the specified number of sampling rows.

script
A step in a job or work flow that allows you to calculate values to pass to other parts of the job or work flow by calling functions, executing if-then-else statements, and assigning values to variables.

secondary information
Data that helps the application determine how to process a string in various scenarios.

segment
The format with which the data records of IDocs are interpreted.

server group
An association of Job Servers on different computers that can automatically measure resource availability, and distribute batch jobs or part of a job to the Job Server with the lightest load at run time.

similarity score
A percentage that indicates how much two fields or values are considered alike, which is calculated by the application after the comparison process.

single use object
An object that is defined only within the context of one job or one data flow.

smart editor

A flexible Data Services tool used for creating scripts, expressions, and custom functions without having to type the names of existing elements like column, function, and variable names.

snowbird

An informal term for a person with multiple residences who typically changes where he or she resides according to the season.

source group

A collection of data that you can use to prepare a second set of match statistics, combining the statistics for two or more regular sources.

source record

A row that contains the data you want to use for updating or creating your best record.

standards

Business rules that define how Data Cleanse will apply capitalization or other output formatting to data.

star schema

A database design used to format data in a data mart, and which is based on a single fact table to which any number of dimensional tables may be joined.

step

An object that is part of the definition of a work or data flow, which is represented by an icon in the flow diagram, and is connected to other steps to indicate the flow of data through the data flow, or the order of execution in the work flow.

street address

A postal delivery location that consists of a street name and house number.

subordinate record

Any record in a match group other than the master record.

substitution parameter

A text string "alias" that you can use within your job and transforms, and is defined in a substitution parameter configuration. At runtime, that parameter is replaced with its value anywhere it is used in your job.

substitution parameter configuration

The definition of the substitution parameters used throughout your job in a particular run-time environment.

suggestion list

A group of potential matches presented to the user for selection of the correct one.

suppression source

An origin of data that contains records of information that should be excluded from other output destinations.

table

Database information that is organized into rows and columns that the software reads data from or loads data into.

target

The object into which the application loads extracted and transformed data in a data flow.

TDPID

The server name Data Services uses when loading with the bulk loader option. See also Teradata Director Program ID.

Teradata Director Program ID

The server name Data Services uses when loading with the bulk loader option. See also TDPID.

territory

The locale value for a geographical location (usually the country) where a local language is used.

thread

The instance of the program running on behalf of a process.

tokenization

The creation of tokens, which assigns meaning to each piece of word that results from hyphenation in the Data Cleanse dictionary.

transform	A step in a data flow that acts on a data set, and is available through the object library in three cateogories: Data Integrator, Data Quality, and Platform.
try/catch block	A combination of a try object and one or more catch objects that define alternate execution paths in case an error occurs during the execution of a job.
unique identifier	In a Data Quality transform, an ID that is unique to a record or group of matching records, and is sequential, static, and will not change when records are updated or re-processed through the application.
unique record	A record that does not have any matching or subordinate records and so does not belong to any match group after the matching process is complete.
web service request	Any message sent from a web client that requires processing by a real-time job.
web services	A platform on which multiple applications can communicate with each other even though constructed in different languages and on different platforms.
weighted scoring	A method of comparison that lets you use values to place more or less importance on various match criteria during the matching process.
work flow	A reusable object that contains steps defining the order of job execution.
workspace	The area on the Designer window where you can manipulate system objects and graphically assemble data movement processes.
Z4Change	A directory of all U.S. ZIP Codes and ZIP+4 Codes, in which those codes that have changed in the last 12 months are flagged.
ZCF	A directory that is used by the USA Regulatory Address Cleanse transform when processing data from the U.S., and contains a table of city names, states, and ZIP Codes, organized by ZIP Code. See also ZIP City File.
ZIP City File	A directory that is used by the USA Regulatory Address Cleanse transform when processing data from the U.S., and contains a table of city names, states, and ZIP Codes, organized by ZIP Code. See also ZCF.
ZIP plus 4	A postal code that consists of both the USPS's 5-digit ZIP Code and the 4-digit add-on code.

4 Management Console Guide

4.1 Introduction

4.1.1 Welcome to SAP Data Services

4.1.1.1 Welcome

SAP Data Services delivers a single enterprise-class solution for data integration, data quality, data profiling, and text data processing that allows you to integrate, transform, improve, and deliver trusted data to critical business processes. It provides one development UI, metadata repository, data connectivity layer, run-time environment, and management console—enabling IT organizations to lower total cost of ownership and accelerate time to value. With SAP Data Services, IT organizations can maximize operational efficiency with a single solution to improve data quality and gain access to heterogeneous sources and applications.

4.1.1.2 Documentation set for SAP Data Services

You should become familiar with all the pieces of documentation that relate to your SAP Data Services product. The latest Data Services documentation can be found on the *SAP Help Portal*.

Document	What this document provides
Adapter SDK Guide	Information about installing, configuring, and running the Data Services Adapter SDK
Administrator Guide	Information about administrative tasks such as monitoring, lifecycle management, security, and so on.
Customer Issues Fixed	Information about customer issues fixed in this release. Note In some releases, this information is displayed the Release Notes.
Designer Guide	Information about how to use Data Services Designer.
Documentation Map	Information about available Data Services books, languages, and locations.
Installation Guide for Windows	Information about and procedures for installing Data Services in a Windows environment.
Installation Guide for UNIX	Information about and procedures for installing Data Services in a UNIX environment.
Integrator Guide	Information for third-party developers to access Data Services functionality using web services and APIs.

Document	What this document provides
Master Guide	Information about the application, its components and scenarios for planning and designing your system landscape. Information about SAP Information Steward is also provided in this guide.
Management Console Guide	Information about how to use Data Services Administrator and Data Services Metadata Reports.
Performance Optimization Guide	Information about how to improve the performance of Data Services.
Reference Guide	Detailed reference material for Data Services Designer.
Release Notes	Important information you need before installing and deploying this version of Data Services.
Technical Manuals	A compiled, searchable, "master" PDF of core Data Services books: ● *Administrator Guide* ● *Designer Guide* ● *Reference Guide* ● *Management Console Guide* ● *Performance Optimization Guide* ● *Integrator Guide* ● *Supplement for J.D. Edwards* ● *Supplement for Oracle Applications* ● *Supplement for PeopleSoft* ● *Supplement for Salesforce.com* ● *Supplement for Siebel* ● *Supplement for SAP* ● *Workbench Guide*
Text Data Processing Extraction Customization Guide	Information about building dictionaries and extraction rules to create your own extraction patterns to use with Text Data Processing transforms.
Text Data Processing Language Reference Guide	Information about the linguistic analysis and extraction processing features that the Text Data Processing component provides, as well as a reference section for each language supported.
Tutorial	A step-by-step introduction to using Data Services.
Upgrade Guide	Information to help you upgrade from previous releases of Data Services and release-specific product behavior changes from earlier versions of Data Services to the latest release.
What's New	Highlights of new key features in this SAP Data Services release. This document is not updated for support package or patch releases.
Workbench Guide	Provides users with information about how to use the Workbench to migrate data and database schema information between different database systems.

In addition, you may need to refer to several Supplemental Guides.

Document	What this document provides
Supplement for SAP	Information about interfaces between Data Services, SAP Applications, SAP Master Data Services, SAP NetWeaver BW, and SAP Master Data Services.
Supplement for SuccessFactors	Information about interfaces between Data Services and SuccessFactors.
Supplement for Salesforce.com	Information about how to install, configure, and use the SAP Data Services Salesforce.com Adapter Interface.
Supplement for J.D. Edwards	Information about interfaces between Data Services and J.D. Edwards World and J.D. Edwards OneWorld.
Supplement for Oracle Applications	Information about the interface between Data Services and Oracle Applications.
Supplement for PeopleSoft	Information about interfaces between Data Servicesand PeopleSoft.
Supplement for Siebel	Information about the interface between Data Services and Siebel.

We also include these manuals for information about SAP BusinessObjects Information platform services.

Document	What this document provides
Information platform services Administrator Guide	Information for administrators who are responsible for configuring, managing, and maintaining an Information platform services installation.
Information platform services Installation Guide for UNIX	Installation procedures for SAP BusinessObjects Information platform services on a UNIX environment.
Information platform services Installation Guide for Windows	Installation procedures for SAP BusinessObjects Information platform services on a Windows environment.

4.1.1.3 Accessing documentation

You can access the complete documentation set for SAP Data Services in several places.

4.1.1.3.1 Accessing documentation on Windows

After you install SAP Data Services, you can access the documentation from the Start menu.

1. Choose *Start* > *Programs* > *SAP Data Services 4.2* > *Data Services Documentation* > *All Guides* .
2. Click the appropriate shortcut for the document that you want to view.

4.1.1.3.2 Accessing documentation on UNIX

After you install SAP Data Services, you can access the documentation by going to the directory where the printable PDF files were installed.

1. Go to `<LINK_DIR>/doc/book/en/`.
2. Using Adobe Reader, open the PDF file of the document that you want to view.

4.1.1.3.3 Accessing documentation from the Web

You can access the complete documentation set for SAP Data Services from the SAP Business Users Support site.

To do this, go to *http://help.sap.com/bods*.

You can view the PDFs online or save them to your computer.

4.1.1.4 SAP information resources

A global network of SAP technology experts provides customer support, education, and consulting to ensure maximum information management benefit to your business.

Useful addresses at a glance:

Address	Content
Customer Support, Consulting, and Education services *http://service.sap.com/*	Information about SAP support programs, as well as links to technical articles, downloads, and online forums. Consulting services can provide you with information about how SAP can help maximize your information management investment. Education services can provide information about training options and modules. From traditional classroom learning to targeted e-learning seminars, SAP can offer a training package to suit your learning needs and preferred learning style.
Product documentation *http://help.sap.com/bods/*	SAP product documentation.
Supported Platforms (Product Availability Matrix) *https://service.sap.com/PAM*	Get information about supported platforms for SAP Data Services. Use the search function to search for Data Services. Click the link for the version of Data Services you are searching for.
SAP Data Services Community Network *http://scn.sap.com/community/data-services*	Get online and timely information about SAP Data Services, including forums, tips and tricks, additional downloads, samples, and much more. All content is to and from the community, so feel free to join in and contact us if you have a submission.
Blueprints *http://scn.sap.com/docs/DOC-8820*	Blueprints for you to download and modify to fit your needs. Each blueprint contains the necessary SAP Data Services project, jobs, data flows, file formats, sample data, template

Address	Content
	tables, and custom functions to run the data flows in your environment with only a few modifications.
SAPTerm *https://portal.wdf.sap.corp/go/sapterm*	SAP's terminology database, the central repository for defining and standardizing the use of specialist terms.

4.1.2 Overview of this guide

4.1.2.1 About this guide

The guide includes information about the SAP Data Services Management Console, a collection of Web-based applications for administering Data Services jobs and services, viewing object relationships, evaluating job execution performance and data validity, and generating data quality reports.

You can install the Management Console on a separate computer from other Data Services components. It runs on your web application server. The Management Console is written in Java and uses a JDBC connection to repositories.

The Management Console includes the following applications:

- *Administrator*
  Use to manage your production environment including batch job execution, real-time services, Web services, adapter instances, server groups, central and profiler repositories, and more.
- *Impact and Lineage Analysis*
  Use to analyze the end-to-end impact and lineage for Data Services tables and columns and SAP BusinessObjects Business Intelligence platform objects such as universes, business views, and reports.
- *Operational Dashboard*
  Use to view dashboards of job execution statistics to see at a glance the status and performance of your job executions for one or more repositories over a given time period.
- *Data Validation Dashboard*
  Use to evaluate the reliability of your target data based on the validation rules you created in your batch jobs to quickly review, assess, and identify potential inconsistencies or errors in source data.
- *Auto Documentation*
  Use to view, analyze, and print graphical representations of all objects as depicted in the Designer including their relationships, properties, and more.
- *Data Quality Reports*
  Use to view and export reports for batch and real-time jobs such as job summaries and data quality transform-specific reports.

4.1.2.2 Who should read this guide

This and other SAP Data Services documentation assume the following:

- You are an application developer, consultant or database administrator working on data extraction, data warehousing, data integration, or data quality.
- You understand your source and target data systems, DBMS, legacy systems, business intelligence, and messaging concepts.
- You understand your organization's data needs.
- You are familiar with SQL (Structured Query Language).
- If you are interested in using this software to design real-time processing, you are familiar with:
    - DTD and XML Schema formats for XML files
    - Publishing Web Services (WSDL, REST, HTTP/S and SOAP protocols, etc.)
- You are familiar with SAP Data Services installation environments: Microsoft Windows or UNIX.

4.2 Logging into the Management Console

When you log in to the Management Console, you must log in as a user defined in the Central Management Server (CMS).

1. Navigate to the Management Console address in a supported web browser:

   ```
   http://<hostname>:28080/DataServices
   ```

   where **<hostname>** is the name of the computer hosting the web application server.

   > i Note
   >
   > If you are logged in to the Designer, you can also access the Management Console home page in several ways:
   >
   > - From the Start page, click *Data Services Management Console*.
   > - From the *Tools* menu, click *Data Services Management Console*.
   > - Click the *Data Services Management Console* tool bar icon.

2. Enter your user credentials for the CMS.
    - *System*
      Specify the server name and optionally the port for the CMS.
    - *User name*
      Specify the user name to use to log into CMS.
    - *Password*
      Specify the password to use to log into the CMS.
    - *Authentication*
      Specify the authentication type used by the CMS.
3. Click *Log on*.
   The software attempts to connect to the CMS using the specified information. When you log in successfully, the list of local repositories that are available to you is displayed.

The Management Console home page opens.

4.2.1 Management Console navigation

After logging in to the Management Console and launching one of the applications, the application name appears under the Management Console banner.

The upper-right side of the main window includes the following links:

- *Home*
  Click to return to the Management Console home page (for example, to select another application).
- *Settings*
  The metadata reporting applications also include a Settings control panel for changing a variety of options depending on the selected application.
- *Logout*
  Click to exit the application and the Management Console and return to the login page.
- Help icon
  Opens the Management Console Guide.

As you navigate around the applications, notice that the top of the right pane often displays a “bread crumb” path to indicate where you are in the application. Depending on the page displayed, sometimes you can click on the bread crumbs to navigate to a different part of the application.

The Administrator, Impact and Lineage Analysis, and Auto Documentation applications also use a navigation tree in the left pane.

Management Console sessions time out after 120 minutes (2 hours) of inactivity.

4.3 Administrator

This section describes the Administrator and how to navigate through its browser-based, graphical user interface.

Use the Administrator to:

- Set up users and their roles
- Add connections to Access Servers and repositories
- Access job data published for Web Services
- Schedule and monitor batch jobs
- Configure and monitor:
  - Access Server status
  - Real-time services
  - Client interfaces including SAP application client interfaces (to read IDocs) and message traffic moving in and out of an Access Server
  - Adapter instances (a prerequisite for creating adapter datastores)

Related Information

Logging into the Management Console [page 1867]

Administrator navigation [page 1869]

4.3.1 Administrator navigation

The layout of the Administrator consists of a window with a navigation tree on the left and pages with tabs on the right.

4.3.1.1 Navigation tree

The navigation tree is divided into several nodes, including:

- Status
- Batch
- Real-Time
- Web Services
- SAP Connections
- Server Groups
- Profiler Repositories
- Management

> Note
>
> The nodes displayed depend on the permissions granted to the user you use to log in to the Management Console. For example, the Profiler Repositories node only appears if you have access to view or manage a profiler repository, as defined in the Central Management Console (CMC).

4.3.1.1.1 Status node

When the Administrator opens, it displays the Status page. The Status page displays the status of the following items (after you have connected them to the Administrator). The red, green, and yellow icons indicate the overall status of each item based on the jobs, services, and other objects they support.

- *Batch*
  Contains the name of the repository associated with the Job Server on which you run the batch jobs. To see batch jobs status, connect the repository to the Administrator.
  Click the repository name to display a list of batch jobs and their status.
- *Real-Time*
  Contains the name of the Access Servers associated with a real-time service. To see real-time jobs status, connect the Access Server to the Administrator.
  Click the Access Server name to display a list of real-time services and their client interfaces.
- *Adapters*

Contains the name of the repository associated with the Job Server on which you run the adapter. To see an adapter's status, enable a Job Server for adapters, and then add the repository associated with that Job Server.

- *Profiler*
  Contains the name of the repository associated with the Profiler Server. To see a profiler repository, connect the profiling repository to the Administrator.
  Click the repository name to display a list of profiler tasks and their status.

4.3.1.1.2 Batch node

After you add at least one repository connection to the Administrator, you can expand the *Batch* node. Then click a repository name to display its Batch Job Status page.

Click the *All Repositories* option to see jobs in all repositories connected to this Administrator (this node only appears if more than one repository is connected).

Each repository under the Batch node includes the following tabs:

- *Batch Job Status*
  View the status of the last execution and in-depth information about each job.
- *Batch Job Configuration*
  Configure execution and scheduling options for individual jobs.
- *Repository Schedules*
  View and configure schedules for all jobs in the repository.

Related Information

Batch Jobs [page 1890]

4.3.1.1.3 Real-Time node

After you add a connection to an Access Server in the Administrator, you can expand the *Real-Time* node. Expand an Access Server name under the Real-Time node to view the options.

Access Server node options	Description
Status	View status of real-time services and client interfaces supported by this Access Server. Control, restart, and set a service provider interval for this Access Server.
Real-time Services	View status for services and service providers, start and stop services, add or remove a service, configure Job Servers for a service.
Client Interfaces	View status for client interfaces, start and stop interfaces, add or remove an interface.

Access Server node options	Description
Logs - Current	View list of current Access Server logs, content of each log, clear logs, configure content of logs for display, enable or disable tracing for each Access Server.
Logs - History	View list of historical Access Server logs, view content of each log, delete logs.

Related Information

Real-Time Jobs [page 1905]
Real-Time Performance [page 1920]

4.3.1.1.4 Web Services node

Use this node to select real-time and batch jobs that you want to publish as Web service operations and to monitor the status of those operations. You can also use the node to set security for jobs published as Web service operations and view the WSDL file that SAP Data Services generates.

Related Information

Support for Web Services [page 1945]

4.3.1.1.5 Adapter Instances node

Use this node to configure a connection between SAP Data Services and an external application by creating an adapter instance and dependent operations. This is a prerequisite requirement for creating a datastore for adapters in the Designer.

After you create a datastore, import data through the adapter and create jobs. Then use this node to view the status of Adapter instances. Options are listed by Job Server under the Adapter Instance node.

Related Information

Adapters [page 1938]

4.3.1.1.6 Server Groups node

The Server Groups node allows you to group Job Servers that are associated with the same repository into a server group.

Use a server group if you want SAP Data Services to automatically use the Job Server on a computer with the lightest load when a batch job is executed. This functionality improves load balancing (throughput) in production environments and also provides a hot backup method. When a job is launched, if a Job Server is down, another Job Server in the same group executes the job.

Related Information

Server Groups [page 1885]

4.3.1.1.7 Profiler Repositories node

After you connect a profiler repository to the Administrator, you can expand the *Profiler Repositories* node. Click a repository name to open the Profiler Tasks Status page.

Related Information

Profile Server Management [page 1929]

4.3.1.1.8 Management node

The Management node contains the configuration options for the Administrator application. Before you can use some features of the Administrator, you must add connections to other SAP Data Services components using the Management node. For example, expand the management node and:

- Expand *Datastore* and click a repository to manage datastore configurations for that repository.
- Click *Access Servers* to add a connection to your Access Servers (for real-time jobs).

Related Information

Administrator Management [page 1873]

4.3.1.2 Pages

The top of the page indicates the currently selected node. Once you select a branch on the navigation tree to go to a page, use the tab row on the page to navigate further.

As you drill into various pages, a “bread crumb” trail often indicates where you are in the Administrator application. Depending on the page displayed, sometimes you can click on the bread crumb links to navigate to a different page.

A dark blue (shaded) tab signifies the active page. Click a light blue tab to go to that page. Some pages do not include a tab row.

4.3.2 Administrator Management

Use the Management features to configure the Administrator.

4.3.2.1 Managing database account changes

SAP Data Services uses several types of user accounts and associated passwords. For various reasons, database account parameters such as user names or passwords change. For example, perhaps your company's compliance and regulations policies require periodically changing account passwords for security.

4.3.2.1.1 Updating local repository login parameters

If the login information, particularly the password, for a repository has changed, SAP Data Services provides an optional password file that all schedules or exported execution commands use. In other words, the software uses this password file to store and update connection information in one location that multiple schedules or exported execution commands share for that repository.

> Note
>
> This description does not apply to central repositories.

The password file:

- Specifies the connection information for the repository.
- Can be stored in a central location for access by others who run jobs in that repository.
- Is created when you create or update a job schedule to minimize associated maintenance.

Related Information

Using a third-party scheduler [page 1899]

4.3.2.1.1.1 Updating the CMS connection information and use a password file

1. Expand the *Management* node.
2. Click *CMS Connection*.
3. Edit the connection information as necessary.
4. Click *Apply*.
5. Click *Generate password file* to create or update the password file.

   The default name and location of the file are `<DS_COMMON_DIR>\conf\repositoryname.txt`.

4.3.2.1.1.2 Updating job schedules

When database account information for your repository changes, the SAP Data Services job schedules associated with that account must also be updated. When you use a password file, the job schedules access it at runtime to automatically retrieve the updated account information.

Related Information

Scheduling jobs [page 1891]

4.3.2.1.2 Updating datastore connection parameters

If the information associated with a datastore connection changes, particularly passwords, you can update the changes using the Administrator.

> i Note
>
> Only users with Administrator role privileges can edit datastore parameters.

4.3.2.1.2.1 Editing the connection information for an individual configuration in a datastore

1. Select *Management* > *Datastore* , and select the repository that contains the datastore configuration that you want to edit.
2. Click the configuration name to configure.
3. Edit the enabled fields as necessary.

4. Click *Apply*. To return all fields to the last set of values applied, click *Reset*.

4.3.2.1.2.2 Editing the connection information for multiple configurations in a datastore

1. Select *Management* > *Datastore* , and select the repository that contains the datastore configurations that you want to edit.
2. Click the datastore name to configure.

   All configurations for that datastore display.
3. Edit the enabled fields as necessary.

   Click *More* to display the page for that individual configuration, which includes more options specific to it.
4. Click *Apply*. To return all fields to the last set of values applied, click *Reset*.

4.3.2.2 Configuring the report server

For each repository registered in the Central Management Console (CMC), a report server configuration is automatically created with default parameters. The Report Server Configuration node in the Management Console Administrator lets you edit the default parameters, including the location where job reports are written upon execution.

1. Select *Management* > *Report Server Configuration* > **`<repository>`** .
   The Report Server Configuration page opens and displays the report export configuration parameters. If the configuration has not yet been saved for the selected repository, the page displays default parameters.
2. Enter the appropriate configuration information.

Option	Description
Host name	The name of the machine that the report server is running on. By default, the current web application server name is used. Localhost is not a valid name.
Communication port	The port number of the machine that the report server is running on.
Export location	The path where the reports will be exported to. The default path is **`<DS_COMMON_DIR>`**`\DataQuality\reports\`. Upon execution, the repository name and job name folders are appended to the path. If the Overwrite option is not selected, a run ID folder is also appended to the path. i Note If you export reports to a location other than a local drive, such as a network drive, before you execute the job you must start the web application server with an account that has access rights to that location.
Export type	The format in which the reports can be exported (PDF or RTF).

Option	Description
Overwrite	Specifies whether existing reports will be overwritten when the reports are exported. If this option is not selected, the reports are exported to a subfolder with the run ID, which specifies a unique identification of an instance of the executed job.
Language	The supported language that the reports are generated in. Note that some reports, such as country-specific certification reports, are designed only to support English, so changing the option for those reports has no effect.

3. Click *Apply* to save the configuration. To return all fields to the last set of values applied, clicking *Reset*.
4. Verify that the security setting for this operation is disabled. Select *Administrator* > *Web Services* and click the *Web Services Configuration* tab. If the Export_DQReport operation is enabled (displays a check in the Session Security column), select the checkbox next to it, select *Disable Session Security* from the pull-down menu, and click the *Apply* button.

To generate and export all of the job reports to the specified location at runtime, select the Export Data Quality Reports option when you execute the job.

Related Information

Adding a job schedule [page 1892]

Reference Guide: Batch Job, Execution options [page 840]

Integrator Guide: To configure web service information using the Administrator [page 2221]

4.3.2.3 Adding Access Servers

The Administrator acts as a front end for Access Servers connected to it. Use the Administrator to:

- Configure real-time jobs as real-time services.
- Configure real-time services with service providers.
- Monitor Access Servers, real-time services, and service providers.

You first must connect an Access Server to the Administrator so that you can use the Administrator to create a real-time service from a real-time job. After a service starts, the Access Server brokers messages between external applications and SAP Data Services.

When a message request comes in, the Access Server communicates with the Job Server to get the repository data needed to run a real-time service and process the message. A reply comes back through the Access Server to the message originator and the Access Server log records the event, which you can monitor from the Administrator.

Use the Access Servers page to connect an Administrator to a repository.

1. Select *Management* > *Access Servers*.
2. Click *Add*.
3. Enter the following information.

Option	Description
Machine Name	Host name of the computer on which the Access Server is installed.
Communication Port	Port assigned to the Access Server in the Server Manager utility.

4. (Optional) Before attempting to register the Access Server with the Administrator, click *Ping* to see if the Access Server is available and exists on the computer and port you specified.
5. Click *Apply*.

   The Administrator registers the Access Server, validates the Access Server connection information, and displays the information on the Access Servers page.

To view a list of Access Servers connected to the Administrator, select *Management* > *Access Servers*.

The Access Servers page lists the Access Servers that are connected to the Administrator. You can also remove a connection to an Access Server from this page.

4.3.2.4 Setting the status interval

Use the Status Interval page to specify the time period for which the Administrator displays the status (using the red, yellow, and green status icons) on the Batch Job Status page.

1. Select *Management* > *Status Interval*.
2. On the Status Interval page, specify the time period.

   You can filter the information on this page in three ways:

   ○ By the last execution of each job
   ○ By number of days
   ○ By range of dates
3. Click *Apply*.

   The Administrator updates the list of job executions and the status interval displays in the table title on the Batch Job Status page. The following example lists the last execution of all jobs.

4.3.2.5 Exporting certification logs

When you run address cleanse jobs with the appropriate options set, you can generate reports to qualify for mailing discounts with certain countries' postal authorities. In the Management Console, you can generate the certification log files required for those certifications.

The Certification Logs page is available to users who are assigned either the Administrator or Operator role.

Related Information

Exporting NCOALink certification logs [page 1878]

Exporting New Zealand SOA certification logs [page 1879]
Exporting DSF2 certification log [page 1879]

4.3.2.5.1 Exporting NCOALink certification logs

Before you export the certification log, you must have run a job containing a USA Regulatory Address Cleanse transform with the NCOA certification options set appropriately. You must also configure your repository in the Central Management Console (CMC).

You can export the certification log for the data in one repository or in all repositories.

> ⚠ Caution
>
> If you select all repositories and have more than one connection to the same repository, your results may contain duplicate records.

1. Select *Management* ▸ *Certification Logs*, and select the repository that contains the certification log that you want to export.
2. Click the *NCOALink* tab.
3. Select the date range that contains the data that you want to export.
4. Select the NCOALink licensee ID for the logs that you want to export, or select All NCOA Licensee IDs.
5. Specify the location where the certification logs will be exported.

   > ℹ Note
   >
   > The location that you specify is relative to the web application server.

   To reset the export location to the default, click the *Reset* button. The default location is `<DS_COMMON_DIR>\DataQuality\certifications\CertificationLogs\<repository>\`.
6. If you want to overwrite an existing log file, click the *Overwrite* option.
7. Click the *Search* button. The page displays the available log files with the specified criteria. You can sort the log files using the column headers.

   The *Data Available* column has a Yes status when there is data for at least one of the log types (PAF, Bala, or CSL). A No status indicates that no data is available and will result in an empty log file for each type.
8. Select the log file(s) that you want to export or select the checkbox next to *Select All*.
9. Click the *Export* button.
   After the log file is exported, a confirmation message is displayed at the top of the page.

Reference Guide: Transforms, NCOALink options [page 1326]

4.3.2.5.2 Exporting New Zealand SOA certification logs

Before you export the certification log, you must have run a job containing a Global Address Cleanse transform with the New Zealand SOA certification options set appropriately. You must also configure your repository in the CMC.

You can export the certification log for the data in one repository or in all repositories.

> ⚠ Caution
>
> If you select all repositories and have more than one connection to the same repository, your results may contain duplicate records.

1. Select ▶ *Management* ▶ *Certification Logs* ◀, and select the repository that contains the certification log that you want to export.
2. Click the *New Zealand SOA* tab.
3. Select whether you want to export all certification log data that is in the selected repository or just the data within a specified date range.

   The Year list contains the current year and the two previous years, because certification logs are required to be retained for two years.
4. Specify the location where the certification logs will be exported.

   The default location is **<DS_COMMON_DIR>**`\DataQuality\certifications\CertificationLogs\`**<repository>**`\`. To reset the export location to the default, click the *Reset* button.
5. If you want to overwrite an existing log file, click the *Overwrite* option.
6. Click the *Export* button.
   After the log file is exported, a confirmation message is displayed at the top of the page.

Related Information

Reference Guide: Transforms, Report options for New Zealand [page 1217]

4.3.2.5.3 Exporting DSF2 certification log

Before you export the certification log, you must have run a job containing a USA Regulatory Address Cleanse transform with the DSF2 certification options set appropriately. You must also configure your repository in the Central Management Console (CMC).

You can export the certification log for the data in one repository or in all repositories.

⚠ Caution

If you select all repositories and have more than one connection to the same repository, your results may contain duplicate records.

1. Open the Data Services Management Console.
2. Click the *Administrator* icon.
3. Select ▶ *Management* ▶ *Certification Logs* ◀, and select the repository that contains the certification log that you want to export.
4. Click the *DSF2* tab.
5. Select the date range that contains the data that you want to export.
6. Select the DSF2 licensee ID drop list and select the logs that you want to export, or select All DSF2 Licensee IDs.
7. Specify the location where the certification logs will be exported.

   i Note

   The location that you specify is relative to the web application server.

   To reset the export location to the default, click the *Reset* button. The default location is **`<DS_COMMON_DIR>`**`\DataQuality\certifications\CertificationLogs\`**`<repository>`**`\`.
8. If you want to overwrite an existing log file, click the *Overwrite* option.
9. Click the *Search* button. The page displays the available log files with the specified criteria. You can sort the log files using the column headers.

   The *Data Available* column has a Yes status when there is data for the log file. A No status indicates that no data is available and will result in an empty log file.
10. Select the log file(s) that you want to export or select the checkbox next to *Select All*.
11. Click the *Export* button.
    After the log file is exported, a confirmation message is displayed at the top of the page.

4.3.3 Central Repository management

This section describes how to manage your secure central repositories using the Administrator.

When you log into the Management Console as a user with the appropriate rights, the name of each secure central repository appears under the *Central Repositories* node. Links under this node include:

- Users and groups
  Use to add, remove, and configure users and groups for secure object access.
- Reports
  Use to generate reports for central repository objects such as viewing the change history of an object.

> ℹ Note
>
> Before you can manage a secure central repository, it must be registered in the Central Management Console (CMC) and have appropriate user access applied.

Related Information

Administrator Guide: To register a repository in the CMC [page 52]

4.3.3.1 Setting up users and groups

The general process for setting up secure central repository users and groups is as follows:

1. Register the secure central repository in the Central Management Console (CMC).
2. Add central repository groups.
3. Associate users with groups.

The following sections describe these procedures.

Related Information

Designer Guide: Implementing Central Repository Security [page 805]

4.3.3.1.1 Adding a group to a central repository

Groups are specific to a secure central repository and are not visible in any other local or central repository.

1. Expand the *Central Repositories* node in the navigation tree and expand the repository to configure.
2. Click *Users and Groups*.
   The Groups and Users page displays.
3. On the Groups tab, click *Add*.
4. Type a *Name* for the group.
5. Optionally, type a *Description* for the group.
6. Click *Apply*.

The group appears on the Groups tab.

4.3.3.1.2 Adding users

1. Expand the *Central Repositories* node in the navigation tree and expand the repository to configure.
2. Click *Users and Groups*.
   The Groups and Users page displays.
3. Click the *Users* tab.
4. Click *Add*.

   On the Add/Edit User page, enter the following information.

Option	Description
User name	Select the user to add to the group. ℹ Note The list of available users includes all users defined in the Central Management Console (CMC).
Default group	The default central repository group to which the user belongs. You can change the default by selecting another from the drop-down list.
Status	Select a value from the drop-down list: ○ *Active* Enables the user's account for normal activities. ○ *Suspended* Select to disable the login for that user.
Description	Optionally, type a description for the user.

   The User is a member of list on the left shows the groups to which this user belongs.
5. Click *Apply*.

   Clicking *Reset* returns all fields to the last set of values applied.

4.3.3.1.3 To add or remove a user from a group

1. Expand the *Central Repositories* node in the navigation tree and expand the repository to configure.
2. Click *Users and Groups*.
3. Click the *Group* tab.
4. Click the group name.
5. The Members list on the left shows the users in this group.

   To add users to a group, click the user names from the Not Members list and click *Add Users*. Select multiple user names using the Ctrl or Shift keys.

   To remove a user from the group, select a user name from the Members list and click *Remove Users*. Select multiple user names using the Ctrl or Shift keys.

6. Click *Apply*.

   Clicking *Reset* returns all fields to the last set of values applied.

Alternately, click the *Users* tab, click the user name, and associate the user with one or more groups by selecting group names and adding or removing them.

Related Information

Designer Guide: Implementing Central Repository Security [page 805]

4.3.3.1.4 Deleting a group

1. Expand the *Central Repositories* node in the navigation tree, expand the repository to configure, and click *Users and Groups*.
2. Click the *Group* tab.
3. Select the check box for the group.
4. Click *Remove*.

> Note
>
> You cannot delete a group in the following instances:
>
> - It is the default group for any user (whether or not they are active).
> - It is the only group with full permissions for an object.
> - A member of the group is undertaking any central repository tasks using the Designer.

4.3.3.2 Viewing reports

You can generate reports about objects in a central repository such as which objects a user currently has checked out or the changes made to an object over a specified time frame.

Expand the central repository to view and expand the *Reports* link.

Related Information

Object state report [page 1884]

Change report [page 1884]

4.3.3.2.1 Object state report

Use the object state report to view details on one or more objects such as whether the objects are checked out and by whom.

Click the *Object State Report* link to display a search page with the following criteria (all fields are optional):

Option	Description
Object name	Type an object name. You can use the % symbol as a wildcard.
Object type	For example select *Batch job*, *Table*, or *Stored procedure*.
State	For example select *Checked out*.
User	Select a central repository user name.

Click *Search* to generate the report. The report has the following columns:

- *Object name*
- *Object type*
- *State*
- *User name*—The user account associated with the check-out or check-in.
- *Associated repository*—The repository to which the object belongs.
- *Time*—Check-out or check-in date and time.
- *Comments*—Comments added when user checked out or checked in the object.

Click the object name to display the object's history.

Related Information

Designer Guide: Viewing object history [page 822]

4.3.3.2.2 Change report

Use the change report to view the change history for an object over a specified period of time.

Click the *Change Report* link to display a search page with the following criteria:

- *Start date*—Enter a date or click the calendar icon to select a start date.
- *End date*—Enter a date or click the calendar icon to select an end date.
- *Object type*—Optionally select an object type; for example batch job, table, or stored procedure.
- *State*—Optionally select an object state; for example *Checked out*.
- *User*—Optionally select a central repository user name.

Click *Search* to generate the report. The report has the following columns:

- *Object name*
- *Object type*

- *State*
- *Version*—The version number of the object.
- *User name*—The user account associated with the check-out or check-in.
- *Associated repository*—The repository to which the object belongs.
- *Time*—Check-out or check-in date and time.
- *Comments*—Comments added when user checked out or checked in the object.

4.3.4 Server Groups

About this section

Use the Administrator to create and maintain server groups.

This section describes how to work with server groups.

Related Information

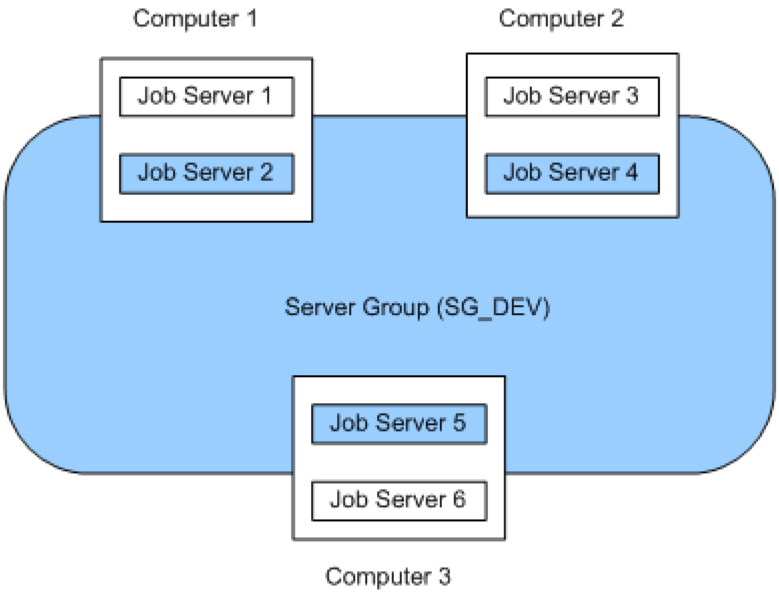
Server group architecture [page 1885]
Adding a server group [page 1888]
Editing and removing a server group [page 1889]
Monitoring Job Server status in a server group [page 1889]
Executing jobs using server groups [page 1890]

4.3.4.1 Server group architecture

You can group Job Servers on different computers into a logical SAP Data Services component called a server group. A server group automatically measures resource availability on each Job Server in the group and distributes scheduled batch jobs to the Job Server with the lightest load at runtime.

There are two rules for creating server groups:

- All the Job Servers in an individual server group must be associated with the same repository, which must be defined as a default repository. The Job Servers in the server group must also have:
  - Identical SAP Data Services versions
  - Identical database server versions
  - Identical locale
- Each computer can only contribute one Job Server to a server group.



The requirement that all Job Servers in a server group be associated with the same repository simply allows you to more easily track which jobs are associated with a server group. It is recommended that you use a naming convention for server groups that includes the name of the repository. For example, for a repository called DEV, a server group might be called `SG_DEV`.

On startup, all Job Servers check the repository to find out if they must start as part of a server group.

Compared to normal Job Servers, Job Servers in a server group each:

- Collect a list of other Job Servers in their server group
- Collect system load statistics every 60 seconds:
  - Number of CPUs (on startup only)
  - Average CPU load
  - Available virtual memory
- Service requests for system load statistics
- Accept server group execution requests

4.3.4.1.1 Load balance index

All Job Servers in a server group collect and consolidate system load statistics and convert them into a load balance index value for each Job Server. A Job Server's load balance index value allows the software to normalize statistics taken from different platforms. The Job Server with the lowest index value is selected to execute the current job. The software polls all Job Server computers every 60 seconds to refresh the load balance index.

4.3.4.1.2 Job execution

After you create a server group, you can select a server group to execute a job from the Designer's Execution Properties window or from the Execute Batch Job, Schedule Batch Job, and Export Batch Job pages in the Administrator.

When you execute a job using a server group, the server group executes the job on the Job Server in the group that is running on the computer that has the lightest load. The Administrator will also resynchronize a Job Server with its repository if there are changes made to the server group configuration settings.

You can execute parts of your job on different Job Servers in a server group. You can select the following distribution levels from the Designer's *Execution Properties* window or from the Execute Batch Job, Schedule Batch Job, and Export Execution Command pages in the Administrator:

- Job level
  A job can execute on an available Job Server.
- Data flow level
  Each data flow within a job can execute on an available Job Server.
- Sub data flow level
  A resource-intensive operation (such as a sort, table comparison, or table lookup) within a data flow can execute on an available Job Server.

Related Information

Performance Optimization Guide: Using grid computing to distribute data flows execution [page 2160]

4.3.4.1.3 Job launcher

The Job Launcher, exported as part of a job's execution commands, includes a specific command line option for server groups. You can use this option to change the Job Servers in a server group.

Related Information

About the job launcher [page 1903]

4.3.4.1.4 Working with server groups and Designer options

Some Designer options assume paths are relative to a Job Server. If your Job Servers are on different machines from your Designer (typically the case in a production environment) you must ensure that connections and directory paths point to the Job Server host that will run the job. Such options include:

- Source and target directories for files
- Bulk load directories
- Source and target connection strings to databases
- Path to repositories

When using server groups consider the additional layer of complexity for connections. For example, if you have three Job Servers in a server group:

- Use the same directory structure across your three host computers for source and target file operations and use relative paths for file names.
- Use the same connection strings to your databases for all three Job Server hosts.

If you use job distribution levels, the Job Servers in the server group must have:

- Identical SAP Data Services versions
- Identical database server versions
- Identical locale
- Identical operating systems

Thoroughly test the Job Server job options when working with server groups.

Adding a server group:

- In the Administrator, use the Server Groups node to create and add a server group.

4.3.4.1.4.1 Adding a server group

1. Select *Server Groups* > *All Server Groups* .
2. Click the *Server Group Configuration* tab.
3. Click *Add*.
4. Follow the instructions on the Add Server Group page to create a server group.
   - When you select a repository, all Job Servers registered with that repository display. You can create one server group per repository.
   - Notice that the Administrator provides a default server group name. It is the name of your repository with the prefix `SG_` (for server group). You can change the default name, however, labeling a server group with the repository name is recommended.
   - One Job Server on a computer can be added to a server group. Use the *Host and Port* column to verify that the Job Servers you select are each installed on a different host.
5. After you select the Job Servers for a server group, click *Apply*.

   The display returns to the Server Group Configuration page.

Related Information

Monitoring Job Server status in a server group [page 1889]

4.3.4.2 Editing and removing a server group

You can select a new set of Job Servers for an existing server group or remove a server group.

Trace messages are written for a change in Job Server status when you create, edit, or remove server groups.

- When a Job Server is upgraded to membership in a server group, the trace message is:
  `Collecting system load statistics, maintaining list of Job Server(s) for this server group, and accepting Job Server execution requests.`
- When a Job Server is downgraded out of a server group, the trace message is:
  `Deleting current system load statistics, and not collecting more. Not accepting job execution requests from a server group.`

4.3.4.2.1 Editing a server group

1. Select a server group from the navigation pane on the left.
2. In the *Server Groups* page, click the *Server Group Configuration* tab.
3. Select a new set of Job Servers.
4. Click *Apply*.

   Your edited server group is saved and the display returns to the *Server Groups Configuration* tab.

4.3.4.2.2 Removing a server group

1. In the *Server Groups* page, click the *Server Group Configuration* tab.
2. Select the check box for the server group(s) that you want to remove.
3. Click *Remove*.

> **Note**
>
> If you delete Job Servers from a repository in order to delete all the Job Servers in a server group, the Administrator displays an invalid status for the server group.

4.3.4.3 Monitoring Job Server status in a server group

If Job Servers are in a server group, you can view their status in the Administrator.

- To monitor the status of these Job Servers, select *Server Groups* > *All Server Groups*.
  The Server Group Status page opens. All existing server groups are displayed with the Job Servers they contain.

Indicator	Description
✅	A green icon indicates that a Job Server is running.
⚠	A yellow icon indicates that a Job Server is not running.
❌	A red icon indicates that the Job Server cannot connect to the repository.

If a server group contains Job Servers with a mix of green, yellow, or red indicators, then its indicator appears yellow:
Otherwise, a server group indicator displays the same color indicator as its Job Servers.

- To view the status for a single server group, select its name.

4.3.4.4 Executing jobs using server groups

After you create a server group, you can select a server group to execute a job from the Designer's *Execution Properties* window or from the Execute Batch Job and Schedule Batch Job pages in the Administrator.

Related Information

Batch Jobs [page 1890]

4.3.5 Batch Jobs

About this section

This section describes how to execute, schedule, and monitor batch jobs from the Administrator.

Before you can manage batch jobs with the Administrator, add repository connections.

4.3.5.1 Executing batch jobs

You can execute batch jobs from the Administrator if their repositories are registered in the Central Management Console (CMC) and your user has the appropriate rights.

1. Select *Batch* > **`<repository>`**.

   The Administrator opens the Batch Job Status page, which lists all of the jobs in the selected repository.

   To view jobs in all repositories from this page, select *Batch* > *All Repositories*. (The All Repositories option appears under the Batch Job node if more than one repository is connected to the Administrator.)

2. Click the *Batch Job Configuration* tab.
3. To the right of the job you want to run, click *Execute*.

   The Administrator opens the Execute Batch Job page.
4. Under *Enter Execution Options*, set the parameters for the execution of this job.
5. Under *Select Trace Options,* set the trace properties for this execution of the job.
6. Click *Execute* to run the job.

   The Administrator returns to the Batch Job Status page.

Related Information

Reference Guide: Objects, Batch Job, Parameters [page 840]
Reference Guide: Objects, Batch Job, Trace properties [page 843]

4.3.5.2 Scheduling jobs

There are three ways to manage job schedules.

Related Information

Using the job scheduler [page 1891]
Scheduling jobs in SAP BusinessObjects Business Intelligence platform [page 1897]
Using a third-party scheduler [page 1899]

4.3.5.2.1 Using the job scheduler

When you schedule batch jobs using the SAP Data Services job scheduler, it creates an entry in the operating system's scheduling utility on the Job Server computer. Windows uses the Task Scheduler and UNIX systems use the CRON utility. (Note that if you make changes to a schedule directly through these utilities, the job scheduler will not reflect those changes.)

Related Information

Adding a job schedule [page 1892]
Activating or deactivating one or more job schedules [page 1895]
Updating a job schedule [page 1895]

Removing a job schedule [page 1896]
Migration considerations [page 1896]

4.3.5.2.1.1 Adding a job schedule

1. Select *Batch* > **<repository>**.
2. Click the *Batch Job Configuration* tab.
3. For the job to configure, click *Add Schedule*.
4. On the *Schedule Batch Job* page, enter the desired options:

Option	Description
Enter a job schedule	
Schedule name	Enter a unique name that describes this schedule. Note You cannot rename a schedule after you create it.
Active	Select this box to enable (activate) this schedule, then click *Apply*. This option allows you to create several schedules for a job and then activate the one(s) you want to run.
Select a scheduler	
Data Services scheduler	Creates the schedule on the Job Server computer.
BOE scheduler	Creates the schedule on the selected Central Management Server (CMS).
Select scheduled day(s) for executing the job	
Calendar	From the drop-down list on the calendar, select: ○ *Day of Week* to schedule the job by the day of the week. You can select one or more days. Click again to deselect. ○ *Day of Month* to schedule the job by date. You can select one or more dates. Click again to deselect. If *Recurring* is selected, then the Administrator schedules this job to repeat every week or month on the selected day. Note that if you select multiple days of the week or month, the job will run on a recurring basis by default.
Select scheduled time for executing the jobs	
Once a day	Enter the time for the scheduler to start the job (hours, minutes, and either AM or PM).
Multiple times a day	○ For the Data Services scheduler, enter the time (hours, minutes, and either AM or PM) for the scheduler to repeatedly run the job

Option	Description
	for the selected duration (in minutes) at the selected interval (in minutes). ○ For the BOE scheduler, enter (in minutes) the repeat interval to run the job. You must also select all days in the calendar (for weekly or monthly). Select a time when all of the required resources are available. Typically, you want to schedule jobs to ensure they finish before the target database or data warehouse must be available to meet increased demand.
Select job execution parameters	
System configuration	Select the system configuration to use when executing this job. A system configuration defines a set of datastore configurations, which define the datastore connections. For more information, see “Creating and managing multiple datastore configurations” in the *Designer Guide*. If a system configuration is not specified, the software uses the default datastore configuration for each datastore. This option is a run-time property. This option is only available if there are system configurations defined in the repository.
Job Server or server group	Select the Job Server or a server group to execute this schedule.
Use password file	Select to create or update the password file that the job schedule accesses for current repository connection information. Deselect the option to generate the batch file with a hard-coded repository information. Note This option is disabled if you have not set up a CMS connection.
Enable auditing	Select this option if you want to collect audit statistics for this specific job execution. This option is selected by default. For more information about auditing, see “Using Auditing” in the *Designer Guide*.
Disable data validation statistics collection	Select this option if you do not want to collect data validation statistics for any validation transforms in this job. This option is not selected by default.
Enable recovery	Select this option to enable the recovery mode when this job runs.
Recover from last failed execution	Select this option if an execution of this job has failed and you want to enable the recovery mode.

Option	Description
Collect statistics for optimization	Select this option to collect statistics that the optimizer will use to choose an optimal cache type (in-memory or pageable). This option is not selected by default. See "Using statistics for cache self-tuning" in the *Performance Optimization Guide*.
Collect statistics for monitoring	Select this option to display cache statistics in the Performance Monitor in the Administrator. This option is not selected by default. See "Monitoring and tuning cache types" in the *Performance Optimization Guide*.
Use collected statistics	Select this option if you want the optimizer to use the cache statistics collected on a previous execution of the job. The option is selected by default. For more information, see "Using statistics for cache self-tuning" in the *Performance Optimization Guide*.
Export Data Quality reports	Generates and exports all specified job reports to the location specified in the *Management* ▸ *Report Server Configuration* node. By default, the reports are exported to **`<DS_COMMON_DIR>`**`\DataQuality\reports\`**`<repository\job>`**.
Distribution level	Select the level within a job that you want to distribute to multiple Job Servers for processing: ○ *Job*: The whole job will execute on an available Job Server. ○ *Data flow*: Each data flow within the job can execute on an available Job Server. ○ *Sub data flow*: Each sub data flow (can be a separate transform or function) within a data flow can execute on an available Job Server. For more information, see "Using grid computing to distribute data flows execution" in the *Performance Optimization Guide*.

5. Click *Apply*. Clicking *Reset* returns all fields to the last set of values applied.

4.3.5.2.1.1.1 Activating or deactivating one or more job schedules

In order for a job schedule to run, it must be active.

To change an existing job schedule, you must first deactivate it, make the changes, then reactivate it.

1. Select *Batch* **`<repository>`** .
2. Click the *Repository Schedules* tab.

   In order for a job schedule to run, it must be active.

   The Repository Schedules tab lists all schedules for all jobs in the repository, and you can remove, activate, or deactivate one or more schedules.

   Alternately, click the Batch Job Configuration tab, then for a particular job, click the Schedules link. The Batch Job Schedules tab lists all schedules for that particular job. Here you can add, remove, activate, or deactivate one or more schedules:

   The Job Server column listed next to each schedule indicates which Job Server will execute it.

   If there is a server group icon in the Job Server column, this indicates the schedule will be executed by the server group, and the schedule is stored on the indicated Job Server. To see which server group is associated with the schedule, roll your cursor over the server group icon.

   If there is CMS icon in the Job Server column, this indicates the job schedule is managed by a Central Management Server.

   Click the System Configuration names, if configured, to open a page that lists the datastore configurations in that system configuration.
3. On either the *Repository Schedules* tab or the *Batch Job Schedules* tab, select one or more check boxes for a schedule.
4. Click *Activate* (or *Deactivate*).

Related Information

Updating a job schedule [page 1895]

4.3.5.2.1.2 Updating a job schedule

To edit a job schedule, you must first deactivate it, make the changes, then reactivate it.

1. Select *Batch* **<repository>**.
2. Click the *Batch Job Configuration* tab.
3. Click the *Schedules* link for the desired job.
4. Click the schedule name to edit.
5. The *Schedule Batch Job* page displays.
6. If the schedule is currently active, deactivate it by clearing the *Active* check box and click *Apply*.

   > Note
   >
   > You do not need to deactivate the schedule to update most of the job execution parameters at the bottom of the page. Only the schedule-related parameters require deactivation in order to update them.

7. Edit the schedule parameters as required.
8. To reactivate the schedule now, select the *Active* check box.
9. Click *Apply*.

   The status bar at the top of the page confirms that the schedule has been created and/or activated.

Related Information

Adding a job schedule [page 1892]

4.3.5.2.1.3 Removing a job schedule

1. Select *Batch* **<repository>**.
2. Click the *Repository Schedules* tab.
3. Select one or more check boxes for a schedule.
4. Click *Remove*.

   The Administrator deletes the information about this job schedule.

4.3.5.2.1.4 Migration considerations

Changes made to the Job Server, such as an upgrade, do not affect schedules created in SAP Data Services as long as:

- The new version of the software is installed in the same directory as the original version (Data Services schedulers use a hard-coded path to the Job Server).
- The new installation uses the Job Server name and port from the previous installation. (This occurs automatically when you install over the existing `DSConfig.txt` file.)

When you export a repository via an `.atl` file, jobs and their schedules (created in Data Services) automatically export as well.

You can also import a repository `.atl` file including jobs and their associated schedules (previously created in Data Services) back into Data Services.

Remember that once imported, you must reactivate job schedules to use them. If the job schedule uses a password file, then reactivating it will automatically generate the password file.

Related Information

Administrator Guide: Importing from a File [page 122]

4.3.5.2.2 Scheduling jobs in SAP BusinessObjects Business Intelligence platform

If you are using SAP BusinessObjects Business Intelligence platform and you want to manage your SAP Data Services job schedules in that application, first create a connection to a Central Management Server (CMS), then configure the schedule to use that server.

4.3.5.2.2.1 Adding a CMS connection

1. Select ▶ *Management* ▶ *CMS Connection* ◀.
2. Click *Add*.
3. On the *CMS Connections* page, enter the connection information.

   The parameters in the top section are the same as when logging in to an SAP BusinessObjects Business Intelligence platform Central Management Console (CMC) or InfoView. For details, refer to the *SAP BusinessObjects Business Intelligence platform InfoView User's Guide*.

   The parameters in the bottom section (User account credentials for executing the program) depend on how the CMS server is set up. For details, refer to "Authentication and program objects" in the *SAP BusinessObjects Business Intelligence platform Administrator Guide*.

Option	Description
System	Type the computer name that hosts the Central Management Server (CMS), a colon, and the port number.
User name	Type the CMC/InfoView user name.
Password	Type the CMC/InfoView user password.
Authentication	Select the authentication type for the server
User account credentials for executing the program (optional)	

Option	Description
Note If you do not have the following option cleared in the Central Management Console, you will be required to enter user account credentials in order for your schedules to run: In the CMC, select *Objects* > *Objects Settings* > *Program objects* and clear the *Use Impersonation* option.	
User name	The CMS computer might require operating system login credentials to run the schedule. If so, type the user name (and password) for the applicable account.
Password	The CMS computer might require operating system login credentials to run the schedule. If so, type the (user name and) password for the applicable account.

4. Click *Apply*.

4.3.5.2.2.2 Creating a job schedule in SAP BusinessObjects Business Intelligence platform

1. Select *Batch* > **`<repository>`**.
2. Click the *Repository Schedules* tab.
3. Click the schedule name to configure.
4. If the schedule is currently active, deactivate it by clearing the *Active* check box and click *Apply*.
5. Edit the schedule parameters as necessary.

> Note
>
> Time-sensitive parameters reflect the time zone of the computer where the Administrator is installed, not where the CMS is installed.

6. Under the *Select a scheduler* section, select *BOE scheduler*.
7. From the drop-down list, select a CMS name.
8. To reactivate the schedule now, select the *Active* check box.
9. Click *Apply*.

   The status bar at the top of the page confirms that the schedule has been created and/or activated.

   If it doesn't already exist, SAP BusinessObjects Business Intelligence platform creates a folder called Data Services and stores the schedule file and a parameters file (called schedulename.txt).

   For a BOE schedule with the *Use password file* option selected, then SAP Data Services also creates a password file in the Data Services folder (called `repositoryname.txt`)

Note

When you deactivate a schedule created on a CMS, SAP BusinessObjects Business Intelligence platform deletes the object. Therefore, any changes made to the calendar will be lost.

4.3.5.2.2.3 Removing a CMS connection

1. Select *Management* > *CMS Connection* .
2. Select the check box for the connection to remove from the administrator.
3. Click *Remove*.

4.3.5.2.3 Using a third-party scheduler

When you schedule jobs using third-party software:

- The job initiates outside of SAP Data Services.
- The job runs from an executable batch file (or shell script for UNIX) exported from Data Services.
- When you execute a Data Services job using the exported execution command on a Unix/Linux environment from a third-party scheduler or any other application, source the `$LINK_DIR/bin/al_env.sh` file before calling the script that contains the command to start the job. This can be done by adding following lines in the beginning of the script containing the execution command:

  ```
  export LINK_DIR=</usr/sw/sap/dataservices>
  . $LINK_DIR/bin/al_env.sh
  ```

  Where /usr/sw/sap/dataservices is the directory where Data Services is installed.

Note

When a third-party scheduler invokes a job, the corresponding Job Server must be running.

Related Information

About the job launcher [page 1903]

4.3.5.2.3.1 Executing a job with a third-party scheduler

1. Export the job's execution command to an executable batch file (`.bat` file for Windows or `.sh` file for UNIX environments).

2. Ensure that the Data Services Service is running (for that job's Job Server) when the job begins to execute.

   The Data Services Service automatically starts the Job Server when you restart the computer on which you installed the Job Server.

   ○ You can also verify whether a Job Server is running at any given time using the Designer. Log in to the repository that contains your job and view the Designer's status bar to verify that the Job Server connected to this repository is running.
   ○ You can verify whether all Job Servers in a server group are running using the Administrator. In the navigation tree select *Server Groups* > *All Server Groups* to view the status of server groups and the Job Servers they contain.
3. Schedule the batch file from the third-party software.

> i Note
>
> To stop an SAP Data Services job launched by a third-party scheduling application, press CTRL+C on the application's keyboard.

4.3.5.2.3.2 To export a job for scheduling

1. Select *Batch* > **`<repository>`**.
2. Click the *Batch Job Configuration* tab.
3. For the batch job to configure, click the *Export Execution Command* link.
4. On the *Export Execution Command* page, enter the desired options for the batch job command file that you want the Administrator to create:

Option	Description
File name	The name of the batch file or script containing the job. The third-party scheduler executes this file. The Administrator automatically appends the appropriate extension: ○ `.sh` for UNIX ○ `.bat` for Windows
System configuration	Select the system configuration to use when executing this job. A system configuration defines a set of datastore configurations, which define the datastore connections. For more information, see “Creating and managing multiple datastore configurations” in the *Designer Guide*. If a system configuration is not specified, the software uses the default datastore configuration for each datastore. This option is a run-time property. This option is only available if there are system configurations defined in the repository.
Job Server or server group	Select the Job Server or a server group to execute this schedule.

Option	Description
Enable auditing	Select this option if you want to collect audit statistics for this specific job execution. The option is selected by default. For more information about auditing, see “Using Auditing” in the *Designer Guide*.
Disable data validation statistics collection	Select this option if you do not want to collect data validation statistics for any validation transforms in this job. The option is not selected by default.
Enable recovery	Select this option to enable the automatic recovery feature. When enabled, the software saves the results from completed steps and allows you to resume failed jobs. See “Automatically recovering jobs” in the *Designer Guide* for information about the recovery options.
Recover from last failed execution	Select this option to resume a failed job. The software retrieves the results from any steps that were previously executed successfully and re-executes any other steps. This option is a run-time property. This option is not available when a job has not yet been executed or when recovery mode was disabled during the previous run.
Use password file	Select to create or update a password file that automatically updates job schedules after changes in database or repository parameters. Deselect the option to generate the batch file with a hard-coded repository user name and password. Note This option is disabled if you have not set up a CMS connection.
Collect statistics for optimization	Select this option to collect statistics that the optimizer will use to choose an optimal cache type (in-memory or pageable). This option is not selected by default. See “Using statistics for cache self-tuning” in the *Performance Optimization Guide*.
Collect statistics for monitoring	Select this option to display cache statistics in the Performance Monitor in the Administrator. The option is not selected by default. For more information, see “Monitoring and tuning cache types” in the *Performance Optimization Guide*.
Use collected statistics	Select this check box if you want the optimizer to use the cache statistics collected on a previous execution of the job. The option is selected by default. See “Using statistics for cache self-tuning” in the *Performance Optimization Guide*.

Option	Description
Export Data Quality reports	Generates and exports all specified job reports to the location specified in the *Management* > *Report Server Configuration* node. By default, the reports are exported to **<DS_COMMON_DIR>**`\DataQuality\reports\`**<repository\job>**.
Distribution level	Select the level within a job that you want to distribute to multiple Job Servers for processing: ○ *Job*: The whole job will execute on one Job Server. ○ *Data flow*: Each data flow within the job will execute on a separate Job Server. ○ *Sub data flow:* Each sub data flow (can be a separate transform or function) within a data flow can execute on a separate Job Server. For more information, see “Using grid computing to distribute data flows execution” in the *Performance Optimization Guide*.

5. Click *Export*.

   The Administrator creates command files **<filename>**`.txt` (the default for filename is the job name) and a batch file for the job and writes them to the local **<DS_COMMON_DIR>**`\log` directory.

i Note

You can relocate the password file from the **<DS_COMMON_DIR>**`\conf` directory, but you must edit the **<filename>**`.txt` file so that it refers to the new location of the password file. Open the file in a text editor and add the relative or absolute file path to the new location of the password file in the argument `-R "`**<repositoryname>**`.txt"`.

4.3.5.2.4 About the job launcher

SAP Data Services exports job execution command files as batch files on Windows or CRON files on UNIX. These files pass parameters and call `AL_RWJobLauncher`. Then, `AL_RWJobLauncher` executes the job, sends it to the appropriate Job Server, and waits for the job to complete.

> ⚠ Caution
>
> Do not modify the exported file without assistance from SAP Business User Support.

Related Information

Administrator Guide: Configuring SSL for Data Services components [page 34]
Administrator Guide: Configuring SSL for the CMS connection [page 41]

4.3.5.2.4.1 Job launcher flag values and arguments

The following table lists job launcher flags and their values.

Flag	Value
`-w`	The job launcher starts the job(s) and then waits before passing back the job status. If -w is not specified, the launcher exits immediately after starting a job.
`-t`	The time, in milliseconds, that the Job Server waits before checking a job's status. This is a companion argument for `-w`.
`-s`	Status or return code. 0 indicates successful completion, non-zero indicates an error condition. Combine `-w`, `-t`, and `-s` to execute the job, wait for completion, and return the status.
`-C`	Name of the engine command file (path to a file which contains the Command line arguments to be sent to the engine).
`-v`	Prints `AL_RWJobLauncher` version number.
`-S`	Lists the server group and Job Servers that it contains using the following syntax: `"SvrGroupName;inet:JobSvr1Name:JobSvr1Host:JobSvr1Port;inet:JobSvr2Name:JobSvr2Host:JobSvr2Port";` For example: `"SG_DEV;inet:HPSVR1:3500;inet:WINSVR4:3505";`
`-R`	The location and name of the password file. Replaces the hard-coded repository connection values for `-S, -N, -U, -P`.

Flag	Value
`-xCR`	Generates and exports all specified job reports to the location specified in the *Management* › *Report Server Configuration* node. By default, the reports are exported to **`<DS_COMMON_DIR>`**`\DataQuality\reports\`**`<repository\job>`**. In order to use this flag, you must disable the security for the Export_DQReport operation in the *Administrator* › *Web Services* › *Web Services Configuration* tab.

There are two arguments that do not use flags:

- `inet` address: The host name and port number of the Job Server. The string must be in quotes. For example:

  ```
  "inet:HPSVR1:3500"
  ```

  If you use a server group, inet addresses are automatically rewritten using the -S flag arguments. On execution, the first Job Server in the group checks with the others and the Job Server with the lightest load executes the job.
- `server log path`: The fully qualified path to the location of the log files. The server log path must be in quotes. The server log path argument does not appear on an exported batch job launch command file. It appears only when Data Services generates a file for an active job schedule and stores it in the following directory: **`<DS_COMMON_DIR>`**`/Log/`**`<JobServerName>`**`/`**`<RepositoryName>`**`/`**`<JobInstanceName>`** . You cannot manually edit server log paths.

Related Information

Integrator Guide: To configure web service information using the Administrator [page 2221]

4.3.5.2.4.2 Job launcher error codes

The job launcher also provides error codes to help debug potential problems. The error messages are:

Error number	Error message
180002	Network failure.
180003	The service that will run the schedule has not started.
180004	`LINK_DIR` is not defined.
180005	The trace message file could not be created.
180006	The error message file could not be created.
180007	The GUID could not be found. The status cannot be returned.
180008	No command line arguments were found.

Error number	Error message
180009	Invalid command line syntax.
180010	Cannot open the command file.

4.3.6 Real-Time Jobs

This section describes how to support real-time jobs using the Administrator.

Before configuring services, add real-time job repository and Access Server connections to the Administrator.

Related Information

Supporting real-time jobs [page 1905]
Configuring and monitoring real-time services [page 1907]
Creating and monitoring client interfaces [page 1915]

4.3.6.1 Supporting real-time jobs

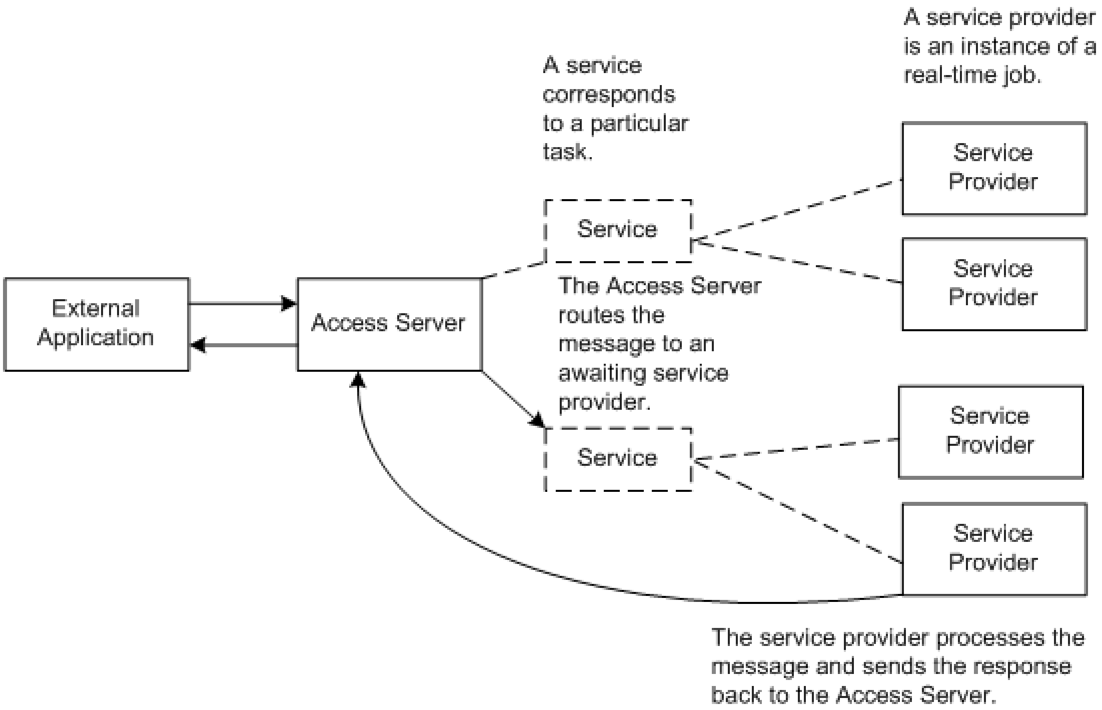
The Access Server manages real-time communication between SAP Data Services and external applications (such as ERP or web applications). The Access Server determines how to process incoming and outgoing messages based on the settings you choose for each real-time job in the Administrator.

In particular you use the Administrator to define:

- Services: A service is a name that identifies a task. The Access Server receives requests for a service. You associate a service with a real-time job. The real-time job contains the real-time processing loop that can process requests for this service and generate a response.
- Service providers: A service provider is the engine process that performs a service; the service provider completes the tasks in a real-time job. A service provider is controlled by a Job Server. A Job Server can control several service providers—each service provider is a unique process instance.

The Access Server uses services and service providers to process message requests. The following is an example:

1. An external application sends a request to the Access Server.
2. The Access Server determines the appropriate service for the request.
3. The Access Server finds the associated service providers and dispatches the request to the next available service provider.
4. Under the control of a Job Server, that service provider completes the processing for the request. A different Job Server might control each service provider.



A service corresponds to a particular task.
A service provider is an instance of a real-time job.
Service Provider
Service Provider
Service
External Application
Access Server
The Access Server routes the message to an awaiting service provider.
Service Provider
Service
Service Provider
The service provider processes the message and sends the response back to the Access Server.

The Access Server manages the entire set of service providers, implementing configuration changes and telling the appropriate Job Servers to start and stop service providers. At a prescribed interval, the Access Server updates service providers, balancing loads and implementing configuration changes. To balance loads, the Access Server monitors requests for services to ensure that no service provider is over-used or under-used. Based on the number of requests for a service, the Access Server tells Job Servers to start or stop service providers.

To support real-time jobs, you must:

- Create any number of Access Servers using the Server Manager utility, then add a connection to each local or remote Access Server using the *Management* node in the Management Console Administrator.
- In the *Real-Time* node of the Administrator, create a service for each real-time job under each Access Server's node.
- Create one or more service providers for each service.
- Start the services.
- Monitor the services.

Related Information

Creating services and service providers [page 1907]
Starting and stopping services [page 1910]
Monitoring services [page 1914]

4.3.6.2 Configuring and monitoring real-time services

To enable an Access Server to support real-time jobs, you must configure and monitor real-time services and service providers for it.

- Configure services by specifying a real-time job and other operational parameters.
- Configure service providers by specifying a Job Server and indicating the maximum and minimum number of instances that you want the Job Server to control. Each service provider is a unique process or instance controlled by a Job Server.

Related Information

Creating services and service providers [page 1907]
Starting and stopping services [page 1910]
Updating service providers [page 1913]
Monitoring services [page 1914]

4.3.6.2.1 Creating services and service providers

In the Administrator, you create a service that processes requests for each real-time job. You also create the service providers to perform that service. A service provider is the process that completes the tasks in a real-time job.

4.3.6.2.1.1 Adding a service

1. Select ▶ *Real-time* ▶ **`<Access Server>`** ▶ *Real-Time Services* ◀.
2. Click the *Real-Time Services Configuration* tab.
3. Click the *Add* button.
4. In the *Service configuration* section, enter information that describes this service.

Parameter	Description
Service name	A unique name for this service.
Job name	Click *Browse Jobs* to view a list of all the real-time jobs available in the repositories that you connected to the Administrator. Select a job name to fill the service configuration form.
Repository name	Logical name for a repository (used in the Administrator only).

Parameter	Description
Processing retry count max	The number of times that the Access Server attempts to restart a job that fails to respond.
Enable job tracing	A flag that indicates whether the service will write trace messages. Select *Enable* for the job to write trace messages.
Startup timeout	The maximum time that the Access Server waits for the service to register after startup (in seconds).
Queuing timeout	The maximum time that the Access Server waits for the service to process the request (in seconds).
Processing timeout	The maximum time that the Access Server waits for a response from the service (in seconds).
Recycle request count max	The number of requests that the Access Server sends to a given real-time service before automatically recycling the flow.
System Configuration	If configured, select the system configuration to use when executing this service. This option is available only if there are system configurations defined in the repository. For more information, see "Parameters" in the *Reference Guide*.
Enable	A flag that indicates whether the Access Server attempts to automatically start this service when the Access Server restarts. Select *Enable* if you want to automatically start this service when the Access Server restarts. This is the default setting. If you clear the *Enable* option, when the Access Server restarts, it does not automatically start this service. If you manually attempt to start a disabled service, an error message appears in the Service's *Status* column.

5. Add one or more job servers to start this service provider. In the *Service provider* section, click the *Add* button to insert a new Job Server.
6. In the *Job Server* list, select a Job Server to control the service provider. Job Servers are defined by host name and port number.

   You may not select a Job Server more than one time.
7. In the *Min instances* and *Max instances* fields, enter a minimum and a maximum number of service providers that you want this Job Server to control for this service.
8. The job server is enabled by default. To configure but not start the service providers controlled by this Job Server, select the checkbox next to the Job Server, and click the *Disable* button.
9. To add a substitution parameter, click the *Add Overridden Parameter* link.
10. From the drop-down list, select the substitution parameter to override, and enter the override value.
11. Click *Apply*.

The Administrator updates the configuration parameters for this service. These configuration parameters apply to all providers of this service.

When you are ready for the Access Server to process requests, start the service.

High-traffic behavior [page 1924]
Response time controls [page 1925]
Starting a service [page 1910]
Reference Guide: Objects, Batch Job, Parameters [page 840]

4.3.6.2.1.2 Adding or changing a service provider for a service

1. Select ▶ *Real-time* ▶ `<Access Server>` ▶ *Real-Time Services* ◀.
2. Click the *Real-Time Services Configuration* tab.
3. Click the name of the service for which you want to change the service provider.
4. In the *Service provider* section, click the *Add* button.
5. In the *Job Server* list, select a Job Server to control the service provider. Job Servers are defined by host name and port number.

   You may not select a Job Server more than one time.
6. In the *Min instances* and *Max instances* fields, enter a minimum and a maximum number of service provider instances that you want this Job Server to control.
7. The job server is enabled by default. To configure but not start the service providers controlled by this Job Server, select the checkbox next to the Job Server, and click the *Disable* button.
8. Click the *Apply* button.

   If the service has already started, the Access Server adds this service provider to the available list when it next updates the service providers.

   If the service has not yet started, the Access Server starts enabled service providers when the service starts.

Related Information

Updating service providers [page 1913]

4.3.6.2.1.3 Setting the service provider update interval

The *Provider update interval for services* option sets the time interval, in seconds, between service provider updates. Valid values range from 10 to 120 seconds. The default is 30 seconds. When updating service providers, the Access Server balances loads and implements any configuration changes you have applied to a service provider.

If the provider update interval is too small, performance can decrease because the Access Server must frequently check for events and collect statistics. It's recommended that you set the Provider update interval for services to 30 seconds. On systems with heavy loads and production systems with fewer start and stop events, you can increase the interval.

1. Select ▶ *Real-Time* > `<Access Server>` > *Status* ◢.

   This is the time interval, in seconds, between service provider updates. Valid values range from 10 to 120 seconds. The default is 30 seconds. When updating service providers, the Access Server balances loads and implements any configuration changes you have applied to a service provider.

   If the provider update interval is too small, performance can decrease because the Access Server must frequently check for events and collect statistics. It's recommended that you set the *Provider update interval for services* option to 30 seconds. On systems with heavy loads and production systems with fewer start and stop events, you can increase the interval.
2. Click the *Access Server Configuration* tab.
3. Enter the desired *Provider update interval for services*.

Related Information

Updating service providers [page 1913]

4.3.6.2.2 Starting and stopping services

After you create the required services and service providers, you can start them. After you start a service or service provider, SAP Data Services ensures that it continues to run. You can also use the Administrator to stop a service (such as for maintenance). Similarly, use the Administrator to remove, enable, or disable services and service providers.

4.3.6.2.2.1 Starting a service

1. Select ▶ *Real-Time* > `<Access Server>` > *Real-Time Services* ◢.
2. In the Real-Time Services Status tab, select the check box next to the service or services that you want to start.
3. Click *Start*.

The Access Server starts the minimum number of service providers for this service.

4.3.6.2.2.2 Enabling a service

1. Select ▶ *Real-Time* ▶ **`<Access Server>`** ▶ *Real-Time Services* ◢.
2. Click the *Real-Time Services Configuration* tab. The table of services displays the status in the Enabled column.
3. Select the check box next to the service or services that you want to enable.
4. Click the *Enable* button.

   The Access Server enables the minimum number of service providers for this service, and the *Enabled* column displays Yes.

This change does not start the service. Instead, the service is enabled the next time that the Access Server attempts to start the service, such as after the Access Server restarts.

4.3.6.2.2.3 Disabling a service

1. Select ▶ *Real-Time* ▶ **`<Access Server>`** ▶ *Real-Time Services* ◢.
2. Click the *Real-Time Services Configuration* tab. The table of services displays the status in the Enabled column.
3. Select the check box next to the service or services that you want to disable.
4. Click the *Disable* button.

This change does not have an immediate effect on the service. Instead, the service is disabled the next time that the Access Server attempts to start the service, such as after the Access Server restarts. If you attempt to start a disabled real-time service, an error message displays in the service's status.

4.3.6.2.2.4 To abort or shut down a service

1. Select ▶ *Real-Time* ▶ **`<Access Server>`** ▶ *Real-Time Services* ◢.
2. In the Real-Time Services Status tab, select the check box next to the service or services that you want to abort or shut down.

Option	Description
Abort	Shuts down all service providers for this service without waiting for them to complete processing. The Access Server responds to current and new requests for this service with an error.
Shutdown	Shuts down all service providers for this service after they complete processing any current requests. The Access Server responds to new requests for this service with an error.

3. Click *Abort* or *Shutdown*.

Related Information

Starting a service [page 1910]
Disabling a service [page 1911]

4.3.6.2.2.5 Removing a service

1. Select ▶ *Real-Time* ▶ **`<Access Server>`** ▶ *Real-Time Services* ▶.
2. Click the *Real-Time Services Configuration* tab.
3. Select the check box next to the service or services that you want to remove.
4. Click *Remove*.

   The Administrator stops processing this service. The Access Server shuts down each of the service providers defined for this service and removes the service from the list.

4.3.6.2.2.6 To remove, enable, or disable a service provider

1. Select ▶ *Real-Time* ▶ **`<Access Server>`** ▶ *Real-Time Services* ▶.
2. Click the *Real-Time Services Configuration* tab.
3. If you want to change a Job Service's service providers, select the check box next to a Job Server.
4. Click one of the buttons below the list of Job Servers to perform the appropriate action:

Option	Description
Enable	Start the service providers controlled by the selected Job Servers. Each Job Server starts the minimum number of service providers. The Access Server now includes the selected Job Servers in the set of available service providers. If a Job Server is already enabled, this choice has no effect.
Remove	Discontinue using the service providers controlled by the selected Job Servers to process requests for this service. The Access Server shuts down the service providers and removes the Job Server from the list.

5. Shut down the service providers controlled by the selected Job Servers. The Access Server finishes processing any current requests and no longer includes the selected Job Servers in the set of service providers available to process requests for this service.
   The Administrator completes this action during the next service provider update.

Related Information

Updating service providers [page 1913]

4.3.6.2.2.7 Restarting a service provider

1. Select *Real-Time* **<Access Server>** *Real-Time Services* .
2. Select the service that you want to restart the service provider for. The *Service Provider Status* page opens.

   > Note
   >
   > Select Restart only if the service providers controlled by this Job Server are currently enabled. To verify the status, select the Real-Time Services Configuration tab and view service provider status in the Job Servers for Service section.

3. Click *Restart*.

   The Administrator completes this action during the next service provider update. The Administrator shuts down any service providers controlled by the selected Job Servers and immediately restarts the minimum number of service providers. For example, you might restart a service provider after a computer running its Job Server reboots following a crash.

4.3.6.2.3 Updating service providers

At a specified provider update interval, the Access Server updates service providers. When updating service providers, the Access Server balances the work load—starting or stopping service providers as necessary—and implements other events that you initiated since the last update.

When balancing the work load, the Access Server checks the number of requests in a service queue and the minimum idle time for a service. If the number of requests in a service queue is greater than the number of service providers started, the Access Server tries to start a new service provider. Conversely, if the minimum idle time for a service is more than 10 minutes, the Access Server will shut down a service provider. However, the number of service providers cannot exceed the maximum number of instances configured nor can it be less than the minimum number of instances configured.

When implementing events that you initiated, the Access Server does the following:

- Enables service providers
- Disables service providers
- Reconfigures service providers
- Restarts service providers
- Adds service providers
- Removes service providers

Related Information

Setting the service provider update interval [page 1910]

4.3.6.2.4 Monitoring services

Use the Administrator to monitor services. With the Administrator you can do the following:

- View service status—From the Access Server Status page or the Real-Time Services Status page, view whether a service is running or not. Based on this information, you can begin troubleshooting problems.
- View service provider status—From the Real-Time Services Status page, click a service name to view:
    - The statistics for a particular service.
    - Detailed statistics about each service provider. Using this information, you can monitor and evaluate system performance.
    - The status of all service providers in that service.
- View logs—The Access Server node provides access to current and historical service provider trace and error logs.

4.3.6.2.4.1 Viewing the status of services

1. Select ▶ *Real-Time* ▸ **`<Access Server>`** ▸ *Real-Time Services* ◀.

   The Administrator opens the Real-Time Services Status page. For each service, this page shows the overall status and statistics about the number of available service providers and the number of started service providers.
2. Verify that the services are working.

Indicator	Description
✓	A green icon indicates that the service is operating properly.
⚠	A yellow icon indicates that some aspect of the service is not working, and that the Access Server is attempting to reestablish the service using error handling.
✖	A red icon indicates that one or more aspects of the service is not working, and the Access Server cannot reestablish the service.
3. If a service shows a yellow or red status, click the service name to see more information.

Related Information

Service statistics [page 1926]
Troubleshooting the Administrator [page 1956]

4.3.6.2.4.2 Viewing the statistics for a service provider

1. Select *Real-Time* > `<Access Server>` > *Real-Time Services*.
2. Click the name of the service.

   This page shows the overall statistics for the service, the service providers for the service (listed by Job Server), and the status of each service provider. Start a service to see its service provider status information.
3. Under *Service Provider Status Information*, click the *Process ID* of a service provider to view its statistics.

   The Administrator opens the Service Provider Status page.

   Under Service Provider Status Information, the page shows the statistics for this service provider.

Related Information

Service provider statistics [page 1927]

4.3.6.3 Creating and monitoring client interfaces

A client is an external application that communicates with SAP Data Services through the Access Server.

There are two types of client interfaces in the Administrator:

- Remote Function Call (RFC) clients
- Message broker clients

Configure RFC clients in the Administrator for real-time jobs that use SAP IDocs. To support these jobs, create an RFC client interface and attach IDoc configuration information to it.

Data Services creates message broker client interfaces when communication occurs between the Access Server and an external application that uses Data Services message client libraries. To monitor message statistics, view the message broker clients of each Access Server as needed.

This section describes configuration and monitoring for each type of client.

For more information about using the Message Client library, see the *SAP Data Services Integrator Guide*.

4.3.6.3.1 RFC clients

You can configure IDoc message sources in the Administrator as well as in the Designer. You can configure other IDoc sources and targets using the Designer.

> i Note
>
> Using the Administrator, create a service for your real-time job that contains an IDoc as a message source before you configure an RFC client.

An RFC client uses the SAP RFC protocol to communicate with the Access Server. An RFC client requires connection information so that an Access Server can register to receive IDocs from an SAP application server. An RFC client can process one or more IDoc types. An RFC client specifies which service will process a particular IDoc type and whether or not the RFC client connection can process an IDoc type in parallel.

The process of creating an RFC client interface for IDocs has two parts:

- Adding an RFC client
- Adding IDoc configurations to an existing RFC client

Configure one RFC client per Access Server. This means that you can process IDocs from one instance of SAP. To process IDocs from more than one instance, configure more than one Access Server.

> i Note
>
> SAP application function modules are responsible for IDoc processing. In SAP Data Services, the RFC client might fail if multiple IDocs are sent from SAP and you previously set the SAP packet size to 1. Therefore:

- Do not enable the option of immediate IDoc dispatch in SAP unless the volume of produced IDocs is very low (no more than one IDoc per minute).
- For batch processing of IDocs, the packet size should never be smaller than 5 or larger than 1000. The following table provides estimates for this parameter:

IDoc Processing Volume	IDocs per day	Packet size
Light	1 to 300	5
Medium	301 to 1000	20
Heavy	1001 to 5000	80
Very Heavy	more than 5000	800

For more information, see the *SAP Data Services Supplement for SAP*.

4.3.6.3.1.1 Adding an RFC client

1. Select *Real-time* › `<Access Server>` › *Client Interfaces*.
2. Click the *Client Interface Configuration* tab.
3. Click *Add*.

The Administrator opens the RFC Client Configuration page.

4. Enter the client configuration information.

Field	Description
RFC program ID	The registered server program ID from transaction SM59.
User name	The user name through which SAP Data Services connects to this SAP application server.
Password	The password for the user account through which SAP Data Services connects to this SAP application server.
SAP application server name	The domain name or IP address of the computer where the SAP application server is running.
Client number	The SAP application client number.
System number	The SAP application system number.
SAP gateway host name	The domain name or IP address of the computer where the SAP RFC gateway is located.
SAP gateway service name	The TCP/IP service name for the SAP application server gateway. Typically, this value is SAPGW and the system number. It can also be a service number, for example 3301.
Use sapnwrfc.ini	Select to use an sapnwrfc.ini file, which overrides the datastore settings associated with this RFC client. The default location to place the sapnwrfc.ini file is in the current directory of the process being executed (%LINK_DIR/bin).
Destination name	If using an sapnwrfc.ini file, enter the destination name to reference.

5. Click *Apply*.

For more information, see the *SAP Data Services Supplement for SAP*.

Related Information

Supplement for SAP: Using the sapnwrfc.ini file [page 2439]

4.3.6.3.2 Adding IDoc configurations to an RFC client

After you create an RFC client, you can list the IDoc types that you want to receive.

4.3.6.3.2.1 Adding an IDoc configuration to an RFC client

1. Select *Real-time* `<Access Server>` *Client Interfaces* .

2. Click the *Client Interface Configuration* tab.
3. Click the name of an existing RFC client interface.

   The RFC Client Configuration page opens.
4. Click the *Supported IDocs* link.
5. Click *Add*.
6. Enter IDoc information:
   a) In the *IDoc Type* box, enter the IDoc type that this SAP application server will send to the Access Server.
   b) In the *Service Name* box, enter the name of the service that will process this IDoc.

      The service identifies the job that processes this IDoc.
   c) If you want the Access Server to read IDocs (of this type and from the specified SAP source) in parallel, check the *Parallel Processing* check box.

      Real-time services that contain an IDoc message source can be processed one at a time or in parallel. The *Parallel Processing* option allows you to increase the number of IDoc source messages processed per minute for the IDoc type specified. This option is disabled by default. The option allows the Access Server to send an IDoc to a service queue (where it waits for a service provider) and continue with the next IDoc without waiting for reply. The maximum number of outstanding IDoc requests in the queue is the number of IDocs received or four, whichever is smaller.

      > i Note
      >
      > Where a strict IDoc processing sequence is required, do not use the Parallel Processing option.
7. Click *Apply*.
8. (Optional) Select *Real-time* > **`<Access Server>`** > *Client Interfaces* .
9. From the Client Interface Status page, select the check box next to the new *RFC* client and click *Start*.

   The Administrator starts the RFC client. A green indicator signifies that the client is running. Detailed status information is provided in the Status column.

Related Information

Configuring and monitoring real-time services [page 1907]

4.3.6.3.2.2 Closing connections to an RFC client interface

1. Select *Real-time* > **`<Access Server>`** > *Client Interfaces* .
2. Select the check box next to the RFC client you want to disconnect.

   If you choose *Shut down*, the Access Server allows the clients to finish processing any active requests before closing the connection. The Access Server responds with an error to any new requests that arrive during that interval.

   If you choose Abort, the Access Server closes the connection to the client without responding to requests currently being processed.

3. Click *Shut down* or *Abort*.

4.3.6.3.3 Message Broker clients

A Message Broker client uses an XML message to communicate with an Access Server.

Message Broker clients include:

- External applications
- Adapters
- Service providers

Use the Administrator to monitor Message Broker clients.

4.3.6.3.4 Monitoring client interfaces

From the Client Interface Status page, you can view the overall status of all client connections.

4.3.6.3.4.1 Viewing the overall status of client connections

1. Select ▶ *Real-time* ▶ `<Access Server>` ▶ *Client Interfaces* ◢.
2. Verify that the RFC client connections are working.

Indicator	Description
✓	A green icon indicates that each client of this type has an open connection with Access Server.
⚠	A yellow icon indicates that at least one client of this type is disconnecting.
✗	A red icon indicates that the Access Server could not reserve the specified port to listen for client requests.

If an RFC client interface has a red status:

a) View the Status column and click the name of the client to view statistics about the particular client connection with a problem.

b) If you want to restart, abort, or shut down a client interface, click the Back button in the navigation bar. The Administrator returns to the Client Interface Status page.

c) Click *Start*, *Abort*, or *Shutdown*.

Related Information

Finding problems [page 1956]

4.3.6.3.4.2 Monitoring Message Broker clients

Select *Real-time* › **`<Access Server>`** › *Client Interfaces* .

Under *Message Broker Clients*, this page lists each message broker client that has registered with the Access Server along with statistics for that client.

> **Note**
>
> The first client in this list is the Administrator. You registered with the Access Server when you added connection information to the Administrator.

Message broker client interface information includes:

Item	Description
Name	The name of the client.
Time Connected	The total time that this client has been connected to the Access Server.
Last Message Received	The length of time since the Access Server has received a message from this client.
Last Message Sent	The length of time since the Access Server has sent a message to this client.
Received Messages	The number of messages that the Access Server has received from this client.
Sent Messages	The number of messages that the Access Server has sent to this client.

4.3.7 Real-Time Performance

About this section

This section discusses the Access Server parameters, statistics for services and service providers, and how to tune the performance of services and service providers.

Related Information

Configuring Access Server output [page 1921]
Service configuration parameters [page 1923]
Service statistics [page 1926]
Service provider statistics [page 1927]
Using statistics and service parameters [page 1928]

4.3.7.1 Configuring Access Server output

You can configure the Access Server to control its operation and output such as sending specific event information to its trace log.

SAP Data Services installation includes a server configuration utility called the Server Manager. The Server Manager allows you to view and change the following Access Server information:

Option	Description
Directory	The location of the configuration and log files for this instance of the Access Server. Do not change this value after the initial configuration.
Communication Port	The port on this computer the Access Server uses to communicate with the Administrator and through which you can add additional configuration information to an Access Server. Make sure that this port number is not used by another application on this computer.
Parameters	Command-line parameters used by the Data Services Service to start this Access Server. For development, consider including the following parameters: `-P -T16` where `-P` indicates that trace messages are recorded, and `-T16` indicates that the Access Server collects events for services and service providers. These parameters are described in the next table.
Enable Access Server	An option to control the automatic start of the Access Server when the Data Services Service starts.

4.3.7.1.1 Configuring an Access Server

1. Open Data Services Server Manager.
2. Navigate to the Access Server tab and click on *Configuration Editor*.

The *Access Server Configuration Editor* opens.

3. Click *Add* to configure a new Access Server or select an existing Access Server, then click *Edit* to change the configuration for that Access Server.
4. Make the appropriate changes in the *Access Server Properties* window.
5. Click *OK* to return to the *Access Server Configuration Editor*.
6. Click *OK* to return to the Server Manager.
7. Click *Restart* to stop and start the Data Services Service with the new Access Server configuration.

The following parameters are available to control the operation and output of an Access Server:

Parameter	Description	
`-A`	Specifies the communication port for an Access Server. The default value is `-A4000`.	
`-C`	Disables display output.	
`-H`	Prints the parameter list to the console.	
`-P`	Enables trace messages to the console and log.	
`-R` **`<root_directory>`**	Indicates the location of the Access Server directory.	
`-T` **`<value>`**	Determines the type of tracing information displayed in the console and the Access Server log. Use any value or any combination of values:	
	1	system
	2	real-time service flow
	4	client
	8	transaction
	16	service
	64	administration
	128	request
	For example, to enable tracing for both system-level and service-level operations, include the value 17 after the `T` parameter.	
`-V`	Displays the version number of the Access Server.	
`-VC`	Displays communication protocol and version number.	
`-X`	Validates the Access Server configuration without launching the Access Server.	

The `-A` and `-R` parameters can also be set using the Server Manager.

The -P and -T parameters can be set using the Administrator. Select *Real-Time* **<Access Server>** *Logs-Current* , and click the *Access Server Log Configuration* tab.

4.3.7.2 Service configuration parameters

Each service contains configuration parameters that control how the Access Server dispatches requests to the assigned real-time job. These parameters determine how the system handles errors that occur during operation.

Often, requirements during development differ from requirements during production. Therefore, the values of your configuration parameters differ during development and production. To ensure that the system works as expected, test the values before committing the Access Server configuration to production use.

Parameters control different categories of Access Server operation:

- Service startup behavior
- High-traffic behavior
- Response time controls

Related Information

Adding a service [page 1907]
Service startup behavior [page 1923]
High-traffic behavior [page 1924]
Response time controls [page 1925]

4.3.7.2.1 Service startup behavior

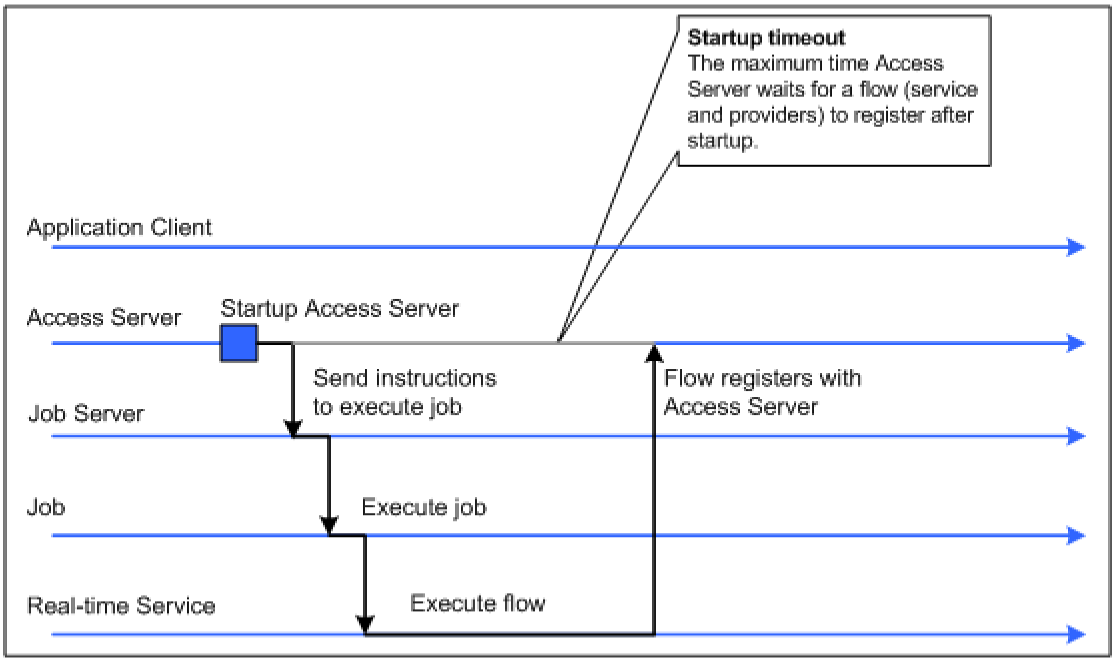
Use two parameters to configure how the Access Server starts service providers associated with a particular service:

- *Startup timeout*—The maximum time that the Access Server waits for a flow (service and its providers) to register after startup.
- *Recycle request count max*—The number of requests that the Access Server sends to a given flow before automatically recycling.

When the Access Server starts, it immediately starts the service providers for each service. If you want the Access Server to start more than one instance of a service to process a particular type of message, you must define more than one service provider for the service.

The Job Servers launch the jobs, which in turn initiate their corresponding real-time services. The first operation of each real-time service is to register with the Access Server.

If an error occurs and a real-time service fails to register, the Access Server instructs the Job Server to restart the job. The Access Server waits the length of time that you configure as the startup timeout before instructing the Job Server to start the job again. The startup timeout is in seconds. The Access Server continues to instruct the Job Server to restart the job until the real-time service registers.



Startup timeout
The maximum time Access Server waits for a flow (service and providers) to register after startup.
Application Client
Access Server
Startup Access Server
Send instructions to execute job
Flow registers with Access Server
Job Server
Job
Execute job
Real-time Service
Execute flow

You can also control how many requests a particular service provider processes. After a provider processes the number of requests specified by the Recycle request count max parameter, the Access Server automatically recycles the service provider—that is, the Access Server automatically stops the current instance of the real-time service and starts a new instance of that service. Setting this parameter to a higher value increases the time that the service provider is available to accept requests for processing. Setting this parameter to a lower value refreshes any data cached in the real-time service more often.

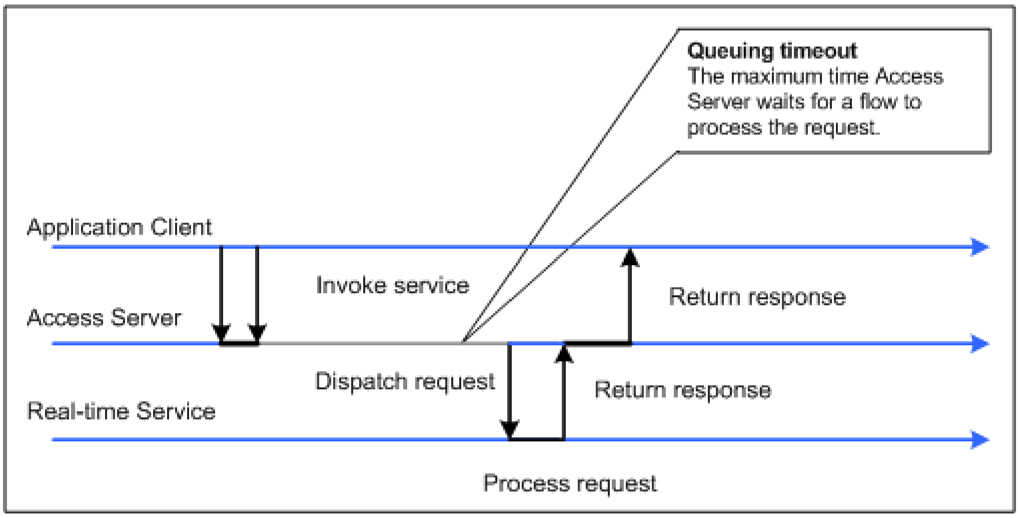
4.3.7.2.2 High-traffic behavior

Use the Queuing Timeout parameter to specify the maximum amount of time the client application must wait for a request to be processed.

If the number of requests the Access Server receives for a particular service exceeds the number of registered service providers that can process those requests, the Access Server queues the requests in the order they are received. When a service provider completes processing a request and responds to the Access Server, the Access Server dispatches the next request in the queue for that service to the open service provider.

If there are many requests and the queue causes requests to exceed the queuing timeout, the Access Server removes the oldest request from the queue and responds to the client with an error indicating that the request failed. You can use the queuing timeout to ensure that the client receives a timely response, even during high-traffic periods.

The queuing timeout is in seconds.



A service experiences high traffic when the available resources cannot process the received requests efficiently. High traffic occurs when the time messages wait to be processed exceeds the time required to process them.

Related Information

Using statistics and service parameters [page 1928]

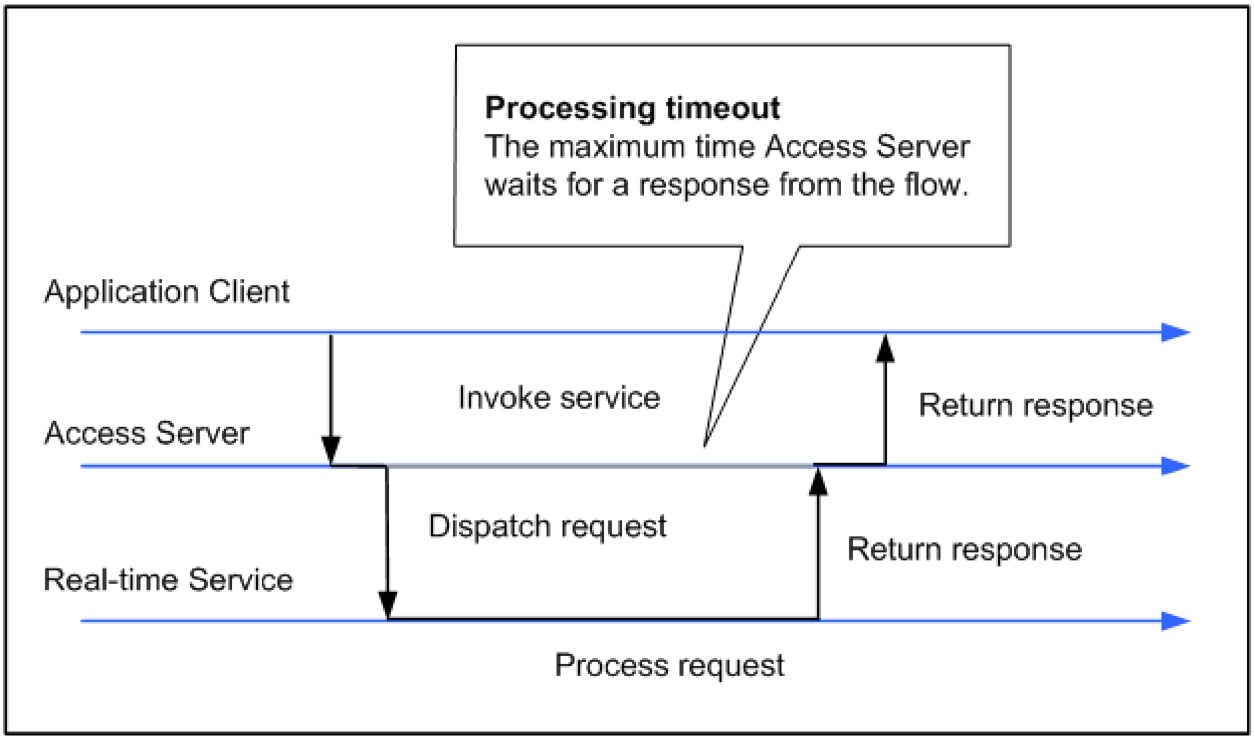
4.3.7.2.3 Response time controls

Use two parameters to configure how long the Access Server waits for responses from service providers for a particular service:

- *Processing timeout*
- *Processing retry count max*

After the Access Server sends a request to a service provider to process, the Access Server waits for the response. If the response does not arrive within the specified processing timeout, the Access Server sends the request to another waiting service provider. The *Processing timeout* is in seconds.

If the first attempt fails, the Access Server will attempt to process the request as many times as you specify in the *Processing retry count max* parameter.



If *Processing retry count max* is set to zero, the maximum response time is equal to the queuing timeout plus the processing timeout.

4.3.7.3 Service statistics

The Real-Time Services Status page for a particular service shows overall statistics.

Statistic	Description
Number of processed requests	The number of requests for this service from any client that the Access Server received and responded to since the last time the Access Server started.
Number of requests in queue	The number of messages that the Access Server has received from a client for this service but has not sent to a service provider for processing. This value reflects the current state of the Access Server.
Maximum queuing time (milliseconds)	The maximum time any request for this service waited after the Access Server received the message and before the Access Server sent the request to a service provider for processing.
Average queuing time (milliseconds)	The average time that requests for this service waited after the Access Server received the request and before the Access Server sent the request to a service provider for processing.

Statistic	Description
Queuing timeout	The number of requests to which the Access Server replied to the client with an error indicating that there was no service provider available to process the request.
Maximum processing time (milliseconds)	The maximum time required to process a request for this service. It is the difference between the time the Access Server sent the request to a service provider and the time that the Access Server responded to the client. The processing time does not include time the request spent in a queue waiting to be sent to a service provider.
Average processing time (milliseconds)	The average time required to process a request for this service. It is the difference between the time the Access Server sent the request to a service provider and the time that the Access Server responded to the client. The processing time does not include time the request spent in a queue waiting to be sent to a service provider.
Processing timeouts	The number of requests that the Access Server sent to a service provider and did not receive a response before exceeding the processing timeout. These requests are either successfully processed by another service provider, or if they are left unprocessed beyond the time indicated by the queuing timeout parameter, the Access Server returns an error to the client.

4.3.7.4 Service provider statistics

The Service Provider Status page shows the statistics for an instance of a real-time service.

When SAP Data Services measures a statistic "from the start," the value does not restart when the Access Server restarts the service provider. The value restarts when the Access Server restarts.

When the software measures a statistic "for the current service provider," the value restarts when the Access Server restarts the service provider, either due to error or when the service provider reaches the maximum number of requests defined for the service.

Statistic	Description
Max processing time (milliseconds)	The longest time it took between when the Access Server sent a message to this service provider and when the service provider returned a response.
Average processing time (milliseconds)	The average time it took between when the Access Server sent a message to this service provider and when the service provider returned a response. If you are running more than one service provider for this service, compare this statistic with the same statistic from the other instances. If this instance is significantly different, look for processing constraints on the computer where this instance runs.

Statistic	Description
Processed requests (for the current service provider)	The number of requests that the Access Server sent to this service provider to which the service provider responded.
Processed requests (since start)	The number of requests that the Access Server sent to this service provider to which the service provider responded.
Error replies received from the start	The number of requests that the Access Server sent to this service provider to which the service provider responded with an error.
Communication errors encountered from the start	The number times that the communication link between the Access Server and this service provider failed.
Timeout errors encountered from the start	The number of times the Access Server sent requests to this service provider and did not receive a response within the time specified by the processing timeout.
Service provider connections (restarts) from the start	The number of times the Access Server restarted this service provider when it did not receive a response from the service provider.
The last time of a successful flow launch	The system time when the Access Server last started the real-time service associated with this service provider. If the Access Server never successfully started an instance of this service provider, the value is "N/A." This time is from the computer running the Access Server.
Time since start attempt	The amount of time since the Access Server last attempted to start this service provider. This value reflects successful and unsuccessful attempts.
Time since last request start	The amount of time since the Access Server last sent a request to this service provider. This value reflects successful and unsuccessful attempts.

4.3.7.5 Using statistics and service parameters

You can use the statistics for a service to tune the service parameters.

Statistic	Description
Average and maximum processing time	If the average or maximum processing time for a service provider is equal or close to the processing timeout value resulting in processing timeouts, consider increasing the processing timeout parameter for the service.
Maximum queuing time	In a tuned system, the maximum and average queuing times should be close together, the difference being an indication of the traffic distribution for this service. Values should not approach the value of the queuing timeout parameter listed for the service.

Statistic	Description
	If the maximum queuing time for a service provider is equal or close to the queuing timeout parameter and there are queuing timeouts listed, consider the following changes: ● Increase the queuing timeout parameter for the service. ● Increase the number of service providers available, either controlled by the same Job Server host or by a different Job Server. If you find that the average time in the queue is longer than the average processing time, the traffic for this service is too high for the resources provided. Consider running multiple service providers to process the same message type. You can add the same job many times in the service list, or you can add the same job controlled by a different Job Server on a separate computer to the service list. If you find that the average queuing time is growing, consider increasing the queuing timeout or adding processing resources.
Processing timeouts	If you see processing timeouts and service providers restarting successfully, consider increasing the number of processing retries allowed for the service.

4.3.8 Profile Server Management

This section describes how to use the Administrator to manage the data in the profiler repository and manage tasks on the profiler server.

The Data Profiler executes on a profiler server to provide the following data profiler information that multiple users can view:

- Column analysis—This information includes minimum value, maximum value, average value, minimum string length, and maximum string length. You can also generate detailed column analysis such as distinct count, distinct percent, median, median string length, pattern count, and pattern percent.
- Relationship analysis—This information identifies data mismatches between any two columns for which you define a relationship, including columns that have an existing primary key and foreign key relationship.

You can execute the Data Profiler on data contained in databases and flat files. Databases include DB2, Oracle, SQL Server, SAP Sybase, and Attunity Connector for mainframe databases. See the *Release Notes* for the complete list of sources that the Data Profiler supports.

This section assumes that you have already installed SAP Data Services, which includes the Data Profiler.

Related Information

Designer Guide: Data Assessment, Using the Data Profiler [page 433]

4.3.8.1 Defining a profiler repository

The Data Profiler repository is a set of tables that holds information about your data that the Data Profiler generates.

1. Create a database to use as your profiler repository.

   The profiler repository can be one of the following database types: DB2, MySQL, Oracle, Microsoft SQL Server, SAP HANA, or SAP Sybase.
2. Create a profiler repository with the Repository Manager.

   Select *Profiler* in the *Repository type* option.
3. Associate the profiler repository with a Job Server with the Server Manager.

Related Information

Administrator Guide: Using the Repository Manager [page 79]
Administrator Guide: Using the Server Manager on Windows [page 84]
Administrator Guide: Using the Server Manager on UNIX systems [page 90]

4.3.8.2 Profiler task parameters

Set configuration parameters to control the amount of resources that profiler tasks use to calculate and generate profiler statistics.

> ℹ Note
>
> If you plan to use Detailed profiling or Relationship profiling, ensure that you use the Server Manager to specify a pageable cache directory that:
>
> - Contains enough disk space for the amount of data you plan to profile.
> - Is on a separate disk or file system from the system where SAP Data Services is installed.

Related Information

Administrator Guide: Using the Server Manager on Windows [page 84]
Administrator Guide: Using the Server Manager on UNIX systems [page 90]

4.3.8.2.1 Configuring profiler task parameters

1. Select *Management* ▸ *Profiler Configuration* to access the Profiler Configuration page.
2. Keep or change the parameters values listed on the Profiler Configuration page.

The Profiler Configuration page groups the parameters into the following categories:

- Task execution parameters
- Task management configuration parameters

Related Information

Task execution parameters [page 1931]

Task management configuration parameters [page 1932]

4.3.8.2.2 Task execution parameters

The Profiler Configuration page groups the Task execution parameters into subcategories Reading Data, Saving Data, and Performance.

Task execution subcategory	Parameter	Default value	Description
Reading Data	Profiling size	All	The maximum number of rows to profile. You might want to specify a maximum number of rows to profile if the tables you profile are very large and you want to reduce memory consumption.
Reading Data	Sampling rows	1	Profiles the first row of the specified number of sampling rows. For example, if you set *Profiling size* to 1000000 and set *Sampling rows* to 100, the Profiler profiles rows number 1, 101, 201, and so forth until 1000000 rows are profiled. Sampling rows throughout the table can give you a more accurate representation rather than profiling just the first 1000000 rows.
Saving Data	Number of distinct values	100	The number of distinct values to save in the profiler repository.
Saving Data	Number of patterns	100	The number of patterns to save in the profiler repository.
Saving Data	Number of days to keep results	90	The number of days to keep the profiler results in the profiler repository.

Task execution subcategory	Parameter	Default value	Description
Saving Data	Number of records to save	100	The number of records to save in the profiler repository for each attribute.
Saving Data	Rows per commit	5000	The number of rows to save before a commit is issued.
Performance	Degree of Parallelism	2	The number of parallel processing threads that the profiler task can use.
Performance	File processing threads	2	The number of file processing threads for file sources.

4.3.8.2.3 Task management configuration parameters

The Profiler Configuration page groups the Task management configuration parameters into subcategories, basic and advanced.

Task management subcategory	Parameter	Default value	Description
Basic	Maximum concurrent tasks	10	The maximum number of profiler tasks to run simultaneously.
Basic	Refresh interval (days)	0	The number of days that must elapse before a profiler task is rerun for the same table or key columns when the user clicks the *Submit* option. The *Submit* option is on the *Submit Column Profile Request* and *Submit Relationship Profile Request* windows in the Designer. The default is 0, which is to always rerun the profiler task when the user clicks the *Submit* option. In other words, there is no limit to the number of Data Profiler tasks that can be run per day. To override this interval, use the *Update* option on the Profile tab of the View Data window in the Designer.
Advanced	Invoke sleep interval (seconds)	5	The number of seconds to sleep before the Data Profiler checks for completion of an invoked task. Invoked tasks run synchronously, and the Data Profiler must check for their completion.
Advanced	Submit sleep interval (seconds)	10	The number of seconds to sleep before the Data Profiler attempts to start pending tasks. Pending tasks have not yet started because the maximum number of concurrent tasks was reached.
Advanced	Inactive interval (minutes)	2	The number of minutes a profiling task can be inactive before the Data Profiler cancels it.

4.3.8.3 Monitoring profiler tasks using the Administrator

You can monitor your profiler task by name in either the Designer or the Administrator.

On the Administrator, you can see the status of profiler tasks, cancel profiler tasks, or delete a profiler task with its generated profile statistics.

1. Expand the *Profiler Repositories* node.
2. Click the profiler repository name.
3. The Profiler Tasks Status window displays.

   This status window contains the following columns:

Column	Description
Select	If you want to cancel a profiler task that is currently running, select this check box and click *Cancel*. If you want to delete a profiler task and its profiler data from the profiler repository, select this check box and click *Delete*. If you click *Delete* on a running task, the Profiler cancels the task before it deletes the data.
Status	The status of a profiler task can be: ○ Done—The task completed successfully. ○ Pending—The task is on the wait queue because the maximum number of concurrent tasks has been reached or another task is profiling the same table. ○ Running—The task is currently executing. ○ Error—The task terminated with an error.
Task Name	The name of the profiler task. The name is a link to the Profiler Task Items report.
Description	The names of the tables on which the profiler task was run.
Run #	The identification number for this profiler task instance.
Last Update	The date and time that this profiler task last performed an action.
Status Message	Is blank if the profiler task completed successfully. Displays an error message if the profiler task failed.

4. Click the task name to display the Profiler Task Items report, which displays the profiling type that was done for each column.

   This Profiler Task Items report contains the following columns:

Column	Description
Status	The status for each column on which the profiler task executed. The status can be: ○ Done—The task completed successfully.

Column	Description
	○ Pending—The task is on the wait queue because the maximum number of concurrent tasks has been reached or another task is profiling the same table. ○ Running—The task is currently executing. ○ Error—The task terminated with an error.
Item	The column number in the data source on which this profiler task executed.
Job Server	The machine name and port number of the Job Server where the profiler task executed.
Process ID	The process ID that executed the profiler task.
Profiling Type	Indicates what type of profiling was done on each column. The Profiling Type can be: ○ Single Table Basic—Column profile with default profile statistics. ○ Single Table Detailed—Column profile with detailed profile statistics. ○ Relational Basic—Relational profile with only key column data. ○ Relational Detailed—Relational profile with data saved from all columns.
Datastore	The name of the datastore.
Source	The name of the data source (table, flat file, or XML file).
Column	The name of the column on which the profiler task executed.
Last Update	The date and time that this profiler task last performed an action.
Status Message	Is blank if the profiler task completed successfully. Displays an error message if the profiler task failed.

Related Information

Designer Guide: Data Assessment, Monitoring profiler tasks using the Designer [page 442]

4.3.9 RFC Server Management

Data Services uses the SAP RFC Server Interface for the following tasks:

- Scheduling SAP jobs
- Reading from SAP Open Hub destinations
- Loading SAP NetWeaver BW
- Viewing Data Services logs from SAP NetWeaver BW

This section describes how to use the RFC Server Interface in the Administrator.

To access the RFC Server Interface, in the Administrator expand the *SAP Connections* node and click *RFC Server Interface*. Two tabs display: *RFC Server Interface Status* and *RFC Server Interface Configuration*.

4.3.9.1 64-bit platform prerequisites

To use the RFC Server Interface on 64-bit UNIX platforms, first confirm that your environment is configured correctly:

1. Ensure that the 64-bit Java Development Kit (JDK) is installed.
2. Ensure that SAP Data Services is correctly installed with a supported web application server.
3. Export the JAVA_HOME environment variable, pointing to the location of the 64-bit JDK.
4. Restart your web application server.

For the latest update of these configuration steps, see *SAP Note 1394367*.

4.3.9.2 Adding an RFC server interface

1. Select *SAP Connections* › *RFC Server Interface*.
2. Click the *RFC Server Interface Configuration* tab.
3. Click *Add*.
   The Administrator opens the RFC Server Configuration page.
4. Enter the configuration information.

   All options except the *RFC Program ID*, *SAP Gateway Host Name*, and *SAP Gateway Service Name* must match the SAP Applications datastore settings.

Field	Description
RFC program ID	The registered server program ID in the SAP RFC destination to which this RFC Server will connect.
User name	The user name through which SAP Data Services connects to this SAP application server. Use the same user name used to create the SAP BW Source datastore.
Password	The password for the user account through which SAP Data Services connects to this SAP application server.
SAP application server name	The domain name or IP address of the computer where the SAP application server is running.
Client number	The SAP application client number.
System number	The SAP application system number.
SAP gateway host name	The domain name or IP address of the computer where the SAP RFC gateway is located.
SAP gateway service name	The TCP/IP service name or service number for the SAP application server gateway. Typically, this value is SAPGW plus the system number.

Field	Description
SAP gateway connection count	The number of TCP/IP connections to the SAP gateway host.

5. Click *Apply*.

The Administrator adds the RFC server interface definition and returns to the *RFC Server Interface Status* page.

After adding the interface, you must manually start it from the *RFC Server Interface Status* page.

4.3.9.3 Starting or stopping an RFC server interface connection

After adding an interface, you must start it manually. To start the interface connection, on the *RFC Server Interface Status* page, select the check box for the interface to start and click *Start*.

To stop an interface connection:

1. Select the check box for the RFC server to disconnect.
2. Click *Abort* or *Shut down*.
   - If you choose *Abort*, the RFC server closes the connection to SAP BW without responding to requests currently being processed.
   - If you choose *Shut down*, the RFC server finishes processing any active requests before closing the connection. Any new requests to this RFC server will result in an error.

4.3.9.4 Monitoring RFC server interfaces

From the RFC Server Interface Status page (expand *SAP Connections* and click *RFC Server Interface*), you can access the status, statistics, and logs for all interface connections.

4.3.9.4.1 Viewing the status of interface connections

The following tables describes the status icons.

Indicator	Description
✅	A green icon indicates that each client of this type has an open connection with SAP BW server.
⚠	A yellow icon indicates that at least one client of this type is disconnecting.
❌	A red icon indicates that there was a problem starting the RFC server or processing an SAP BW request.

If an RFC server interface has a red status, view the *Status* column and click the name of the interface to view the log details.

To restart, abort, or shut down an interface, click the Back button in the navigation bar to return to the RFC Server Interface Status page.

Related Information

Finding problems [page 1956]

4.3.9.4.2 Monitoring interface statistics

The *RFC Server Interface Statistics* section lists each configured interface and statistics for that interface:

Item	Description
Name	The name of the RFC server interface.
Time connected	The total time that this interface has been connected to the SAP BW server.
Last message received	The length of time since the RFC server has received a message from SAP BW.
Last message sent	The length of time since the RFC server has sent a message to SAP BW.
Received messages	The number of messages that the RFC server has received from SAP BW.
Sent messages	The number of messages that the RFC server has sent to SAP BW.

4.3.9.4.3 Viewing RFC server interface logs

You can view the last three logs for an interface, each of which is 500 Kb in size. To view the logs for an interface, from the *RFC Server Interface Status* page, click the name of the interface. A page with two tabs displays:

- *RFC Server Log Viewer*: This tab displays the most recent log for the interface with the log path displayed at the top of the window.
- *RFC Server History Log*: This tab displays the previous two logs for the interface. Click a log name to view it.

4.3.9.5 Removing one or more RFC server interfaces

1. Under the *SAP Connections* node, click *RFC server Interface*.
2. On the *RFC Server Interface Configuration* tab, select the check box for one or more interfaces.
3. Click *Remove*.

4.3.10 Adapters

About this section

This section describes how to add an adapter to the SAP Data Services system, how to start an adapter instance, and how to monitor an adapter's operation instances.

Related Information

Overview of adapters [page 1938]
Adding and configuring adapter instances [page 1939]
Starting and stopping adapter instances [page 1943]
Monitoring adapter instances [page 1944]

4.3.10.1 Overview of adapters

An SAP Data Services adapter is a Java program that allows Data Services to communicate with front-office and back-office applications. Depending on the adapter implementation, adapter capabilities include the ability to:

- Browse application metadata.
- Import application metadata into the repository.
- Move batch and real-time data between Data Services and information resource applications.

Adapters can handle the following types of metadata: tables, documents, functions, outbound messages, and message functions. Each of these can be used in real-time or batch jobs. Outbound messages and message functions are the only objects that include operations.

An adapter can process several predefined operations. An operation is a unit of work or set of tasks that the adapter completes. Operations include:

- Taking messages from an application and send them to a real-time service for processing, possibly returning a response to the application.
- Taking messages from a real-time service and send them to an application for processing, possibly returning a response to the real-time service.
- Taking messages produced by a function call inside a real-time service, send the messages to an application, and return responses to the function.

An adapter connects Data Services to a specific information resource application. You can create one or more instances of an adapter. Each adapter instance requires a configuration file. That configuration file defines the operations available.

All adapters communicate with Data Services through a designated Job Server. You must first install an adapter on the Job Server's computer before you can use the Administrator and Designer to integrate the adapter with Data Services. See your specific adapter's documentation for its installation instructions.

After installing the adapter, configure its instances and operations in the Administrator before creating adapter datastores in the Designer, because you must select an adapter instance name as part of an adapter datastore configuration. It might help to think of the *Adapter Instances* node of the Administrator as part of your adapter datastore configuration.

To enable an adapter datastore connection:

1. Use the Server Manager to configure a Job Server that supports adapters.
2. Use the Administrator to add, configure, and start an adapter instance using the *Adapter Instances* node.
3. Use the Designer to create an adapter datastore and import metadata. Use the metadata accessed through the adapter to create batch and/or real-time jobs.

Related Information

Administrator Guide: Using the Server Manager on Windows [page 84]
Designer Guide: Datastores, Adapter datastores [page 233]

4.3.10.2 Adding and configuring adapter instances

Use the Administrator to add adapter instance configuration information to SAP Data Services and to edit an existing configuration.

Until you add an adapter interface using the Administrator, you cannot run jobs using information from that adapter.

4.3.10.2.1 Adding an adapter instance

1. Select *Adapter Instances* > `<Job Server>`.
2. Click the *Adapter Configuration* tab.
3. Click *Add*.
4. Click an adapter from the list of those installed on the Job Server with which you are working.

   > Note
   >
   > The HTTP adapter and the Web Services adapter automatically install with every Job Server. Both adapters allow you to call external applications from SAP Data Services, one using the HTTP or HTTPS protocol and the other using the SOAP protocol. Use the Web Services adapter to create outbound calls because it automatically configures and starts when a Job Server is enabled for use with adapters. However, if you want to use the HTTP adapter, you can, but you must build it like any other SAP Data Services adapter.

   For more information about the HTTP adapter see the *HTTP Adapter Guide.*
5. Enter the required information to create an adapter instance.
6. Click *Apply*.

   The Administrator adds the adapter instance to the list available to SAP Data Services.

Related Information

Support for Web Services [page 1945]
Adapter instance configuration information [page 1940]

4.3.10.2.2 Editing an adapter's configuration

1. Select ▶ *Adapter Instances* ▶ `<Job Server>` ◀.
2. Click the *Adapter Configuration* tab.
3. Click the name of the adapter instance that you want to edit.

   The Administrator displays the current configuration information.
4. Edit the configuration information.
5. Click *Apply*.

   The Administrator updates the information.

Related Information

Adapter instance configuration information [page 1940]

4.3.10.2.3 Adapter instance configuration information

Complete the following fields in the Administrator to set up an adapter instance in SAP Data Services.

> **Note**
>
> If your adapter instance is for batch jobs, the Adapter Instance Name is the only required option.

Option	Description
Adapter Instance Name	A unique name that identifies this instance of the adapter. If your adapter instance is for batch jobs, this is the only required option.
Access Server Host	To run an adapter instance in a real-time job, you must configure a service that will be called from a given Access Server. Enter the host ID of the computer running the Access Server for which you will configure a service for a real-time job that contains this adapter instance.
Access Server Port	The communication port of the Access Server host is used to both connect an Access Server to SAP Data Services components and to broker messages with external

Option	Description
	applications. After you log in to the Administrator, select ▸ *Real-Time* ▸ **<Access Server>** ▸ *Client Interfaces* ◂ to view an Access Server's message broker port information.
Adapter Retry Count	The number of times to retry an adapter instance if it fails or crashes. Enter 0 to indicate no retries. Enter a negative number to retry the instance indefinitely.
Adapter Retry Interval	The number of milliseconds to wait between adapter retry attempts.

Classpath	All adapter Java programs require specific jar files in the CLASSPATH to use when starting the javaw.exe. For example:
	• `<LINK_DIR>\lib\acta_adapter_sdk.jar`
	• `<LINK_DIR>\lib\acta_broker_client.jar`
	• `<LINK_DIR>\lib\acta_tool.jar`
	• `<LINK_DIR>\ext\lib\xerces.jar`
	Your adapter program might require different jar files.
	You can change the system CLASSPATH environmental variable, or you can use this option to enter a CLASSPATH parameter for the required jar files. If you use this option, enter, for example:
	`C:\Data Services\lib`
	`\acta_adapter_sdk.jar; Data Services`
	`\lib\acta_broker_client.jar;`
	`    Data Services\lib\acta_tool.jar;`
	`    Data Services\ext\lib\xerces.jar`

Autostart	To enable the adapter interface to start automatically when SAP Data Services starts, set this option to True.
Trace mode	A flag that controls the amount of trace messages that the adapter writes. There are two settings: • *True*—The adapter interface writes additional information messages to help debug problems. • *False*—The adapter interface writes only minimal information messages. The adapter writes trace messages to the **`<adapter_instance_name>`**`_trace.txt` file in the **`<DS_COMMON_DIR>`**`\adapters\logs` directory.
Additional java launcher options	In addition to the classpath, you can use additional options when launching java processes (javaw.exe for Windows and java.exe for UNIX platforms). Here are some examples: • If you do not define a value in this box, the default options for memory usage are: `-Xms128m -Xmx256m.`

Option	Description
	- If you get an out-of-memory error from an adapter, then you can re-configure its instance by editing the additional java launcher options. For example: –`Xms512m -Xmx1024m` - If an adapter requires that you define a system property, do so by editing the additional java launcher options: –`Xms128m -Xmx256m foo="string"`
Adapter type name	(Read-only) The name of the adapter used to create this instance.
Adapter version	(Read-only) The version of the adapter used to create this instance.

Adapter Class	(Read-only) A name that identifies the adapter class. The name depends on the type of adapter:
	- For prepackaged adapters, see the adapter documentation.
	- For custom adapters, this is the adapter's fully qualified Java class name:
	`package_name.class_name`
	where:
	○ **`<package_name>`** is the Java package name for the adapter as defined in the adapter's Java file.
	○ **`<class_name>`** is the Java class name for the adapter as defined in the adapter's Java file.
	For example, suppose the adapter's Java file contains these lines:
	`package com.acta.adapter.SiebelAdapter`
	`public class SiebelAdapter implements`
	Then, the adapter class name is:
	`com.acta.adapter.SiebelAdapter.SiebelAd`
	`apter`

Root Directory	Examine the adapter's root directory name. Edit this name as needed.

4.3.10.2.3.1 Adding operation instances to an adapter instance

1. Select ▸ *Adapter Instances* ▸ **`<Job Server>`** ▸.
2. Click the *Adapter Configuration* tab.

3. Click *Operations* under Dependent Objects. The Adapter Operation Configuration page opens.
4. Click *Add* to configure a new operation.

   Here you can also click the link of an existing operation instance to edit its configuration.
5. Select an operation type from the list.

   The options that appear on this page depend on the adapter's specific design.
6. Click *Apply*.
7. Complete the information on the Adapter Operation Configuration page.

   The options and descriptions that appear on this page depend on the adapter's specific design. Consult your adapter-specific documentation for details.
8. Click *Apply*.

4.3.10.3 Starting and stopping adapter instances

Use the Administrator to start and stop an adapter instance and its operations.

- After you configure an adapter instance, each time you stop and start the Access Server, you stop and start the adapter instance and its operations.
- After you restart an adapter instance, the service that uses it fails to process the next message it receives. Therefore, when you restart an adapter instance, also restart its associated services.

4.3.10.3.1 Starting an adapter instance

1. Select *Adapter Instances* `<Job Server>`.
2. Select the check box next to the adapter instance you want to start.
3. Click *Start*.

   The Administrator starts the adapter instance and all of its operations.

4.3.10.3.2 Stopping an adapter instance

1. Select *Adapter Instances* `<Job Server>`.
2. Select the check box next to the adapter instance you want to stop.
3. Click either *Shutdown* or *Abort*:
   - Select *Shutdown* to stop an adapter and all of its operations gracefully. The adapter will complete any pending operations before shutting down.
   - Select *Abort* if you want to stop all operations immediately. Select *Abort* only if incomplete operations are acceptable.

4.3.10.3.3 Starting or stopping an adapter operation instance

1. Select *Adapter Instances* **`<Job Server>`**.
2. Select the check box next to the operation instance you want to start or stop.

   When you start an adapter instance, its operations will also start. However, you can also start and stop individual operation instances manually using this page.
3. Click either *Start* or *Shutdown*.

4.3.10.4 Monitoring adapter instances

Use the Administrator to monitor adapters and their operations.

4.3.10.4.1 Monitoring the adapter instances and operations

1. Select *Adapter Instances* **`<Job Server>`**.

   The Adapter Instance Status page lists each adapter instance and its operations.
2. Find the overall status of a particular adapter instance or operation by examining the indicators.

Indicator	Description
✔	A green icon indicates that the adapter instance or operation has started and is currently running.
⚠	A yellow icon indicates that the adapter instance or operation is not currently running.
✖	A red icon indicates that the adapter instance or operation has experienced an error.

   For each operation, this page lists four statistics:

Statistic	Description
Requests Processed	The number of requests for this operation instance that were processed. Processing of these requests is complete.
Requests Pending	The number of requests for this operation instance that are still pending. Processing of these requests is not complete.
Requests Failed	The number of requests for this operation instance that have failed. The operation has stopped processing these requests.
Status	For operations, displays error text. You can also find more detailed adapter instance information in the Status column. Possible values include: ○ Initialized

Statistic	Description
	○ Starting ○ Started ○ Shutting Down ○ Shutdown ○ Error text—Displays the last error message that occurred as the adapter instance shut down or indicates that the configuration has changed. To allow the adapter instance to use the changes, restart the adapter instance.

For more detailed information about the adapter instance, view the error and trace log files.

4.3.10.4.2 Monitoring adapter instance statistics

1. Select *Adapter Instances* › `<Job Server>`.
2. Click the name of an adapter instance.

   The statistics for the instance appear. The options and descriptions that appear on this page depend on the adapter's specific design. Consult your adapter-specific documentation for details.

4.3.11 Support for Web Services

For information about using SAP Data Services as both a Web services server and client, see the *Integrator Guide*.

4.3.12 Support for HTTP

About this section

The HTTP functionality is installed with every Job Server. This section describes how to configure and use this functionality with SAP Data Services.

Related Information

Overview [page 1946]

Adapter installation and configuration [page 1946]

4.3.12.1 Overview

Hypertext Transfer Protocol (HTTP) is an application-level protocol for distributed, collaborative, hypermedia information systems. HTTP has been in use by the World-Wide Web global information initiative since 1990 and its use has increased steadily over the years, mainly because it has proven useful as a generic middleware protocol.

HTTP is a request/response protocol. A client sends a request to a server specifying a "request method", a Universal Resource Identifier (URL), and protocol version, followed by a message containing client information and usually body content.

The server responds with a status line including the message's protocol version and a success or error code, followed by a message containing server information and usually body content.

HTTP communication usually takes place over TCP/IP connections. The default port is TCP 80 [19], but other ports can be used. This does not preclude HTTP from being implemented on top of any other protocol on the Internet, or on other networks. HTTP only presumes a reliable transport; any protocol that provides such a guarantee can be used.

HTTP can also utilize a Secure Socket Layer (SSL) to implement security at the protocol level. In this manner, data exchange is protected from any unscrupulous elements.

SAP Data Services supports HTTP in the following manner:

- Data transfer can be done using either HTTP or HTTPS (HTTP with SSL) protocols
- The transport mechanism is always TCP/IP
- Both batch and real-time jobs can request data from HTTP-enabled servers, acting as HTTP clients
- Real-time jobs can be executed via HTTP requests, therefore making SAP Data Services act as an HTTP server

4.3.12.2 Adapter installation and configuration

The ability to handle requests to execute real-time jobs as an HTTP server comes pre-configured with SAP Data Services and it is implemented as a servlet deployed inside the Web Server. The ability to call other services as an HTTP client is implemented as an HTTP adapter and it requires further configuration, as explained in subsequent sections.

4.3.12.2.1 URL for HTTP requests

The SAP Data Services server URL format is:

```
http://<host>:<port>/DataServices/servlet/HTTP?ServiceName={GetService}
```

Where:

- **<host>** is the IP address/host name of the Access Server
- **<port>** is the port number of the Access server

These values are the same as in the URL of the Administrator.

4.3.12.2.2 Configuring the HTTP adapter

When you configure the HTTP adapter you must configure one or more instances of the adapter as well as one or more operation instances for each adapter instance.

Adapter operations identify the integration operations available with the configured adapter instance.

Operations provided with the HTTP Adapter include:

- Request/Reply Operation
  This operation is used to execute a remote HTTP service in the Request Reply mode i.e. it makes the request to the remote machine where the HTTP server is running and wait for the reply.
- Request/Acknowledge Operation
  This operation is used to execute a remote HTTP service in the Request Acknowledge mode i.e. it makes the request to the remote machine where the HTTP Adapter server is running and does not wait for the reply; instead, it sends an acknowledgement if the operation is successful.

All adapters communicate with SAP Data Services through a designated Adapter Manager Job Server. Use the Server Manager utility to configure adapter connections with the Adapter Manager Job Server.

Use the Administrator to add an HTTP adapter to the SAP Data Services system and to edit existing adapter configurations. Until you add the adapter in the Administrator, you cannot run jobs using information from that adapter.

Related Information

Administrator Guide: Using the Server Manager on Windows, To configure Job Servers [page 84]

4.3.12.2.2.1 Adding an adapter instance in the Administrator

1. Select ▶ *Adapter Instances* ▸ **`<Job Server>`** ◀.
2. Click the *Adapter Configuration* tab.
3. Click *Add*.
4. Select the HTTP adapter from the list of those available on this Job Server.
5. Enter the required information to create an HTTP adapter instance.
6. Click *Apply*.

   The Administrator adds the adapter instance to the list of those available to the SAP Data Services system.

Related Information

Adapter instance startup configuration [page 1948]

4.3.12.2.2.2 Adapter instance startup configuration

Complete the following fields in the Administrator to set up an HTTP adapter instance in the SAP Data Services system:

Option	Description
Adapter Instance Name	Enter a unique name that identifies this instance of the HTTP Adapter.
Access Server Host	Enter the host ID of the computer running the Access Server that connects to this adapter instance. This information is used by the web application server.
Access Server Port	The Access Server host's message broker port. After you log into the Administrator for this Access Server, select *Configuration* > *Interfaces* to view message broker port information.
Character Set	Used to convert text characters to and from bytes for data.
Metadata Character Set	Used to convert text characters to and from bytes for metadata.
Adapter Retry Count	The number of times for SAP Data Services to retry the adapter instance if it fails or crashes. Enter a negative number to retry indefinitely or enter 0 for no retries.
Adapter Retry Interval	Sets the number of milliseconds between adapter retry attempts.

Classpath	All adapter Java programs require specific jar files in the CLASSPATH to use when starting the `javaw.exe`. For example:
	`LINK_DIR/lib/acta_adapter_sdk.jar`
	`LINK_DIR/lib/acta_broker_client.jar`
	`LINK_DIR/lib/acta_tool.jar`
	`LINK_DIR/ext/lib/xerces.jar`
	`LINK_DIR/lib/acta_http_adapter.jar`
	`LINK_DIR/lib/jcert.jar`
	`LINK_DIR/lib/jnet.jar`
	`LINK_DIR/lib/jsse.jar`

Autostart	When set to *True*, the adapter interface automatically starts when the Administrator starts.
Trace Mode	Set this flag to control the number of trace messages the adapter writes. There are two settings: • *True*—The adapter interface writes additional information messages to help debug problems. • *False*—The adapter interface writes minimal information messages. The adapter writes trace messages to the **`<adapter_instance_name>`**`_trace.txt` file in the **`<DS_COMMON_DIR>`**`/adapters/logs` directory.
Additional Java Launcher Options	Enable to launch the java process that hosts the adapter.

Option	Description
Application command line parameters	Additional command line parameters used for the `javaw.exe` command line and for the adapter itself. See specific adapter documentation for details.
Adapter Type name	(Read-only) The name of the adapter used to create this instance.
Adapter Version	(Read-only) The version of the adapter used to create this instance.
Adapter Class	(Read-only) A name that identifies the adapter class. The name depends on the type of adapter.
Keystore Password	(Optional) The software checks the integrity of the keystore data only if you enter a password. Without a password, the software does not check the integrity of the keystore data. This value is required if using HTTPS protocol to make requests.

4.3.12.2.3 Configuring an operation instance

4.3.12.2.3.1 Adding an operation instance to an adapter instance

1. Select *Adapter Instances* > **`<Job Server>`**.
2. Click the *Adapter Configuration* tab.
3. Under Dependent Objects, click *Operations*.
4. Click *Add* to configure a new operation. Or, you can click the link of an existing operation instance to edit its configuration.
5. Select an operation type from the list (*Request/Reply* or *Request/Acknowledge*), then click *Apply*. The options that appear depend on the operation specific design.
6. Complete the operation instance configuration form.
7. Click *Apply*.

Related Information

Configuring a Request/Reply operation instance [page 1950]

4.3.12.2.3.2 Configuring a Request/Reply operation instance

When creating or editing a Request/Reply operation instance, you must complete the following fields:

Option	Description
Operation Instance	The unique operation instance name. In the Designer, the Request/Reply operation metadata object will be imported with this name.
Thread Count	The number of copies of Request/Reply operations to run in parallel. For parallel (asynchronous) processing of messages coming from a real-time service, use more than one copy. If the sequence of messages is important (synchronous processing), do not use more than one thread. (Multiple copies of real-time services must be supported by multiple copies of Request/Reply.) The default is 1.
Display Name	The operation instance display name. This display name will be visible in the Designer's metadata browsing window.
Description	A description of the operation instance. This description will display in the Designer's metadata browsing window.
Enable	Set to True for the Adapter SDK to start this operation instance when adapter starts; otherwise, set to False.
Target URL	The URL where you want to send the HTTP request from SAP Data Services (the HTTP server address).
Request Method	The HTTP request method used to submit the request. The possible values are POST and GET.
Content-Type	Used to set the content type header of the request. It specifies the nature of the data by giving type and subtype identifiers.
Content-Language	The ISO code for the language in which the request document is written. For example: 'en' means that the language is English in one of its forms.
Content-Encoding	Specifies the encoding mechanism used for sending the request. Current valid entries are x-compress and x-gzip.
Continue If Untrusted	Specifies whether to continue the operation with an untrusted HTTP server. If True, the operation continues; if False, the operation terminates.
Request DTD	The DTD file name that defines the Request XMLmessage used in the operation.
Request XML Root Element	The name of the XML root element in the Request DTD.
Reply DTD	The DTD file name that defines the Reply XML message used in the operation.
Reply XML Root Element	The name of the XML root element in the Reply DTD.

4.3.12.2.3.3 Configuring a Request/Acknowledgement operation instance

When creating or editing a Request/Acknowledgement operation instance, you must complete the following fields:

Option	Description
Operation Instance	The unique operation instance name. In the Designer, the Request/Acknowledge operation metadata object is imported with this name.
Thread Count	The number of copies of Request/Acknowledgement operations to run in parallel. For parallel (asynchronous) processing of messages coming from a real-time service, use more than one copy. If the sequence of messages is important (synchronous processing), do not use more than one thread. (Multiple copies of real-time services must be supported by multiple copies of Request/Acknowledgement) Default is 1.
Display Name	The operation instance display name. This display name will be visible in the Designer's metadata browsing window.
Description	A description of the operation instance. This description will display in the Designer's metadata browsing window.
Enable	Set to True for the Adapter SDK to start this operation instance when the adapter starts; otherwise, set to False.
Target URL	The URL where you want to send the HTTP request.
Request Method	The HTTP request method to be used for submitting the request. The possible values are POST and GET.
Content-Type	Used to set the content type header of the request. It specifies the nature of the data by giving type and subtype identifiers.
Content-Language	The ISO code for the language in which the request document is written. For example: 'en' means that the language is English in one of its forms.
Content-Encoding	Specifies the encoding mechanism used for sending the request. Current valid entries are x-compress and x-gzip.
Continue If Untrusted	Specifies whether to continue the operation instance with an untrusted HTTP server. If True, the operation instance continues; if False, the operation instance terminates.
Request DTD	The DTD file name that defines the Request XML message used in this operation.
Request XML Root Element	The name of the XML root element in the Request DTD.

Restart the HTTP Adapter instance for the configuration changes to take effect.

4.3.12.2.4 Defining the HTTP adapter datastore

You can use the HTTP adapter in a batch or real-time data flow by selecting one of the following objects:

- An Outbound message (for Request/Acknowledge operations)
- A Message Function (for Request/Reply operations)

However, before you select these objects, you must first define an HTTP adapter datastore in the Designer, and then import the operation instances defined for the HTTP adapter instance. A data flow can then pass a message to one of the adapter operation instances defined in the datastore.

To define an adapter datastore, you must:

- Define a datastore object for each adapter instance.
- Define one function or one outbound message for each operation instance to which you want to pass a message.

The following sections summarize the Designer tasks for defining an adapter datastore. For more details, see the *Designer Guide*.

Related Information

Define a datastore object [page 1952]

4.3.12.2.4.1 Define a datastore object

In the Designer object library, you must define a datastore object for each adapter instance.

4.3.12.2.4.1.1 Defining an HTTP adapter datastore

1. Go to the *Datastores* tab in the object library, right-click and select *New* from the menu.

   The *Create New Datastore* editor appears.
2. Name the datastore. It's recommended that you incorporate "HTTP" into the name.
3. For *Datastore type*, select *Adapter*.

   > Note
   >
   > Datastore configuration options change depending on the type of datastore that you are creating.
4. For *Job Server*, select the Job Server configured to handle your HTTP adapter.
5. For *Adapter instance name*, choose the instance name you configured in the Administrator.
6. Click *OK* to save values and create the datastore.

Related Information

Configuring the HTTP adapter [page 1947]

4.3.12.2.4.2 Importing message functions and outbound messages to the datastore

SAP Data Services can pass messages from a data flow to an operation instance. You must import either a function or an outbound message (depending on the type of operation involved) in the Designer datastore library for each operation instance.

HTTP adapter operations contain the following invocation types:

Operation	Invocation Type
Request/Reply	Message Function
Request/Acknowledge	Outbound Message

4.3.12.2.4.2.1 Importing message functions and outbound messages

1. In the Designer, double-click the datastore that is associated with your HTTP Adapter Instance.

   The Adapter Metadata Browser window opens.
2. Right-click the operation instance that you want to import and select *Import* from the menu.

   The operation instance you selected is added to the datastore.

You can use imported message functions and outbound messages in your real-time data flows.

4.3.12.2.5 Configuring SSL with the HTTP adapter

With Secure Socket Layer (SSL), the HTTP adapter can use secure transport over TCP/IP networks.

To connect to an SSL-enabled web application server other than the packaged Tomcat server, you must obtain the keystore and certificate from that HTTP service provider. The following procedure describes how to configure the client.

4.3.12.2.5.1 Configuring the client to access a public SSL-enabled Web server

1. Generate the client keystore.
2. Obtain a signed certificate from the SSL-enabled web server.
3. Import the certificate into the client keystore.

4.3.12.2.5.2 Generating a keystore file

If you need to generate a keystore file for your web application server, you can use the `keytool` tool included with the Java Runtime Environment.

1. Open a command prompt, and navigate to the `bin` folder for your Java installation.
2. At the command prompt, run the `keytool` command:

   ```
   keytool -genkey -alias tomcat -keyalg RSA -keystore <path/to/keystore.file>
   ```

   Replace **`<path/to/keystore.file>`** with the desired filename and location for the generated keystore file. For example, `D:\tomcat.keystore`.

   > Note
   >
   > If you do not specify the **`-keystore`** parameter, the keystore file is generated in the home directory of the user who executes the command.

3. Enter the password for the keystore.
4. Enter the host name parameter value from the Target URL property of the operation instance for the first and last name.
5. Enter information about your organization and city as appropriate for each prompt.

   This information is displayed to users who attempt to access secure pages within your application.
6. Press `Enter` to automatically use the keystore password as the key password for the certificate.

The keystore file containing the certificate that can be used by your web application server is generated in the specified location.

4.3.12.2.5.3 Configuring SSL on the web application server

For SAP Data Services to work with SSL, the web application server must be configured to support SSL connections. The `server.xml` file can be used to configure the packaged Tomcat application server.

> Note
>
> For other web application servers, refer to the product documentation about how to configure SSL support.

1. Open `server.xml` in a text editor. This file is located in the `Tomcat55\conf` directory at the same level as `LINK_DIR`.

2. Locate the commented `connector` element in the XML:

```
<!-- Define a SSL HTTP/1.1 Connector on port 8443 -->
<!--
<Connector port="8443" maxHttpHeaderSize="8192"
  maxThreads="150" minSpareThreads="25" maxSpareThreads="75"
  enableLookups="false" disableUploadTimeout="true"
  acceptCount="100" scheme="https" secure="true"
  clientAuth="false" sslProtocol="TLS" />
 -->
```

3. Remove the comment (`<!-- -->`) tags around the `connector` element.
4. Add the `keystoreFile` and `keystorePath` attributes into the `connector` element.

```
keystoreFile="<path/to/keystore/file>"
keystorePass="<keystore_password>"
```

5. Restart the Tomcat application server.

4.3.12.2.5.4 Importing a certificate into the client keystore

The HTTP Adapter client internally handles the details of certificate authentication by implementing the X509TrustManager interface and using SSLSocketFactory classes from the HttpsURLConnection class.

When a HTTPS request is made to the SSL-enabled web server, the client requests the server's certificate, which may be issued by some standard authority such as VeriSign.

If, when the HTTP client checks its certificate store (located in `%LINK_DIR%\ext\Jre\lib\security`), the client determines that the certificate is trusted, the client receives all of the requested data from web server.

The HTTP client requires a password to query the local keystore for verification. As part of the adapter configuration, enter this password as the value of the `keystorePassword` parameter.

If the HTTP client encounters an untrusted certificate, the client throws the SSLException to its caller and checks the value of the `continueIfUntrusted` parameter. If the parameter is set to *false*, the SSLException displays with an informative message and gets logged in trace files. Further, the client does not receive any data from the server. If the parameter `continueIfUntrusted` is set to *true*, then the software logs the SSLException in error and trace files and the client receives data from the server. The certificate file `untrust.cer` is downloaded in the user's current working directory or under `LINK_DIR/bin` directory.

To import the certificate file to the JDK certificate keystore, use the keytool command:

```
keytool -import -alias <DESCRIPTION> -file untrust.cer  -keystore <Full path of
Cacerts file in the <java.home>/lib/security/ directory> cacerts  -storepass
<password>
```

where `DESCRIPTION` can be any text in double quotes. The `storepass` expects the same password with which you created the keystore in the web server.

You will also be prompted for a keystore password; enter whatever password you want. The keytool command will print the certificate information and ask you to verify it. Enter **`yes`** to complete the import process.

4.3.13 Troubleshooting the Administrator

About this section

The Administrator provides status and error information. Use this information to discover problems with your implementation and to find the source of those problems. This section describes how you can use the Administrator to find and help resolve job processing issues.

Related Information

Reestablishing network connections [page 1956]
Finding problems [page 1956]
Error and trace logs [page 1957]
Resolving connectivity problems [page 1962]
Restarting the Access Server [page 1963]

4.3.13.1 Reestablishing network connections

When you disconnect from your network and re-connect or otherwise change an IP address (Dynamic IPs), the Administrator encounters a database connection error.

To reestablish network connections for your repository, you can do one of two things:

- Rename the repository in the Administrator. This change forces the Administrator to drop and recreate the connection to the database.
- Restart the Administrator.

4.3.13.2 Finding problems

The Administrator uses colored indicators to show the status of the various system components. Generally, the indicators mean the following:

Indicator	Description
✓	A green icon indicates that the object is running properly.
⚠	A yellow icon indicates that some aspect of this object is not working. Either the Access Server is in the process of its error-handling efforts to reestablish an operation, or the Access Server is waiting for a manual intervention. For example, when you first add a service to the Access Server configuration, the service displays a yellow icon until you manually start the service or until you restart the Access Server.

Indicator	Description
❌	A red icon indicates that one or more aspects of this object is not working, and the error handling efforts of Access Server were not able to reestablish the operation of the object.

When you see a yellow or red icon, the system requires manual intervention. You must:

- Determine which object is not operating properly.
- Determine the cause of the problem.
- Fix the problem.
- Restart the affected service providers if necessary.

4.3.13.2.1 Determining which object is not operating properly

1. In the Administrator, click *Home*.

   If there is an error anywhere in the system, you will see a red indicator next to a repository or Access Server name.
2. If you see a red indicator, click a repository or Access Server name.

   The page for that repository or Access Server appears.
3. Look for another red indicator on objects listed at this level.
4. If you can identify lower-level objects that have a red indicator, repeat the previous two steps.

   When you have identified the lowest level object with the error, you are ready to determine the cause of the error.

4.3.13.2.2 Determining the cause of the error

1. Examine the error log for the affected subsystem, such as a batch job, a service provider, or an adapter interface, or for the Access Server itself.

   Use the timestamp on the error entries to determine which error accounts for the problem that you are experiencing.
2. Cross-reference the error to the trace information.

   When you identify the appropriate error message, you can use the timestamp to determine what other events occurred immediately before the error.

   For example, if an error occurred for a specific service provider, you can use the error timestamp in the service provider error log to look up Access Server activities that preceded the error.

4.3.13.3 Error and trace logs

The Administrator provides access to trace and error log files for each service provider, each batch job that ran, and for the Access Server. Use these detailed log files to evaluate and determine the cause of errors.

4.3.13.3.1 Batch job logs

The Batch Jobs Status page provides access to trace, monitor, and error log files for each batch job that ran during a specified period. For information about setting that period, see Setting the status interval.

For information about monitor logs, deleting logs, and the *Ignore Error Status* button see Monitoring jobs.

4.3.13.3.1.1 Viewing a batch job trace log

The trace log file lists the executed steps and the time that execution began. Use the trace log to determine where an execution failed, whether the execution steps occurred in the order you expect, and which parts of the execution were the most time-consuming.

1. Select *Batch Jobs* `<repository>`.
2. Identify the instance of the job execution in which you are interested by the job name, start time, and so on.
3. Under *Job Information* for that instance, click *Trace*.

   The Administrator opens the Job Trace Log page.

4.3.13.3.1.2 Viewing a batch job error log

The error log file shows the name of the object that was executing when an error occurred and the text of the resulting error message. If the job ran against SAP application data, the error log might also include ABAP errors.

Use the error log to determine how an execution failed. If the execution completed without error, the error log is blank.

1. Select *Batch Jobs* `<repository>`.
2. Identify the instance of the job execution in which you are interested by the job name, start time, and so on.
3. Under *Job Information* for that instance, click *Error*.

   The Administrator opens the Job Error Log page.

4.3.13.3.2 Service provider logs

The Service Provider Status page provides access to the error and trace log files for a service provider. These are the log files produced by the Job Server that controls the service provider.

4.3.13.3.2.1 Viewing the logs for a service provider

1. Select *Real-Time* `<Access Server>` *Real-time Services*.

2. Click the name of a service.

   The Administrator opens the Real-time Service Status page. This page shows a list of service providers for the service and overall statistics for the service.
3. Click the name of the service provider process ID in which you are interested.

   The Administrator opens the Service Provider Status page.
4. Click a link to view the desired service provider log.

   To delete these logs, set the log retention period. To filter the list of real-time services on the Real-time Service Status page by date, set the status interval.

Link	Description
Trace Log	Opens the Trace Log page for the current service provider execution. This link appears only if the real-time service is registered with the Access Server.
Error Log	Opens the Error Log page for the current service provider execution. This page lists errors generated by the software, by the source or target DBMS, or the operating system for job execution. If the error log is empty, the job has not encountered errors in message processing. This link appears only if the real-time service is registered with the Access Server.

The computer running the Job Server stores text files containing the batch and service provider trace, error and monitor logs. If you installed SAP Data Services in the default installation location, these files are located in the <**<DS_COMMON_DIR>**>/Logs/**<JobServerName>**/**<RepoName>** folder.

The name of the log file describes the contents of the file:
<type>_**<timestamp>**_**<sequence>**_**<jobname>**.txt, where:

- **<type>** is trace, monitor, or error.
- **<timestamp>** is the system date and time from when the job created the log.
- **<sequence>** is the number of this job related to all jobs run by this Job Server instance.
- **<jobname>** is the name of the job instance.

Batch job trace and error logs are also available on the *Log* tab of the Designer project area. To see the logs for jobs run on a particular Job Server, log in to the repository associated with the Job Server when you start the Designer.

Related Information

Setting the status interval [page 1877]

4.3.13.3.3 Access Server logs

Trace and error logs for each Access Server are available in *Real-Time* > **<Access Server>** > *Logs-Current* and *Real-Time* > **<Access Server>** > *Logs-History*. In addition, these files are located in the Access Server configuration location, which you specify when you configure the Access Server.

> **Note**
>
> For remote troubleshooting, you can also connect to any Access Server through the Administrator.

4.3.13.3.3.1 To view the current day's logs

1. Select ▶ *Real-time* ▶ `<Access Server>` ▶ *Logs-Current* ◀.
2. This page lists the error log file followed by the trace log file. The Administrator shows the last 100,000 bytes of the Access Server error log or trace log for the current date.

   The date of the file is included in the name:
   - `error_MM_DD_YYYY.log`
   - `trace_MM_DD_YYYY.log`
3. To view a file, click the file name. The Administrator shows the last 100,000 bytes of the Access Server error log or trace log for the current date.
   - The error log contains error information that the Access Server generates.
   - The trace log contains a variety of system information. You can control the information the Access Server writes to the trace log.

Related Information

Configuring the trace log file [page 1960]

4.3.13.3.3.2 Viewing the previous day's logs

1. Select ▶ *Real-Time* ▶ `<Access Server>` ▶ *Logs-History* ◀.
2. This page lists error log files followed by trace log files. The date of the file is included in the name:
   - `error_MM_DD_YYYY.log`
   - `trace_MM_DD_YYYY.log`
3. To view a file, click the file name.

4.3.13.3.3.3 Configuring the trace log file

1. Select ▶ *Real-Time* ▶ `<Access Server>` ▶ *Logs-Current* ◀.
2. Click the *Access Server Log Configuration* tab.
3. Under *Log Contents*, the Administrator lists several trace parameters that control the information that the Access Server writes to the trace file.

Name	Description
Admin	Writes a message when an Access Server connection to the Administrator changes.
Flow	Writes a message when an Access Server exchanges information with a real-time service.
Request	Writes a message when an Access Server receives requests.
Security	Writes a message when an Access Server processes authentication information (IP addresses, user name, or password).
Service	Writes a message when an Access Server starts or stops a service.
System	Writes a message when an Access Server initializes, activates, or terminates.

4. Select the check box next to the name if you want the Access Server to write corresponding messages to the trace log file.
5. Under *Log Tracing*, select the *Enabled* check box.
6. Click *Apply*.

   The Administrator changes the Access Server configuration. The Access Server will now write the selected trace messages to the trace log.

> i Note
>
> Until you set the parameters on this page, the Access Server uses the startup parameters to determine trace options. Each time you restart the Access Server, the startup parameters take precedence over parameters set on this page. You can control the content of this log by setting parameters when configuring the Access Server.

Related Information

Restarting the Access Server [page 1963]
Configuring Access Server output [page 1921]

4.3.13.3.3.4 To delete Access Server logs

1. Select *Real-Time* › `<Access Server>` › *Logs-Current* or *Real-Time* › `<Access Server>` › *Logs-History* .
2. Select the check box next to any log file that you want to delete.

   Alternatively, to delete all of the log files, select the Select all check box.
3. Click *Clear* or *Delete*.

   The Administrator clears the file size for current logs and deletes the selected history files from the display and from the Access Server log directory.

4.3.13.3.4 Adapter logs

For more detailed information about an adapter or an adapter's operations, see the adapter's error and trace log files.

4.3.13.3.4.1 Viewing log files for an adapter instance

1. Select *Adapter Instance* **`<Job Server>`**.
2. Find the adapter instance for which you want to view logs and from the *Log Files* column, click the *Error Log* or *Trace Log* link.
3. The corresponding page opens.

   These log files are also found in the **`<DS_COMMON_DIR>`**`\adapters\log` directory. The error log file is named **`<adapter_instance_name>`**`_error.txt` and the trace log file is named **`<adapter_instance_name>`**`_trace.txt`.

4.3.13.4 Resolving connectivity problems

If you have determined that you have connectivity problems among your real-time system components, consider the following possible failures:

- `Application client cannot connect to Access Server`
  For example, an error appears in the logs generated by your application client or in the command prompt when you execute the client test utility that looks like this:
- `Error: unable to get host address`
  If you specified an IP address and received this error, your network might not support static IP address resolution. Try using the computer name instead.
  Match the port number that you specified in the client test utility (or in the Message Client library call) to the Access Server's port number.
  Make sure that the port that you specified is not in use by other applications on the computer where an Access Server is installed.
- `Access Server cannot connect to Job Server`
  If this error occurs, you would see a red indicator for a service provider and an error log for the Access Server.
  Match the host name and port number of the Job Server for the service being called (configured in the Administrator) to the host name and port number that the Job Server is configured to use (as listed in the Server Manager).
  To make sure that the Job Server is running, check the Windows Task Manager for the `Al_jobserver.exe` and `Al_jobservice.exe` processes or open the Designer, log in to the repository that corresponds to the Job Server, and look for the Job Server icon at the bottom of the window.
- `Job Server cannot start real-time service`
  If this error occurs, the status indicator for the related service and its service provider would be red and you would be able to open the error log file from the Service Provider Status page.
  Make sure that the job is properly indicated for the service called in the Real-Time Service Status page.
  Make sure that the real-time jobs are available in the repository associated with the Job Server.

Make sure the repository and the Access Server are connected to the Administrator and that the repository is available.
If you change the password for your repository database, the Job Server will not be able to start real-time services. To fix this problem, re-register your repository in the Administrator and reconfigure the real-time services.

- `Real-time service cannot register with Access Server`
  If this error occurs, you would see:
  - A red indicator for the service provider.
  - An error log in the Logs-Current page (the startup timeout will eventually be triggered).
  - An error log available from the Service Provider Status page.

  Make sure the Access Server host name correctly identifies the computer where the Access Server is running.
- `Access Server cannot connect back to application client`
  If this error occurs, you would see an error log under the Access Server's Logs-Current node.
  Make sure that the host name and port used by the message broker client to communicate with the Access Server is correct.

4.3.13.5 Restarting the Access Server

To restart the Access Server, you can use either of two methods:

- Controlled Restart
  The Access Server responds to new and queued messages with a shutdown error. It waits for service providers to complete processing existing messages, then returns the responses to those clients. Next, the Access Server closes existing client connections (including adapters), stops, and restarts itself. Finally, the Access Server reads the current configuration settings and restarts services, service providers, and adapters. Restarting the Access Server this way requires as much time as it takes to process requests in the system.
- Abort and Restart
  The Access Server responds to new and queued messages with a shutdown error. It shuts down existing service providers and responds to these messages with a shutdown error. Next, the Access Server closes existing client connections (including adapters), stops, and restarts itself. Finally, the Access Server reads the current configuration settings and restarts services, service providers, and adapters.

4.3.13.5.1 Performing a controlled restart of the Access Server

1. Select *Real-Time* > **`<Access Server>`** > *Status*.
2. Under *Life Cycle Management*, click *Controlled Restart*.
3. Click the *Real-Time Services* node to verify that all services started properly.

   The Access Server allows running services to complete and returns incoming and queued messages to the client with a message that the Access Server has shut down. When all services have stopped, the Access Server stops and restarts itself. The Access Server reads the new configuration settings and starts services as indicated.

If all service providers started properly, the Real-Time Service Status page shows a green indicator next to each service name. A red indicator signifies that a component of the service did not start.

4.3.13.5.2 Performing an abort and restart of the Access Server

1. Select *Real-Time* > **`<Access Server>`** > *Status* .
2. Under *Life Cycle Management*, click *Abort and Restart*.
3. Click the *Real-Time Services* node to verify that all services started properly.

4.4 Metadata Reports

This section describes the overall requirements for enabling and viewing metadata reports including software and configuration requirements and logging in to the Management Console.

4.4.1 Requirements

Use the SAP Data Services Administrator to configure repositories for metadata reporting applications to access.

To make metadata reports available for objects, the metadata reporting applications require:

- A web application server
- JDBC drivers to connect to a repository
- Configured repositories

4.4.2 Repository reporting tables and views

The SAP Data Services repository is a database that stores your software components and the built-in design components and their properties. The open architecture of the repository allows for metadata sharing with other enterprise tools.

Within your repository, the software populates a special set of reporting tables with metadata describing the objects in your repository. When you query these tables, you can perform analyses on your applications.

The following table lists the Metadata reporting tables and what they contain:

Name	Contains
AL_ATTR	Attribute information about native objects
AL_AUDIT	Audit information about each data flow execution

Name	Contains
AL_AUDIT_INFO	Information about audit statistics
AL_CMS_BV	Components of a Business View
AL_CMS_BV_FIELDS	Business Fields within Business Elements in a Business View
AL_CMS_REPORTS	Information that uniquely identifies Crystal Reports reports, SAP BusinessObjects Desktop Intelligence documents, or SAP BusinessObjects Web Intelligence documents
AL_CMS_REPORTSUSAGE	Tables, columns, Business Views, or SAP BusinessObjects Universe Builder universes that a Crystal Reports report, SAP BusinessObjects Desktop Intelligence document, or SAP BusinessObjects Web Intelligence document uses
AL_CMS_FOLDER	Folder names in which a Crystal Reports report, SAP BusinessObjects Desktop Intelligence document, or SAP BusinessObjects Web Intelligence document resides
AL_CMS_UNV	Information that uniquely identifies universes
AL_CMS_UNV_OBJ	Universe classes and the child objects, with the source column and table
AL_HISTORY	Execution statistics about jobs and data flows
AL_INDEX	Index information about imported tables
AL_LANG	Information about native (.atl) objects
AL_LANGXMLTEXT	Information about objects represented in XML format
AL_PCOLUMN	Column information about imported table partitions
AL_PKEY	Primary key information about imported tables
AL_QD_VRULE	Validation rule names
AL_QD_VRULE_OFLOW	Rule name if it cannot fit it into AL_QD_VRULE (if there is an overflow)
AL_QD_STATS	Runtime validation rule statistics
AL_QD_ROW_DATA	Sample row data for which the validation rules have failed
AL_QD_COLINFO	All the column information for the failed validation rules
AL_USAGE	All ancestor-descendant relationships between objects
ALVW_COLUMNATTR	Attribute information about imported columns
ALVW_COLUMNINFO	Information about imported column
ALVW_FKREL	Primary-foreign key relationships among imported tables
ALVW_FLOW_STAT	Execution statistics about individual transforms within data flows
ALVW_FUNCINFO	Information about both native functions and functions imported from external systems
ALVW_MAPPING	Mapping and lineage information for target tables
ALVW_PARENT_CHILD	Direct parent-child relationships between objects
AL_SETOPTIONS	Option settings for all objects

Name	Contains
ALVW_TABLEATTR	Attribute information about imported (external) tables
ALVW_TABLEINFO	Information about imported tables

i Note

This is not the complete list because some repository tables and views are for internal use.

The software automatically creates reporting tables for each new or upgraded repository. Except for AL_USAGE, the software automatically updates all reporting tables.

Related Information

Reference Guide: Metadata in Repository Tables and Views [page 1721]

4.4.3 Logging into the Management Console

To access the metadata reporting applications, first log into the Management Console. The first time you log into the Management Console, use the default user name and password (`admin/admin`). It's recommended that you change the defaults thereafter by updating user roles in the Administrator.

1. The first step depends on your operating system.
   - On Windows, choose *Start* › *Programs* › *SAP Data Services* **`<x.x>`** › *Data Services Management Console*.
     If you encounter an error, check to see whether your web application server is installed and running. If you are using the packaged Tomcat application server and it is running but you cannot log in, see the Troubleshooting the Administrator section.
   - On UNIX or Windows, open a browser, enter the following case-sensitive URL, then press Enter:
     `http://<hostname>:28080/DataServices/`
2. Enter the default user name (`admin`) and password (`admin`) and click *Log in*.

   The Management Console home page opens.
3. To launch one of the metadata reporting applications, click its icon (or name).

   If you are logged in to the Designer, you can also access the Management Console home page as follows:
   - From the *Tools* menu, click *Data Services Management Console*.
   - Click the *Data Services Management Console* tool bar icon.

4.4.3.1 Management Console navigation

After you log in to the Management Console and launch one of the applications, the application name appears under the Management Console banner.

The upper-right side of the main window includes the following links:

- *Home*—Returns to the Management Console home page (for example, to select another application).
- *Settings*—Use the Settings control panel to change a variety of options depending on the application.
- *Logout*—Exits the application and the Management Console and return to the login page.
- Help icon—Opens the *Management Console Guide*.

As you navigate around the applications, notice the top of the right-hand pane often displays a "bread crumb" path to indicate where you are in the application. Depending on the page displayed, sometimes you can click on the bread crumbs to navigate to a different part of the application.

The Administrator, Impact and Lineage Analysis, and Auto Documentation applications also use a navigation tree in the left-hand pane.

Management Console sessions time out after 120 minutes (2 hours) of inactivity.

4.5 Impact and Lineage Analysis Reports

The Impact and Lineage Analysis application provides a simple, graphical, and intuitive way to view and navigate through various dependencies between objects.

Impact and lineage analysis allows you to identify which objects will be affected if you change or remove other connected objects.

For example for impact analysis, a typical question might be, “If I drop the source column Region from this table, which targets will be affected?”

For lineage analysis, the question might be, “Where does the data come from that populates the Customer_ID column in this target?”

In addition to the objects in your datastores, impact and lineage analysis allows you to view the connections to other objects including universes, classes and objects, Business Views, Business Elements and Fields, and reports (Crystal Reports, SAP BusinessObjects Desktop Intelligence documents, and SAP BusinessObjects Web Intelligence documents).

Metadata Integrator

Metadata Integrator is required to view BusinessObjects objects in the Impact and Lineage reports. However, Metadata Integrator is no longer a component available with Data Services, beginning with the 4.1 release.

From Data Services 4.1, you cannot directly configure Metadata Integrator to collect from Business Intelligence platform XI 3.x or 4.0. The Data Services XI 3.x or 4.0 Metadata Integrator can continue to work with the Data Services 4.1 repository; however, this will not work with an SAP HANA repository.

If you have a previous version, you can continue to view impact and lineage for objects from a Business Intelligence platform 3.x or 4.0 system after executing the previous version of Metadata Integrator to load metadata to the Data Services 4.1 repository.

If you are migrating from SAP Data Services XI 3.x or 4.0, and have Business Intelligence platform Metadata Integrator configured to collect from a CMS repository version XI 3.x or 4.0, you must retain the Business Intelligence platform 3.x or 4.0 client machine with Data Services XI 3.x or 4.0 Metadata Integrator installation to continue to collect CMS metadata from Business Intelligence platform XI 3.x or 4.0 systems.

You can continue to use the Data Services-specific impact and lineage.

For full functionality, you will need to use the Metadata/CMS integrator found in SAP Information Steward.

> **Note**
>
> You must add permissions for the Business Intelligence platform 4.0 FP3 user to retrieve the Data Services 4.1 repository password. Otherwise, their Metadata Integrator instance cannot get BusinessObjects objects when running on Data Services 4.0. See the *Data Services Administrator Guide* for more information.

4.5.1 Navigation

From the Management Console home page, view impact and lineage information by clicking the *Impact and Lineage Analysis* link.

The Impact and Lineage Analysis page contains two primary panes:

- The left pane contains a hierarchy (tree) of objects. The top of the tree is the default repository. This pane also includes a search tool.
- The right pane displays object content and context based on how you navigate in both panes.

In general, expand the tree in the left pane by clicking plus signs (+) next to object nodes. Select an object in the tree to learn more about it. Details associated with an object appear in the right pane on one or more tabs. Tabs vary depending on the object you select.

The top level of the navigation tree displays the current repository. (You can change this repository in the Settings control panel; for details, see *Impact and Lineage Analysis Settings control panel* [page 1973].)

Objects in a repository include:

- Datastores—Contain tables and columns.
- CMS server(s)—After you configure the Metadata Integrator, this node contains folders as defined in the Central Management Console, Universes, and Business Views.
  The Universe node displays classes, and each class contains objects. Business Views contain Business Elements, and each Business Element has Business Fields. Any object can contain one or more reports.

To narrow the view of objects to display in the navigation tree or to quickly find specific objects in the repository, use the *Objects to analyze* search feature. You can do one or both of the following:

1. Select a category in the *Select an object type* drop-down list:
   - Table and column
   - Universe
   - Class and object

- Business view
    - Element and field
    - Report

   AND/OR
2. Search for a specific object by typing all or part of the object name in the search field. The search field is not case sensitive, spaces are allowed, and you can use the percent symbol (%) as a wildcard.
3. Click the search icon (binoculars).

Metadata Reports highlights with a red border each object that meets your search criteria.

- To repopulate the CMS navigation tree with any objects that might have been changed (added, deleted, renamed, and so on) in the CMS repository after you display an impact and lineage report, log out and log back in to the Management Console to display the changes.
- If you receive an error such as the following:

  ```
  This image is scaled to 50% of the original image. You could avoid scaling the
  image by allocating more memory to the current java process.
  ```

  it means the java process (JVM) does not have enough memory to process the current task. Circumvent this error by allocating more heap memory to the Java process associated with the Web server.

4.5.1.1 To increase the java heap memory in Windows

1. In the Windows Services control panel, stop the Data Services Web Server.
2. In the installation directory, navigate to \ext\WebServer\conf.
3. Using a text editor, open the wrapper.properties file.
4. To allocate a minimum of 256 MB and a maximum of 512 MB to the java process, add the following parameters to wrapper.cmd_ line:

   ```
   -Xms256M -Xmx512M
   ```

   The result will appear as follows:

   ```
   wrapper.cmd_line=$(wrapper.javabin) -Xms256M -Xmx512M -Djava.endorsed.dirs==$
   (ACTAHOME)\ext\webserver\common\endorsed ...
   ```

5. Save and close the file.

4.5.1.2 Increasing the java heap memory in UNIX

1. Stop the Data Services Web Server.
2. In the installation directory, navigate to /ext/WebServer/bin.
3. Using a text editor, open the setclasspath.sh file.

4. To allocate a minimum of 256 MB and a maximum of 512 MB to the java process, add the following lines to the end of the setclasspath.sh file:

```
JAVA_OPTS="-Xms256M -Xmx512M"
export JAVA_OPTS
```

5. Save and close the file.

4.5.2 Analysis options

The following table lists the types of objects that can appear in the navigation tree and provides a summary of what information appears in the right pane when you select that object type.

To view or hide a pane in the display such as an attributes pane, click the up/down arrow in its header bar.

Moving the cursor over an object displays a pop-up window with more information about that object; for example:

- Table: Data flow (if applicable), datastore, and owner
- Business Objects report: Depending on the report type, the pop-up window displays the CMS server name, the Business View name, or the Universe name, for example.
- Universe objects: CMS server, universe, and class

The following table lists the objects in the navigation tree, the corresponding tabs, and the content of each.

Object	Tab	Associated content
Repository	Overview	*Repository name* *Repository type*—The database type *Repository version*—The repository version number
Datastore	Overview	Overview information varies depending on the datastore type. The following entries apply to a datastore on Microsoft SQL Server. *Datastore type*—Database *Database type*—Microsoft_SQL_Server *User*—**<Database user name>** *Case sensitive*—Whether or not the database is case sensitive *Configuration*—**<The configuration selected in the datastore editor >** *SQL_Server version*—Microsoft SQL Server 2000 *Database name*—**<Database name >** *Server name*—**<The host computer name>**
Table	Overview	*Table name*—Table name *Datastore*—Datastore to which this table belongs

Object	Tab	Associated content
		Owner name—The table owner name in the database. *Business name*—Business-use name of the table if defined *Table type*—Table or template table *Last update date*—When the software last updated the table
	Impact	Graphically shows the end-to-end impact of the selected source table and the targets it affects. Clicking a table in the Impact diagram displays the object's attributes, which are the same as on the Overview tab.
	Lineage	Contains the same information as on the Impact tab except it describes the flow from target to source.
	Mapping tree	Displays the overall mapping information for each column in the table. Select between *Group by data flow* or *Group by column*.
Column	Overview	*Column name*—Column name *Table name*—Parent table of the column *Data type*—The data type for the column *Nullable*—yes/no *Primary key*—yes/no *Foreign key*—yes/no
	Impact	Graphically shows the end-to-end impact of the selected source column and the targets it affects. Clicking a column in the Impact diagram displays the object's attributes, which are the same as on the Overview tab.
	Lineage	Contains the same information as on the Impact tab except it describes the flow from target to source. It also displays any data flow objects associated with the column. Move the cursor over a data flow icon to display a pop-up window with the mapping information. Click on a data flow icon to open another pop-up window that displays the Auto Documentation information including mapping. Notice that in the auto documentation window, any objects that are not part of the lineage for this column are dimmed.
Universe	Overview	*Universe* name *Folder*—The folder name on the CMS server to where the Universe has been exported

Object	Tab	Associated content
		CMS server—The name of the CMS server for this Universe *Description*—The description created for the Universe in Designer
Business View	Overview	*Business View* name *Folder*—The folder name on the CMS server to where the Business View has been exported *Last update date*—When the Business View was last updated in the Business View Manager *CMS server*—The name of the CMS server for this Business View
Class	Overview	*Class* name *Universe*—Universe to which this class belongs *CMS server*—The name of the CMS server for this class
Object	Overview	*Object* name *Class*—The class to which this object belongs *Universe*—Universe to which this object belongs *CMS Server*—The name of the CMS server for this object *Source column*—The name of the source column for this object followed by the `<owner.table name>`
	Impact	Shows all of the reports that use the selected object
	Lineage	Shows column-level lineage for the selected object
Business Element	Overview	*Business element* name *Business view*—The Business View to which this business element belongs *CMS server*—The name of the CMS server for this object
Business Field	Overview	*Business field* name *Business element*—The Business Element to which this Business Field belongs *Business view*—The Business View to which this Business Field belongs *CMS server*—The name of the CMS server for this object
	Impact	Shows all the reports that use the field.
	Lineage	Shows column-level lineage for the selected Business Field.
Reports: Crystal	Overview	*Report* name

Object	Tab	Associated content
and Web Intelligence/ Desktop Intelligence		*Folder*—The folder on the CMS server where the report is stored *CMS server*—The name of the CMS server for this report *Last update date*—When the report was last updated
	Lineage	Shows the lineage to the Universe objects or Business View fields on which the report is based (if any) and the column-level lineage in the datastore.

Related Information

Auto Documentation Reports [page 1990]
Table-level and column-level analysis [page 1973]

4.5.3 Table-level and column-level analysis

Impact and lineage analysis at the table level shows datastores, tables, and reports/documents.

Impact and lineage analysis at the column level shows datastores, objects, fields, and reports/documents.

> **Note**
>
> If a report includes conditions predefined in a Universe, the columns used by those conditions do not appear on the Impact and Lineage Analysis report because the metadata collected for Universes is limited to the tables and columns referenced directly by Universe objects.

4.5.4 Impact and Lineage Analysis Settings control panel

The Impact and Lineage Analysis Settings control panel allows you to change the options for your reports. To open it, click *Settings* in the upper-right corner of the window.

4.5.4.1 Settings tab

The Settings tab allows you to change repositories. Select a repository from the drop-down list box and click *Apply*.

4.5.4.2 Refresh Usage Data tab

On the Refresh Usage Data tab, you can manually calculate column mappings.

4.5.4.2.1 Calculating column mappings

SAP Data Services can calculate information about target tables and columns and the sources used to populate them, for example for impact and lineage or auto documentation reports.

Calculating column mappings populates the internal ALVW_MAPPING view and the AL_COLMAP_NAMES table. The ALVW_MAPPING view provides current data to metadata reporting applications like Impact and Lineage Analysis. If you need to generate a report about a data flow that processes nested (NRDM) data, query the AL_COLMAP_NAMES table using a custom report.

Whenever a column mapping calculation is in progress, the Designer displays a status icon at the bottom right of the window. You can double-click this icon to cancel the process.

To calculate column mappings, you can:

- Enable the option in the Designer to automatically calculate column mappings.
- Execute the column mapping process manually from either the Designer or the Impact and Lineage Analysis application in the Management Console.

Related Information

Reference Guide: Metadata in Repository Tables and Views, Storing nested column-mapping data [page 1731]

4.5.4.2.1.1 To automatically calculate column mappings

To set the option to automatically calculate column mapping information, in the Designer select *Tools* > *Options* > *Designer* > *General* > *Automatically calculate column mappings*. This option is selected by default.

Note that if the Designer option *Automatically calculate column mappings* is cleared, any subsequent changes made to the data flow require that you manually recalculate the column mappings to ensure the ALVW_MAPPING view and the AL_COLMAP_NAMES table have the most current information.

4.5.4.2.1.2 To manually calculate column mappings

If the Designer option *Automatically calculate column mappings* is cleared and you want to generate reports, you can manually calculate the mappings. You can manually calculate column mappings at any time in either the Designer or the Management Console.

In the Designer, right-click in the object library and select ▶ *Repository* ▶ *Calculate column mappings* ◀.

In the Management Console:

1. Select *Impact and Lineage Analysis*.
2. Open the *Settings* control panel.
3. Click the *Refresh Usage Data* tab.
4. Select the Job Server that is associated with the repository you want to use.
5. Click *Calculate Column Mapping*.

On the Impact and Lineage Analysis *Overview* tab, you can expand *Data Flow Column Mapping Calculation* to view a list of data flows and the calculation status of each. If the mapping calculation is complete, the *Status* indicator is checked.

4.5.4.3 About tab

This tab provides SAP Data Services version information.

4.6 Operational Dashboard Reports

Operational dashboard reports provide graphical depictions of SAP Data Services job execution statistics. This feedback allows you to view at a glance the status and performance of your job executions for one or more repositories over a given time period. You can then use this information to streamline and monitor your job scheduling and management for maximizing overall efficiency and performance.

For more information about how to use these reports to answer performance questions, see the *Performance Optimization Guide*.

Related Information

Performance Optimization Guide: Measuring Performance [page 2106]

4.6.1 Dashboards home page

To view operational dashboards, on the Management Console home page, click *Operational Dashboard*.

The upper-right corner identifies the repository for the reports you are viewing. You can change the repository to view in the dashboards *Settings* control panel.

You can drill into these dashboards for more details. The navigation path at the top of the window indicates where you are in the operational dashboard reports hierarchy. Click the hyperlinks to navigate to different levels. Click the *Operational* tab to return to the dashboards home page.

There are two categories of dashboards: Job Execution Statistics and Job Execution Duration. Each category contains a current (snapshot) report and a historical (trend) report. Hence, the dashboards in the top row provide a snapshot for the last 24 hours, and the dashboards on the bottom row display trends over the last 7 days.

- Job execution statistics—Left side of dashboards home page. These reports depict job execution statistics—in general, how many jobs succeeded or had errors.
  - Current (snapshot) pie chart
  - Historical (trend) bar chart
- Job execution duration—Right side of page. These reports depict how long it took the jobs to run and whether those run times were within acceptable limits.
  Each report type includes a current (snapshot) speedometer and a historical (trend) line chart.

The following sections describe the contents of these reports and their subreports.

4.6.2 Job execution statistics

Job execution statistics display in two formats on the left side of the page:

- Current (snapshot) pie chart
- Historical (trend) bar chart

The color codes on these two charts apply to the status of the job's execution:

- Succeeded (green)
- One or more warnings (orange)
- One or more errors (red)
- Still running (blue)

4.6.2.1 Current (snapshot) pie chart

The pie chart displays status information for jobs that ran in the time period displayed. You can change the start time and execution time window in the dashboard Settings control panel.

The chart identifies the number and ratio of jobs that succeeded, had one or more warnings, had one or more errors, or are still currently running.

Click on the pie "slices" to drill into the report, which displays a table that shows the jobs in that status group. From there you can click on the status tabs to view the list of jobs in each group.

Each Job Execution Statistics table includes:

Option	Description
Repository name	The repository associated to this job.
Job name	The name of the job in the Designer.
Start time and End time	The start and end timestamps in the format hh:mm:ss.
Execution time	The elapsed time to execute the job.

Option	Description
System configuration	The name of the system configuration that applies to that job.

Related Information

Designer Guide: Datastores, Defining a system configuration [page 252]
Configuring the Job Execution Duration dashboard [page 1977]

4.6.2.2 Historical (trend) bar chart

The Job Execution Statistics History bar chart depicts how many jobs succeeded, had warnings, failed, or are still currently running on each of the last 7 days.

As with the Job Execution Statistics pie chart, you can click on the individual bars to drill into the report to display the Job Execution Statistics status tables (succeeded, warning, error, and so on) for a particular day.

Related Information

Current (snapshot) pie chart [page 1976]

4.6.3 Job Execution Duration

Job Execution Duration reports display in two dashboards on the right side of the dashboards home page:

- Current (snapshot) pie chart
- Historical (trend) line chart

These two charts describe whether all jobs in the selected repositories executed within the acceptable time frame that you established using the dashboard Settings control panel. This window is the amount of time that you allot to run your jobs so your target data warehouse is available to applications and users during business hours, for example.

4.6.3.1 Configuring the Job Execution Duration dashboard

The recommended process for setting up the Job Execution Duration dashboard is as follows.

1. In the Administrator, schedule your jobs for when you want them to run.

   Example: Schedule all jobs to start executing at 1:00 AM.

2. In the Operational Dashboard application, click *Settings* to open the control panel.
3. Select the repository to configure.
4. For the *View data starting at* value, enter the beginning of the time frame in which you want to view job execution as a whole on the speedometer dashboard (in the format HH:MM, from 00:00 to 23:59).

   For example, if all of your jobs begin to execute at 1:00 AM, it would be logical to set the *View data starting at* value to 1:00.
5. Enter a value for *Job execution time window* in number of hours (from 0 to 24) that you have available to run your ETL jobs.

   For example, if you want all of your jobs to finish executing by 5 AM, enter 4 hours, which would be the time window between 1 AM and 5 AM.
6. Optionally, add a value for the *Job execution time window tolerance* in increments of 1 hour.

   > Note
   >
   > The total of the *Job execution time window* value and the *Job execution time window tolerance* value cannot exceed 24.

   For example, suppose you determine that in some circumstances it is okay if some jobs finish executing by 6:00 AM. In this case, set the *Job execution time window tolerance* to 1 (extending the window from 5:00 AM to 6:00 AM).

Related Information

Management Console Guide: Batch Jobs, Scheduling jobs [page 1891]

4.6.3.2 Current (snapshot) speedometer

The speedometer graphic displays the current window of time allotted for your jobs to complete their executions and whether or not the jobs as a whole finished within the selected job execution time window.

> Note
>
> This dashboard does not indicate whether a job succeeded or had errors; it only displays execution duration. Drill into the speedometer dashboard to see a table that displays whether or not the job succeeded and if and where it finished executing within the job execution time window.

Continuing with the example described in the preceding process, the following morning, after running your jobs overnight, you want to verify that they executed within the time window of 1 AM to 5 AM. Open the Operational Dashboard application and view the Job Execution Duration speedometer dashboard.

The speedometer needle points in the green zone, which represents the *Job execution time window* setting in the Settings control panel. In the example, that setting was 4 hours (from 1:00 AM to 5:00 AM). Therefore, all jobs in the repository finished executing within the desired time frame.

The solid red bar indicates when the first job actually started, which in the case of the example was 1:00 AM.

The time below the needle hub indicates when the last job finished executing for the selected repository. If the start time of the first job execution and the *View data starting at* value are the same, as in the example, that value equates to the total execution time for all the jobs (1:15 in the example).

If, however, you entered a *View data starting at* value other than when the first job actually started, to calculate the overall job execution duration period, subtract the time the first job started (indicated by the red bar and noted below the dashboard) from the time below the needle hub.

The time period displayed above the speedometer graphic indicates the viewing period. For example,

3/6/07 1:00 AM - 3/6/07 2:57 PM

indicates that you are viewing a dashboard that reflects all jobs that ran between 1:00 AM and 2:57 PM. The time 1:00 AM is the same as the *View data starting at* value. The time 2:57 PM is when you opened the Operational Dashboard control panel, which acts as a time stamp for the end period of the data you are actually viewing.

Therefore, the color zones on both Job Execution Duration dashboards (the speedometer and the history line chart) represent:

- Green (normal)—All jobs executed within the job execution time window. Specify this window with the *Job execution time window* setting. The green range of the speedometer represents this value.
- Yellow (warning)—At least one job finished executing during the tolerance period. Tolerance is the amount of time that jobs can run beyond your normal *Job execution time window*. Specify this tolerance limit with the *Job execution time window tolerance* setting. This value is represented in the yellow range of the speedometer and in line charts.
- Red (exceeded)—At least one job finished executing beyond the normal or warning (tolerance) limits.

4.6.3.2.1 Viewing job execution duration details

Click the speedometer dashboard to drill into the report and display a table of the Job Execution Duration for all jobs.

The Job Execution Duration table displays the repository name, the job name (for successful jobs, click the job name to drill down to the Data Flow Execution Duration table), the start and end time of the job execution, the execution time (elapsed), the status, and whether the job is associated with a system configuration.

4.6.3.2.2 Viewing data flow execution duration details

From the *Job Execution Duration details* window, you can drill down to a job to view its data flow execution duration times and audit details if applicable. Click on a job name to display the Data Flow Execution Duration.

The Data Flow Execution Duration table shows the repository name, the data flow name, the job name, the start and end time of the data flow execution, the elapsed execution time, the number of rows extracted and loaded, and the audit status.

If you enabled auditing for the job, the Audit status column displays one of the following statuses:

- Not audited
- Success: All audit rules succeeded

- Collected:This status occurs when you define audit labels to collect statistics but do not define audit rules
- Failed: Audit rule failed

You can view the Audit Details page from the Table tab by clicking a value in the Audit status column.

4.6.3.2.3 Viewing audit details

If auditing has been enabled, on the Data Flow Execution Duration table, click the audit status for the data flow to display the Audit Details page.

In addition to job name, data flow name, and job start time, the report includes:

- Audit rule information, if applicable
- Audit failed information, if applicable
- A table with the audit labels and values

Related Information

Designer Guide: Data Assessment, Using Auditing [page 452]

4.6.3.3 Historical (trend) line chart

The Job Execution Duration History line chart shows the trend of job execution performance over the last 7 days. The vertical axis is in hours, the horizontal axis shows the date, and the colored dots indicate the overall results of job execution duration based on the settings defined in the Settings control panel.

Each point denotes the Job Execution Duration (total elapsed time) of all the jobs for that day.

Click on the points to drill in to display the Job Execution Duration table.

Also as with the speedometer dashboard, you can drill into the job for data flow execution duration times and audit details by clicking on a job name to display the Data Flow Execution Duration window. Additionally, if auditing has been enabled, click on the audit status to display the Audit Details page.

Click the *View all history* button to display two tables:

- *Job Execution History*: This table lets you view execution history for all jobs or individual jobs. You can also select over how many days you want to view the history.
  This table displays the same information as in the Job Execution Duration table: repository name, job name, the start and end time of the job execution, the execution time (elapsed), the status, and whether the job is associated with a system configuration.
  - Click the Trace, Monitor, or Error link to open the Log Viewer page, which displays the logs associated with the job. Click the tabs to view the other types of logs.
  - Click the Performance Monitor link to open the Performance Monitor page.
- *Data Flow Execution History*: This table includes three options for customizing the display:

- *Data Flow*: Enter a data flow name for which to search and click *Search*.
- *Job Name*: Select all jobs or an individual job.
- *View history for x days*: Select over how many days you want to view the history

This table displays almost the same information as in the Data Flow Execution Duration table: repository name, data flow name, job name, the start and end time of the data flow execution, the execution time (elapsed), and the number of rows extracted and loaded.

4.7 Data Validation Dashboard Reports

Data Validation dashboard reports provide graphical depictions that let you evaluate the reliability of your target data based on the validation rules you created in your SAP Data Services batch jobs. This feedback allows business users to quickly review, assess, and identify potential inconsistencies or errors in source data.

4.7.1 Configuring Data Validation dashboards

To generate meaningful Data Validation dashboards, follow this process:

1. In your jobs in Designer, create data flows that contain validation transforms with validation rules.

   You use validation transforms to:

   - Verify that your source data meets your business rules.
   - Take the appropriate actions when the data does not meet your business rules.
2. In the Data Validation application, create functional areas. A functional area is a virtual group of jobs that relate to the same business function, for example Human Resources or Customers. Functional areas can contain multiple jobs and one or more data validation business rules.
3. In the Data Validation application, create business rules. Business rules are typical categories of data, for example Social Security Number or Address.

   These business rules contain validation rules that you created in your validation transforms in your data flows.

Begin by opening the Management Console and clicking the *Data Validation* name or icon link on the Home page.

Related Information

Creating functional areas [page 1982]

Creating business rules [page 1983]

Designer Guide: Data Assessment, Using the Validation transform [page 450]

Reference Guide: Transforms, Validation transform [page 1472]

4.7.1.1 Creating functional areas

After you create data flows with validation transforms and rules in Designer, next create functional areas.

> i Note
>
> If you do not create any functional areas, the dashboard displays statistics for all jobs for the selected repository.

4.7.1.1.1 To create functional areas

1. In the Data Validation module, click the *Settings* link.

   The *Repository* tab displays.
2. Verify the desired repository displays.

   To change the repository, select a different one from the drop-down list and click *Apply*.
3. Click the *Functional area* tab.

   The selected repository displays.
4. Type a name for the new functional area (such as `Customer`) and optionally a description.
5. Click *Save*.

   A list of batch jobs (and the associated system configuration for each, if any) appears that lets you select the jobs you want to include in this functional area.

   You can change the sort order of the table by clicking the arrow in a column heading.
6. From the list of Available batch jobs, select the check box for each job to include in this functional area and click the arrow button to move it to the *Associated batch jobs* window.
   - Jobs are not reusable among functional areas.
   - In the Administrator, deleting job information on the Batch Job Status page (Batch Jobs History) also clears data validation statistics from Data Validation Metadata Reports.
7. Click *Apply* to save the changes and keep the Functional area window open, for example to add more functional areas.

   Clicking *OK* saves your changes and closes the Settings control panel.

   Clicking *Cancel* closes the Settings control panel without saving changes.

To add another functional area, on the Functional area tab click *Add* and follow steps 4 through 7 in the previous procedure.

To display a different functional area for editing, select it from the drop-down list.

Delete a functional area by clicking *Delete* next to the functional area selected in the drop-down list.

Next, create business rules to associate the validation rules in your data flows with your functional areas.

Related Information

Designer Guide: Datastores, Creating and managing multiple datastore configurations [page 239]

4.7.1.2 Creating business rules

After creating functional areas, associate business rules to each functional area as follows.

> Note
>
> If you do not create business rules, each validation rule in the jobs that you have associated with a functional area becomes its own business rule.

4.7.1.2.1 To create business rules

1. In the Settings control panel, click the *Business rule* tab.

   On the *Business rule* tab, the default repository displays. (To change the repository, click the *Repository* tab, select a different repository, and click *Apply*.)
2. From the drop-down list, select the functional area to which this business rule will belong.
3. In the business rule definition area, type a name for the business rule such as *Phone number*.
4. Select a priority for how significant this group will be to your business end users: High, Medium, or Low.
5. Type an optional description for the business rule such as *Phone and FAX*. In this example, the validation rule checks to see if telephone and fax numbers in the USA conform to the seven-digit standard.
6. Click *Save*.

   A list of validation rules appears. Select the validation rules you want to include in this business rule. See the table below for a description of the columns in the lists of validation rules (scroll horizontally to view the other columns).
7. From the list of *Available validation rules*, select the check box for all of the rules to include in this business rule and click the arrow button to move it to the Associated validation rules pane.

   > Note
   >
   > Validation rules are not reusable among business rules (you can use a validation rule only once and only in one business rule).
8. Click *Apply* to save the changes and keep the *Business rule* window open, for example to add more business rules.

Clicking *OK* saves your changes and closes the Settings control panel.

Clicking *Cancel* closes the Settings control panel without saving changes.

The columns in the validation rule lists are as follows. Scroll horizontally to view the other columns. Note that you can change the sort order of the tables by clicking the arrow in a column heading.

Column	Description
Validation rule name	The validation rule name. The default is the column name, unless you create a new name in the Validation transform *Properties* dialog box.
Description	The description for the validation rule.
Full path	Describes the hierarchy in the software from the job level to the data flow level to indicate where this validation rule has been defined.
System configuration	The name of the system configuration selected for this job.

To add another business rule, on the *Business rule* tab click *Add* and follow steps 3 through 8 in the previous procedure.

To display a different functional area so you can edit its business rules, select it from the *Functional area* drop-down list.

To display a different business rule for editing, select it from the *Business rule* drop-down list.

Delete a business rule by clicking *Delete* next to the business rule selected in the drop-down list.

Related Information

Designer Guide: Data Assessment, Using the Validation transform [page 450]
Reference Guide: Transforms, Validation transform [page 1472]
Designer Guide: Datastores, Creating and managing multiple datastore configurations [page 239]

4.7.1.3 Enabling data validation statistics collection

To enable data validation statistics collection for your reports, you must verify two options—one at the validation transform level and one at the job execution level.

4.7.1.3.1 Validation transform level

In Designer, navigate to the validation transforms from which you want to collect data validation statistics for your reports. For the columns that have been enabled for validation, in the transform editor click the *Validation transform options* tab and select the check box *Collect data validation statistics*.

4.7.1.3.2 Job execution level

When you execute a job, the Execution Properties window displays. On the Parameters tab, clear the option *Disable data validation statistics collection* (the default) before executing the job.

To execute a job without collecting statistics, select the *Disable data validation statistics collection* option, which suppresses statistics collection for all the validation rules in that job.

4.7.2 Viewing Data Validation dashboards

To view Data Validation dashboards, on the Management Console Home page, click *Data Validation*. The functional area view displays.

The upper-right corner identifies the repository for the reports you are viewing. You can change the repository to view in the Settings control panel.

Some dashboards let you to drill in to some of the components for more details. The navigation path at the top of the window indicates where you are in the Data Validation dashboard reports hierarchy. Click the hyperlinks to navigate to different levels.

Related Information

Functional area view [page 1985]

Repository tab [page 1990]

4.7.3 Functional area view

The top-level Data Validation dashboard view is the functional area view. This view includes two dashboards:

Dashboard	Description
Functional area pie chart	A current (snapshot) report.
History line chart	A historical (trend) report that displays trends over the last 7 days. To display this chart, click the link below the pie chart.

To change the functional area dashboards to view, select a different functional area from the drop-down list at the top of the window. Select *All* to view data for all batch jobs in that repository.

If there are no functional areas defined, the chart displays statistics for all jobs for the selected repository.

Related Information

Functional area pie chart [page 1986]
History line chart [page 1986]

4.7.3.1 Functional area pie chart

The pie chart displays status information for jobs that ran in the time period displayed. The data collection period begins at the time set on the Repository tab in the Settings control panel and ends with the time you open the report Web page.

The color codes on this chart apply to the volume of validation rules that passed or failed:

- Green—The percentage of rules that passed for the selected functional area.
- Red—The percentage of rules that failed for the selected functional area with a High priority label.

> Note
>
> If you have All selected for Functional area, the failed portion appears red and does not include priority information.

- Orange—The percentage of rules that failed for the selected functional area with a Medium priority label.
- Blue—The percentage of rules that failed for the selected functional area with a Low priority label.

Click on the failed pie "slices" to drill into the report:

- If there is at least one functional area and business rule defined, the Business rule view displays.
- If no functional areas or business rules are defined, the Validation rule view displays.

Related Information

Repository tab [page 1990]
Creating business rules [page 1983]
Business rule view [page 1987]
Validation rule view [page 1987]

4.7.3.2 History line chart

The History line chart displays the percentage of all validation rule failures that occurred on each of the last seven days. The software collects the number of failures for the last run of all of the batch jobs that are associated with this functional area on each day.

To display the History line chart, click the link below the pie chart.

4.7.4 Business rule view

The Business rule dashboard is a bar chart that shows the percentage of validation failures for each defined business rule. You access this chart by clicking on one of the failed "slices" of the functional area pie chart.

> ℹ Note
>
> If no functional areas or business rules have been defined, drilling down on the functional area pie chart displays the Validation rule view. Therefore, the "business rules" are the same as the validation rules.

The data collection period begins at the time set on the Repository tab in the Settings control panel and ends with the time you open the report Web page.

You can filter the view by selecting an option from the Priority drop-down list:

- All
- High priority
- Medium priority
- Low priority

The chart displays 10 bars per page; click the *Next* or *Previous* links to view more.

To view the business rules associated with another functional area, select it from the Functional area drop-down list.

To see the validation rules that apply to a particular business rule, click on that bar in the chart. The Validation Rule View displays.

Related Information

Repository tab [page 1990]
Validation rule view [page 1987]

4.7.5 Validation rule view

When you view the Functional area pie chart (the Data Validation Home page) and click on one of the failed pie "slices" to drill into the report, if no functional areas or business rules have been defined, the Validation rule view displays.

The Validation Rule page includes two dashboards:

Dashboard	Description
Validation rule bar chart	A current (snapshot) report.
History line chart	A historical (trend) report that displays trends over the last 7 days. To display this chart, click the link below the Validation rules bar chart.

The chart displays 10 bars per page; click the *Next* or *Previous* links to view more.

To view the validation rules for a different business rule, select it from the *Business rule* drop-down list.

Related Information

Validation rule bar chart [page 1988]
History line chart [page 1988]

4.7.5.1 Validation rule bar chart

The Validation rule bar chart displays the percentage of rows that failed for each validation rule.

The Data collection period begins at the time set on the Repository tab in the Settings control panel and ends with the time you open the report Web page.

You can click on a bar to display the Sample data view.

Related Information

Repository tab [page 1990]
Sample data view [page 1988]

4.7.5.2 History line chart

The History line chart displays the percentage of all validation rule failures that occurred on each of the last seven days. The software collects the number of failures for the last run of all of the batch jobs that are associated with this functional area.

To display this chart, click the link below the Validation rules bar chart.

4.7.6 Sample data view

If you have enabled the option to collect sample data in a validation transform, the Sample data page includes two images:

- *Sample data table* [page 1989]
- *History line chart* [page 1989]

If you have not configured the validation transform to collect sample data, only the History line chart displays.

To view sample data from another validation rule, select it from the drop-down list.

Related Information

Reference Guide: Transforms, Validation transform [page 1472]

4.7.6.1 Sample data table

If you have configured the validation transform to collect sample data , this page displays up to 50 rows of sample data in tabular form.

The column that maps to the currently selected validation rule appears highlighted.

Related Information

Reference Guide: Transforms, Validation transform [page 1472]

4.7.6.2 History line chart

The History line chart displays the percentage of all validation rule failures that occurred on each of the last seven days. The software collects the number of failures for the last run of all of the batch jobs that are associated with this functional area.

To display this chart, click the link below the sample data table.

4.7.7 Data Validation dashboards Settings control panel

The dashboard settings window allows you to change the options for your reports.

In the upper-right corner of the window, click *Settings*.

The three settings tabs are:

- *Repository tab* [page 1990]
- *Functional area tab* [page 1990]
- *Business rule tab* [page 1990]

For all of the Settings pages:

- Click *Apply* to save the changes and keep the Business rules dialog box open, for example to add more business rules.

- Clicking *OK* saves your changes and closes the Settings control panel.
- Clicking *Cancel* closes the Settings control panel without saving changes.

4.7.7.1 Repository tab

The settings on the Repository tab include:

- *Repository*—Select a repository to view from the drop-down list.
- *View data starting at*—Enter the time from when you want start viewing data in the format HH:MM (from 00:00 to 23:59). On the Data Validation dashboard charts, the end of the time window is the moment you open one of the dashboard Web pages.
  For example, entering 02:00 means your data validation reports will display data from the repository starting at 2:00 a.m. through the time you open the report page. Each dashboard page displays the time frame for which the dashboard statistics apply.

4.7.7.2 Functional area tab

For details on how to use the Functional area tab settings, see *Creating functional areas* [page 1982].

4.7.7.3 Business rule tab

For details on how to use the business rule tab settings, see *Creating business rules* [page 1983].

4.8 Auto Documentation Reports

Auto Documentation reports provide a convenient and comprehensive way to create printed documentation for all of the objects you create in SAP Data Services. Auto Documentation reports capture critical information for understanding your jobs so you can see at a glance the entire ETL process.

After you create a project, you can use Auto Documentation reports to quickly create a PDF or Microsoft Word file that captures a selection of job, work flow, and/or data flow information including graphical representations and key mapping details.

The types of information provided by Auto Documentation reports include:

- Object properties—Apply to work flows, data flows, and ABAP data flows
- Variables and parameters—Apply to jobs, work flows, data flows, and ABAP data flows
- Table usage—Shows all tables used in this object and its child objects.
  For example for a data flow, table usage information includes datastores and the source and target tables for each

- Thumbnails—An image that reflects the selected object with respect to all other objects in the parent container. Applies to all objects except jobs.
- Mapping tree—Applies to data flows

The next section includes object descriptions that describe these components in more detail as they apply to that object.

4.8.1 Navigation

Auto Documentation reports allow you to navigate to any project, job, work flow, data flow, or ABAP data flow created in the Designer and view information about the object and its components.

To open Auto Documentation reports, from the Management Console Home page, click *Auto Documentation*.

Auto Documentation navigation is similar to that of Impact and Lineage reports. The Auto Documentation page has two primary panes:

- The left pane shows a hierarchy (tree) of objects.
- The right pane shows object content and context.

Expand the tree to select an object to analyze. Select an object to display pertinent information in the right pane. In the right pane, select tabs to display desired information. Tabs vary depending on the object you are exploring.

Note that if the subcategory within a tab has a window icon on the far right side of its header bar, you can collapse or expand that part of the display.

Related Information

Impact and Lineage Analysis Reports [page 1967]

4.8.1.1 Searching for a specific object

1. Type the object name in the *Objects to analyze* search field. The search field is not case sensitive, you may use the percent symbol (%) as a wildcard, and spaces are allowed.
2. Click the search icon (binoculars) or press Enter.

The top level of the navigation tree displays the current repository. You can change this repository in the Settings control panel.

When you first open Auto Documentation, in the right pane the Project tab displays with hyperlinks to the projects in the repository. You can click on these links to drill into the project to display a list of jobs. You can also continue to click the job name links to continue drilling into objects for more information (thumbnails, object properties, and so on).

You can also navigate to this content by selecting objects in the navigation tree. The hierarchy of the tree matches the hierarchy of objects created in Designer.

- Repository
- Project
- Job
- Work flow
- Data flow

4.8.1.2 Repository

Clicking a repository name in the navigation tree displays the Overview tab in the right pane, which includes the following:

- Repository name—The name given to the repository in the Repository Manager
- Repository type—The type of repository such as the database type
- Repository version—The repository version

4.8.1.3 Project

Clicking on a project name in the navigation tree displays the Project tab in the right pane, which displays the list of jobs in the project. You can click on these jobs to drill into the hierarchy.

4.8.1.4 Job

Clicking on a job name displays information on two tabs:

- *Name of job*—This tab includes:
  - Description
  - A graphical image of the next level of objects in the job (for example one or more work flows or data flows)
  - Variables and parameters used in the job
- *Table usage*—This tab lists the datastores and associated tables contained in the selected object if applicable.

4.8.1.5 Work flow

Clicking on a work flow name displays information on two tabs:

- *Name of work flow*—This tab includes:
  - Thumbnail—This image reflects the selected object with respect to all other objects in the parent container.
    For example, if this work flow is the only one in the job, it appears alone; but if there are two other work flows in the job, they will also appear in the thumbnail image. You can click the other thumbnail images to navigate to them, which replaces the content in the right pane with that of the selected object.

    - A graphical image of the object's workspace window as it appears in the Designer.
      You can click on objects to drill into them for more details. Objects that have a workspace in Designer will display that workspace.
    - Object properties—Displays properties such as *Execute only once* or *Recover as a unit* if set.
    - Variables and parameters used in the work flow
- *Table usage*—This tab lists the datastores and associated tables contained in the selected object if applicable.

4.8.1.6 Data flow

Clicking a data flow name displays information on three tabs:

- *Name of data flow*—This tab includes:
    - Thumbnail—This image reflects the selected object with respect to all other objects in the parent container.
    - A graphical image of the object's workspace window as it appears in Designer.
      You can click on an object in the data flow to drill into it for more information:
      A table displays the following information when selected:
        - A thumbnail of the table with respect to the other objects in the data flow
        - Table properties including Optimizer hints (caching and join rank settings) and Table basics (datastore and table name)

      A transform displays the following information when selected:
        - A thumbnail of the transform with respect to the other objects in the data flow
        - Mapping details including column names, mapping expressions, descriptions, and data types.

      To go to the top level of the data flow object, click the data flow name in the navigation tree, or click the Back button on your browser.
    - Object properties—Data flow properties such as *Execute only once* and *Degree of parallelism*
    - Variables and parameters used in the job
- *Mapping tree*—This tab displays a list of target tables. You can expand or collapse each table display by clicking its header bar. Each target table lists its target columns and the mapping expressions (sources) for each.
- *Table usage*—This tab lists the datastores and associated tables contained in the selected object if applicable.

4.8.2 Generating documentation for an object

For most objects, you can quickly generate documentation in Adobe PDF or Microsoft Word format by clicking the printer icon next to the object name in the right pane.

4.8.2.1 Printing Auto Documentation for an object

1. Select the highest-level object you want to document in the left pane.

2. In the right pane, click the printer icon next to the object name.
3. In the Print window, select the check boxes for the items to include in your printed report.
4. Select PDF or Microsoft Word format.
5. Click *Print*.

   The Windows File download dialog box displays. Click Open to generate and open the file now, or click Save to save the file to any location.
6. After saving or printing your report, click *Close* to close the Print window.

4.8.3 Auto Documentation Settings control panel

The Auto Documentation Settings control panel allows you to change the options for your reports.

In the upper-right corner of the window, click *Settings*.

The following options are available in the *Settings* tab:

- *Repository*—Select a repository from the drop-down list box and click *Apply*.
- *ImageDisplay*—Specify whether a whole or partial image is displayed for large images. Setting the option to *Partial* improves performance and memory utilization.

The *About* tab provides software version information.

4.9 Data Quality Reports

Many Data Quality transforms generate information about the data being processed. Data Quality reports provide access to that data processing information. You can view and export these Crystal Reports for batch and real-time jobs. The statistics-generating transforms include Match, USA Regulatory Address Cleanse, Data Cleanse, Global Address Cleanse, Geocoder, and DSF2 Walk Sequencer transforms. Report types include addressing reports, transform-specific reports, and transform group reports.

> i Note
>
> Viewing or exporting data quality reports requires that you have first installed the Data Services APS services on the same machine that contains the BI platform (or IPS) Central Management Server. See the *Data Services Installation Guide* and *Master Guide* for more information.

Configuring report generation

To enable report generation, ensure the option *Generate report data* in the transform editor is enabled, or use substitution variables to set this and other transform options at a repository level.

For details about setting the options for transforms, see the *Reference Guide*. For details about using substitution variables, see the *Designer Guide*.

The following table lists the available reports and their associated transforms.

Report	Transform(s)
US CASS report: USPS Form 3553	USA Regulatory Address Cleanse
NCOALink Processing Summary report	USA Regulatory Address Cleanse
US Addressing report	USA Regulatory Address Cleanse
US Regulatory Locking report	USA Regulatory Address Cleanse
Delivery Sequence Invoice report	DSF2 Walk Sequencer
Canadian SERP report: Statement of Address Accuracy	Global Address Cleanse
Australia AMAS report: Address Matching Processing Summary	Global Address Cleanse
Address Information Codes Sample report	Global Address Cleanse and USA Regulatory Address Cleanse
Address Information Code Summary report	Global Address Cleanse and USA Regulatory Address Cleanse
Address Validation Summary report	Global Address Cleanse and USA Regulatory Address Cleanse
Address Type Summary report	Global Address Cleanse and USA Regulatory Address Cleanse
Address Standardization Sample report	Global Address Cleanse and USA Regulatory Address Cleanse
Address Quality Code Summary report	Global Address Cleanse
Data Cleanse Information Code Summary report	Data Cleanse
Data Cleanse Status Code Summary report	Data Cleanse
Best Record Summary report	Match
Match Contribution report	Match
Match Criteria Summary report	Match
Match Source Stats Summary report	Match
Match Duplicate Sample report	Match
Match Input Source Output Select report	Match
Match Multi-source Frequency report	Match
Geocoder Summary report	Geocoder

Opening and viewing reports

To view Data Quality reports, from the Management Console Home page, click *Data Quality Reports*. The *Batch job reports* tab appears.

Note

To view a Data Quality report, after clicking it, you will need to enter a user name and password for the Data Services repository. Once you have logged in, you may view as many Data Quality reports as you want during a single session in the Management Console without needing to provide the password again. This is the default behavior. See the *Administrator Guide* for more information, including how to change this behavior.

ℹ Note

Reports require the Arial Unicode MS font. This font is designed to support a wide variety of code pages and is included with Microsoft Office 2002 and later. To view Unicode data in PDF reports, this font must be installed on the computer being used to view the reports. For more information about the Arial Unicode MS font, including how to install from a Microsoft Office CD, visit the Microsoft Web site.

Related Information

Designer Guide: Multiple data source statistics reporting [page 679]
Administrator Guide: Password protection for a Data Services repository [page 45]

4.9.1 Lists of available reports

After opening the Data Quality Reports module in the Data Services Management Console, the *Batch job reports* tab displays a list of jobs and their associated available reports. Click the *Real-time job reports* tab to display reports available for real-time jobs. The *Real-time job reports* tab includes the same information that is on the *Batch job reports* tab.

The upper-right corner of either the Batch or Real-time pages displays the repository for the reports you are viewing. You can change the repository that you want to view in the *Settings* control panel.

You can filter the list of reports displayed by selecting a job name and/or a date or date range.

To filter by job, select the job name from the *Job name* drop-down menu. Or type the name, or type part of the name and a wildcard character (% or *), into the wildcard search string box and click *Search*. The Search field is not case sensitive and spaces are allowed.

To filter by when the job(s) executed, select one of the following options:

- Show last execution of a job.
- Show status relative to today: Select the number of previous days over which to view job executions.
- Show status as a set period: Type the date range or select the dates by clicking the calendar icons.

Click *Search* to update the list.

The report list includes the following headings. You can sort or reverse sort on any column by clicking the arrow next to the column name.

- Report. Click the icon in this column to go to a page that lists the reports for the associated job.

- Job name. The name of the job in the Designer.
- Status. The execution status of the job: green (succeeded), yellow (had one or more warnings), red (had one or more errors), or blue (still executing).
- Start time and End time. The start and end dates (in the format yyyy-mm-dd) and times (in the format hh:mm:ss).
- Execution time. The elapsed time to execute the job.
- Rows extracted and Rows loaded. The number of rows read by the job and the number of rows loaded to the target.

Related Information

Data Quality Reports Settings control panel [page 1998]

4.9.2 List of reports by job

On the list of available reports page (either the *Batch job reports* or *Real-time reports* tabs), click an icon in the Report column to display a page with the list of reports that are available for the associated job. The job name displays at the top of the page.

Filter the list by performing one of the following actions:

- Select a report name from the drop-down list. This action automatically populates the Search box and submits the request.
- Type the name or part of the name and a wildcard character (% or *) into the Search box and click *Search*. The Search field is not case sensitive and spaces are allowed.

The list of reports includes the following column headings. You can sort or reverse sort on any column by clicking the arrow next to the column name.

- Report. Click the icon in this column to open the report, which displays in a new browser window. The three icons represent the type of report:
  - Summary
  - Transform-specific report
  - Report for a group of transforms (match set or associate set)
- Path name. The transform location within the job if the report comes from a transform, match set, or associate set. The location displays in the form of <data flow name>/<transform name>. If the report comes from a job summary report, the job name displays.
- Report name. The type of report (for example Address Type Summary report or Match Contribution report).
- Object name. The source object used for the report, typically the transform name used in the data flow (blank for job summary reports).

4.9.3 Data Quality Reports Settings control panel

Use the Settings control panel to select a different repository for viewing reports. In the upper-right corner of the window, click *Settings*. Select a repository from the drop-down list box and click *Apply*.

4.9.4 Report options

After opening a report, use the toolbars at the top (and bottom) of the report window to perform the following tasks:

- Export to one of the following formats: Crystal Report (RPT), Adobe Acrobat (PDF), Microsoft Word - Editable (RTF), or Rich Text Format (RTF). The Export Report dialog box also lets you select a page range to export.
- Print the full report or a range of pages
- Show the group tree, which displays a hierarchical navigation tree pane. Select links in the tree to navigate to different sections of the report.
- Navigate through the report using the page links and fields at the top and bottom of the report page
- Refresh the report
- Search for text
- Resize the view

In many of the reports, you can select the transform name, path, charts, or other components to display a separate report that is specific to that component. To identify which components are enabled for viewing as a subreport, move the cursor over the report and look for objects that make it change to a hand icon. The description (name) of the newly displayed report then appears in the tab at the top of the report. The tabs displays all the subreports you have accessed. Select *Main Report* to return to the original report.

4.9.5 Troubleshooting reports

The following are several report tips and solutions that you can use to troubleshoot report problems.

Font

Reports require the Arial Unicode MS font. This font is designed to support a wide variety of code pages and is included with Microsoft Office 2002 and later. To view Unicode data in PDF reports, this font must be installed on the computer being used to view the reports. For more information about the Arial Unicode MS font, including how to install from a Microsoft Office CD, visit the Microsoft Web site.

Slow reports or timeout error

If you encounter a timeout error or notice that your reports are running appreciably slower, your DBA should update the database statistics on your repository database, primarily the AL_STATISTICS ADDRINFOCODEDATA ADDRSTATUSCODEDATA table. In Oracle, this is called "Gather statistics."

If you use an Oracle database, here are some additional options that your DBA can modify to try to correct the issue (other databases may have similar options):

- Increase the Processes value to 400 or greater.
- Increase the PGA Memory to 194MB or greater.
- Set the Cursor_Sharing value to Force.

4.9.6 USA CASS report: USPS Form 3553

Description

The Coding Accuracy Support System (CASS) report is a facsimile of United States Postal Service (USPS) Form 3553. You need this form to qualify mailings for postage discounts. For more information about CASS, visit the USPS RIBBS (Rapid Information Bulletin Board) web site at *https://ribbs.usps.gov/* .

To enable the report

To generate this report, use the USA Regulatory Address Cleanse transform. Ensure the following options have been defined, or configure the appropriate substitution parameters:

- Enable ▶ *Report And Analysis* ▶ *Generate Report Data* ◀.
- Disable ▶ *Non Certified Options* ▶ *Disable Certification* ◀.
- Set all applicable options in the *CASS Report Options* option group.
- Set all applicable options in the *Assignment Options* group to **<Yes>** and specify a valid directory path for each. Applicable options are those that are required for CASS.

Related Information

Designer Guide: Data Quality, Beyond the basic address cleansing, Multiple data source statistics reporting [page 679]

4.9.7 NCOALink Processing Summary Report

Description

The NCOALink Processing Summary Report can provide a detailed breakdown of the various codes returned by NCOALink and ANKLink processing, information regarding how the NCOALink job was configured, and summary information for some job processing statistics. The report generates information and completes the applicable fields based on your service provider level. The NCOALink Processing Summary Report can be used for USPS certification and audit purposes.

To enable the report

To generate this report, use the USA Regulatory Address Cleanse transform. On the *Options* tab, enable the following options or configure the appropriate substitution parameters:

- Set ▶ *Assignment Options* › *Enable NCOALink* ◀ to Yes.
- Set ▶ *Report And Analysis* › *Generate Report Data* ◀ to Yes.
- Ensure that the other required NCOALink fields on the Options tab have been correctly configured.

How to read this report

The first section of the report includes the report title, the date of the report, and other general information about your job as follows:

- The job name
- The run ID, which specifies a unique identification of an instance of the executed job
- The name of the repository where the job is located
- The official transform name
- The path to the transform in the form <data flow name>/<transform name>

Depending on the transform option settings, the remainder of the report includes the following sections:

- Move Update Summary: Contains information about the job configuration and statistics for move-updated addresses as well as pre-move update counts for Postcode2, DPV, LACSLink, and SuiteLink matches.
  The *Data Returned* value shows the processing mode for the mailing list. The possible values are *C* (change of address), *F* (return codes), or *S* (statistics). For a detailed description of the values, see the *Reference Guide*.
  To change the processing mode, modify the ▶ *NCOALink* › *Processing Options* › *List Processing Mode* ◀ option in the transform.
  The *Match Logic* value is a single character code that denotes the combination of move types processed. The setting for each move type (business, individual, and family) displays in the area of the report immediately below the list of all processes used. To change the match logic, modify the ▶ *NCOALink* › *Processing Options* › *Retrieve Move Types* ◀ option in the transform.
  The *Mail Class* character code is derived from the settings for processing standard mail, first class mail, package services, and periodicals. The setting for each mail class is shown in the section immediately below

the list of all processes used. To change the settings, modify the previously noted fields located in the *NCOALink* > *Processing Options* option group in the transform.

- NCOALink Move Type Summary: Displays statistics for the types of moves (Individual, Family, or Business) processed.
- NCOALink Return Code Summary: Displays a summary of the NCOALink codes returned.
- Move Effective Date Distribution Analysis: Contains the number of records in each category and time period. Categories include new address provided, new address not available, and new address not provided. Time frames include in months: 0-3, 4-6, 7-12, 13-18, 19 plus.
- ANKLink Return Code Summary: If ANKLink is enabled, displays a summary of the ANKLink codes returned. The section won't display if there aren't any ANKLInk return codes in the output.
- Return Code Descriptions: If enabled in the *NCOALink* > *Report Options* > *Generate Return Code Descriptions* option, displays detailed return code descriptions.
- Service Provider Summary: Contains information specific to processing for limited or full service providers. This section does not display if processing the job as an end user.

Related Information

Management Console Guide: Administrator, Exporting NCOALink certification logs [page 1878]
Reference Guide: Transforms, NCOALink options [page 1326]
Designer Guide: Data Quality, Multiple data source statistics reporting [page 679]

4.9.8 Delivery Sequence Invoice report

Description

The DSF2 Delivery Sequence Invoice is required by the USPS when you claim walk sequence discounts or when you are certifying.

The Delivery Sequence Invoice report is automatically generated when you include the DSF2 Walk Sequencer transform in your job.

> Note
>
> The DSF2 Walk Sequencer transform adds walk sequencing information to your data. However, to claim walk sequence postage discounts, you must further process your data using presorting software (such as the SAP BusinessObjects Presort product). There are four walk sequence discounts for which you may be eligible:
>
> - Carrier Route
> - Walk Sequence
> - 90% Residential Saturation
> - 75% Total Active Saturation

➡ Tip

The Delivery Sequence Invoice report can be large, sometimes exceeding 1000 pages. The number of pages relates to the number of postcode1/sortcode route combinations in your input.

4.9.8.1 Contents of report

The Delivery Sequence Invoice contains header information and information for each collection of data processed. Header information includes the licensee name, customer ID, site location, and processing date. The body of the report lists data for each postcode/sortcode route combination. The list below describes the data reported in the Delivery Sequence Invoice.

Data	Description
Total Deliveries	Indicates the total number of deliveries within the specified postcode/ sortcode combination.
Total Residences	Indicates the total number of residences within the specified postcode/ sortcode combination.
Delivery Points Sequenced	Indicates the number of delivery points sequenced by the transform for the specific postcode/sortcode combination
Residences Sequenced	Indicates the number of residences sequenced for the specific postcode/sortcode combination.
Percent Residences	Indicates the percent of the residences sequenced by the transform for the specified postcode/sortcode combination. The formula is 100 (residences sequenced ÷ total residences).
Percent Active Deliveries	Indicates the percent of delivery points sequenced by the transform for the specified postcode/sortcode compination.The formula is 100 (delivery points sequenced ÷ total deliveries).

Discounts	Indicates the type of discount the postcode/sortcode combination is eligible for.
	A = Sortcode Route (Carrier Route)
	B = 125 Walk Sequence
	C = 90% Residential Saturation
	D = 75% Total Active Saturation

4.9.9 US Addressing Report

The US Addressing Report provides a detailed breakdown of the various codes returned by DPV, DSF2, LACSLink, and SuiteLink processing. DPV, SuiteLink, and LACSLink are mandatory for USPS address processing according to CASS guidelines.

Related Information

Designer Guide: Data Quality, Beyond the basic address cleansing, Multiple data source statistics reporting [page 679]

4.9.9.1 To enable the report

To enable the US Addressing Report with the USA Regulatory Address Cleanse transform, complete the following options or configure the appropriate substitution variables:

- In the Report and Analysis group, select `<Yes>` for the *Generate Report Data* option.
- In the Reference Files group, set the *DPV Path*, *DSF2 Augment Path*, *LACSLink Path*, and *SuiteLink Path* as appropriate (you can use substitution variables).
- In the Assignment options group, set *Enable DPV*, *Enable DSF2 Augment*, *Enable LACSLink*, and *Enable SuiteLink* to `<Yes>` as appropriate.

4.9.9.2 Percent calculation

Many areas of the USA Regulatory Address Cleanse transform reports include percentages. The software calculates the denominator portion of the percentage calculation based on the following for the U.S. Addressing Report and the Address Validation Summary report:

US Addressing Report: The calculation of the denominator is based on the total of all DPV return codes of Y, D, S, and the addresses that are not DPV valid.

Address Validation Summary report: The calculation of the denominator is based on the total of all records processed by the USA Regulatory Address Cleanse transform.

For both reports, the following record types will no longer be factored into the percentage calculation:

- Number of records where all input fields mapped into the transform contain NULL or blank values.
- Number of records that contain Unicode characters.
- Number of records that are not processed because of Z4Change functionality.

Related Information

US Addressing Report [page 2003]
Address Validation Summary report [page 2016]

4.9.9.3 Information in the US Addressing report

The first section of the US Addressing Report includes the report title, the date of the report, and other general information about your job as follows:

- The job name
- The run ID, which specifies a unique identification of an instance of the executed job
- The name of the repository where the job is located
- The official transform name
- The path to the transform in this format: `<data flow name>` / `<transform name>`
- Audit information, which specifies how many records were processed during address cleansing, the start and end time, any idle time, and the amount of active processing time

The remainder of the report includes:

- LACSLink summary
- Counts for the LACSLink return codes encountered during processing
- DPV summary
- Counts for the DPV return codes encountered during processing
- SuiteLink return codes
- DSF2 counts from the Second Generation Delivery Sequence File (DSF2) Summary
- DSF2 Address Delivery Types

> Note
>
> Pre and post NCOALink processing sections appear in the report when NCOALink is enabled in the job. Pre NCOALink counts exist for DPV, DSF2, LACSLink, and SuiteLink. Post NCOALink counts exist for DPV and DSF2 counts/statistics.

4.9.9.4 DPV sections

The US Addressing Report contains the following sections for DPV:

Section name	Contents
Delivery Point Validation (DPV) Summary	Separate DPV number and percent for each DPV status indicator of Y, S, and D.

Section name	Contents
DPV Return Codes	Number and percent for DPV validated/not valid, CMRA validated, DPV vacant addresses, and DPV NoStats addresses.

When processing for NCOALink, the US Addressing Report includes pre and post NCOALink processing information for the Delivery Point Validation (DPV) Summary and DPV Return Codes sections.

4.9.9.5 Information in the DSF2 sections

The US Addressing Report contains the following sections for DSF2:

Section name	Contents
Second Generation Delivery Sequence File (DSF2) Summary	Number and percentage of addresses in your file that match these DSF2 address categories: • Drop addresses (including CMRA) • Business addresses • Throwback addresses • Seasonal addresses • Educational Institute addresses When you are processing for NCOALink, the US Addressing Report includes pre-NCOALink processing information and post-NCOALink processing information for this section.
Address Delivery Types	Number and percentage of addresses for these delivery type categories: • Curb • Central • Door Slot • Neighborhood Delivery Centralized Box Unit When processing for NCOALink, the US Addressing Report includes pre and post NCOALink processing information for this section.

4.9.9.6 LACSLink sections

The US Addressing Report contains the following sections for LACSLink:

Section name	Contents
Locatable Address Conversion Summary	Number and percent of records that were converted and the number and percentages of addresses that were not converted through LACSLink.
LACSLink Return Codes	Number and percent of records for each return code type.

When processing for NCOALink, the US Addressing Report includes pre and post NCOALink processing information for the Locatable Address Conversion Summary and the LACSLink Return Codes sections.

4.9.9.7 SuiteLink sections

The US Addressing Report contains the following section for SuiteLink:

Section name	Contents
SuiteLink Return Codes	The number and percent of SuiteLink matches for the following return codes: *A:* Secondary exists and assignment made. *00:* Lookup was attempted but no assignment.

When processing for NCOALink, the US Address Report includes SuiteLink Return Codes only for pre NCOALink processing.

4.9.10 DSF2 Augment Statistics Log File

The USPS requires DSF2 licensees to save monthly information about their processing in the DSF2 Augment Statistics Log File. The USPS has a specific naming format for the log files:

```
[DSF2_Licensee_ID][mm][yy].dat
```

Access the DSF2 Augment Statistics Log File through the Management Console.

> i Note
>
> The DSF2 Log File is based on when the job completes, not when the job starts. For example, a job that is started on 31 December and completes on 1 January will be included in the January DSF2 Log File.

The USPS dictates the content of the DSF2 Log File and requires that you submit log to them monthly. For details, see the DSF2 Licensee Performance Requirements document, which is available on the USPS RIBBS website. The DSF2 licensee must keep the log file data for at least 5 years.

You must submit the DSF2 Augment Statistics Log File to the USPS (National Customer Support Center) within the first seven (7) calendar days of each month.

Related Information

Exporting DSF2 certification log [page 1879]

4.9.11 US Regulatory Locking Report

Description

The software generates this report only when it encounters a false positive address during DPV or LACSLink processing with the USA Regulatory Address Cleanse transform.

The USPS includes false positive addresses with the DPV and LACSLink directories as a security precaution. Depending on what type of user you are, the behavior varies when the software encounters a false positive address.

If you use DPV or LACSLink processing for purposes other than NCOALink or if you are an NCOALink end user without an alternate stop processing agreement, the US Regulatory Locking Report contains the false positive address record (lock record) and lock code. You need this information in order to retrieve the unlock code from the SAP Service Marketplace.

If you are an NCOALink service provider or end user with an alternate stop processing agreement, the US Regulatory Locking Report contains the path to the DPV or LACSLink log files. The log files must be submitted to the USPS.

For more information about DPV and LACSLink locking and unlocking, see the *Designer Guide*.

To enable this report

To enable this report with the USA Regulatory Address Cleanse transform, verify the following options, or configure the appropriate substitution parameters:

- In the Report And Analysis options group, ensure *Generate Report Data* is set to Yes.
- In the Reference Files options group, set the *DPV Path* or *LACSLink Path* as appropriate.
- In the Assignment options group, set *Enable DPV* or *Enable LACSLink* to Yes.

How to read this report

The first section of the report includes the report title, the date of the report, and other general information about your job as follows:

- The job name
- The run ID, which specifies a unique identification of an instance of the executed job
- The name of the repository where the job is located

- The official transform name
- The path to the transform in the form data <flow name>/<transform name>
- Audit information, which specifies how many records were processed during address cleansing, the start and end times, any idle time, and the amount of active processing time

Depending on your user type, the second section of the report contains either the lock code as well as the information related to the record that caused the directory locking or the path to the DPV or LACSLink log files.

4.9.12 Canadian SERP report: Statement of Address Accuracy

Description

The Canadian Software Evaluation and Recognition Program (SERP) Statement of Address Accuracy report includes statistical information about Canadian address cleanse processing such as the Address Accuracy Level.

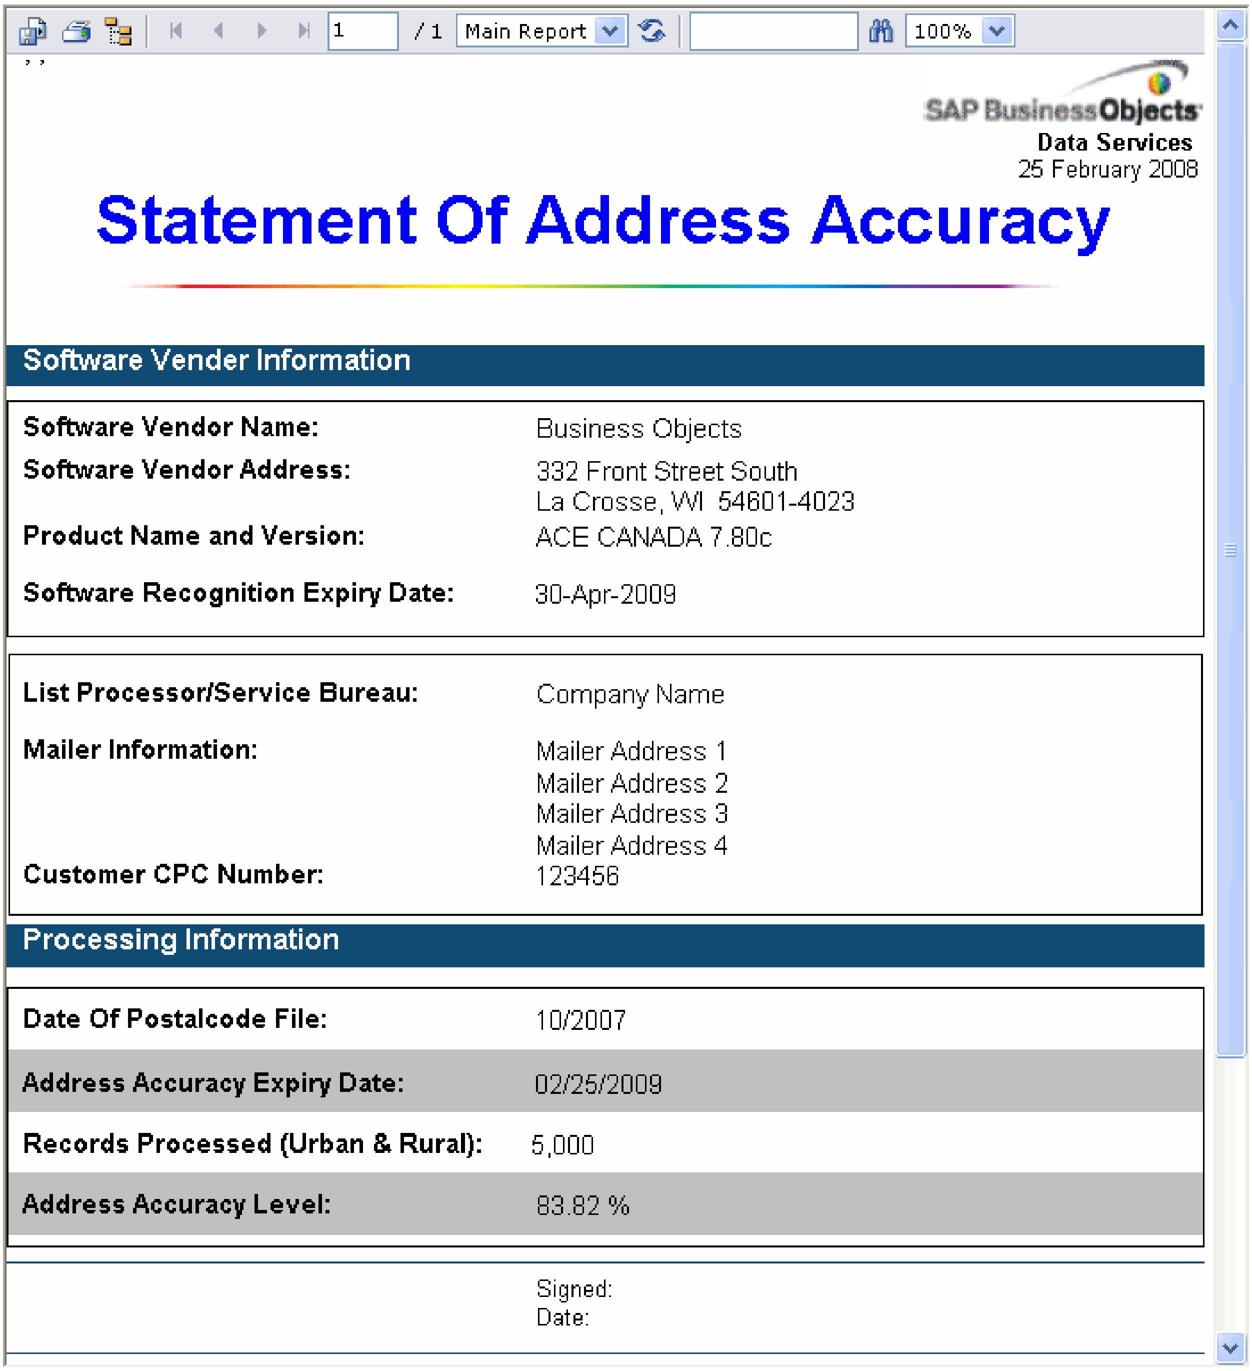
To generate the report

To generate this report with the Global Address Cleanse transform, ensure the following options are defined, or configure the appropriate substitution parameters:

- In the Global Address Cleanse transform, enable ▶ *Report And Analysis* ▸ *Generate Report Data* ◀.
- In the *Canada* group, complete all applicable options in the *Report Options* subgroup.
- In the *Engines* section, set *Canada* to *Yes*.

Example

The following is an example of the Statement of Address Accuracy report.



SAP BusinessObjects
Data Services
25 February 2008

Statement Of Address Accuracy

Software Vender Information

Software Vendor Name:	Business Objects
Software Vendor Address:	332 Front Street South La Crosse, WI 54601-4023
Product Name and Version:	ACE CANADA 7.80c
Software Recognition Expiry Date:	30-Apr-2009

List Processor/Service Bureau:	Company Name
Mailer Information:	Mailer Address 1 Mailer Address 2 Mailer Address 3 Mailer Address 4
Customer CPC Number:	123456

Processing Information

Date Of Postalcode File:	10/2007
Address Accuracy Expiry Date:	02/25/2009
Records Processed (Urban & Rural):	5,000
Address Accuracy Level:	83.82 %

4.9.13 Australian AMAS report: Address Matching Processing Summary

Description

The Australian Address Matching Approval System (AMAS) Address Matching Processing Summary report includes statistical information about Australian address cleanse processing.

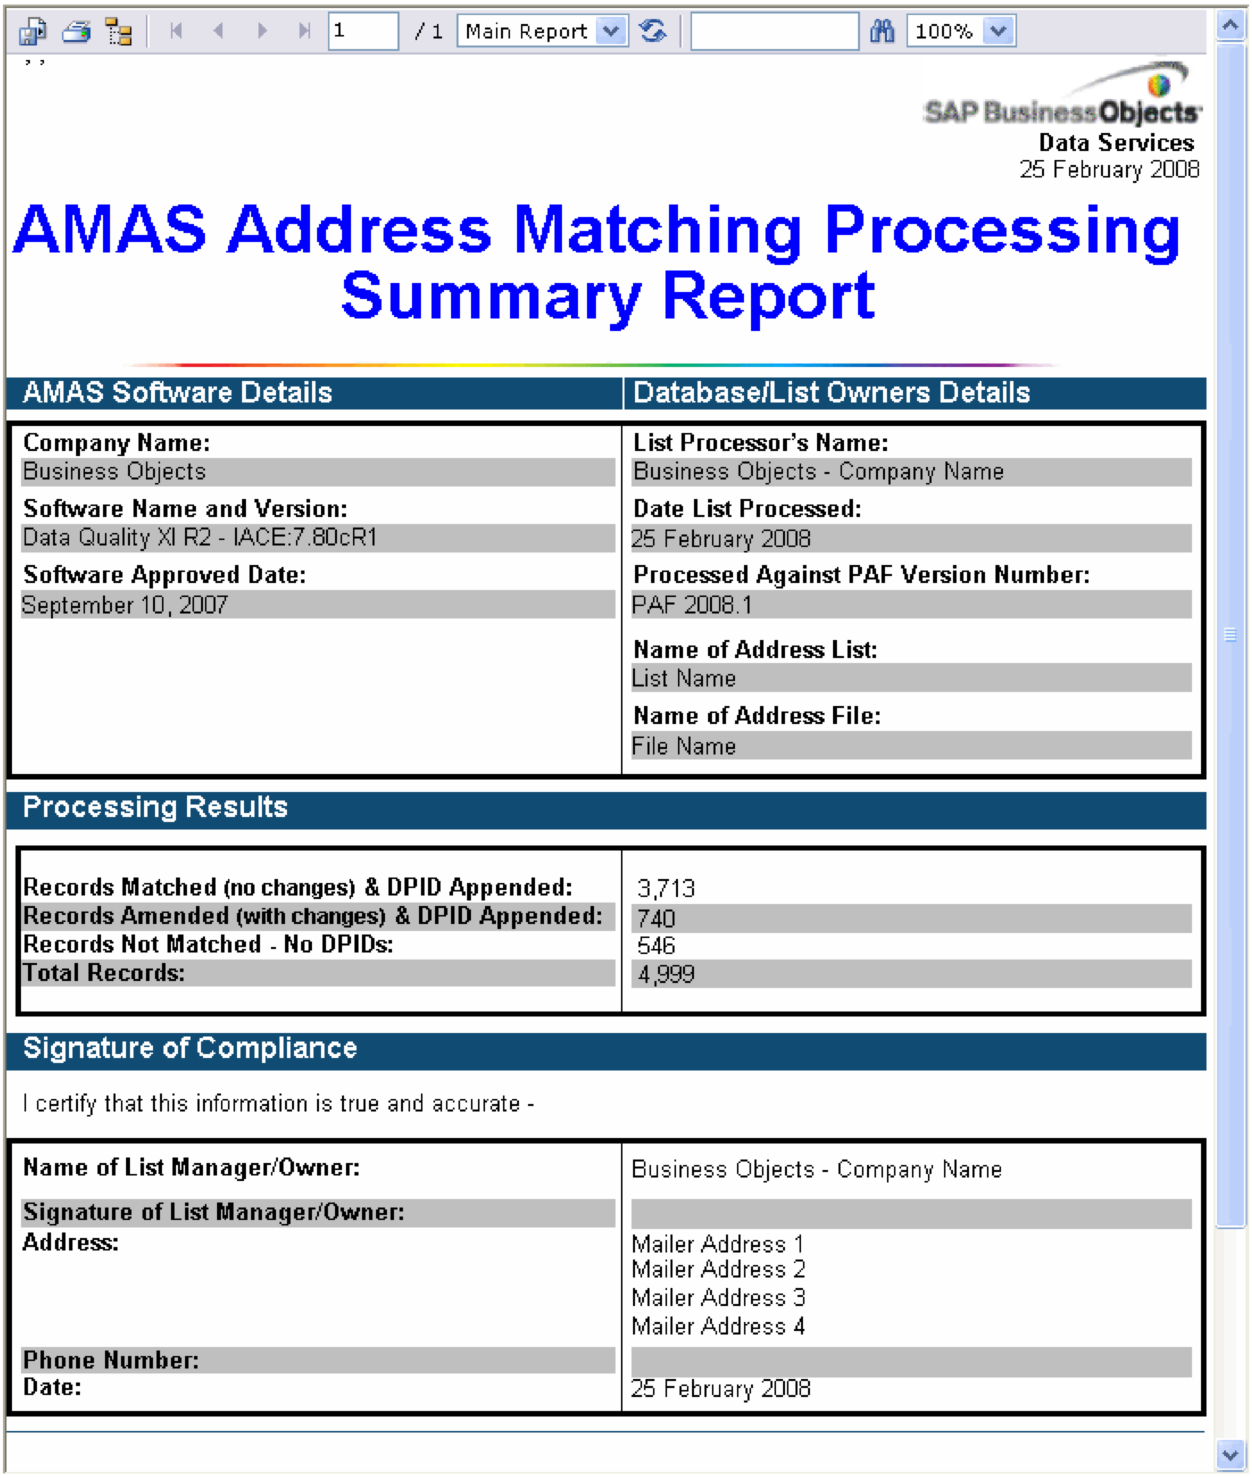
To generate the report

To generate this report with the Global Address Cleanse transform, ensure the following options have been defined, or configure the appropriate substitution parameters:

- In the Global Address Cleanse transform, enable *Report And Analysis* › *Generate Report Data*.
- In the *Australia* group, complete all applicable options in the *Report Options* subgroup.
- In the *Engines* section, set *Australia* to *Yes*.

Example

The following is an example of the Address Matching Processing Summary report.



SAP BusinessObjects
Data Services
25 February 2008

AMAS Address Matching Processing Summary Report

AMAS Software Details

4.9.14 New Zealand Statement of Accuracy (SOA) report

Description

The New Zealand Statement of Accuracy (SOA) report includes statistical information about address cleansing for New Zealand.

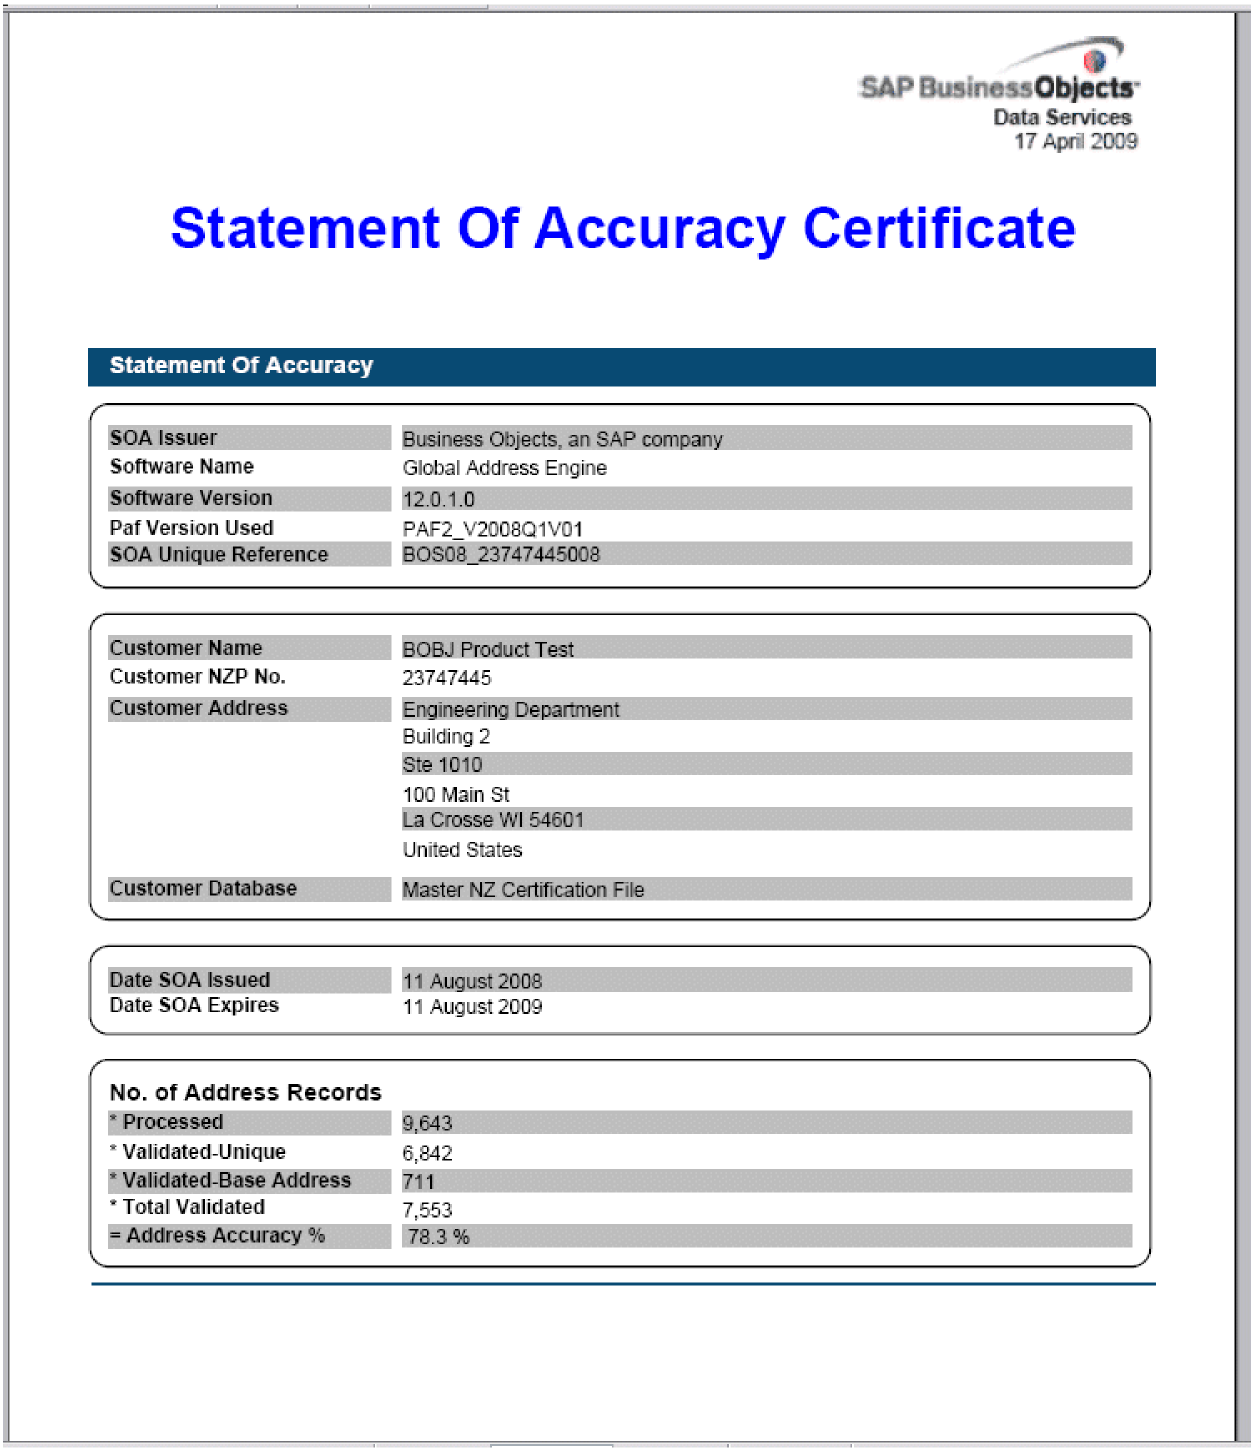
To enable the report

- In the Global Address Cleanse transform, enable ▶ *Report And Analysis* › *Generate Report Data* ◢.
- In the Global Address Cleanse transform, set ▶ *Country Options* › *Disable Certification* ◢ to *No*.
- Complete all applicable options in the ▶ *Global Address* › *Report Options* › *New Zealand subgroup* ◢.
- In the *Engines* section, set *Global Address* to *Yes*.

> **Note**
>
> The software does not produce the SOA Report when Global Address certification is disabled or when there are no New Zealand addresses included in the present job.

Example

The following is an example of the New Zealand Statement of Accuracy report.



SAP BusinessObjects
Data Services
17 April 2009

Statement Of Accuracy Certificate

Statement Of Accuracy

SOA Issuer	Business Objects, an SAP company
Software Name	Global Address Engine
Software Version	12.0.1.0
Paf Version Used	PAF2_V2008Q1V01
SOA Unique Reference	BOS08_23747445008

Customer Name	BOBJ Product Test
Customer NZP No.	23747445
Customer Address	Engineering Department Building 2 Ste 1010 100 Main St La Crosse WI 54601 United States
Customer Database	Master NZ Certification File

Date SOA Issued	11 August 2008
Date SOA Expires	11 August 2009

No. of Address Records

* Processed	9,643
* Validated-Unique	6,842
* Validated-Base Address	711
* Total Validated	7,553
= Address Accuracy %	78.3 %

4.9.15 Address Information Codes Sample report

Description

The Address Information Codes Sample report is a sampling of the records that were assigned information codes (Global Address Cleanse) or fault codes (USA Regulatory Address Cleanse) during processing. The transform uses these codes to indicate why it was unable to standardize the address. These codes can help you correct the data in specific records or find a pattern of incorrect data entry.

The software initially outputs the first fault record encountered. After that, it outputs every 100th fault record (for example 1, 101, 201, and so on). There is a maximum of 500 fault records.

> Note
>
> Depending on your configuration settings, you might see different information/fault records each time the transform processes a particular set of input records.

How to read this report

The first section of the report includes the report title, the date of the report, and other general information about your job as follows:

- Job name
- Run ID, which specifies a unique identification of an instance of the executed job
- Repository name where the job is located
- Full transform name
- Path to the transform in the form <data flow name>/<transform name>
- Engine name. For the Global Address Cleanse transform, it is the name of the global engine that processed the data, and for the USA Regulatory Address Cleanse transform, it is always USA.

The second section of the report includes a table that specifies the field details for each record for which an information/fault code was found. The table is subdivided by country.

The third section of the report lists a description of each information/fault code.

Related Information

Reference Guide: Address Cleanse reference, Information codes (Global Address Cleanse) [page 1409]
Reference Guide: Address Cleanse reference, USA Regulatory Address Cleanse transform fault codes [page 1417]

4.9.16 Address Information Code Summary report

Description

The Address Information Code Summary report provides record counts of each information or fault code of a specific project.

How to read this report

The first page of the report is a summary of all the information codes if one of the following is true:

- The job contains more than one USA Regulatory Address Cleanse or Global Address Cleanse transform.
- A single Global Address Cleanse transform processes records from more than one engine.

Subsequent pages will include a report for each transform or engine.

The first section of the summary page includes the report title, the date of the report, and other general information about your job as follows:

- Job name
- Run ID, which specifies a unique identification of an instance of the executed job
- Repository name where the job is located
- Official transform name
- Path to the transform in the form <data flow name>/<transform name>
- Audit information, which specifies how many records were processed during address cleansing, the start and end time, any idle time, and the amount of active processing time

The second part of the report includes a bar graph that shows how many different information/fault codes were assigned during processing. With this graph, you should be able to see which information/fault code occurred the most frequently, which could help you detect any consistent problems with your data.

The section below the bar graph shows how many different information/fault codes occurred along with a description of each code. For the Global Address Cleanse transform, this section is organized by engine name. At the end of the listing, the report shows the total number of information/fault codes assigned.

Related Information

Reference Guide: Transforms, Information codes (Global Address Cleanse) [page 1409]
Reference Guide: Transforms, USA Regulatory Address Cleanse transform fault codes [page 1417]

4.9.17 Address Validation Summary report

Description

The Address Validation Summary report provides record validation statistics for each Global Address Cleanse transform or USA Regulatory Address Cleanse transform of a specific job.

How to read this report

The first section includes the report title, the date of the report, and other general information about your job as follows:

- Job name
- Run ID, which specifies a unique identification of an instance of the executed job
- Repository name where the job is located
- Official transform name
- Path to the transform in the form `<data flow name>` / `<transform name>`
- Audit information, which specifies how many records were processed during address cleansing, the start and end time, any idle time, and the amount of active processing time

The second section of this report includes a bar graph that shows the output fields and how many were unchanged or corrected during address cleansing.

The third section of this report also shows the same data as in the second section, but in a table.

If NCOALink processing is enabled, this report also displays pre and post NCOALink processing graphs and statistics.

Related Information

Percent calculation [page 2003]

4.9.18 Address Type Summary report

Description

The Address Type Summary report contains record counts of each Assignment_Type field value used per Global Address Cleanse transform or Address_Type field value per USA Regulatory Address Cleanse transform of a specific job.

How to read this report

The first section of the report includes the report title, the date of the report, and other general information about your job as follows:

- Job name
- Run ID, which specifies a unique identification of an instance of the executed job
- Repository name where the job is located
- Official transform name
- Path to the transform in the form <data flow name>/<transform name>
- Audit information, which specifies how many records were processed during address cleansing, the start and end time, any idle time, and the amount of active processing time

The second section includes a pie chart that shows the percentage for the values of the Assignment_Type field (Global Address Cleanse) and the Address_Type field (USA Regulatory Address Cleanse) used in the transform.

The third section of this report also shows this same data as in the second section, but in a table.

If NCOALink processing is enabled, this report also displays pre and post NCOALink processing graphs and statistics.

Related Information

Reference Guide: Data Quality Fields, Global Address Cleanse fields [page 1224]
Reference Guide: Data Quality Fields, USA Regulatory Address Cleanse fields [page 1349]

4.9.19 Address Standardization Sample report

Description

The Address Standardization Sample report shows records where fields changed during processing. The fields displayed are your input fields and the associated output fields. Status codes are on the report to indicate why the change was necessary. This information helps you to determine which fields are frequently incorrect. You can also use this report to verify that your addresses are standardized correctly.

How to read this report

The first section of the report includes the report title, the date of the report, and other general information about your job as follows:

- Job name
- Run ID, which specifies a unique identification of an instance of the executed job

- Repository name where the job is located
- Full transform name
- Path to the transform in the form <data flow name>/<transform name>
- Engine name. For the Global Address Cleanse transform, it is the name of the global engine that processed the data, and for the USA Regulatory Address Cleanse transform, it is always USA.

The second section of the report includes the table that shows which records had fields that were standardized along with the status code that explains why the change was necessary. The section also shows the country and the input source taken from the Physical Source field.

The final page of the report has a description of the status codes.

Related Information

Reference Guide: Transforms, Status codes (Global Address Cleanse) [page 1412]
Reference Guide: Transforms, Status Codes (USA Regulatory Address Cleanse) [page 1418]

4.9.20 Address Quality Code Summary report

Description

The Address Quality Code Summary report provides record counts of each quality code assigned per Global Address Cleanse transform for a specific job. This report is not available for the USA Regulatory Address Cleanse transform.

How to read this report

The first page of the report is a summary of all the information codes if:

- The job contains more than one Global Address Cleanse transform.
- A single Global Address Cleanse transform processes records from more than one engine.

In these cases, subsequent pages will include a report for each transform or engine.

The first section of the report includes the report title, the date of the report, and other general information about your job as follows:

- Job name
- Run ID, which specifies a unique identification of an instance of the executed job
- Repository name where the job is located
- Official transform name
- Path to the transform in the form <data flow name>/<transform name>
- Audit information, which specifies how many records were processed during address cleansing, the start and end time, any idle time, and the amount of active processing time

The second section of the report includes a pie chart that shows the percentage of the quality codes that were assigned during processing. This chart illustrates the level of quality of your data.

The third section of the report shows, in a table format, the quality codes that were assigned, the record count, and a description of each quality code. This section is also divided by engine name and the country.

Related Information

Reference Guide: Transforms, Quality codes (Global Address Cleanse) [page 1416]

4.9.21 Data Cleanse Information Code Summary report

Description

The Data Cleanse Information Code Summary report provides record counts of each information code for a specific job. The information codes identify characteristics about the data. For example:

- some data went to the Extra output fields
- some person data has a family name, but not a given name
- a date's year was converted from 2-digits to 4-digits

How to read this report

The first section of the summary page includes the report title, date, and other general information about your job as follows:

- Job name
- Run ID, which specifies a unique identification of an instance of the executed job
- Repository name where the job is located
- Official transform name
- Path to the transform <dataflow name>/<transform name>
- Audit information, which specifies how many records were processed during data cleansing, the start and end time, any idle time, and the amount of active processing time.

The report begins with a summary of the frequency of information codes. The rest of the charts show the information codes per parser such as Date, Person, Firm, Phone, and so on. With the information in this report, you should be able to see which information codes occurred most frequently. This information could help you detect any consistent problems with the data.

To enable the report

In the Designer, choose ▶ *Tools* ▸ *Substitution Parameter Configurations* ◀ and configure the *Generate Report Data* option to [$$ReportsDataCleanse]. This is a parameter that can be configured to either *Yes* or *No* for report generation.

Then, in the Data Cleanse transform, enable ▶ *Report And Analysis* ▸ *Generate Report Data* ◀

Related Information

Data Services Reference Guide: Transforms, Data Quality transforms, Report and analysis [page 1149]

4.9.22 Data Cleanse Status Code Summary report

Description

The Data Cleanse Status Code Summary report provides record counts for each generated status code. The status codes describe the standards applied in the Data Cleanse transform.

How to read this report

The first section of the summary page includes the report title, date, and other general information about your job as follows:

- Job name
- Run ID, which specifies a unique identification of an instance of the executed job
- Repository name where the job is located
- Official transform name
- Path to the transform <dataflow name>/<transform name>
- Audit information, which specifies how many records were processed during data cleansing, the start and end time, any idle time, and the amount of active processing time.

The charts include a list of status code names, descriptions, and the number of records that used each status code. The report includes a chart and data for each parser, for example, Date, Phone, Firm, Person, and so on. With this report, you should have a better understanding of the generated status codes that show how the data is standardized and can be used for better matching results with the Match transform.

To enable the report

In the Designer, choose ▸ *Tools* ▸ *Substitution Parameter Configurations* and configure the *Generate Report Data* option to [$$ReportsDataCleanse]. This is a parameter that can be configured to either *Yes* or *No* for report generation.

Then, in the Data Cleanse transform, enable ▸ *Report And Analysis* ▸ *Generate Report Data*

Related Information

Data Services Reference Guide: Transforms, Data Quality transforms, Data Cleanse reference, Status Codes (Data Cleanse) [page 1425]

4.9.23 Geocoder Summary report

Description

The Geocoder Summary report includes statistical information about geocoding.

To enable the report

In the Geocoder transform, enable ▸ *Report And Analysis* ▸ *Generate Report Data*.

Related Information

Reference Guide: Transforms, Data Quality transforms, Report and analysis [page 1180]

4.9.24 Overview of match reports

Setting up match reports

To set up the Physical Source Field, Logical Source Field, and matching process transforms, refer to the *Designer Guide:* Data Quality, Match section. Verify the appropriate substitution parameter configurations.

Common match report information

The first section includes general information about your job such as:

- The job name
- The run ID, which specifies a unique identification of an instance of the executed job
- The repository where the job is located
- The official transform name
- The path to the transform in the form `<data flow name>` / `<transform name>`

4.9.25 Best Record Summary report

Description

The purpose of best record post-processing is to salvage data from matching records—that is, members of match groups—and consolidate, or post, that data to a best record or to all matching records. The Best Record Summary report shows statistics about the best record process used in the match. It indicates what settings were selected and the results of the posting.

If your results show any trends that could be improved by adjustments to your settings, then change those settings and re-process the step.

How to read this report

The Best Record Contribution table shows the overall results of the posting. The report columns are as follows.

Report column	Description
Best Record Name	The name of the Best Record operation you specified in the Match transform.
Posting Destination	The destination (either Master, Subordinate, or ALL) for the post.
Post Only Once Per Destination	Setting shows *Yes* or *No* to indicate whether more than one posting will be attempted for each record.
Post Attempts	The number of Best Record operations that were attempted. This is the total of the protected drops, destination field drops, filter drops, and posts completes.
Protect Drops	The number of operations that were cancelled because a posting destination was protected.
Destination Field Drops	Operations that were canceled because the Best Record operation was set to allow posting only once per destination record.
Strategy Drops	Operations that were canceled because the Best Record strategy returned *False*.
Post Completes	The number of Best Record operations that successfully completed.

The next section of the report contains audit information such as:

- How many records were processed during the match
- The start and end time
- Any idle time
- The total amount of time it took to run the Match transform

The Best Record Strategy section shows:

- The name of the best record strategy field containing the statistics
- The source and destination fields used in the best record action.

Related Information

Designer Guide: Data Quality, Set up for match reports [page 584]
Reference Guide: Transforms, Post-match processing [page 1295]

4.9.26 Match Contribution report

Description

The Match Contribution report provides you with information on the effect of the individual break groups and individual criteria on the total matching process. By studying the largest and smallest break groups and their break keys, you can determine whether they must be realigned for more accurate distribution in the matching process. The software generates one report for each match set.

You can also look at the criteria that are making the highest percentage of match/no-match decisions to verify the accuracy as well as the effectiveness of the criteria settings.

The size of the break groups has a significant impact on the speed of the matching process. If you have many large break groups (break groups with large numbers of records), the matching process slows down because it has to do so many comparisons. If that is the case, you might want to adjust your break group formation strategy so the resulting break groups are smaller.

Results showing break groups with only a single record could indicate criteria that is too restrictive. Because data in one break group is never compared with data in another break group, the restrictive criteria could be isolating data that would otherwise match.

Use this report in conjunction with the Match Criteria Summary report to understand the contributions of the various criteria and to view the detailed criteria definitions.

Break Group Contribution

The Break Group Contribution table lists the smallest and largest break group contributors. This section contains data only if you create break groups in your job.

Other information includes:

Total number of break groups	The number of break groups created based on your break group settings.
Theoretical maximum comparisons	The number of comparisons that would be made without using any break group strategy (or putting all records in a single break group).
Break group comparisons	The number of actual comparisons made because of breaking.
Comparisons per hour	The number of comparisons made per hour.
Hours saved by breaking	The amount of time saved because of breaking.
Max records in compare buffer	The maximum number of records that can fit in the memory buffer used for comparison. This value, in conjunction with the largest break group size, can be used to fine-tune performance of match process. If the largest break group size is smaller than the number of records that can fit in the compare buffer, then the records will be stored and accessed from memory. This makes the process go faster. However, if the largest break group is bigger, then some caching will be involved and it may slow down processing. In order to fix it, you can either change the breaking strategy to make smaller break groups or you can increase the buffer size by doing the following: 1. In the Designer, Choose ▸ *Tools* ▸ *Options* ▸ *Job Server* ▸ *General* ◢. 2. In the *Section* box, type **`MatchSettings`**. 3. In the *Key* box, type **`MemoryInKBForComparisons`**. 4. In the *Value* box, type the number of kilobytes of memory you want as your buffer. The default value is 4096 KB. 5. Click *OK*.

Audit Information

The Audit Information section specifies how many records were processed during the match, the start and end time, any idle time, and the total amount of time it took to run the Match transform.

The audit section is followed by the Match Set Name and the Match Level Name(s) if the match set has multiple levels.

Match Criteria Contribution

The last section shows the Match Criteria Contribution listed by criteria name and in order of the criteria execution. Focus on the criteria that are the most productive—that is, the criteria making the most decisions. The criteria that make the most decisions should be the first to be evaluated, so order your criteria appropriately in your Match transform. This will help with performance.

Related Information

Designer Guide: Data Quality, Set up for match reports [page 584]
Reference Guide: Transforms, Match transform options, Group forming [page 1269]
Match Criteria Summary report [page 2025]

4.9.27 Match Criteria Summary report

Description

The software generates one Match Criteria Summary report per match set. Use the report to obtain a consolidated view of all key settings and the criteria settings. Using this report can help you determine whether the values you set for each criteria are giving you the results you require.

After reading this report in conjunction with the Match Contribution report, which shows the break group contributions, you might decide to adjust field compare lengths or settings like match/no match score. The Match Criteria Summary report gives you the necessary information to fine-tune the settings and to compare multiple match criteria for consistency.

In the audit information section of the report, you will find information such as:

- How many records were processed during the match
- The start and end time
- Any idle time
- The total amount of time it took to run the Match transform.

The audit section is followed by the Match Set Name and the Match Level Name(s) if the match set has multiple levels.

The Match Input Fields table shows settings for the input fields used for this match including the criteria name, match criteria, field compare length, and any preprocessing options such as punctuation and casing.

The Detailed Criteria Definition table gives you a more detailed breakdown of the match criteria definitions listed by criteria in the order of execution. A list of the Match Level Options displays below the table so you can verify your settings.

> Note
>
> In cases where the *Blank Field Operation* is set to *EVAL*, the evaluation score appears as a number instead of the word IGNORE.

Related Information

Reference Guide: Transforms, Match transform options [page 1264]
Match Contribution report [page 2023]

4.9.28 Match Duplicate Sample report

Description

The Match Duplicate Sample report provides some duplicate records as a sample of the match results. One report is generated for each Match transform in the job. If a given transform results in no matches, the software does not generate a report for that transform.

The samples are taken from a maximum of 500 records per transform starting from group number 1, using every 10th match group, and up to 20 records from the selected match groups.

The Physical Source Field table displays the data sources used in the job, including the number of records sampled for that data source.

The Match Duplicate Results table displays the Match duplicate results including record number, group number, score, match type, logical source ID, and input field(s). The records are listed by group number in ascending order. If you do not see data in the Logical Source Field column, be sure that you have included an Input Sources operation in the Match transform, or defined the field that contains the logical source value.

> Note
>
> Depending on your configurations settings, you might see different information/fault records each time the transform processes a particular set of input records.

Related Information

Designer Guide: Data Quality, Set up for match reports [page 584]

4.9.29 Match Input Source Output Select report

Description

The Match Input Source Output Select report shows you which types of records and the number of records that were flagged to be kept or dropped per source.

- *Keeps:* Records you selected in the Output Flag Selection operation of the Match transform (Match Editor).
- *Drops:* Records you did not select in the Output Flag Selection operation of the Match transform (Match Editor).

Report columns

Column	Description
Net Input	The number of records in the source.
Single Source Masters	Highest ranking member of a match group whose members all came from the same source. Can be from Normal or Special sources.
Single Source Subordinate	A record that is a subordinate member of a match group whose members all came from the same source. Can be from Normal or Special sources.
Multiple Source Masters	Highest ranking member of a match group whose members came from more than one source. Can be from Normal or Special sources.
Multiple Source Subordinate	A record that is a subordinate member of a match group whose members came from more than one source. Can be from Normal or Special sources.
Suppress Masters	A record that came from a Suppress source and is the highest ranking member of a match group.
Suppress Subordinate	A record that came from a Suppress source and is a subordinate member of a match group.
Suppress Matches	Subordinate member of a match group that includes a higher-priority record that came from a Suppress source. Can be from Normal or Special type sources.
Suppress Uniques	Records that came from a Suppress source for which no matching records were found.
Uniques	Records that are not members of any match group. No matching records were found. These can be from sources with a Normal or Special source type.
Net Output	The number of records in the source minus the number of records dropped.
% Kept	The percentage of records that were not dropped from the original input source.

Related Information

Reference Guide: Match transform, Output flag selection options [page 1306]

4.9.30 Match Multi-source Frequency report

Description

The Multi-source Frequency report shows, for each input source, how many of its records were found to match records in other sources.

The format of the Multi-source Frequency report is always the same. There is a row for each of the input sources of the job. The columns show, first, the name of the source, then the total number of the source's records that appeared in more than one source. The remaining columns show how many records in that source were found in 2 sources, 3 sources, 4 sources, and so on.

If you created source groups, multi-source matches for the source groups are included in a separate table in the report.

- If a record from source1 matches a record from source2, then that record is included in the number in the 2 source column. If a record from source1 matches a record from source2 and also a record from source4, then that record is included in the number in the 3 source column.
- The entry in each column shows the number of multi-source instances—that is, how many records appeared on more than one source, not how many times they appeared. For example, if a record from source1 matches three records from source2, then that record adds one to the this source's total in the 2 source column—it's not added to the 4 source column, nor is three added to the 2 source column.
- When determining the number of sources on which a record appeared, the software does not count single-source matches, or any matches to records from special or suppression sources.

4.9.31 Match Source Statistics Summary report

Description

The Match Source Statistics report provides information about the distribution of the duplicates found in various input source records including how the duplicates were distributed as master records and subordinate records. The duplicates could be distributed within one logical source (intrasource matches) or across multiple logical sources (intersource matches). This report shows the distribution of the duplicates in general and then the results for each source. The software generates one report per match set.

To generate a meaningful Match Source Statistics report, you must have a Group Statistics operation in your Match or Associate transform. You must also generate basic statistics in those Group Statistics operations.

If you also add an Input Source operation and generate input source statistics in the Group Statistics operations, you will find additional columns related to suppression records

How to read this report

A pie chart shows what percentage of the duplicates were multiple source masters, multiple source subordinates, single source masters, and single source subordinates.

The source percentages are also detailed in a key list, indicating the distribution of the masters and subordinates.

Match Statistics table

The Match Statistics table lists the statistics for each source, enabling you to understand the impact of statistics such as total record counts and individual source counts. You can compare the number of masters and subordinates generated to the source record counts.

The columns list how many masters came from a single source or from multiple sources. Statistics are also given for the number of subordinates derived from a single source and from multiple sources.

Additional columns for input source statistics

If you chose to count input source statistics in the Group Statistics operation, you will also find the following columns.

Column	Description
Suppress Matches	The number of records that match a record in a Suppress-type source.
Total Non Dupes	The number of master records and uniques in the input source.
Suppress Uniques	The number of unique records in the Suppress-type source.
Suppress Masters	The number of master records in the Suppress-type source.
Suppress Subordinate	The number of subordinate records in the Suppress-type source.

Source by Source Statistics table

The Source by Source Statistics table details the information by source, generating statistics for the number of duplicates that are both intersource (between distinct sources) and intrasource (within a single source).

The Source Name and Comparison Source Name columns display how many times a subordinate record in the specified comparison source was found when the master was from the named source. The other two columns (Number of Inter-Source Matches and Number of Intra-Source Matches) display how many matches were found with the master in one source and the subordinate in another source (intersource) and how many matches were found with the master and subordinate in the same source (intrasource).

For example, you can compare data from two sources: Source 1 lists people who have in-ground swimming pools and Source 2 lists people who have children under the age of two. Your goal is to find the people that fit in both categories. With this report, you can now send your Swimming Pool Safety pamphlet to pool owners who have children under the age of two.

5 Workbench Guide

5.1 Introduction

5.1.1 Welcome to SAP Data Services

5.1.1.1 Welcome

SAP Data Services delivers a single enterprise-class solution for data integration, data quality, data profiling, and text data processing that allows you to integrate, transform, improve, and deliver trusted data to critical business processes. It provides one development UI, metadata repository, data connectivity layer, run-time environment, and management console—enabling IT organizations to lower total cost of ownership and accelerate time to value. With SAP Data Services, IT organizations can maximize operational efficiency with a single solution to improve data quality and gain access to heterogeneous sources and applications.

5.1.1.2 Documentation set for SAP Data Services

You should become familiar with all the pieces of documentation that relate to your SAP Data Services product. The latest Data Services documentation can be found on the *SAP Help Portal*.

Document	What this document provides
Adapter SDK Guide	Information about installing, configuring, and running the Data Services Adapter SDK
Administrator Guide	Information about administrative tasks such as monitoring, lifecycle management, security, and so on.
Customer Issues Fixed	Information about customer issues fixed in this release. ℹ Note In some releases, this information is displayed the Release Notes.
Designer Guide	Information about how to use Data Services Designer.
Documentation Map	Information about available Data Services books, languages, and locations.
Installation Guide for Windows	Information about and procedures for installing Data Services in a Windows environment.
Installation Guide for UNIX	Information about and procedures for installing Data Services in a UNIX environment.
Integrator Guide	Information for third-party developers to access Data Services functionality using web services and APIs.

Document	What this document provides
Master Guide	Information about the application, its components and scenarios for planning and designing your system landscape. Information about SAP Information Steward is also provided in this guide.
Management Console Guide	Information about how to use Data Services Administrator and Data Services Metadata Reports.
Performance Optimization Guide	Information about how to improve the performance of Data Services.
Reference Guide	Detailed reference material for Data Services Designer.
Release Notes	Important information you need before installing and deploying this version of Data Services.
Technical Manuals	A compiled, searchable, “master” PDF of core Data Services books: ● *Administrator Guide* ● *Designer Guide* ● *Reference Guide* ● *Management Console Guide* ● *Performance Optimization Guide* ● *Integrator Guide* ● *Supplement for J.D. Edwards* ● *Supplement for Oracle Applications* ● *Supplement for PeopleSoft* ● *Supplement for Salesforce.com* ● *Supplement for Siebel* ● *Supplement for SAP* ● *Workbench Guide*
Text Data Processing Extraction Customization Guide	Information about building dictionaries and extraction rules to create your own extraction patterns to use with Text Data Processing transforms.
Text Data Processing Language Reference Guide	Information about the linguistic analysis and extraction processing features that the Text Data Processing component provides, as well as a reference section for each language supported.
Tutorial	A step-by-step introduction to using Data Services.
Upgrade Guide	Information to help you upgrade from previous releases of Data Services and release-specific product behavior changes from earlier versions of Data Services to the latest release.
What's New	Highlights of new key features in this SAP Data Services release. This document is not updated for support package or patch releases.
Workbench Guide	Provides users with information about how to use the Workbench to migrate data and database schema information between different database systems.

In addition, you may need to refer to several Supplemental Guides.

Document	What this document provides
Supplement for SAP	Information about interfaces between Data Services, SAP Applications, SAP Master Data Services, SAP NetWeaver BW, and SAP Master Data Services.
Supplement for SuccessFactors	Information about interfaces between Data Services and SuccessFactors.
Supplement for Salesforce.com	Information about how to install, configure, and use the SAP Data Services Salesforce.com Adapter Interface.
Supplement for J.D. Edwards	Information about interfaces between Data Services and J.D. Edwards World and J.D. Edwards OneWorld.
Supplement for Oracle Applications	Information about the interface between Data Services and Oracle Applications.
Supplement for PeopleSoft	Information about interfaces between Data Servicesand PeopleSoft.
Supplement for Siebel	Information about the interface between Data Services and Siebel.

We also include these manuals for information about SAP BusinessObjects Information platform services.

Document	What this document provides
Information platform services Administrator Guide	Information for administrators who are responsible for configuring, managing, and maintaining an Information platform services installation.
Information platform services Installation Guide for UNIX	Installation procedures for SAP BusinessObjects Information platform services on a UNIX environment.
Information platform services Installation Guide for Windows	Installation procedures for SAP BusinessObjects Information platform services on a Windows environment.

5.1.1.3 Accessing documentation

You can access the complete documentation set for SAP Data Services in several places.

5.1.1.3.1 Accessing documentation on Windows

After you install SAP Data Services, you can access the documentation from the Start menu.

1. Choose *Start* > *Programs* > *SAP Data Services 4.2* > *Data Services Documentation* > *All Guides*.
2. Click the appropriate shortcut for the document that you want to view.

5.1.1.3.2 Accessing documentation on UNIX

After you install SAP Data Services, you can access the documentation by going to the directory where the printable PDF files were installed.

1. Go to `<LINK_DIR>/doc/book/en/`.
2. Using Adobe Reader, open the PDF file of the document that you want to view.

5.1.1.3.3 Accessing documentation from the Web

You can access the complete documentation set for SAP Data Services from the SAP Business Users Support site.

To do this, go to *http://help.sap.com/bods*.

You can view the PDFs online or save them to your computer.

5.1.1.4 SAP information resources

A global network of SAP technology experts provides customer support, education, and consulting to ensure maximum information management benefit to your business.

Useful addresses at a glance:

Address	Content
Customer Support, Consulting, and Education services *http://service.sap.com/*	Information about SAP support programs, as well as links to technical articles, downloads, and online forums. Consulting services can provide you with information about how SAP can help maximize your information management investment. Education services can provide information about training options and modules. From traditional classroom learning to targeted e-learning seminars, SAP can offer a training package to suit your learning needs and preferred learning style.
Product documentation *http://help.sap.com/bods/*	SAP product documentation.
Supported Platforms (Product Availability Matrix) *https://service.sap.com/PAM*	Get information about supported platforms for SAP Data Services. Use the search function to search for Data Services. Click the link for the version of Data Services you are searching for.
SAP Data Services Community Network *http://scn.sap.com/community/data-services*	Get online and timely information about SAP Data Services, including forums, tips and tricks, additional downloads, samples, and much more. All content is to and from the community, so feel free to join in and contact us if you have a submission.
Blueprints *http://scn.sap.com/docs/DOC-8820*	Blueprints for you to download and modify to fit your needs. Each blueprint contains the necessary SAP Data Services project, jobs, data flows, file formats, sample data, template

Address	Content
	tables, and custom functions to run the data flows in your environment with only a few modifications.
SAPTerm *https://portal.wdf.sap.corp/go/sapterm*	SAP's terminology database, the central repository for defining and standardizing the use of specialist terms.

5.1.2 Overview of this guide

Welcome to the *Workbench Guide*. The Data Services Workbench provides a graphical user interface (GUI) development environment in which you define data application logic to migrate data and database schema information between different databases in a data warehousing environment.

Key features of the Workbench include:

- Browsing table metadata and data.
- Selecting individual source tables for migration.
- Specifying the order in which the source tables should be migrated.
- Adjusting the table schema in detail. For example, adding or removing columns, defining constraints, partitions, indexes, and so on.
- Specifying filters and simple projection expressions.
- Specifying source and target table options such as array fetch size and bulk-loading options.
- Executing a replication job as an initial load or delta load.
- Modeling and consuming a data quality job.

5.1.2.1 About this guide

This guide contains two kinds of information:

- Conceptual information that helps you understand the Data Services Workbench and how it works.
- Procedural information that explains in a step-by-step manner how to accomplish a task.

You will find this guide most useful:

- While you are learning about the product.
- While you are performing tasks in the design and early testing phases of your data-movement projects.
- As a general source of information during any phase of your projects.

5.1.2.2 Who should read this guide

This and other Data Services product documentation assumes the following:

- You are an application developer, consultant, or database administrator working on data warehousing.

- You understand your source data systems and RDMBS.
- You understand your organization's data needs.
- You are familiar with SQL (Structured Query Language).
- You are familiar with Data Services installation environments — Microsoft Windows or UNIX.

5.1.3 Naming Conventions

In this documentation, the following naming conventions apply:

Terminology

- “Data Services system” refers to “SAP Data Services”.
- “BI platform” refers to “SAP BusinessObjects BI platform”.

  > Note
  >
  > The BI platform components required by Data Services may also be provided by SAP BusinessObjects Information platform services (IPS).

- “CMC” refers to the Central Management Console provided by the BI or IPS platform.
- “CMS” refers to the Central Management Server provided by BI or IPS platform.

Variables

Variables	Description
`<INSTALL_DIR>`	The installation directory for the SAP software. Default location: • `C:\Program Files (x86)\SAP BusinessObjects` • `$HOME/sap businessobjects`
`<BIP_INSTALL_DIR>`	The root directory of the BI or IPS platform. Default location: • **`<INSTALL_DIR>`**`\SAP BusinessObjects Enterprise XI 4.0` • **`<INSTALL_DIR>`**`/enterprise_xi40` Note These paths are the same for both the SAP BusinessObjects BI platform and SAP BusinessObjects Information platform services.

Variables	Description
`<LINK_DIR>`	The root directory of the Data Services system. Default location: - All platforms **`<INSTALL_DIR>`**`/Data Services` This system environment variable is created automatically during installation.

`<DS_COMMON_DIR>`	The common configuration directory for the Data Services system.
	Default location:
	- Windows (Vista and newer)
	`ALLUSERSPROFILE\SAP BusinessObjects\Data Services`
	- Windows (Older versions)
	`ALLUSERSPROFILE\Application Data\SAP BusinessObjects\Data Services`
	- UNIX systems (for compatibility)
	`<LINK_DIR>`
	This system environment variable is created automatically during installation.

`<DS_USER_DIR>`	The user-specific configuration directory for the Data Services system.
	Default location:
	- Windows (Vista and newer)
	`USERPROFILE\AppData\Local\SAP BusinessObjects\Data Services`
	- Windows (Older versions)
	`USERPROFILE\Local Settings\Application Data\SAP BusinessObjects\Data Services`
	This user environment variable is created automatically during installation.
	i Note
	This variable is used only for Data Services client applications on Windows, such as the Designer. **`<DS_USER_DIR>`** is not used on UNIX platforms.

5.2 Workbench User Interface

This section provides basic information about the Workbench user interface.

5.2.1 Logging into the Workbench

Before you can use the Workbench to create, edit, and execute replication jobs, you must log in as a user defined in the Central Management Server (CMS).

1. Launch the Workbench.

   The Workbench can be accessed from the Windows Start Menu: *All Programs* › *SAP Data Services* **<x.x>** › *Data Services Workbench*.
2. Enter your user credentials for the CMS.

Option	Description
System	The server name and optionally the port number for the CMS.
User name	The user name to use to log into the CMS.
Password	The password to use to log into the CMS.
Authentication mode	The authentication type used by the CMS.

3. Click *Connect*.
   The software attempts to connect to the CMS using the specified information. If the authentication is successful, the Workbench window is displayed.

5.2.2 Workbench window

By default, the Workbench user interface consists of several primary elements:

- Menu bar
- Toolbar
- Project explorer
  The Workbench project explorer contains the current project, and all jobs and datastores that are a part of it.
- Workspace
  The workspace is the area of the Workbench window where you define, display, and modify objects. When you create a new object, the Workbench automatically opens a new editor tab in the workspace. The workspace is also used to display the data of a source table and to display the job status and execution logs.

Workspace editors

The workspace area of the Workbench contains tabs for the editors you currently have open. The editors that may appear in the workspace include the following:

- Replication job editor
  The replication job editor allows you to display and edit replication job options. For example, the target table schema, projections expressions and filters, and replication groups. The name of the open replication job is indicated in the tab's title. If the replication job contains unsaved data, it is indicated with an asterisk (*).
- Data Flow editor
  The data flow editor allows you to create data flows and include them in the replication job. The supported tranforms are Query transform, Case transform, Merge transform, Row Generation transform, MAP Operation transform, and SQL transform. You can reference existing data flows from the Replication Job by dragging and dropping the data flows in from the Explorer. You can verify all data flows and specify whether the data flow is for initial load, delta load, or both.
- Datastore editor

The datastore editor allows you to display and edit datastore properties, browse and import metadata, and display and edit table properties. The name of the open datastore is indicated in the tab's title. If the datastore contains unsaved data, it is indicated with an asterisk (*).

- File Format editor
  The file format editor allows you to set properties for file format templates and source and target file formats.
- Monitoring editor
  The monitoring editor displays your replication jobs' status, execution progress, and any applicable logs. Trace, monitor, and error logs are available.

Related Information

Replication job editor [page 2041]
Datastore editor [page 2045]
Data Flow editor [page 2043]
Monitoring editor [page 2057]
File Format editor [page 2046]

5.2.3 Menu bar

This section contains a brief description of the Workbench menus.

5.2.3.1 File menu

The File menu contains standard Windows as well as software-specific options.

Option	Description
New	Define a new folder, project, datastore, data flow, or replication job.
Open File	Open an existing Workbench file.
Close	Close the active Workbench editor.
Close All	Close all open editors.
Save	Save the object in the active editor.
Save All	Save all objects in open editors.
Exit	Exit the Workbench.

5.2.3.2 Edit menu

The Edit menu contains standard Windows options.

Option	Description
Undo	Undo the last operation.
Redo	Redo the last undone operation.
Cut	Cut the selected objects or text and place it on the clipboard.
Copy	Copy the selected objects or text to the clipboard.
Paste	Paste the contents of the clipboard into the active editor or text box.
Delete	Delete the selected objects or text.
Select All	Select all objects in the active editor or all text in the active text box.

5.2.3.3 Tools menu

The Tools menu contains replication job editor and datastore editor options.

Option	Description
Open monitoring editor	Open the job monitoring editor.
Quick replication wizard	Start the quick replication wizard.
Export to ATL	Export a selected replication job to the local file system.
Deploy	Deploy a replication job or datastore definition to a Data Services repository.
Execute	Deploy a replication job to a Data Services repository and execute the job. Note This option is available only for the replication job editor.

5.2.3.4 Validate menu

The Validate menu contains replication job editor and datastore editor validation options.

Option	Description
Validate	Validate the active Workbench replication job for errors.

Option	Description
	ℹ Note The *Validate* option is available only for the replication job editor.
Show DDL	Display the data definition language (DDL) for the active Workbench object. ℹ Note The *Show DDL* option is available only for the replication job editor and only applies when the replication job editor is active.
Show ATL	Display the ATL for the active Workbench object. ℹ Note Do not use this option to create a file for import into Data Services. Use the ▶ *Tools* ▶ *Export Replication Job option* ◢ to export a replication job.

5.2.3.5 Window menu

The Window menu provides software-specific window options.

Option	Description
Data Cleansing Solutions	Display the Data Cleansing Solutions tab in the workspace area.
Error Log	Display the Error Log tab in the workspace area.
Problems	Display the Problems tab in the workspace area.
Project Explorer	Display the project explorer.
Reference Analysis	Display a reference impact analysis for the active Workbench object in the workspace area.
Other	Display other window panes.
Reset Perspective	Reset the Workbench interface perspective to its default settings.
Preferences	Display the Preferences window.

5.2.3.6 Help menu

The Help menu provides standard help options.

Option	Description
Welcome	Display the Workbench welcome screen.
Help	Display the SAP Data Services Workbench Guide.
About	Display information about the software including the version of the Workbench and copyright information.
Key Assist	Display information about keyboard shortcuts available in the Workbench.

5.2.3.7 Replication job editor

The Workbench replication job editor opens in the workspace when you create a new replication job or open an existing replication job from the project explorer.

The replication job editor consists of several areas:

- Project explorer
  Displays the name of the source datastore and all imported tables.
- Target datastore pane
  Displays the name of the target datastore and all mapped tables and columns. In this pane, mapped objects may be grouped into replication groups.
- Replication job configuration pane
  When you select an object such as a datastore table or column in the replication job editor, its configuration options are displayed in this pane.
  The option groups that are available depend on the type of object that is selected:

Object	Available options
Project explorer	Properties
Replication job	Properties Variables Scripts
Replication group	Properties
Target table	Properties Columns Foreign Keys Indexes Options Filter data DDL Options

Object	Available options
	Delta load
Column	Properties

You can adjust the size of each pane by dragging the borders between them. In addition, you can hide or reveal the replication job configuration pane by clicking the arrows in the center of its border.

Related Information

Using the replication job editor [page 2068]

5.2.4 Toolbar

In addition to many of the standard Windows tools, the software provides application specific tools, including:

Icon	Tool	Description
🗋	New	Define a new folder, project, datastore, or replication job.
💾	Save	Save the object in the active editor.
✂	Cut	Cut the selected objects or text and place it on the clipboard.
	Copy	Copy the selected objects or text to the clipboard.
📋	Paste	Paste the contents of the clipboard into the active editor or text box.
✕	Delete	Delete the selected objects or text.
	Open monitoring editor	Open the job monitoring editor.
✓	Validate	Validate the active Workbench resource for errors.
DDL	Show DDL	Display the data definition language (DDL) for the active Workbench resource.
ATL	Deploy ATL	Deploy the ATL for the active replication job to the Data Services repository.
▶	Execute	Deploy the ATL for the active replication job to the Data Services repository, and execute the replication job.
	Quick replication wizard	Start the quick replication wizard to easily define source and target datastores and create a basic replication job.

5.2.5 Project explorer

The project explorer contains the projects currently defined in the user workspace. Each Workbench project is represented as a folder containing all datastores and replication jobs associated with that project.

When you create new projects, datastores, data flows, file formats, and replication jobs, they are displayed in the project explorer. You can also use the project explorer to import and export Workbench project information.

5.2.6 Data Flow editor

Workbench Data Flow editor enables you to create data flows and include them in the replication job. The supported tranforms are the Query transform, Case transform, Merge transform, Row Generation transform, MAP Operation transform, and SQL transform. You can reference existing data flows from the Replication Job by dragging and dropping the data flows in from the Explorer. You can verify all data flows and specify whether the data flow is for initial load, delta load, or both.

You also have the ability to convert replication tables to data flows. Highlight multiple replication tables, right click the selection, and select convert data. You have the option to generate a single data flow or one data flow per replicated table.

Data Flow editor options

The Workbench Data Flow editor includes the Data Flow diagram, a list of input schemas for the selected transform, a list of available Transforms, and a tabbed area containing the properties of the object currently selected in the Data Flow diagram.

Object	Available options
Data Flow diagram	The Data Flow diagram is composed of a graphical area and a palette of elements you can drop on the graphical area. The Data Flow diagram toolbar includes options, such as Zoom slider, Snap to Grid, Highlight Related Element, and so on.
Data Flow diagram toolbar	The Data Flow diagram toolbar includes the following: • Zoom slider • Snap to grid • Enable highlight related elements • Enable descriptions in the diagram • Summary mode • Save a screenshot of the diagram
Transforms	This panel displays all available transforms. Drag and drop the transforms onto the Data Flow diagram.
Input Schemas panel	This panel displays all the available input schemas / fields that the user can drag-and-drop to the properties area. Every field that is being used in the current prop-

Object	Available options
	erty tab is marked with a black triangle. Some fields are marked with a key icon indicating they are part of the primary key.
Object properties	Displays the properties of the object that is currently selected in the Data Flow diagram.

The options for Table Reader properties, File Reader properties, Table Loader properties, Merge properties, Case properties, SQL properties, Row Generation properties, Map Operation properties, Date Generation properties, and the Effective Date properties are the same as the Data Services Designer.

The Template Table Loader uses the same database specific loader options as Data Services Designer as well as some extra options:

- Use NVARCHAR for VARCHAR
- Drop and re-create table
- Double quote names
- Table Type (for HANA only)

Use data file as source or target

You can select and drop data from the Project Explorer onto the Data Flow diagram and choose to use it as a source or target.

Validation in the Data Flow editor

Objects containing errors will be underlined in red and a tooltip will show the list of errors/warnings for an element.

5.2.6.1 Additional Data Flow options

The Workbench Data flow Editor includes several options that are not available in Designer Data Flow editor.

Template file loader

Located in the Transforms panel, the Template File loader enables you to add data to a file without having to create a file format. Drop the Template file loader onto the Data Flow diagram and set the template file properties. You must enter the fully qualified file name(s).

Detect Mappings

Located on the Mappings tab, the Detect mappings option assists you during target to source mapping by detecting source fields with similar names. The dialog provides a list of proposed candidate mappings for you to view and confirm. Every proposed candidate field has a matching score (from 0 to 100), and proposals are displayed from the highest score to the lowest to allow you to see the most relevant proposals first. Only the proposals that are confirmed are applied.

Detect Joins

Join detection combines both foreign key relationships analysis (if the source has foreign keys) and name, data type matching. Every join that is detected is assigned a detection score and shown in a confirmation dialog. A join found using foreign key detection will always have a score of 100, and a detection using name will have a score between 0 and 99 depending on the similarity of the fields that are proposed as a join.

Create Query transform

The Data Flow feature allows you to right-click and select to add a new query transform to the data flow. Workbench will create the query transform object, connect it to both selected sources, connect it to the loader, run the detect joins, and detect mapping.

The Data Flow detections page under Preference gives you the flexibility to be more restrictive for the minimum score and allows you to choose whether to always confirm the detections or not.

Related Information

Data Flow Detections [page 2057]

5.2.7 Datastore editor

The Workbench datastore editor opens in the workspace when you create a new datastore or open an existing datastore from the project explorer or replication job editor.

The datastore editor consists of these areas:

- Navigation pane
  The navigation pane displays the configuration and imported tables and views of the datastore. For SAP datastores, the navigation pane also displays the imported SAP extractors.
  When the datastore configuration is active, you can edit the datastore properties and settings. When the datastore tables, extractors, or views are active, you can import or re-import tables, extractors, and views, view data, and compare imported metadata with the metadata in the database.

- Object properties pane
  Displays tabs for the properties and options for the object currently selected in the navigation pane. The option tabs that are available depend on the type of object that is selected:

Object	Available option
Table	Properties Columns Foreign Keys Indexes Partitions Attributes
Column	Properties Attributes

You can adjust the size of each pane by dragging the borders between them. In addition, you can hide or reveal the navigation pane by clicking the arrow in the center of its border.

Using the Datastore editor [page 2067]

5.2.8 File Format editor

A file format describes the structure of an ASCII file. A file format consists of multiple properties. You set the properties in the *File Format editor*.

The work area on the left, in the *File Format editor*, lists file format properties that are not field specific. The following table lists all of the options. These options are filtered by the mode you are using.

Option	Possible values	Description	Mode
General			
File format	Delimited	The format of the data in the text file. Available properties change based on the selected file format type.	New, Edit
Adaptable file reading	Yes, No	Indicates whether the schema of a delimited file format is adaptable or fixed. • *Yes* indicates that the schema is adaptable. The actual file can contain fewer or more columns than indicated by the file format. If a row contains fewer columns than expected, the software loads null val-	New, Edit, Source

Option	Possible values	Description	Mode
		ues into the columns missing data. If a row contains more columns than expected, the software ignores the additional data. • *No* indicates that the schema is fixed. The software requires the number of columns in each row to match the number of columns specified in the file format. The default is *No*. If you select *Yes*, you must ensure that the selected column and row delimiters do not appear inside the actual data.	
Custom transfer	Yes, No	Enables the software to use a third-party file transfer program. Displays additional Custom transfer program options in the *File Format Editor* below the Input/ Output properties.	All
Skip error handling	Yes, No	Selecting *Yes* disables the Error Handling section in the Format editor. The default is *No.*	New, Edit, Source
Number of processing threads	Integer greater than 0, {none}, {default}	Specifies the number of threads for parallel processing. Parallel processing can improve performance by maximizing CPU usage on the Job Server computer. For example, if you have four CPUs, enter 4 for this option. For more information, see “File multi-threading” in the *Performance Optimization Guide*. For jobs that process USPS certification tests, the value should be set to *{none}*.	All
Data File(s)			
File location	Local, Job Server	During design, indicates the files are located on the local machine or on the machine that runs the Job Server. If you select Job Server, you must enter the absolute path to files. Remember that UNIX systems are case-sensitive. During execution, all files must be located on the Job Server machine that executes the job. If you use different files to design your job, change the file specified (through the Root directory and File properties) before you execute the job.	All
Root folder	Path name for the file or blank	The directory where the file is located. For added flexibility, you can enter a variable for this option. If you enter a directory name, then enter only the file name for the *File* property.	New, Edit

Option	Possible values	Description	Mode
		If you leave the root directory blank, then enter a file name that includes the full path name in the *File* property.	
File name(s)	File name(s), file name(s) including full path name, or blank	In new and edit modes, specifies an existing file on which you base the file format description. Data from this file appears in the Column Attributes area. In these modes, you can leave this property blank. In source and target modes, specify the location of the actual file for this source or target. In these modes, you cannot leave this property blank. For added flexibility, you can enter: ● A variable that is set to a particular file with full path name. Use variables to specify file names that you cannot otherwise enter, such as file names that contain multi-byte characters. ● A list of files, separated by commas, or a file name containing a wildcard. In this case, the software reads all these files as a single source. See “Reading multiple files at one time” in the *Designer Guide*.	All
Delimiters			
Column delimiter	Tab, Semicolon, Comma, Space, or any character sequence	For delimited file formats, the character sequence that indicates the end of one column and the beginning of the next.	New, Edit
Row delimiter	{new line}, {Windows new line}, {Unix new line}, or any character sequence	A character sequence that indicates where one row of data ends and the next begins.	New, Edit
Row delimiter within text string	Character, Row delimiter	Defines how the row delimiter is interpreted within a text string. ● *Character*: The specified row delimiter is treated as a character within the text string. ● *Row delimiter*: The specified row delimiter is interpreted and defines rows within the text string.	New, Edit
Text delimiter	Single quotation marks ('), double quotation marks ("), or {none}	Denotes the start and end of a text string. All characters (including those specified as column delimiters) between the first and second occurrence of this character is a single text string. The treatment of the row characters is defined by the *Row within text string* setting.	New, Edit

Option	Possible values	Description	Mode
ℹ Note Data in columns cannot include the column or row delimiter, unless you also specify a text delimiter. For example, if you specify a comma as your column delimiter, none of the data in the file can contain commas. However, if you specify a comma as the column delimiter and a single quote as the text delimiter, commas are allowed in strings in the data. You can use any ASCII characters (including non-printing characters) for column and row delimiters. You can specify an ASCII character by entering a forward slash (/) followed by the decimal representation of the character. For example, to use Y umlaut (Ÿ) as a delimiter, enter /255 in the delimiter property box.			
Default Format			
Escape character	Any character sequence, or {none}	A special character sequence that causes the software to ignore the normal column delimiter. Characters following the escape character sequence are never used as column delimiters. For example, suppose you specify a forward slash as the escape character and a comma as the column delimiter. Then, you must have a forward slash to have a comma appear inside a field.	New, Edit
NULL indicator	{none} or any other character sequence	A special character sequence that the software interprets as NULL data. The software ignores any NULL indicator specified in the file format for blob columns.	New, Edit
Ignore row marker(s)	{none} or any other character sequence	A character sequence, which when found at the beginning of rows, causes the software to ignore the row when reading the file or automatically creating metadata. To enter multiple character sequences, separate each with a semi-colon. To include a semi-colon or backslash as a marking character, precede with a backslash.	New, Edit, Source
Date format	yyyy.mm.dd or other combinations	The date format for reading or writing date values to and from the file.	New, Edit
Time format	hh24:mi:ss or other combinations	The time format for reading or writing time values to and from the file.	New, Edit
Date-Time format	yyyy.mm.dd hh24:mi:ss or other combinations	The datetime format for reading or writing datetime values to and from the file.	New, Edit

Option	Possible values	Description	Mode
Input/Output			
Style	Headers or BOF/EOF	The format of the start and end of the file. Available properties in the Input/Output property group may change, based on this selection.	New, Edit
Skipped rows	Integer	For file formats using Headers style, the number of rows skipped when reading the file. Specify a non-zero value when the file includes comments or other non-data information.	New, Edit
Skip row header	Yes, No	For file formats using the Headers style, indicates whether the first row of data in the file contains the column names and should be skipped when reading the file. The software uses this property in addition to the *Skipped rows* property. When you select *Yes*, the software does not read data from the first row, and uses data in the first row to determine the file's column names.	New, Edit
Write row header	Yes, No	For file formats using Headers style, indicates whether to write column names in the first row of the output file.	New, Edit
Write BOM	Yes, No	For file formats using UTF-8 and UTF-16, determines the writing of BOM characters into the file. Choose Yes if you want to include BOM characters into a UTF-8 or UTF-16 file in which byte order is not otherwise defined. For a UTF-16 file, the software assumes the file to be UTF-16be, unless BOM characters are added by this property.	New, Edit
Beginning string in a file	Any character sequence, including a blank space, an empty string, or {none}	For file formats using BOF/EOF style, the string that marks the start of data in the file.	New, Edit
Ending string in a file	Any character sequence, including a blank space, an empty string, or {none}	For file formats using BOF/EOF style, the string that marks the end of data in the file.	New, Edit
Custom Transfer options			
Program executable	File name	(Required) The name of the custom transfer program or its initialization script. For example: MyProgram.exe or MyProgram.cmd.	New, Edit
User name	Any character sequence, including a blank	(Optional) Log in ID for the server to which the custom transfer program connects. You may want to allow a	New, Edit

Option	Possible values	Description	Mode
	space, an empty string, or {none}	custom program user to enter their user name when they enter their password in the software.	
Password	Any character sequence, including a blank space, an empty string, or {none}	(optional) Password for the server to which the custom transfer program connects. Passwords entered into this option are encrypted.	New, Edit
Arguments	Any character sequence, including a blank space, an empty string, or {none)	(Optional) You can create arguments in your custom transfer program and then specifically flag them from within the software using this box. For example, you might have security or compression mechanisms in your program. You can also link connection data to your transfer program's flags.	New, Edit
Locale			
Language	The three-letter language abbreviations specified in the ISO 639-2/T standard	Specifies the human language (for example, Korean, Japanese, or English) in which data is stored or processed. Select from the displayed list.	New, Edit
Code Page	The list of supported code pages. See Supported Locales and Encodings.	Specifies the sequence of bits that defines a character. For example, the Japanese code page contains ASCII, Greek, Cyrillic, and Japanese characters, thereby supporting the English, Greek, Russian, and Japanese languages.	New, Edit
Error Handling			
Log data conversion warnings	Yes, No	Determines whether to include data-type conversion warnings in the error log. The default is *Yes*.	New, Edit, Source
Log row format warnings	Yes, No	Determines whether to include row-format warnings in the error log. The default is *Yes*.	New, Edit, Source
Maximum warnings to log	Integer greater than 0 or {no limit}	If *Log data conversion warnings* or *Log row format warnings* is enabled, you can limit how many warnings the software logs. The default is *{no limit}*.	New, Edit, Source
Capture data conversion errors	Yes, No	Determines whether to capture data-type conversion errors when processing a flat-file source. The default is *No*.	New, Edit, Source
Capture row format errors	Yes, No	Determines whether to capture row-format errors when processing a flat-file source. The default is *Yes*.	New, Edit, Source
Accepted bad records in file	Integer greater than 0 or {no limit}	Specify the number of bad records in a file that will be accepted.	

Option	Possible values	Description	Mode
Write error rows to file	Yes, No	Determines whether to write invalid rows to an error file. The default is *No*.	New, Edit, Source
Error file root directory	Directory path or blank	If *Write error rows to file* is enabled, type the root directory in which to save the error file. For added flexibility, you can enter a variable for this option. If you type a directory path here, then only enter the file name in the *Error file name* property. If you leave *Error file root directory* blank, then type a full path and file name in the *Error file name* property.	New, Edit, Source
Error file name	File name, file name including full path name, or blank	If *Write error rows to file* is enabled, type the name of the file in which to record the invalid rows. For added flexibility, you can enter a variable that is set to a particular file with full path name. Use variables to specify file names that you cannot otherwise enter such as file names that contain multi-byte characters.	New, Edit, Source

The Fields work area in the *File Format editor* contains properties about the fields in the file format.

Property	Possible values	Description
Field name	Any sequence of letters or numbers, not including blank spaces	A name that identifies data in this column. If your file format uses the Headers style and you select *Yes* for the *Write row header* property, the software writes the field names in the target file.
Data type	blob, date, datetime, decimal, double, integer, interval, long, numeric, real, time, varchar	The data type of values in this column. The long data type is not available in fixed-width formats.
Format	{none}	For all data types other than varchar, specifies the format for this particular field. You can use this property to overwrite the default format. For example, if one date field is different than others, you can specify the different format here.
Nullable	Yes, No	Indicates whether the the field will accept NULL values.
Description	Any sequence of letters or numbers, not including blank spaces	Text that that specifies the type of data in a column. Typically use the field name, or a name similar to the field name. For example, if your field name is LastName, you may want to name the content type Family_Name.

If you delete a file format template from the object library, you must also delete all file sources and targets that are based on that file format template.

Related Information

Using the File Format editor [page 2076]

5.2.9 Target file properties

The following properties are available on the Target file properties tab in the *Replication Job editor*.

Option	Possible values	Description
General		
File format	Delimited	The format of the data in the text file. Available properties change based on the selected file format type.
Adaptable Schema	Yes, No	Indicates whether the schema of a delimited file format is adaptable or fixed. ● *Yes* indicates that the schema is adaptable. The actual file can contain fewer or more columns than indicated by the file format. If a row contains fewer columns than expected, the software loads null values into the columns missing data. If a row contains more columns than expected, the software ignores the additional data. ● *No* indicates that the schema is fixed. The software requires the number of columns in each row to match the number of columns specified in the file format. The default is *No*. If you select *Yes*, you must ensure that the selected column and row delimiters do not appear inside the actual data.
Custom transfer program	Yes, No	Enables the software to use a third-party file transfer program. Displays additional Custom transfer program options in the *File Format Editor* below the Input/Output properties.
Parallel process threads	Integer greater than 0, {none}, {default}	Specifies the number of threads for parallel processing. Parallel processing can improve performance by maximizing CPU usage on the Job Server computer. For example, if you have four CPUs, enter 4 for this option. For more information, see “File multi-threading” in the *Performance Optimization Guide*. For jobs that process USPS certification tests, the value should be set to *{none}*.
Data File		
Location	Local, Job Server	During design, indicates the files are located on the local machine or on the machine that runs the Job Server. If you select Job Server, you must enter the absolute path to files. Remember that UNIX systems are case-sensitive.

Option	Possible values	Description
		During execution, all files must be located on the Job Server machine that executes the job. If you use different files to design your job, change the file specified (through the Root directory and File properties) before you execute the job.
Root directory	Path name for the file	The parent directory for the specified file name. If the directory name is entered, the file will be generated there and the file name format will be: `<jobname_tablename>.<extension>`. If the directory is blank, the file will be generated under **`<DS_COMMON_DIR>`**`/workspace/`.
File Extension	File extension	The file extension to be applied to all loader files in the replication job.
Delimiters		
Column	Tab, Semicolon, Comma, Space, or any character sequence	For delimited file formats, the character sequence that indicates the end of one column and the beginning of the next.
Row	{new line}, {Windows new line}, {Unix new line}, or any character sequence	A character sequence that indicates where one row of data ends and the next begins.
Row within text string	Character, Row delimiter	Defines how the row delimiter is interpreted within a text string. - *Character*: The specified row delimiter is treated as a character within the text string. - *Row delimiter*: The specified row delimiter is interpreted and defines rows within the text string.
Text	Single quotation marks ('), double quotation marks ("), or {none}	Denotes the start and end of a text string. All characters (including those specified as column delimiters) between the first and second occurrence of this character is a single text string. The treatment of the row characters is defined by the *Row within text string* setting.
Note Data in columns cannot include the column or row delimiter, unless you also specify a text delimiter. For example, if you specify a comma as your column delimiter, none of the data in the file can contain commas. However, if you specify a comma as the column delimiter and a single quote as the text delimiter, commas are allowed in strings in the data. You can use any ASCII characters (including non-printing characters) for column and row delimiters. You can specify an ASCII character by entering a forward slash (/) followed by the decimal representation of the character. For example, to use Y umlaut (Ÿ) as a delimiter, enter /255 in the delimiter property box.		
Default Format		

Option	Possible values	Description
Escape character	Any character sequence, or {none}	A special character sequence that causes the software to ignore the normal column delimiter. Characters following the escape character sequence are never used as column delimiters. For example, suppose you specify a forward slash as the escape character and a comma as the column delimiter. Then, you must have a forward slash to have a comma appear inside a field.
NULL indicator	{none} or any other character sequence	A special character sequence that the software interprets as NULL data. The software ignores any NULL indicator specified in the file format for blob columns.
Ignore row marker(s)	{none} or any other character sequence	A character sequence, which when found at the beginning of rows, causes the software to ignore the row when reading the file or automatically creating metadata. To enter multiple character sequences, separate each with a semi-colon. To include a semi-colon or backslash as a marking character, precede with a backslash.
Date format	yyyy.mm.dd or other combinations	The date format for reading or writing date values to and from the file.
Time format	hh24:mi:ss or other combinations	The time format for reading or writing time values to and from the file.
Date-Time format	yyyy.mm.dd hh24:mi:ss or other combinations	The datetime format for reading or writing datetime values to and from the file.
Validate decimal data	Yes, No	Perform decimal validation and formatting on output.
Input/Output		
Style	Headers or BOF/EOF	The format of the start and end of the file. Available properties in the Input/Output property group may change, based on this selection.
Skipped rows	Integer	For file formats using Headers style, the number of rows skipped when reading the file. Specify a non-zero value when the file includes comments or other non-data information.
Write row header	Yes, No	For file formats using Headers style, indicates whether to write column names in the first row of the output file.
Write BOM	Yes, No	For file formats using UTF-8 and UTF-16, determines the writing of BOM characters into the file. Choose Yes if you want to include BOM characters into a UTF-8 or UTF-16 file in which byte order is

Option	Possible values	Description
		not otherwise defined. For a UTF-16 file, the software assumes the file to be UTF-16be, unless BOM characters are added by this property.
BOF marker	Any character sequence, including a blank space, an empty string, or {none}	For file formats using BOF/EOF style, the string that marks the start of data in the file.
EOF marker	Any character sequence, including a blank space, an empty string, or {none}	For file formats using BOF/EOF style, the string that marks the end of data in the file.
Custom Transfer options		
Custom transfer program executable	File name	(Required) The name of the custom transfer program or its initialization script. For example: MyProgram.exe or MyProgram.cmd.
Custom transfer user name	Any character sequence, including a blank space, an empty string, or {none}	(Optional) Log in ID for the server to which the custom transfer program connects. You may want to allow a custom program user to enter their user name when they enter their password in the software.
Custom transfer password	Any character sequence, including a blank space, an empty string, or {none}	(optional) Password for the server to which the custom transfer program connects. Passwords entered into this option are encrypted.
Custom transfer arguments	Any character sequence, including a blank space, an empty string, or {none)	(Optional) You can create arguments in your custom transfer program and then specifically flag them from within the software using this box. For example, you might have security or compression mechanisms in your program. You can also link connection data to your transfer program's flags.
Locale		
Language	The three-letter language abbreviations specified in the ISO 639-2/T standard	Specifies the human language (for example, Korean, Japanese, or English) in which data is stored or processed. Select from the displayed list.
Code Page	The list of supported code pages. See Supported Locales and Encodings.	Specifies the sequence of bits that defines a character. For example, the Japanese code page contains ASCII, Greek, Cyrillic, and Japanese characters, thereby supporting the English, Greek, Russian, and Japanese languages.

5.2.10 Monitoring editor

The Workbench Monitoring editor opens in the workspace when you click the icon in the toolbar or select it from the *Tools* menu.

The monitoring editor consists of several areas:

Area	Description
Job selection toolbar	Displays the Data Services jobs available in the repository to which the Workbench is connected and allows you to execute them. i Note The monitoring editor displays all standard Data Services jobs in the repository, not Workbench-specific replication jobs.
Execution history pane	Displays the execution history for the selected job. Each line indicates the current status, execution date, and duration of a single job execution instance.
Execution history dashboard pane	Displays a graphical representation of the history for the selected job. You can change the type of chart by choosing from the drop-down box in the upper-right corner of the pane.
Execution details pane	Displays the details for the individual job execution instance selected in the execution history pane. You can view the trace, monitor, and error logs for the execution instance, as well as the execution statistics.

You can adjust the size of each pane by dragging the borders between them. In addition, you can hide or reveal the dashboard and details panes by clicking the arrows in the center of their borders.

5.2.11 Preferences

The Preferences options allow you to Customize several areas of Data Services Workbench.

5.2.11.1 Data Services

From the main Data Services page, specify the Maximum number of errors to show in tooltips.

5.2.11.1.1 Data Flow Detections

The Data Flow Detection options allow you to customize the way detection algorithms work, for example, setting the minimum scores to display in the Detect Mapping and Detect Join dialogs.

Mappings detection

Option	Description
Minimum score threshold	Select the minimum mapping score to display. Scores at or above this setting are displayed in the Mapping detection dialog.
Enable mapping detection in create Query context menu	Check to enable mapping detection when creating a query transform from the context menu of a multiple selection of source elements of the data flow and of one Loader.
Minimum score threshold	Select the minimum mapping score to display. Scores at or above this setting are displayed in the Mapping detection dialog. This option only applies to the Enable Mapping Detection option in the create query context menu.
Always confirm mappings	Select to always confirm mappings when creating a new Query transform. This option applies to the Enable Mapping Detection option in the create query context menu.

Joins detection

Option	Description
Minimum score threshold	Select the minimum join score to display. Scores at or above this setting are displayed in the join detection dialog.
Enable join detection in create Query context menu	Check to enable mapping detection when creating a query transform from the context menu of a multiple selection of source elements of the data flow and of one loader.
Minimum score threshold	Select the minimum mapping score to display. Scores at or above this setting are displayed in the Mapping detection dialog.
Always confirm joins	Select to always confirm joins when creating a new query transform. This option applies to the Enable Join detection option in the create query context menu.

5.2.11.1.2 Data Flow editor

Data Flow preferences allow you to customize various settings of the Data Flow editor, including the way that the Auto-arrange option arranges the elements in the Data Flow diagram (for example, minimizing spacing between elements).

Option	Description
Top Margin	Specify the top margin spacing.
Left Margin	Specify the left margin spacing.
Horizontal Margin	Specify the horizontal margin spacing.
Vertical Margin	Specify the vertical margin spacing.
Horizontal Alignment	Specify the horizontal alignment: • Left Aligned • Center Aligned • Right Aligned
Automatically put names in edit mode when an element is dropped in the diagram	Check this option place the field names in edit mode when they are dropped into the diagram.

5.2.11.1.3 Data preview

Data preview preferences allow you to customize the way Data preview opens and to change the maximum number of rows and kilobytes to retrieve.

Option	Description
Max Rows to retrieve from Tables	Specify the maximum number of rows to retrieve from the database.
Max Size (in KB) to retrieve from Files	Specify the maximum number of kilobytes to retrieve from the files.
Data Preview opening mode	Specify the viewing method: • In an Editor • In a View • In a Dialog

5.2.11.1.4 Datastore editor

The Datastore editor preferences page allows you to specify whether to import the row count of the table when importing the metadata and select the table and column information you want to display.

Option	Description
Automatically detect row count when importing tables (might be slower)	Specify whether to import the row count of the table when importing the metadata. If selected, the row count will appear in the table properties and the project explorer.
Tables:	
Prefix tables with owner	Check to prefix tables with owner.
Show column count	Check to show column count.
Show row count	Check to show row count.
Show row size	Check to show row size.
Show description	Check to show the table description.
Columns:	
Show datatype	Check to show the column datatype.
Show description	Check to show the column description.

5.2.11.1.5 Expression editor

Customize the Expression editor by setting the Content assist and Syntax coloring options.

Content assist options

Option	Description
Insert single proposals automatically	Select this option to automatically insert single proposals.
Insert schema qualified column names	Select this option to schema qualified column names.
Enable auto activation	Select this option to enable automatic activation.
Activation delay (ms)	Enter the activation delay in milliseconds. Default value is 200.
Activation triggers	Select the activation triggers you want to include: '.' to propose qualified names '$' to propose variables '[' to propose substitution parameters

Syntax coloring

Use the syntax coloring options to set the color and fonts of the expression editor syntax.

5.2.11.1.6 Expression macros

These options allow you to manage the expression macros (creation, edition, and deletion) and import and export macros from this screen.

Expression macro listing

Button/option	Description
New folder	Create a new folder.
New macro	Create a new expression macro.
Delete	Delete selected expression macro(s).
Move up	Move selected macro up.
Move down	Move selected macro down.

General tab

Option	Description
Description	Describes the use for selected function.
Expression	Enter the expression macro you want to add.

Conditions tab

Option	Description
Restrict to following datatypes	Check to only apply the expression macro to select datatypes. Select the datatypes from the dropdown list.
Restrict to following mapping types	Check to apply the expression macro to select mapping types. Select mapping types from the dropdown list.

Option	Description
Restrict to the following content types	Check to only apply expression macro to select content types. Select the content types from the dropdown list.
Restrict to the following field name pattern	Check to restrict a specific field name pattern. Select the field name pattern from the dropdown list.

Other options/buttons

Option/button	Description
Import	Import the expression macros from file.
Export	Export the expression macros to a file.
Restore defaults	Restores the expression macros back to the defaults included with Data Services Workbench.

5.2.11.1.7 File Format editor

The File Format editor options allow you to specify the number of kilobytes to scan during Data Preview and the detection algorithms of files.

Option	Description
Maximum file size to use for the detect fields	Specify the number of kilobytes to scan during the detection algorithms of files.
Maximum file size to use for Data Preview	Specify the number of kilobytes to scan during data preview.

5.2.11.1.7.1 Detection settings

The Data Type detection options affect the data types detected when creating a file format from an existing file and detecting data types. If a field's values match one of the listed formats, Workbench will assign the corresponding data type to the field: Date, Time or DateTime. Workbench attempts to detect the formats in the order they appear in the list for each format.

Option	Descriptioin
DateTime Formats	Add, edit, delete, or reorder DateTime formats.
Date Formats	Add, edit, delete, or reorder Date formats.
Time Formats	Add, edit, delete, or reorder Time formats.

Option	Descriptioin
Locales	Add, edit, delete, or reorder Locales. The configured locales can affect the detection of decimal data types if thousands-separators or decimal-separators are used. For example, 10.237.329,95 will not be recognized as a decimal (10,2) unless a locale that is configured with appropriate decimal characters (German) is included in the list.
Null Values	Add, edit, delete, or reorder null values.

5.2.11.1.8 Project explorer

These options allow you to fine-tune the way Data Services Workbench project files are displayed in the project explorer. For example, you can specify how to group the tables of the Datastore file.

Table 178: General

Option	Description
Show file extensions	Check to show file extensions.

Table 179: Data stores

Option	Description
Show table count	Check to show the table count.
Show database count	Check to show the database type.
Show description	Check to show the datastore description.

Table 180: Tables

Option	Description
Show columns count	Check to show the number of columns.
Show table type	Check to show the table type.
Show row count	Check to show the table row count.
Show description	Check to show the description.
show row size	Check to show the row size.

Table 181: Tree structure

Option	Description
Group table by type	Check to group tables by type.
Group table by owner	Check to group tables by owner.
Enable table chunking	Check to enable table chunking.

Option	Description
Chunk size	If *Enable table chunking* is selected, enter the number of tables.

Table 182: Columns

Option	Description
Show data type	Check to show the data type.
Show description	Check to show the description.

5.2.11.2 General

The Preferences section allows you to set your preferences for the following:

- General
- Appearance
- Content Types
- Editors
- Keys
- Perspectives
- Workspace

5.2.11.3 Languages

Enter the product languages you want to use in Workbench. To apply language changes you must restart Workbench.

5.3 Database Migration

Migrating data and schema information between different database systems is a complex task that can take days or even months depending on the type of database systems, the complexity of the database schema, and the size of the data set being migrated. In addition, incompatibilities between the source and target database types could require manual schema and data corrections.

The Data Services Workbench simplifies this database migration process considerably. In the Workbench, you provide connection information for the source and target databases and select the tables that you want to migrate. The Workbench automatically creates Data Services jobs, work flows, and data flows and imports them into a Data Services repository.

After you have created the replication jobs, you can use the Workbench to execute the jobs and monitor their progress. If required, you can also edit the generated data flows in the Designer, and use other Data Services tools to schedule and execute the jobs.

5.3.1 Migrating data and schema information

The process of migrating data and schema information from one database to another with the Workbench generally consists of a few basic steps:

1. Create a project in the project explorer.
2. Create a source datastore definition.
3. Create a target datastore definition.
4. Create a replication job using your source and target datastores.
   a. Select the source objects that you want to migrate.
   b. Group the target objects and specify the order of migration.
   c. Adjust the target schema as required.
   d. Specify the replication behavior for the job.
5. Deploy and execute the replication job.

You can choose to perform the datastore and replication job definition steps manually with the standard individual datastore and replication job editors, or you can complete the process using the quick replication wizard. If you use the replication wizard, you can modify your replication job by using the standard editors after the wizard completes.

Related Information

Project explorer [page 2043]
Datastore editor [page 2045]
Replication job editor [page 2041]

5.3.1.1 Creating a Workbench project

If you want to create a new project, start the new project wizard in one of the following ways:

- Right-click inside the project explorer and choose *New* > *Project*.
- Choose *New* > *Project* from the *File* menu.
- Click the *New* toolbar icon. Choose *General* > *Project* and click *Next*.

1. Specify the name for the new project and click *Next*.

   > **Note**
   >
   > The project name can contain only alphanumeric characters and the underscore character.

2. If you want to save the files for the project to a different location, uncheck *Use default location* and specify a location for the project files.
3. Select the Data Services repository.
4. Click *Finish* to create the project.

The new project is displayed in the project explorer.

You can now add Workbench objects such as datastores and replication jobs to your project.

5.3.1.2 Using the quick replication wizard

You can use the quick replication wizard to easily migrate source data to one of the supported target databases or files.

1. Click the *Quick replication wizard* icon in the toolbar.
   The quick replication wizard is displayed.
2. Specify the name for the new replication project and click *Next*.

   > **i** Note
   >
   > The project name can contain only alphanumeric characters and the underscore character.

   The source datastore configuration screen is displayed.
3. Specify the settings for the source datastore and click *Next*.
   a) Select the datastore type.
   The available configuration settings for the selected database or application type are displayed.
   b) Set the datastore configuration settings as required for your database or application.

   > **i** Note
   >
   > Required settings are marked with an asterisk (*), and required settings that are missing a value are highlighted in red in the *Property name* column. Settings that have changed from the default value are listed in bold.

   c) Click *Test connection* to verify that the connection settings are valid.

   If the connection test fails, correct the datastore connection settings and re-test the connection.

   > **i** Note
   >
   > The connection test is between the database or application and the Central Management Console (CMC) host, not the Workbench host. Ensure that the connection settings between the CMC and datastore database or application are valid.

   The source object selection screen is displayed.
4. Select the objects that you want to replicate to the target datastore or files and click *Next*.
   The configure target settings screen is displayed.
5. Specify the settings for the target datastore or files and click *Next*.
   a) Select a target type of *Files* or *Datastore*
   b) If the target type is Datastore, select the datastore type.
   The available configuration settings for the selected database or application type are displayed.
   c) Set the configuration settings as required for your database, files, or application.

> **Note**
>
> Required settings are marked with an asterisk (*), and required settings that are missing a value are highlighted in red in the *Property name* column. Settings that have changed from the default value are listed in bold.

   d) When you select datastore as the target type, cick *Test connection* to verify that the connection settings are valid.

      If the connection test fails, correct the datastore connection settings and re-test the connection.

   The repository and job server selection screen is displayed.

6. If you want to execute the replication job without making any further changes, select *Execute replication job now*.
   a) In the left column, select the Data Services repository to use.

      The jobs generated by the Workbench will be stored in this repository. By default, the first repository in the list is selected.

   b) In the right column, select the Data Services Job Server to use to execute the replication job.

      By default, the Job Server associated with the selected repository is used.
7. Click *Finish* to save the replication job and and execute it with the selected settings, if applicable.
   If you chose to execute the replication job, the monitoring editor is displayed.

The Workbench saves the replication job and datastore definitions to the local file system. If you chose to execute the replication job now, it also creates Data Services jobs and datastores for the replication job, imports them to the selected repository, and executes them using the selected Job Server.

5.3.1.3 Using the Datastore editor

The datastore editor provides a powerful interface that allows you to fine-tune your datastore definition, including importing database tables, inserting or modifying columns, keys, indexes, and partitions, modifying attributes, and so on.

> **Tip**
>
> The datastores defined and used in the Workbench are standard Data Services datastores. For more information about Data Services datastores, see the *Reference Guide*.

If you have already created a datastore, open it in the datastore editor by double-clicking the datastore name in the project explorer.

If you want to create a new datastore definition, start the new datastore wizard in one of the following ways:

- Right-click your project in the project explorer and choose *New* > *Datastore*.
- Select your project in the project explorer and choose *New* > *Datastore* from the *File* menu.
- Select your project in the project explorer and click the *New* toolbar icon. Choose *Data Services* > *Datastore* and click *Next*.

1. Specify the name for the new datastore and click *Next*.

> Note
>
> The datastore name can contain only alphanumeric characters and the underscore character.

2. Specify the settings for the datastore and click *Next*.
   a) Select the datastore type.
   The available configuration settings for the selected database or application type are displayed.
   b) Set the datastore configuration settings as required for your database or application.

   > Note
   >
   > Required settings are marked with an asterisk (*), and required settings that are missing a value are highlighted in red in the *Property name* column. Settings that have changed from the default value are listed in bold.

   c) Click *Test connection* to verify that the connection settings are valid.
   If the connection test fails, correct the datastore connection settings and re-test the connection.

   The object selection screen is displayed.
3. Select the objects that you want to import to the datastore definition and click *Finish*.

The new datastore is opened in the datastore editor.

You can now use the datastore editor to further customize your datastore definition. For example, you can select a table or view and modify its properties, columns, keys, and so on, or use the configurations section to add additional configurations to your datastore.

Related Information

Datastore editor [page 2059]

5.3.1.4 Using the replication job editor

The replication job editor provides a powerful interface that allows you to fine-tune your replication job, including filtering datastore tables, customizing target replication groups, modifying table and column mappings, and so on.

> Note
>
> The replication jobs defined and used in the Workbench are defined in Workbench-specific metadata. When you deploy the replication job to a Data Services repository, the Workbench uses this metadata to create standard Data Services objects such as job, work flows, and data flows. For more information about Data Services objects, see the *Reference Guide*.

If you have already created a replication job, open it in the replication job editor by double-clicking the replication job name in the project explorer.

If you want to create a new replication job, start the new replication job wizard in one of the following ways:

- Right-click your project in the project explorer and choose *New* > *Replication Job*.
- Select your project in the project explorer and choose *New* > *Replication Job* from the *File* menu.
- Select your project in the project explorer and click the *New* toolbar icon. Choose *Data Services* > *Replication job* and click *Next*.

1. Specify the name and description for the new replication job and click *Finish*.

   > Note
   >
   > The replication job name can contain only alphanumeric characters and the underscore character.

   The new replication job is opened in the replication job editor.
2. Select a Replication Target Type:
   - *Datastore*
   - *Files*
3. Do one of the following:
   - If you selected *Datastore*, Click *...* to specify the source and target datastores.

   A list of available datastores is displayed. If you have not already created the datastores, you can define the datastores later.

   - If you selected *Files*, set the target file properties. You must enter the root directory.

You can now use the replication job editor to further customize your replication job definition. For example, you can change the replication behavior, modify the target schema, customize column mappings, and so on.

Related Information

Replication job editor [page 2041]

Reference Guide: Objects [page 832]

5.3.1.4.1 Modifying replication job properties

When you open a replication job or select the root replication job node in the target datastore pane, the configuration area displays several tabs that you can use to configure the way that the Workbench processes the replication job:

Tab	Description
Properties	Replication target type of Datastore: Displays the replication target type, name, owner, replication behavior and description for the replication job. Replication target type of Files: Displays the replication target type, name, description and target file properties.

Tab	Description
Variables	Displays information about the variables available for use in the replication job. You can add or delete variables, as well as alter variable properties such as data type, length, precision, scale, and default value.
Scripts	Displays the pre-load and post-load scripts for the replication job. You can modify the scripts directly in the text box or by clicking *Edit* to launch the Workbench expression editor. You can also validate the scripts.

Related Information

Using the expression editor [page 2087]

5.3.1.4.1.1 Replication behavior

When you deploy and execute a Workbench replication job, the Workbench automatically generates the ETL metadata for the job and deploys it to a Data Services repository. The metadata that is generated depends on the replication behavior setting for the replication job.

The following replication behavior options are available:

- Schema and data
  In the schema and data scenario, the Workbench assumes that the tables do not exist in the target database and need to be created. As a result, the ETL job metadata that is generated includes the following objects:
  - Source and target datastores
  - Source and target tables
  - A Data Services job that contains both the script to create the target tables, as well as the work flows and data flows that move data from the source tables to the target tables.
- Data only
  In the data-only scenario, the Workbench assumes that the tables already exist in the target database. As a result, the ETL job metadata that is generated includes the following objects:
  - Source and target datastores
  - Source and target tables
  - A Data Services job that contains work flows and data flows that move data from the source tables to the target tables.

Note

Schema and data is the default replication behavior.

5.3.1.4.2 Adjusting the target schema

5.3.1.4.2.1 Modifying target table properties

When you select a table in the target datastore pane, the configuration area displays several tabs that you can use to configure the way that the Workbench processes that table:

Tab	Description
Properties	Displays the table name, owner, and description and provides the ability to view the data in the source table.
Columns	Displays information about the target table columns. After the table has been imported, you can insert and delete columns from the target table. You can also change column names, data types, descriptions, and so on, as well as alter the column mappings with the expression editor.
Foreign Keys	Displays information about the table's primary and foreign keys, if any. After the keys have been imported, you can add, delete, and modify them.
Indexes	Displays information about the table's indexes. The primary index is listed first and followed by any secondary indexes. You can add or remove indexes, as well as add or remove columns from existing indexes.
Options	Displays options that Data Services uses to read the source table and load the target table. For more information about the available source and target options, see the *Reference Guide*. i Note Only options used by the Workbench are displayed.
Filter data	Allows you to filter the rows of the source table. You can use basic filter editor or the expression editor to modify the filter.
DDL Options	Allows you to specify the behavior of DDL generation. For example, whether to create foreign keys or indexes.
Delta load	Displays options that modify the delta load behavior for a table. For more information about the available delta load options, see *Delta load migration* [page 2078].

Related Information

Reference Guide: Objects, Descriptions of objects, Source [page 947]
Reference Guide: Objects, Descriptions of objects, Target [page 960]

5.3.1.4.2.2 Grouping target tables

Many data warehouse tables have referential integrity constraints such as primary key and foreign key relationships. The primary key table needs to be loaded before the foreign key table if there is a relationship between two tables.

You can avoid referential integrity issues by using the replication job editor to group tables. For example, you can put the primary key tables in the first group and foreign key tables in the second group. In another scenario, you could put dimension tables in the first group and fact tables in the second group.

By default, tables are added to the Default_Group that is created in a new replication job. However, there is no limit to the number of replication groups supported in a Workbench replication job.

To group tables in the replication job editor:

1. Create a new replication group in the target schema.
   a) Right-click on the replication job root node in the target schema pane and choose *New replication group*.
   A new replication group is added to the target schema.
   b) Assign a meaningful name to the replication group by highlighting the new replication group and clicking it again.
2. Assign tables to the new group by dragging them from the source pane to the replication group.

   > ℹ Note
   >
   > A table may belong to only one group in the target schema. You can create multiple target tables from a single source table, but each target table must be named uniquely.

3. Use the up and down arrows in the target schema to order the replication groups as needed for your requirements. When the replication job is executed, the groups will be migrated starting from the top of the list.

   You can also rearrange replication groups by dragging them within the target schema.

   > ➡ Tip
   >
   > To automatically order the tables in the target schema by their dependencies, click *Auto order*.

> ℹ Note
>
> Replication groups can be sequential or parallel. In a sequential group, the data flows generated by the Workbench will be executed in sequential order. In a parallel group, the data flows are executed in parallel. To change the group type, right-click on the group and choose *Parallel* or *Sequential* from the *Change replication group type* menu.

5.3.1.4.2.3 Changing column data types

Data Services supports conversion to and from its internal data types and performs data type conversions when it imports metadata from external sources or targets into the repository, as well as when it loads data into an external table. When the Workbench creates target tables, the software converts from internal data types to the data types used by the target database.

For more information about internal data type conversions in Data Services, see the *Reference Guide*.

The Workbench allows you to overwrite the default data conversion rules. To change the data type for a column:

1. Expand the table containing the column in the target schema pane.
2. Select the target column.
   The column details are displayed in the configuration pane.
3. Select the new data type for the column from the *Data type* drop-down box.

   If required for the new data type, set the *Length*, *Precision*, and *Scale* for the column.

Related Information

Reference Guide: Data Types, Data type conversion, Conversion to or from internal data types [page 1040]

5.3.1.4.3 Filtering datastore tables

In a replication job, you might want to migrate only a subset of the rows from a particular source table to your target datastore.

To migrate a subset of table rows, use a filter on the datastore table in the replication job editor:

1. Select the table that you want to filter in the target schema pane.
2. Click the *Filter data* tab in the configuration pane.
3. For basic filtering, use the table filters configuration window.
   a) Select *Basic* and click *Edit filter*.
      The table filters configuration window is displayed.
   b) Drag the columns you want to use to filter from the columns pane to the filters pane.
      The columns are displayed in the filters panel and grouped together with a logical `AND` or `OR` grouping operator.
   c) For each column, define the filter logic by specifying the comparison operator and value.

      > ➡ Tip
      >
      > You can create more complex, nested filter expressions by dragging the columns on top of each other. The nesting layout is displayed in a graphical preview.

   d) Change the grouping logic as required by double-clicking the grouping operator.
   e) To remove a filter, click the column or grouping operator to highlight the filter and click the *Remove selected filter* button.

f) When you are satisfied with the filter, click *OK*.

The filter is displayed in the *Filter data* tab.

4. For more advanced filtering, use the Workbench expression editor to define the filter.
   a) Select *Advanced* and click *Edit filter*.
   The expression editor is displayed.
   b) Complete your filtering expression and click *OK*.
   The filter expression is displayed in the *Filter data* tab.
   c) To validate your filter expression, click *Validate*.

Related Information

Using the expression editor [page 2087]

5.3.1.5 Using the Data Flow editor

The Data Flow editor enables you to create data flows and include them in the replication job. You also have the ability to convert replication tables to data flows. Highlight multiple replication tables, right-click the selection, and select convert data. You have the option to generate a single data flow or one data flow per replicated table.

If you have already created a data flow, open it in the Data Flow editor by clicking the data flow name in the project explorer.

To create a new data flow, do one of the following:

- Select your project in the project explorer and right-click your data flow in the project explorer and choose ▸ *New* ▸ *Data flow* ◂.
- Select your project in the project explorer and choose ▸ *New* ▸ *Data Flow* ◂ from the *File* menu.
- Select your project in the project explorer and click the *New* toolbar icon. Choose ▸ *Data Services* ▸ *Data Flow* ◂ and click *Next*.

1. Specify the name for the new data flow and click *Next*.

   > Note
   >
   > The data flow name can contain only alphanumeric characters and the underscore character.

2. Enter the description for the new data flow and click *Finish*.

The new data flow is opened in the Data Flow editor.

Related Information

Data Flow editor [page 2043]

Expression macros [page 2075]

Reference Guide: Objects, Descriptions of objects, Data Flow [page 857]
Data Flow editor [page 2059]

5.3.1.6 Converting replication tables to data flows

To convert a replication table to a data flow:

1. Highlight the replication tables you want to convert.
2. Right-click the selection.
3. Select one of the following:
   - ○ *Generate a single data flow*
   - ○ *One data flow per replicated table*

5.3.1.7 Expression macros

You have the option to apply expression macros to multiple fields at one time when working in the Query transform of a data flow. You can access the Workbench Preferences options from the Query transform. This enables you to create new expression macros and apply them to the fields as needed.

5.3.1.7.1 Creating an expression macro

To create a new expression macro, access the Preferences Expression macros options one of the following ways:

- From the Data Flow Mappings tab, right-click a field and choose ▶ *Apply expression macro* ▶ *Manage expression macros* ◀.
- Choose *Preferences* from the *Window* menu and select the *Expression Macros* option.

1. Click the *New macro* button and enter the macro name.
2. From the *General tab*, enter a Description for the macro.
3. From the General tab, enter the Expression.
4. From the Conditions tab, select any conditions you want to apply to the expression macro.

Related Information

Expression macros [page 2061]

5.3.1.7.2 Applying an expression macro to multiple fields

To apply an expression macro to multiple fields at one time:

1. Select the fields you want to include.
2. Right-click the highlighted fields and select *Apply expression macros*.
3. Select one of the expressions from the list or select *Manage expression macros* to add a new expression macro.

5.3.1.8 Using the File Format editor

The File Format editor allows you to set properties for file format templates and source and target file formats.

If you have already created a file format, open it in the File Format editor by clicking the file format name in the project explorer.

If you want to create a new file format, start the File Format wizard in one of the following ways:

- Select your project in the project explorer, right-click and choose ▶ *New* ▸ *Flat File Format* ◀.
- Select your project in the project explorer and click the *New* toolbar icon. Choose ▶ *Data Services* ▸ *Flat File Format* ◀ and click *Next*.

5.3.1.8.1 Manually create a new file format

To manually create a file format with default properties:

1. Select *Manually create a new File Format* and click *Next*:
2. Specify the name and description for the new file format and click *Finish*.

> ℹ Note
>
> The name can contain only alphanumeric and underscore characters.

The new file format is opened in the File Format editor.

Now you can further define the properties for the file format templates using the the File Format editor.

5.3.1.8.2 Automatically import file formats

This option enables you to import multiple files with different formats at the same time and generate multiple file formats. You have the option to auto-detect or specify the file formats.

To automatically import file formats from existing files:

1. Select *Automatically import File Formats from existing files* and click *Next*:
2. Under *File location*, select Local or Job Server and click *Add files*.
3. Select the file(s) you want to add and click *Next*.
4. Do one of the following:
   - Click *Next* to set the detection options.
   - Click *Finish* to run auto-detection.
5. If you chose to set detection options, set the detection options and click *Finish*.

The new file format is opened in the File Format editor.

Now you can use the File Format editor to further define the properties for the file format templates.

5.3.1.9 Deploying and executing the replication job

When you are satisfied with your replication job configuration, you can deploy it to a Data Services repository and execute it.

1. Double-click the replication job in the project explorer to open it in the replication job editor.
2. Click *Validate* to verify that the replication job is free of errors.
3. If you want to deploy the job but not execute it, click *Deploy*.
   a) Select the repository where you want to deploy the replication job and click *OK*.
   A progress bar indicating the deployment progress is displayed.

   A message indicating the success or failure of the deployment is displayed. If any errors occur during deployment, the message includes any details available.
4. If you want to deploy and execute the job immediately, click *Execute*.
   a) Select the repository where you want to deploy the replication job and click *Next*.
   The job execution parameters screen is displayed.
   b) Specify whether to execute the job as an initial load or delta load.
   c) Specify the job server and other execution options to use when executing the job in the *Execution options* tab.
   d) If you want to include additional information in the trace log, change the values in the *Trace* tab to *Yes* as required.
   e) Click *Finish* to deploy and execute the job.
   A progress bar indicating the deployment progress is displayed. If you want to halt the deployment, click the *Cancel operation* button next to the progress bar.

   The monitoring editor for the job is displayed.

Related Information

Monitoring editor [page 2057]

5.3.1.9.1 Error recovery

If an error occurs while your replication job is being executed, only some rows may be inserted into a target table.

There are several methods that you can use to prevent duplicate rows from being inserted into the target table, including:

- Data flow design
  You can design the replication job to completely replace the target table each time the job is executed. You might choose to use this method if the number of rows changed in the target table is a significant percentage of the target table. You can also use techniques such as bulk loading options to improve the overall performance of the replication job.
- Auto-correct load target table option
  You can use the auto-correct load option to check the target table for existing rows before new rows are added to the table. However, this option can needlessly slow jobs that are not executed in recovery mode. You might choose to use this method if the number of rows changed in the target table is a relatively small percentage of the target table.
- Pre-load SQL commands
  You can use pre-load SQL commands to remove partial database updates that have occurred during an incomplete job execution. Typically, the pre-load SQL command deletes rows based on a variable set before the partial insertion began.

5.3.2 Delta load migration

Delta load jobs move rows that have been added or modified since the last time the job was executed. There are many reasons to implement a delta load job, but the most common is to reduce the time the loading process takes. Instead of loading millions of rows each time the job is run, you can process only the few that have changed. Another reason could be to maintain historical data; you might want to keep the old data in your data warehouse and add the current state so that you can see the changes over time.

5.3.2.1 Delta load jobs in the Workbench

When you create a replication job that has a table configured with a delta load method, the Workbench automatically creates two sets of metadata: a first load job and a delta load job. The first load job performs a full replication, with any user-defined filters applied, from the source datastore to the target datastore. The delta load job can be used to capture only changed data after the first load.

The Workbench creates two scripts within the delta load job: the pre-load script and the post-load script. These scripts keep track of the time each job is executed so that the next execution can continue from where the last one ended. You can customize the pre-load and post-load scripts in the *Scripts* property tab for the replication job.

To help keep track of the delta job executions, the Workbench maintains an internal table in the target datastore that is created after the successful execution of the first load job. Because of this, the full replication job must be successfully executed at least once before the delta load job can be executed.

ℹ Note

By default, all target tables within the Workbench delta load job are created with the *Auto correct load* option enabled. For more information about this option, see the “Target tables” section in the *Reference Guide*.

ℹ Note

The delta load mode is disabled in the replication job execution if the selected target type is **Files**.

Delta job execution

During execution, the delta job first determines the last time that it was executed, if ever. It uses the last execution time in a filter within the data flows to select only those records that are new. After the data flows have completed successfully, the delta job updates the internal metadata with the current time, so that any future delta execution starts from that time.

Related Information

Reference Guide: Objects, Descriptions of objects, Target tables [page 963]

5.3.2.2 Delta load options for tables

For each table, the Workbench supports several delta load options:

ℹ Note

The delta load option will be disabled when a target type of **Files** is selected. In this case, only the No delta load option will be enabled.

- No delta load
  The Workbench skips this table in the delta load.
- Reload the full table
  The Workbench performs a complete refresh of the table.
- Use timestamp column
  The Workbench uses a timestamp column or columns from the table to perform the delta load. Data Services uses the timestamp from each load to extract only new data from after the last execution.
  If a table has more than one datetime or timestamp column, you must choose the column to use for the delta load process. If a table does not contain a datetime or timestamp column, this option is disabled. If you use a column that contains only the date, you can also choose to use an additional column that specifies the time.
- Use CDC
  The Workbench uses the changed data capture (CDC) functionality provided by a supported SAP application to extract only the data that has changed.

If the datastore does not support CDC functionality, this option is disabled.

- Use custom filter
  The Workbench uses a user-defined filter to determine the start time used to perform the delta load.

> ➜ Tip
>
> In the Workbench, the delta load job works best with tables that use a timestamp column as the primary key.

To change the delta load method for a table, right-click the table in the target schema pane and choose the delta load method under *Change delta load support*. You can also select the table in the target schema pane and choose the delta load method in the *Delta load* tab of the replication job editor.

5.3.2.3 Delta load options for SAP applications

For applications that support changed data capture (CDC) functionality, the Workbench automatically extracts changed data for the delta load.

You can use the Workbench-generated variable `$END_TIME` to specify the time frame for which to extract changed data:

- If the value of `$END_TIME` is not specified, the Workbench uses the current system time for its value. Each delta load will extract new data from the last execution to the current date-time.
- If you want to continue from a previous execution, retrieve the timestamp of the execution you want to recover from your application and assign it to `$END_TIME` in the replication job pre-load script.

> i Note
>
> The Workbench treats applications that do not support CDC as tables for the delta load.

5.4 Using an SAP Information Steward Data Cleansing Solution

The Workbench Data Cleansing Solution feature allows a technical ETL developer with no data quality expertise to create a data flow containing a data cleansing solution and validate the results in a production environment.

First, a data steward uses the Data Cleansing Advisor feature of SAP Information Steward to create and publish a data cleansing solution. The data cleansing solution is stored in the SAP BusinessObjects Business Intelligence platform's Central Management Server (CMS). In the Workbench, the ETL developer then models the data cleansing solution as a Data Cleansing Solution transform within the context of a data flow, and maps the transform's input and output schema to production sources and targets, and validates the results in the production environment. Finally, the ETL developer generates and deploys the data flow as ATL to the Data Services repository for execution in the Data Services engine.

For more information about data modeling in the Workbench, see the *SAP Data Services Workbench Guide*. For more information about input and output fields and options, see the *SAP Data Services Reference Guide*. For more information about Data Cleansing Advisor, see the *SAP Information Steward User Guide*.

5.4.1 Viewing data cleansing solutions

You can create multiple data flows that use a data cleansing solution. Each data flow can contain one or more unique instances of the Data Cleansing Solution transform that references the data cleansing solution.

The Data Cleansing Solution transform references the latest published version of the data cleansing solution from Data Cleansing Advisor. If a data cleansing solution is updated and republished in Data Cleansing Advisor, Workbench automatically uses the updated solution, and you must redeploy the data flow to the Data Services repository.

1. Select ▶ *Window* ▶ *Data Cleansing Solutions* ◀. The Data Cleansing Solutions tab opens in the workspace and displays the data cleansing solutions that have been published in the Data Quality Advisor.
   The Published column contains the date and time that the solution was published. Workbench displays only the latest active version of a data cleansing solution published in the Data Cleansing Advisor. Icons display the status of the data cleansing solution.

Icon	Description
▦	Indicates a new data cleansing solution that has not been used.
▦	Indicates a current data cleansing solution that has been used in one or more data flows.
▦	Indicates an updated data cleansing solution that has been republished since it was used.

2. To refresh the list of data cleansing solution, click the refresh icon (↻).
3. Click a column header to sort the data cleansing solutions by the content in that column.
4. To view more details about and identify the appropriate data cleansing solution, double-click a solution.
   The Data Cleansing Solution Details window opens and displays information about the solution such as the publication date and time, cleansing and matching settings, and the connection information and input schema that were used to create the data cleansing solution in Information Steward.
5. To open all of the data flows that contain a data cleansing solution, right-click the solution and select *Open Containing Data Flows* from the menu.

5.4.1.1 Deleting a data cleansing solution

You can delete a data cleansing solution in Workbench only if its corresponding project has first been deleted in the Data Cleansing Advisor in Information Steward.

To delete a data cleansing solution, right-click the solution and select *Delete* from the menu.

5.4.2 Configuring a data flow

Before you start modeling, a data cleansing solution must have already been created in SAP Information Steward and published to the CMS, and you should create a project, datastore, and data flow in the Workbench.

1. Open or create a data flow. The palette of elements on the right side of the window contains readers, loaders, and Platform and Data Integrator transforms.
2. Add a reader and loader to the data flow, as well as any other transforms required to manipulate the data.
3. Select ▸ *Window* ▸ *Data Cleansing Solutions* ◂.
   The Data Cleansing Solutions tab opens in the workspace and displays the data cleansing solutions that have been published in the Data Cleansing Advisor.
4. Select a data cleansing solution and drag it into the graphical area of the Data Flow editor. A Data Cleansing Solution transform is placed in the data flow that represents the data quality transforms, such as Data Cleanse, Global Address Cleanse, and Match. The underlying transforms included in the Data Cleansing Solution transform depend on the data cleansing solution recommendations that were chosen in Information Steward.
   The object properties panel opens below the data flow graphical area with three tabs.

Property tab	Description
Input	Displays a list of all input fields provided by the data cleansing solution that must be mapped in order for the data cleansing solution to be executed in Data Services. The specific input fields vary depending on the configuration of the data cleansing solution. The Description column displays a text description of the input field based on the content type that was identified by Data Cleansing Advisor.
Properties	Displays the Data Services options that you can set for the Data Cleansing Solution transform. Data quality configuration options (the business rules of cleansing and matching) are not editable within the Workbench. If an option setting must be modified, this is done in the Data Cleansing Advisor feature in SAP Information Steward, and the data cleansing solution must be republished.
Output	Displays a list of all available output fields from the data cleansing solution. The available output fields may vary depending on the configuration of the data cleansing solution.

5. To perform basic cleansing on your data to prepare it for more accurate cleansing and matching results, add a Basic Cleanse transform to the data flow and select the appropriate options. Typically, this basic cleansing is performed in Information Steward rather than Data Services Workbench.
6. Connect the Data Cleansing Solution transform to the reader and loader or other transforms in the data flow.
7. To automatically map fields from the reader to the Data Cleansing Solution transform, select the Input tab and click the *Detect Mappings* button.
   The Detect Mapping window opens and displays the field names candidates for mapping.
8. To confirm all of the suggested field mappings, click the *Confirm All* button; otherwise, select individual field names and click *Confirm* or *Reject* as appropriate. Click *OK*.
9. To manually map fields, select a field in the Input Schema and drag it to the appropriate row in the Input tab.
10. In the Output tab, select the field names that you want to output from the Available Output Fields and drag them into the Selected Fields list. If you want to output passthrough fields containing the original data before it was processed, select them in the Input Schema and drag them into the Selected Fields list. Use the Up and Down buttons to reorder the fields as you want to output them.

For information about transform options and input and output fields, see the *SAP Data Services Reference Guide*.

Related Information

Using the Basic Cleanse transform [page 2083]

5.4.2.1 Using the Basic Cleanse transform

In Information Steward, the Data Cleansing Advisor lets the data steward set up textual changes (transformations) to apply to specified columns in the data. Transformations set up in the wizard can help prepare the data for more accurate cleansing and matching results. When the data cleansing solution is published and then used in a data flow in Workbench, the transformations are represented in the Data Cleansing Solution transform, and the options are not editable.

Although basic cleansing is typically set up by the data steward in Information Steward, in Workbench, you can also add a Basic Cleanse transform, a specialized type of Query transform, to your data flow to perform the same cleansing on your data.

When the data flow is converted to ATL and deployed to the Data Services repository, the Basic Cleanse transform is converted to a Query transform.

Option	Description
Remove control characters	Removes control characters from the selected column.
Remove double quotes	Removes double quotation marks (") that appear anywhere in the selected column.
Remove leading spaces	Removes spaces before the text in the selected column.
Remove single quotes	Removes single quotation marks (') that appear anywhere in the selected column.
Remove trailing spaces	Remove spaces after the text in the selected column.
Replace null values with <default>	Enter the text that you want to take the place of empty fields in the selected column.
Search and replace	In the *Replace* box, enter the text that you want to delete from the selected column. In the *with* box, enter the text that you want to take the place of the deleted text. Click *Add*. Repeat these steps for each string of text that you want to replace. Use the up and down arrow buttons if you need to reorder search-and-replace values.

5.4.3 Modifying the reference data location

The location of the reference data is always set to the substitution parameter, $$RefFilesAddressCleanse, and cannot be modified within Workbench. The substitution parameter is set to the default location of the reference data during the Data Services installation, and Workbench automatically finds the reference data if you haven't modified the default.

To use a different reference data location to run a Data Cleansing Solution transform within Workbench, use the Data Services Designer to log into the repository that you want to modify, and edit the substitution parameter, $$RefFilesAddressCleanse, to point to the desired reference file directory. All Data Cleansing Solution transforms in Workbench will use this new location when executing a data flow for the repository.

5.4.4 Modifying the reports substitution variables

Enabling and disabling of data quality reports is set by the substitution parameters, $$ReportsAddressCleanse and $$ReportsMatch, and cannot be modified within Workbench. This allows reporting to be controlled at runtime within Data Services rather than being set within Workbench.

To enable or disable data quality reports for Workbench, use the Data Services Designer to log into the repository that you want to modify, and edit the substitution parameters, $$ReportsAddressCleanse and $$ReportsMatch.

5.4.5 Validating a data flow

To validate a data flow, click the *Validate* button. The status bar displays the validation status and the number of errors and warnings, if any.

Workbench performs the following validation on the Data Cleansing Solution transform:

- The Data Cleansing Solution can be retrieved from the SAP BusinessObjects Business Intelligence platform's Central Management Server (CMS).
- All input fields specified by the Data Cleansing Solution are mapped.
- All output fields in the Data Cleansing Solution transform output schema have a unique field name.
- At least one output field is specified in the Data Cleansing Solution transform.

If a validation error is found, the error is displayed in the Problems tab. Double-click an error to open the relevant Property tab in the Data Flow editor.

5.4.6 Deploying a data flow

Deploying a data flow publishes it to the Data Services repository.

The Data Cleansing Solution transform references the latest published version of the data cleansing solution from Data Cleansing Advisor. If a data cleansing solution is updated and republished in Data Cleansing Advisor, Workbench automatically uses the updated solution, and you must redeploy the data flow to the Data Services repository.

1. With the data flow open in the Data Flow editor, click the *Deploy* button. If you haven't saved the data flow, a prompt opens asking if you want to save the changes. Click *Yes* to save the changes.
   The Choose Repository window opens.
2. Select the Data Services repository that you want to deploy to, and click *OK*. When deployment is complete, an information window opens stating that the data flow was successfully deployed on the repository.
3. Click *Close*.

Deploying a data flow generates ATL that represents the elements in the data flow and can be executed by Data Services. After you deploy the job to the Data Services repository, you can open, modify, and execute it as a new, separate job instance in the Data Services Designer. However, any changes that you make in Data Services Designer are not saved to the Workbench instance of the job.

5.4.7 Executing a data flow

The execution process validates a data flow, generates ATL, deploys it to a Data Services repository, and executes the data flow.

1. With the data flow open in the Data Flow editor, click the *Execute* button.
   If you haven't saved the data flow, a prompt opens asking if you want to save the changes.
2. Click *Yes* to save the changes.
   The Execute job wizard opens.
3. In Step 1 of the Execute Job wizard, select the Data Services repository that you want to use and click *Next*.
   The wizard proceeds to the next step.
4. In Step 2 of the Execute Job wizard, select the appropriate execution parameters and click *Finish*.
   The job executes, and the monitor editor opens and displays the job status, execution progress, and any applicable logs. Trace, monitor, and error logs are available. When the job is completed, the job status is displayed at the top.

5.4.8 Viewing data

To view the data before and after it is processed, you can view data in both the reader and loader transforms.

1. In the graphical area of the Data Flow editor, select the reader or loader.
2. In the Properties tab for the selected loader, click the *View Data* button. A data grid opens and displays the first 200 records.
3. To view more data rows, edit the *Max Rows* field and click the refresh button.

5.4.9 Modifying a Workbench job in Data Services Designer

Workbench allows limited changes to transform options and fields in the data flow. In Data Services Designer, you can modify a data flow that was created in Workbench more extensively; however, any changes that you make in the Designer cannot be exported to or viewed in the Workbench. In the Designer, you see the individual transforms (Data Cleanse, Global Address Cleanse, and Match) that were represented by the Data Cleansing Solution transform in Workbench. You can change options, input fields, and output fields for Data Cleanse and Global Address Cleanse. You cannot modify Match settings. You can edit connection between all of the transforms on the canvas as necessary.

1. In the *Local Object Library* of the Data Services Designer, click the *Jobs* tab, and expand *Batch Jobs* to display the Workbench data cleansing solution job.
2. Double-click the job. The job opens on the canvas and contains a work flow.

3. Double-click the work flow. The work flow opens and contains a data flow.
4. Double-click the data flow. The data flow opens. Rather than displaying the single Data Cleansing Solution transform, the data flow contains the data quality transforms that the Data Cleansing Solution transform represents, such as Data Cleanse, Global Address Cleanse, and Match. The data quality transforms used depends on the configuration of the data cleansing solution created in Information Steward.
5. Modify and execute the job as necessary.

Any changes that you make in Data Services Designer are not saved to the Workbench instance of the job.

5.5 Additional Information

5.5.1 Supported data migration sources and targets

Supported sources

The Workbench supports the following database and application types as migration sources:

- Data Services-supported databases
  - Attunity Connector
  - HP Neoview
  - DB2
  - SAP HANA
  - Informix
  - Microsoft SQL Server
  - MySQL
  - Netezza
  - ODBC
  - Oracle
  - SQL Anywhere
  - Sybase ASE
  - Sybase IQ
  - Teradata
- SAP Applications
- SAP BW Source

i Note

For more information about the available options for each supported datastore source type, see the *Reference Guide*.

Supported targets

The Workbench supports the following database types as migration targets:

- SAP HANA
- DB2
- Netezza
- Oracle
- Sybase IQ
- Teradata
- Sybase ASE
- SQL Anywhere
- Microsoft SQL Server

> Note
>
> For more information about the available options for each supported datastore target type, see the *Reference Guide*.

Related Information

Reference Guide: Objects, Descriptions of objects, Datastore [page 860]

5.5.2 Using the expression editor

The expression editor allows you to use variables, functions, and basic logic structures in many areas of a replication job. For example, you can use the expression editor to customize the mapping of a target column or the replication job's pre-load or post-load scripts.

5.5.2.1 Supported operators

This section describes the operators that can be used in Workbench expressions and filters.

Operator	Description
+	Addition
-	Subtraction
*	Multiplication
/	Division

Operator	Description
=	Comparison, equal to
<	Comparison, less than
<=	Comparison, less than or equal to
>	Comparison, greater than
>=	Comparison, greater than or equal to
!=	Comparison, not equal to
||	Concatenate
%	Modulus Returns the remainder when one number is divided by another.
AND	Logical AND
OR	Logical OR
NOT	Logical NOT
IS NULL	Comparison, is a NULL value
IS NOT NULL	Comparison, is not a NULL value

5.5.2.2 Including functions in expressions

In Data Services, functions take input values and produce a return value. Input values can be parameters passed into a data flow, values from a column of data, or variables defined inside a script. This section discusses functions and how to include them in a Workbench replication job.

5.5.2.2.1 Built-in functions

This section describes each built-in function available in Data Services.

The following tables list the names and descriptions of functions, grouped by each function's category in the Workbench expression editor.

For a complete listing of all built-in functions and their syntax, parameters, and return values, see “Functions and Procedures, Descriptions of built-in functions” in the *Reference Guide*.

Aggregate functions

Function	Description
avg	Calculates the average of a given set of values.
count	Counts the number of values in a table column.
count_distinct	Count the number of distinct non-null values in a table column.
max	Returns the maximum value from a list.
min	Returns the minimum value from a list.
sum	Calculates the sum of a given set of values.

Conversion functions

Function	Description
cast	Returns a value in the cast data type.
extract_from_xml	Extracts XML directly from single column in a database table, and converts it into its internal nested relational data model (NRDM).
interval_to_char	Returns a string representation of the interval.
julian_to_date	Converts a Julian value to a date.
load_to_xml	Generates XML text from NRDM and loads it into a single database column (Assumes the database supports XML text in its columns).
long_to_varchar	Converts a data type from long to varchar.
num_to_interval	Converts a numeric value to an interval.
to_char	Converts a date or numeric type to a string.
to_date	Converts a string to a date.
to_decimal	Converts a varchar to a decimal.
varchar_to_long	Converts a data type from varchar to long.

Cryptographic functions

Function	Description
decrypt_aes	Decrypts the input string using the user-specified passphrase and key length using the AES algorithm.

Function	Description
encrypt_aes	Encrypts the input string using the user-specified passphrase and key length using the AES algorithm.

Database functions

Function	Description
key_generation	Generates keys for the specified table, after determining the appropriate starting value.
sql	Runs a SQL operation in the specified database.
total_rows	Returns the number of rows in a particular table in a datastore.

Date functions

Function	Description
add_months	Adds a given number of months to a date.
concat_date_time	Returns a datetime from separate date and time inputs.
date_diff	Returns the difference between two dates or times.
date_part	Extracts a component of a given date.
day_in_month	Determines the day in the month on which the given date falls.
day_in_week	Determines the day in the week on which the given date falls.
day_in_year	Determines the day in the year on which the given date falls.
fiscal_day	Converts a given date into an integer value representing a day in a fiscal year.
isweekend	Indicates that a date corresponds to Saturday or Sunday.
julian	Converts a date to its integer Julian value, the number of days between the start of the Julian calendar and the date.
last_date	Returns the last date of the month for a given date.
month	Determines the month in which the given date falls.
quarter	Determines the quarter in which the given date falls.
sysdate	Returns the current date as listed by the Job Server's operating system.
systime	Returns the current time as listed by the Job Server's operating system.

Function	Description
week_in_month	Determines the week in the month in which the given date falls.
week_in_year	Determines the week in the year in which the given date falls.
year	Determines the year in which the given date falls.

Environment functions

Function	Description
get_env	Returns a value for the specified environmental variable.
get_error_filename	Returns the full path and file name for the error log.
get_monitor_filename	Returns the full path and file name for the monitor log.
get_trace_filename	Returns the full path and file name for the trace log.
is_set_env	Verifies if the specified environment variable is set.
set_env	Sets an environmental variable temporarily to a specified value.

Lookup functions

Function	Description
lookup	Finds a value in one table or file based on values in a second table or file.
lookup_ext	Finds data from a database table, flat file, or memory datastore table.

Math functions

Function	Description
abs	Returns the absolute value of an input number.
ceil	Returns the smallest integer value greater than or equal to an input number.
floor	Returns the largest integer value less than or equal to an input number.
In	Returns the natural logarithm of the given numeric expression.

Function	Description
log	Returns the base-10 logarithm of the given numeric expression.
mod	Returns the remainder when one number is divided by another.
power	Returns the value of the give expression to the specified power.
rand	Returns a random number between 0 and 1.
rand_ext	Returns a random number between 0 and 1.
round	Rounds a given number to the specified precision.
sqrt	Returns the square root of the given expression.
trunc	Truncates a given number to the specified precision.

Miscellaneous functions

Function	Description
base64_decode	Returns the source data after decoding the base64-encoded input.
base64_encode	Returns the base64-encoded data in the engine locale character set.
current_configuration	Returns the name of the datastore configuration in use at runtime.
current_system_configuration	Returns the name of the system configuration in use at runtime. If no system configuration is defined, returns a NULL value.
dataflow_name	Returns the data flow name in which this call exists. If the call is not in a data flow, returns NULL.
datastore_field_value	Retrieves the value of a specified datastore field.
db_database_name	Returns the database name of the datastore configuration in use at runtime.
db_owner	Returns the real owner name for the datastore configuration that is in use at runtime.
db_type	Returns the database type of the datastore configuration in use at runtime.
db_version	Returns the database version of the datastore configuration in use at runtime.
decode	Returns an expression based on the first condition in the specified list that evaluates to TRUE.
file_exists	Checks to see if a given file or directory exists.

Function	Description
gen_row_num	Returns an integer value beginning with 1 then incremented sequentially by 1 for each additional call. This function can be used to generate a column of row IDs.
gen_row_num_by_group	Returns group row number of the record.
gen_uuid	Returns a unique varchar string identifier.
get_domain_description	Returns the description of a value when given the domain name and the value.
get_file_attribute	Returns date created, date modified, or size (in bytes) of a physical file.
greatest	Returns greatest of the list of one or more expressions.
host_name	Returns the name of the computer on which the job is executing.
ifthenelse	Allows conditional logic in mapping and selection operations.
is_group_changed	Returns 1 if the group is changed, 0 otherwise.
isempty	Indicates if a nested table contains data.
job_name	Returns the name of the job in which the call to this function exists.
job_run_id	Retrieves the job run ID for the current job execution.
least	Returns the least in a list of one ormore expressions.
nvl	Replaces NULL values.
previous_row_value	Returns the column value of previous row.
pushdown_sql	Allows you to create dynamic WHERE clauses.
raise_exception	Calling this function causes an exception to be generated.
raise_exception_ext	Same as raise_exception, but takes a second parameter for an exit code.
repository_name	Returns a database connection string and owner name. For example: beq-local.DBUser. This is the ID for the repository from which the job is run.
sleep	Suspends the execution of the data flow or work flow from where it is called.
system_user_name	Returns the user name used to log into the Job Server's operating system.
table_attribute	Retrieves the value of a specified table attribute.
truncate_table	Allows you to explicitly expunge data from a memory table.
wait_for_file	Returns the existing files that match the input file pattern.
workflow_name	Returns the work flow in which this call exists. Returns the name of the inner most work flow in cases where several work flows enclose this function call. If no work flow is found, returns job name.

SAP functions

Function	Description
sap_openhub_processchain_execute	Starts the process chain that extracts data from an SAP NetWeaver Business Warehouse(BW) and loads the extracted data into an Open Hub Destination table.
sap_openhub_set_read_status	Sends the read status for the Open Hub table to SAP NetWeaver BW.

String functions

Function	Description
ascii	Returns the decimal value of the first character for the given string using ASCII character set. If the character passed is not a valid ASCII character, -1 is returned.
chr	Get character representation of provided ASCII value.
double_metaphone	Encodes the input string usin the Double Metaphone algorithm and returns a string.
index	Returns the index of a given word in a string.
init_cap	Changes the characters in a string to title case.
length	Returns the number of characters in a given string.
literal	Returns an input constant expression without interpolation. Allows you to assign a pattern to a variable without interpolation.
lower	Changes the characters in a string to lowercase.
lpad	Pads a string with characters froma specified pattern.
lpad_ext	Pads a string with logical characters from a specified pattern.
ltrim	Removes specified characters from the start of a string.
ltrim_blanks	Removes blank characters from the start of a string.
ltrim_blanks_ext	Removes blank and control characters from the start of a string.
match_pattern	Matches whole input strings to simple patterns supported by Data Services. This function does not match substrings.
match_regex	Matches whole input strings to the pattern that you specify with regular expressions (regular expressions based on the POSIX standard) and flags. This function does not match substrings.
match_simple	
print	Prints the given string to the trace log.

Function	Description
replace_substr	Returns a string where every occurrence of a given search string in the input is substituted by the given replacement string.
replace_substr_ext	Takes an input string, replaces specified occurrences of a specified sub-string with a specified replacement and returns the result. You can also use this function to search for hexadecimal or reference characters.
rpad	Pads a string with characters from a given pattern.
rpad_ext	Pads a string with logical characters from a given pattern.
rtrim	Removes given characters from the end of a string.
rtrim_blanks	Removes blank characters from the end of a string.
rtrim_blanks_ext	Removes blank and control characters from the end of a string.
search_replace	Searches input parameters and replaces by matching criteria and values specified by search table.
soundex	Encodes the input string using the Soundex algorithm and returns a string. Use when you want to push down the function to the database level.
substr	Returns a specific portion of a string starting at a given point in the string.
upper	Changes the characters in a string to uppercase.
word	Returns one word out of a string.
word_ext	Returns the word identified by its position in a delimited string.

System functions

Function	Description
exec	Sends a command to the operating system for execution.
mail_to	Sends the specified e-mail message.
smtp_to	Sends the specified e-mail message using the SMTP protocol.

User functions

You can create your own functions by writing script functions in SAP Data Services scripting language using the Designer smart editor.

For more information about user-defined custom functions, see “Functions and Procedures, Custom functions” in the *Reference Guide*.

Validation functions

Function	Description
is_valid_date	Indicates if an expression can be converted into a valid date value.
is_valid_datetime	Indicates if an expression can be converted into a valid datetime value.
is_valid_decimal	Indicates if an expression can be converted into a valid decimal value.
is_valid_double	Indicates if an expression can be converted into a valid double value.
is_valid_int	Indicates if an expression can be converted into a valid integer value.
is_valid_real	Indicates if an expression can be converted into a valid real value.
is_valid_time	Indicates if an expression can be converted into a valid time value.

Related Information

Reference Guide: Functions and Procedures, Descriptions of built-in functions [page 1515]
Reference Guide: Functions and Procedures, Custom functions [page 1694]

5.5.3 Managing Workbench project information

5.5.3.1 Creating a Workbench project

If you want to create a new project, start the new project wizard in one of the following ways:

- Right-click inside the project explorer and choose *New* > *Project*.
- Choose *New* > *Project* from the *File* menu.
- Click the *New* toolbar icon. Choose *General* > *Project* and click *Next*.

1. Specify the name for the new project and click *Next*.

   Note

   The project name can contain only alphanumeric characters and the underscore character.

2. If you want to save the files for the project to a different location, uncheck *Use default location* and specify a location for the project files.
3. Select the Data Services repository.

4. Click *Finish* to create the project.

The new project is displayed in the project explorer.

You can now add Workbench objects such as datastores and replication jobs to your project.

5.5.3.2 Exporting resources and preferences

Use the Export wizard to export Workbench folders, resources, and user preferences.

1. Right-click within the project explorer pane and choose *Export*.
   The Export wizard appears.
2. Select the type of export that you want to perform and click *Next*.
   - Archive File
     Exports selected Workbench resources to a `.zip` or `.tar` archive on the local file system.
   - File System
     Exports selected Workbench resources directly to a location on the local file system.
   - Preferences
     Exports Workbench configuration preferences to a location on the local file system.
3. If you are exporting to an archive file or a location on the file system, select the resources to export and set the export options as desired.
   a) Select the folders and resources that you want to export.

   Folders appear in the left pane and resources appear in the right pane.

   > ➜ Tip
   >
   > Folders with a grayed-out selection box are not explicitly selected, but contain objects that will be exported.

   b) Click *Browse* to specify the location where the archive file or resource files will be created.
   c) If you are exporting to an archive file, select the type of archive file to create.
   d) Select the directory structure mode.

Option	Description
Create directory structure for files	Creates the directory structure for all selected resources, even if no folders are explicitly selected.
Create only selected directories	Creates the directory structure only for folders that are explicitly selected.

4. If you are exporting preferences, select the preferences to export and set the export options as desired.
   a) Select the preferences to export, or select *Export all* to export all Workbench preferences.
   b) Click *Browse* to specify the location where the preference file will be exported.
5. Click *Finish*.
   The selected resources or preferences are exported to the specified archive file or file system location.

5.5.3.3 Importing resources and preferences

Use the Import wizard to import Workbench folders, resources, and user preferences.

1. Right-click within the project explorer pane and choose *Import*.
   The Import wizard appears.
2. Select the type of export that you want to perform and click *Next*.
   - Archive File
     Imports selected Workbench resources from a `.zip` or `.tar` archive on the local file system.
   - File System
     Imports selected Workbench resource files from a location on the local file system.
   - Preferences
     Imports Workbench configuration preferences from a file on the local file system.
3. If you are importing from an archive file or a location on the file system, select the resources to import and set the import options as desired.
   a) Click *Browse* to specify the location of the archive file or resource files.
   b) Select the folders and resources that you want to import.

      Folders appear in the left pane and resources appear in the right pane.

      > ➜ Tip
      >
      > Folders with a grayed-out selection box are not explicitly selected, but contain objects that will be imported.

   c) Click *Browse* to specify the folder where the imported resources will be stored.
4. If you are importing preferences, select the preferences to import.
   a) Click *Browse* to specify the preference file to import.
   b) Select the preferences to import, or select *Import all* to import all Workbench preferences.
5. Click *Finish*.
   The selected resources or preferences are imported to the Workbench.

6 Performance Optimization Guide

6.1 Welcome to SAP Data Services

6.1.1 Welcome

SAP Data Services delivers a single enterprise-class solution for data integration, data quality, data profiling, and text data processing that allows you to integrate, transform, improve, and deliver trusted data to critical business processes. It provides one development UI, metadata repository, data connectivity layer, run-time environment, and management console—enabling IT organizations to lower total cost of ownership and accelerate time to value. With SAP Data Services, IT organizations can maximize operational efficiency with a single solution to improve data quality and gain access to heterogeneous sources and applications.

6.1.2 Documentation set for SAP Data Services

You should become familiar with all the pieces of documentation that relate to your SAP Data Services product. The latest Data Services documentation can be found on the *SAP Help Portal*.

Document	What this document provides
Adapter SDK Guide	Information about installing, configuring, and running the Data Services Adapter SDK
Administrator Guide	Information about administrative tasks such as monitoring, lifecycle management, security, and so on.
Customer Issues Fixed	Information about customer issues fixed in this release. i Note In some releases, this information is displayed the Release Notes.
Designer Guide	Information about how to use Data Services Designer.
Documentation Map	Information about available Data Services books, languages, and locations.
Installation Guide for Windows	Information about and procedures for installing Data Services in a Windows environment.
Installation Guide for UNIX	Information about and procedures for installing Data Services in a UNIX environment.
Integrator Guide	Information for third-party developers to access Data Services functionality using web services and APIs.
Master Guide	Information about the application, its components and scenarios for planning and designing your system landscape. Information about SAP Information Steward is also provided in this guide.

Document	What this document provides
Management Console Guide	Information about how to use Data Services Administrator and Data Services Metadata Reports.
Performance Optimization Guide	Information about how to improve the performance of Data Services.
Reference Guide	Detailed reference material for Data Services Designer.
Release Notes	Important information you need before installing and deploying this version of Data Services.
Technical Manuals	A compiled, searchable, “master” PDF of core Data Services books: ● *Administrator Guide* ● *Designer Guide* ● *Reference Guide* ● *Management Console Guide* ● *Performance Optimization Guide* ● *Integrator Guide* ● *Supplement for J.D. Edwards* ● *Supplement for Oracle Applications* ● *Supplement for PeopleSoft* ● *Supplement for Salesforce.com* ● *Supplement for Siebel* ● *Supplement for SAP* ● *Workbench Guide*
Text Data Processing Extraction Customization Guide	Information about building dictionaries and extraction rules to create your own extraction patterns to use with Text Data Processing transforms.
Text Data Processing Language Reference Guide	Information about the linguistic analysis and extraction processing features that the Text Data Processing component provides, as well as a reference section for each language supported.
Tutorial	A step-by-step introduction to using Data Services.
Upgrade Guide	Information to help you upgrade from previous releases of Data Services and release-specific product behavior changes from earlier versions of Data Services to the latest release.
What's New	Highlights of new key features in this SAP Data Services release. This document is not updated for support package or patch releases.
Workbench Guide	Provides users with information about how to use the Workbench to migrate data and database schema information between different database systems.

In addition, you may need to refer to several Supplemental Guides.

Document	What this document provides
Supplement for SAP	Information about interfaces between Data Services, SAP Applications, SAP Master Data Services, SAP NetWeaver BW, and SAP Master Data Services.

Document	What this document provides
Supplement for SuccessFactors	Information about interfaces between Data Services and SuccessFactors.
Supplement for Salesforce.com	Information about how to install, configure, and use the SAP Data Services Salesforce.com Adapter Interface.
Supplement for J.D. Edwards	Information about interfaces between Data Services and J.D. Edwards World and J.D. Edwards OneWorld.
Supplement for Oracle Applications	Information about the interface between Data Services and Oracle Applications.
Supplement for PeopleSoft	Information about interfaces between Data Servicesand PeopleSoft.
Supplement for Siebel	Information about the interface between Data Services and Siebel.

We also include these manuals for information about SAP BusinessObjects Information platform services.

Document	What this document provides
Information platform services Administrator Guide	Information for administrators who are responsible for configuring, managing, and maintaining an Information platform services installation.
Information platform services Installation Guide for UNIX	Installation procedures for SAP BusinessObjects Information platform services on a UNIX environment.
Information platform services Installation Guide for Windows	Installation procedures for SAP BusinessObjects Information platform services on a Windows environment.

6.1.3 Accessing documentation

You can access the complete documentation set for SAP Data Services in several places.

6.1.3.1 Accessing documentation on Windows

After you install SAP Data Services, you can access the documentation from the Start menu.

1. Choose *Start* > *Programs* > *SAP Data Services 4.2* > *Data Services Documentation* > *All Guides* .
2. Click the appropriate shortcut for the document that you want to view.

6.1.3.2 Accessing documentation on UNIX

After you install SAP Data Services, you can access the documentation by going to the directory where the printable PDF files were installed.

1. Go to **`<LINK_DIR>`**`/doc/book/en/`.

2. Using Adobe Reader, open the PDF file of the document that you want to view.

6.1.3.3 Accessing documentation from the Web

You can access the complete documentation set for SAP Data Services from the SAP Business Users Support site.

To do this, go to *http://help.sap.com/bods*.

You can view the PDFs online or save them to your computer.

6.1.4 SAP information resources

A global network of SAP technology experts provides customer support, education, and consulting to ensure maximum information management benefit to your business.

Useful addresses at a glance:

Address	Content
Customer Support, Consulting, and Education services *http://service.sap.com/*	Information about SAP support programs, as well as links to technical articles, downloads, and online forums. Consulting services can provide you with information about how SAP can help maximize your information management investment. Education services can provide information about training options and modules. From traditional classroom learning to targeted e-learning seminars, SAP can offer a training package to suit your learning needs and preferred learning style.
Product documentation *http://help.sap.com/bods/*	SAP product documentation.
Supported Platforms (Product Availability Matrix) *https://service.sap.com/PAM*	Get information about supported platforms for SAP Data Services. Use the search function to search for Data Services. Click the link for the version of Data Services you are searching for.
SAP Data Services Community Network *http://scn.sap.com/community/data-services*	Get online and timely information about SAP Data Services, including forums, tips and tricks, additional downloads, samples, and much more. All content is to and from the community, so feel free to join in and contact us if you have a submission.
Blueprints *http://scn.sap.com/docs/DOC-8820*	Blueprints for you to download and modify to fit your needs. Each blueprint contains the necessary SAP Data Services project, jobs, data flows, file formats, sample data, template tables, and custom functions to run the data flows in your environment with only a few modifications.

Address	Content
SAPTerm *https://portal.wdf.sap.corp/go/sapterm* ➦	SAP's terminology database, the central repository for defining and standardizing the use of specialist terms.

6.2 Environment Test Strategy

This section covers suggested methods of tuning source and target database applications, their operating systems, and the network used by your SAP Data Services environment. It also introduces key job execution options.

This section contains the following topics:

- *The source OS and database server* [page 2103]
- *The target OS and database server* [page 2104]
- *The network* [page 2104]
- *Job Server OS and job options* [page 2105]

To test and tune jobs, work with all four of these components in the order shown above.

In addition to the information in this section, you can use your UNIX or Windows operating system and database server documentation for specific techniques, commands, and utilities that can help you measure and tune the SAP Data Services environment.

6.2.1 The source OS and database server

Tune the source operating system and database to quickly read data from disks.

6.2.1.1 Operating system

Make the input and output (I/O) operations as fast as possible. The read-ahead protocol, offered by most operating systems, can greatly improve performance. This protocol allows you to set the size of each I/O operation. Usually its default value is 4 to 8 kilobytes which is too small. Set it to at least 64K on most platforms.

6.2.1.2 Database

Tune your database on the source side to perform SELECTs as quickly as possible.

In the database layer, you can improve the performance of SELECTs in several ways, such as the following:

- Create indexes on appropriate columns, based on your data flows.
- Increase the size of each I/O from the database server to match the OS read-ahead I/O size.
- Increase the size of the shared buffer to allow more data to be cached in the database server.
- Cache tables that are small enough to fit in the shared buffer. For example, if jobs access the same piece of data on a database server, then cache that data. Caching data on database servers will reduce the number of I/O operations and speed up access to database tables.

See your database server documentation for more information about techniques, commands, and utilities that can help you measure and tune the the source databases in your jobs.

6.2.2 The target OS and database server

Tune the target operating system and database to quickly write data to disks.

6.2.2.1 Operating system

Make the input and output operations as fast as possible. For example, the asynchronous I/O, offered by most operating systems, can greatly improve performance. Turn on the asynchronous I/O.

6.2.2.2 Database

Tune your database on the target side to perform INSERTs and UPDATES as quickly as possible.

In the database layer, there are several ways to improve the performance of these operations.

Here are some examples from Oracle:

- Turn off archive logging.
- Turn off redo logging for all tables.
- Tune rollback segments for better performance.
- Place redo log files and data files on a raw device, if possible.
- Increase the size of the shared buffer.

See your database server documentation for more information about techniques, commands, and utilities that can help you measure and tune the the target databases in your jobs.

6.2.3 The network

When reading and writing data involves going through your network, its ability to efficiently move large amounts of data with minimal overhead is very important. Do not underestimate the importance of network tuning (even if you have a very fast network with lots of bandwidth).

Set network buffers to reduce the number of round trips to the database servers across the network. For example, adjust the size of the network buffer in the database client so that each client request completely fills a small number of network packets.

6.2.4 Job Server OS and job options

Tune the Job Server operating system and set job execution options to improve performance and take advantage of self-tuning features of SAP Data Services.

6.2.4.1 Operating system

SAP Data Services jobs are multi-threaded applications. Typically a single data flow in a job initiates one `al_engine` process that in turn initiates at least 4 threads.

For maximum performance benefits:

- Consider a design that will run one `al_engine` process per CPU at a time.
- Tune the Job Server OS so that threads spread to all available CPUs.

For more information, see *Checking system utilization* [page 2108].

6.2.4.2 Jobs

You can tune job execution options after:

- Tuning the database and operating system on the source and the target computers
- Adjusting the size of the network buffer
- Your data flow design seems optimal

You can tune the following execution options to improve the performance of your jobs:

- *Monitor sample rate*
- *Collect statistics for optimization* and *Use collected statistics*

6.2.4.2.1 Setting Monitor sample rate

During job execution, the SAP Data Services writes information to the monitor log file and updates job events after the number of seconds specified in *Monitor sample rate* has elapsed. The default value is 5. Increase *Monitor sample rate* to reduce the number of calls to the operating system to write to the log file.

When setting *Monitor sample rate*, you must evaluate performance improvements gained by making fewer calls to the operating system against your ability to view more detailed statistics during job execution. With a higher *Monitor sample rate*, the software collects more data before calling the operating system to open the file, and performance improves. However, with a higher monitor rate, more time passes before you can view statistics during job execution.

> Note
>
> If you use a virus scanner on your files, exclude the SAP Data Services log from the virus scan. Otherwise, the virus scan analyzes the log repeatedly during the job execution, which causes a performance degradation.

6.2.4.2.2 Collecting statistics for self-tuning

SAP Data Services provides a self-tuning feature to determine the optimal cache type (in-memory or pageable) to use for a data flow.

6.2.4.2.3 Taking advantage of the self-tuning feature

1. When you first execute a job, select the option *Collect statistics for optimization* to collect statistics which include number of rows and width of each row. Ensure that you collect statistics with data volumes that represent your production environment. This option is not selected by default.
2. The next time you execute the job, this option is selected by default.
3. When changes occur in data volumes, re-run your job with *Collect statistics for optimization* to ensure that the software has the most current statistics to optimize cache types.

Related Information

Using Caches [page 2129]

6.3 Measuring Performance

6.3.1 Data Services processes and threads

Data Services uses processes and threads to execute jobs that extract data from sources, transform the data, and load data into a data warehouse. The number of concurrently executing processes and threads affects the performance of Data Services jobs.

6.3.1.1 Processes

The processes used to run jobs are:

- al_jobserver
  The al_jobserver initiates one process for each Job Server configured on a computer. This process does not use much CPU power because it is only responsible for launching each job and monitoring the job's execution.
- al_engine
  For batch jobs, an al_engine process runs when a job starts and for each of its data flows. Real-time jobs run as a single process.
  The number of processes a batch job initiates also depends upon the number of:
  - parallel work flows
  - parallel data flows
  - sub data flows

Related Information

Analyzing log files for task duration [page 2110]

6.3.1.2 Threads

A data flow typically initiates one `al_engine` process, which creates one thread per data flow object. A data flow object can be a source, transform, or target. For example, two sources, a query, and a target could initiate four threads.

If you are using parallel objects in data flows, the thread count will increase to approximately one thread for each source or target table partition. If you set the *Degree of parallelism* (DOP) option for your data flow to a value greater than one, the thread count per transform will increase. For example, a DOP of `5` allows five concurrent threads for a Query transform. To run objects within data flows in parallel, use the following features:

- Table partitioning
- File multithreading
- Degree of parallelism for data flows

Related Information

Using Parallel Execution [page 2137]

6.3.2 Measuring performance of jobs

You can use several techniques to measure performance of SAP Data Services jobs.

6.3.2.1 Checking system utilization

The number of processes and threads concurrently executing affects the utilization of system resources (see *Data Services processes and threads* [page 2106]).

Check the utilization of the following system resources:

- CPU
- Memory
- Disk
- Network

To monitor these system resources, use the following tools:

For UNIX:

- top or a third party utility (such as glance for HPUX)

For Windows:

- Performance tab on the Task Manager

Depending on the performance of your jobs and the utilization of system resources, you might want to adjust the number of processes and threads. The following sections describe different situations and suggests features to adjust the number of processes and threads for each situation.

6.3.2.1.1 CPU utilization

SAP Data Services is designed to maximize the use of CPUs and memory available to run the job.

The total number of concurrent threads a job can run depends upon job design and environment. Test your job while watching multi-threaded processes to see how much CPU and memory the job requires. Make needed adjustments to your job design and environment and test again to confirm improvements.

For example, if you run a job and see that the CPU utilization is very high, you might decrease the DOP value or run less parallel jobs or data flows. Otherwise, CPU thrashing might occur.

For another example, if you run a job and see that only half a CPU is being used, or if you run eight jobs on an eight-way computer and CPU usage is only 50%, you can be interpret this CPU utilization in several ways:

- One interpretation might be that the software is able to push most of the processing down to source and/or target databases.
- Another interpretation might be that there are bottlenecks in the database server or the network connection. Bottlenecks on database servers do not allow readers or loaders in jobs to use Job Server CPUs efficiently.
  To determine bottlenecks, examine:
  - Disk service time on database server computers
    Disk service time typically should be below 15 milliseconds. Consult your server documentation for methods of improving performance. For example, having a fast disk controller, moving database server log files to a raw device, and increasing log size could improve disk service time.
  - Number of threads per process allowed on each database server operating system. For example:

    - On HPUX, the number of kernel threads per process is configurable. The CPU to thread ratio defaults to one-to-one. It is recommended that you set the number of kernel threads per CPU to between 512 and 1024.
    - On Solaris and AIX, the number of threads per process is not configurable. The number of threads per process depends on system resources. If a process terminates with a message like "Cannot create threads," you should consider tuning the job.
      For example, use the *Run as a separate process* option to split a data flow or use the Data_Transfer transform to create two sub data flows to execute sequentially. Since each sub data flow is executed by a different al_engine process, the number of threads needed for each will be 50% less than in your previous job design.
      If you are using the *Degree of parallelism* option in your data flow, reduce the number for this option in the data flow Properties window.
  - Network connection speed
    Determine the rate that your data is being transferred across your network.
    - If the network is a bottle neck, you might change your job execution distribution level from sub data flow to data flow or job to execute the entire data flow on the local Job Server.
    - If the capacity of your network is much larger, you might retrieve multiple rows from source databases using fewer requests.
- Yet another interpretation might be that the system is under-utilized. In this case, you might increase the value for the *Degree of parallelism* option and increase the number of parallel jobs and data flows.

Related Information

Using Parallel Execution [page 2137]
Using grid computing to distribute data flow execution [page 2160]
Using array fetch size [page 2205]

6.3.2.1.2 Memory

For memory utilization, you might have one of the following different cases:

- Low amount of physical memory.
  In this case, you might take one of the following actions:
  - Add more memory to the Job Server.
  - Redesign your data flow to run memory-consuming operations in separate sub data flows that each use a smaller amount of memory, and distribute the sub data flows over different Job Servers to access memory on multiple machines.
  - Redesign your data flow to push down memory-consuming operations to the database.

  For example, if your data flow reads data from a table, joins it to a file, and then groups it to calculate an average, the group by operation might be occurring in memory. If you stage the data after the join and before the group by into a database on a different computer, then when a sub data flow reads the staged data and continues with the group processing, it can utilize memory from the database server on a different computer. This situation optimizes your system as a whole.

- Large amount of memory but it is under-utilized.
  In this case, you might cache more data. Caching data can improve the performance of data transformations because it reduces the number of times the system must access the database.
  There are two types of caches available: in-memory and pageable.
- Paging occurs.
  Pageable cache is the default cache type for data flows. On Windows, UNIX, and Linux, the virtual memory available to the al_engine process is 3.5 gigabytes (500 megabytes of virtual memory is reserved for other engine operations, totaling 4GB). You can change this default limit by increasing the value of the `MAX_64BIT_PROCESS_VM_IN_MB` parameter in the `DSConfig.txt` file.
  If more memory is needed than these virtual memory limits, the software starts paging to continue executing the data flow.
  If your job or data flow requires more memory than these limits, you can take advantage of one of the following features to avoid paging:
  - Split the data flow into sub data flows that can each use the amount of memory set by the virtual memory limits.
    Each data flow or each memory-intensive operation within a data flow can run as a separate process that uses separate memory from each other to improve performance and throughput.
  - Push-down memory-intensive operations to the database server so that less memory is used on the Job Server computer.

Related Information

Caching data [page 2129]

6.3.2.2 Analyzing log files for task duration

The trace log shows the progress of an execution through each component (object) of a job. The following depiction of a trace log shows a separate process ID (Pid) and time stamp for the job, data flow, and each sub data flow.

Pid	Tid	Type	Time Stamp	Message
...		...	...	...
5696	5964	JOB	2/11/2012 11:56:37 PM	Processing job <Group_Orders_Job>.
...		...	...	...
4252	4044	DATAFLOW	2/11/2012 11:56:38 PM	Process to execute data flow

Pid	Tid	Type	Time Stamp	Message
				<Group_Orders_DF> is started.
1604	984	DATAFLOW	2/11/2012 11:56:42 PM	Process to execute sub data flow <Group_Orders_DF_1> is started.
...		...	...	...
5648	5068	DATAFLOW	2/11/2012 11:56:48 PM	Process to execute sub data flow <Group_Orders_DF_2> is started.
...		...	...	...

Trace logs also include messages about sub data flows, caches, and statistics.

Related Information

Splitting a data flow into sub data flows [page 2153]
Caching data [page 2129]
Reference Guide: Objects, Log [page 935]

6.3.2.3 Reading the Monitor Log for execution statistics

The Monitor log file indicates how many rows SAP Data Services produces or loads for a job. By viewing this log during job execution, you can observe the progress of row-counts to determine the location of bottlenecks. You can use the Monitor log to answer questions such as the following:

- What transform is running at any moment?
- How many rows have been processed so far?
  The frequency that the Monitor log refreshes the statistics is based on Monitor sample rate.
- How long does it take to build the cache for a lookup or comparison table? How long does it take to process the cache?
  If take long time to build the cache, use persistent cache.
- How long does it take to sort?
  If take long time to sort, you can redesign your data flow to push down the sort operation to the database.
- How much time elapses before a blocking operation sends out the first row?
  If your data flow contains resource-intensive operations after the blocking operation, you can add Data_Transfer transforms to push-down the resource-intensive operations.

You can view the Monitor log from the following tools:

- The Designer, as the job executes, when you click the Monitor icon.
- The Administrator of the Management Console, when you click the Monitor link for a job from the Batch Job Status page.

The Monitor log in the Designer shows the path for each object in the job, the number of rows processed, and the elapsed time for each object. The Absolute time column displays the total time from the start of the job to when the software completes the execution of the data flow object.

Related Information

Setting Monitor sample rate [page 2105]
Using persistent cache [page 2134]
Push-down operations [page 2116]
Data_Transfer transform for push-down operations [page 2122]
Reference Guide: Objects, Log [page 935]

6.3.2.4 Reading the Performance Monitor for execution statistics

The Performance Monitor displays execution information for each work flow, data flow, and sub data flow within a job. You can display the execution times in a table format. You can use the Performance Monitor to answer questions such as the following:

- Which data flows might be bottlenecks?
- How much time did a a data flow or sub data flow take to execute?
- How many rows did the data flow or sub data flow process?
- How much memory did a specific data flow use?

> Note
>
> Memory statistics (Cache Size column) display in the Performance Monitor only if you select the *Collect statistics for monitoring* option when you execute the job.

6.3.2.4.1 To view the Performance Monitor

1. Access the Management Console with one of the following methods:
   - In the Designer top menu bar, click *Tools* and select *Management Console*.
   - Click ▶ *Start* ▸ *Programs* ▸ *SAP Data Services* **`<x.x>`** ▸ *Data Services Management Console* ◀.
2. On the launch page, click *Administrator*.
3. Select ▶ *Batch* ▸ **`<repository>`** ◀
4. On the Batch Job Status page, find a job execution instance.
5. Under *Job Information* for an instance, click *Performance Monitor*.

Related Information

To monitor and tune in-memory and pageable caches [page 2135]

6.3.2.5 Reading Operational Dashboards for execution statistics

Operational dashboard reports contain job and data flow execution information for one or more repositories over a given time period (for example the last day or week). You can use operational statistics reports to answer some of the following questions:

- Are jobs executing within the allotted time frames?
- How many jobs succeeded or failed over a given execution period?
- How is the execution time for a job evolving over time?
- How many rows did the data flow process?

6.3.2.5.1 Comparing execution times for the same job over time

1. Open the Management Console via one of the following methods:
    - In the Designer top menu bar, choose *Tools* > *Management Console*.
    - Choose *Start* > *Programs* > *SAP Data Services <x>.<x>* > *Data Services Management Console*.
2. On the launch page, click *Operational Dashboard*.
3. Look at the graphs in Job Execution Statistic History or Job Execution Duration History to see if performance is increasing or decreasing.
4. On the Job Execution Duration History page, if there is a specific day that looks high or low compared to the other execution times, click that point on the graph to view the Job Execution Duration graph for all of the jobs that ran that day.
5. Click *View all history* to compare different executions of a specific job or data flow.
6. On the Job Execution History tab, you can select a specific job and number of days.
7. On the Data Flow Execution History tab, you can select a specific job and number of days, as well as search for a specific data flow.

Related Information

Management Console Guide: Operational Dashboard Reports [page 1975]

6.4 Tuning Overview

This section presents an overview of the different Data Services tuning options, with cross-references to subsequent chapters for more details.

6.4.1 Strategies to execute jobs

6.4.1.1 Maximizing push-down operations to the database server

SAP Data Services generates SQL SELECT statements to retrieve the data from source databases. The software automatically distributes the processing workload by pushing down as much as possible to the source database server.

Pushing down operations provides the following advantages:

- Use the power of the database server to execute SELECT operations (such as joins, Group By, and common functions such as decode and string functions). Often the database is optimized for these operations.
- Minimize the amount of data sent over the network. Fewer rows can be retrieved when the SQL statements include filters or aggregations.

You can also do a full push down from the source to the target, which means the software sends SQL INSERT INTO... SELECT statements to the target database. The following features enable a full push down:

- Data_Transfer transform
- Database links and linked datastores

Related Information

Maximizing Push-Down Operations [page 2116]

6.4.1.2 Improving throughput

Use the following features to improve throughput:

- Using caches for faster access to data
  You can improve the performance of data transformations by caching as much data as possible. By caching data in memory, you limit the number of times the system must access the database.
- Bulk loading to the target
  The software supports database bulk loading engines including the Oracle bulk load API. You can have multiple bulk load processes running in parallel.
- Other tuning techniques

- Source-based performance options
  - Join ordering
  - Minimizing extracted data
  - Using array fetch size
- Target-based performance options
  - Loading method
  - Rows per commit
- Job design performance options
  - Loading only changed data
  - Minimizing data type conversion
  - Minimizing locale conversion
  - Precision in operations

6.4.1.3 Using advanced tuning options

If your jobs have CPU-intensive and memory-intensive operations, you can use the following advanced tuning features to improve performance:

- Parallel processes—Individual work flows and data flows can execute in parallel if you do not connect them in the Designer workspace.
- Parallel threads—The software supports partitioned source tables, partitioned target tables, and degree of parallelism. These options allow you to control the number of instances for a source, target, and transform that can run in parallel within a data flow. Each instance runs as a separate thread and can run on a separate CPU.
- Server groups and distribution levels—You can group Job Servers on different computers into a logical component called a server group. A server group automatically measures resource availability on each Job Server in the group and distributes scheduled batch jobs to the computer with the lightest load at runtime. This functionality also provides a hot backup method. If one Job Server in a server group is down, another Job Server in the group processes the job.
  You can distribute the execution of data flows or sub data flows within a batch job across multiple Job Servers within a Server Group to better balance resource-intensive operations.

Related Information

Using Parallel Execution [page 2137]

Management Console Guide: Server Groups [page 1885]

Using grid computing to distribute data flow execution [page 2160]

6.5 Maximizing Push-Down Operations

For SQL sources and targets, SAP Data Services creates database-specific SQL statements based on the data flow diagrams in a job. The software generates SQL SELECT statements to retrieve the data from source databases. To optimize performance, the software pushes down as many SELECT operations as possible to the source database and combines as many operations as possible into one request to the database. It can push down SELECT operations such as joins, Group By, and common functions such as decode and string functions.

Data flow design influences the number of operations that the software can push to the database. Before running a job, you can view the SQL that is generated and adjust your design to maximize the SQL that is pushed down to improve performance.

You can use database links and the Data_Transfer transform to push down more operations.

6.5.1 Push-down operations

By pushing down operations to the source database, Data Services reduces the number of rows and operations that the engine must retrieve and process, which improves performance. When determining which operations to push to the database, Data Services examines the database and its environment.

6.5.1.1 Full push-down operations

The Optimizer always first tries to do a full push-down operation. A full push-down operation is when all transform operations can be pushed down to the databases and the data streams directly from the source database to the target database. SAP Data Services sends SQL INSERT INTO... SELECT statements to the target database where SELECT retrieves data from the source.

The software does a full push-down operation to the source and target databases when the following conditions are met:

- All of the operations between the source table and target table can be pushed down.
- The source and target tables are from the same datastore, they are in datastores that have a database link defined between them, or if the datastore has linked remote servers.

To enable a full push-down from the source to the target, you can also use the following features:

- Data_Transfer transform
- Database links
- Use Linked Remote Servers option

For database targets that support the *Allow merge or upsert* option, when all other operations in the data flow can be pushed down to the source database, the auto-correct loading operation may also be pushed down for a full push-down operation to the target. The software sends an SQL MERGE INTO `<target>` statement that implements the *Ignore columns with value* and *Ignore columns with null* options.

6.5.1.2 Partial push-down operations

When a full push-down operation is not possible, SAP Data Services still pushes down the SELECT statement to the source database. Operations within the SELECT statement that the software can push to the database include:

- Aggregations — Aggregate functions, typically used with a *Group by* statement, always produce a data set smaller than or the same size as the original data set.
- Distinct rows — When you select *Distinct rows* from the *Select* tab in the query editor, the software will only output unique rows.
- Filtering — Filtering can produce a data set smaller than or equal to the original data set.
- Joins — Joins typically produce a data set smaller than or similar in size to the original tables. The software can push down joins when either of the following conditions exist:
  - The source tables are in the same datastore
  - The source tables are in datastores that have a database link defined between them
- Ordering — Ordering does not affect data-set size. The software can efficiently sort data sets that fit in memory. It is recommended that you push down the Order By for very large data sets.
- Projection — Projection is the subset of columns that you map on the *Mapping* tab in the query editor. Projection normally produces a smaller data set because it only returns columns needed by subsequent operations in a data flow.
- Functions — Most functions that have equivalents in the underlying database are appropriately translated. These functions include decode, aggregation, and string functions.

6.5.1.3 Operations that cannot be pushed down

SAP Data Services cannot push some transform operations to the database. For example:

- Expressions that include functions that do not have database correspondents
- Load operations that contain triggers
- Transforms other than Query
- Joins between sources that are on different database servers that do not have database links defined between them.

Similarly, the software cannot always combine operations into single requests. For example, when a stored procedure contains a COMMIT statement or does not return a value, the software cannot combine the stored procedure SQL with the SQL for other operations in a query.

The software can only push operations supported by the DBMS down to that DBMS. Therefore, for best performance, try not to intersperse SAP Data Services transforms among operations that can be pushed down to the database.

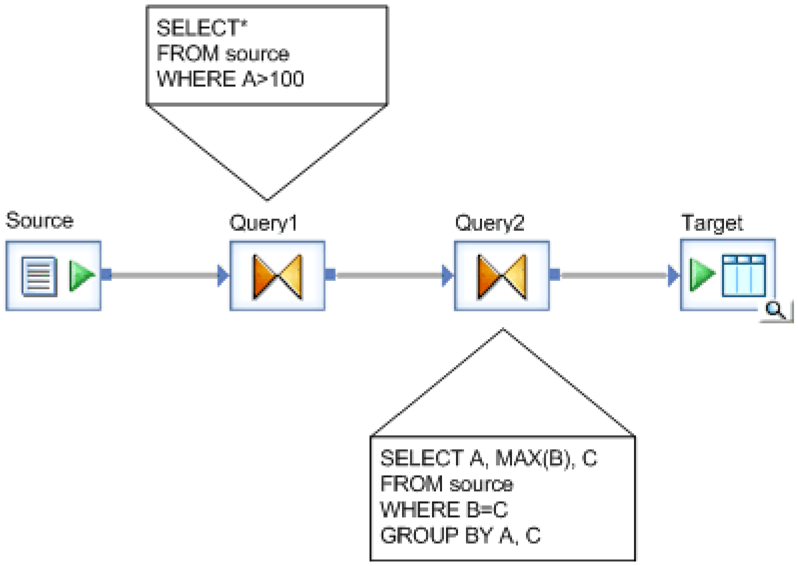
6.5.2 Push-down examples

The following are typical push-down scenarios.

6.5.2.1 Collapsing transforms to push down operations example

When determining how to push operations to the database, SAP Data Services first collapses all the transforms into the minimum set of transformations expressed in terms of the source table columns. Next, the software pushes all possible operations on tables of the same database down to that DBMS.

For example, the following data flow extracts rows from a single source table.



The first query selects only the rows in the source where column A contains a value greater than 100. The second query refines the extraction further, reducing the number of columns returned and further reducing the qualifying rows.

The software collapses the two queries into a single command for the DBMS to execute. The following command uses AND to combine the WHERE clauses from the two queries:

```
SELECT A, MAX(B), C
      FROM source
      WHERE A > 100 AND B = C
      GROUP BY A, C
```

The software can push down all the operations in this SELECT statement to the source DBMS.

6.5.2.2 Full push down from the source to the target example

If the source and target are in the same datastore, the software can do a full push-down operation where the INSERT into the target uses a SELECT from the source. In the sample data flow in scenario 1, a full push down passes the following statement to the database:

```
INSERT INTO target (A, B, C)
   SELECT A, MAX(B), C
```

```
       FROM source
       WHERE A > 100 AND B = C
       GROUP BY A, C
```

If the source and target are not in the same datastore, the software can also do a full push-down operation if you use one of the following features:

- Add a Data _Transfer transform before the target.
- Define a database link between the two datastores.

6.5.2.3 Full push down for auto correct load to the target example

For supported databases, if you enable the *Auto correct load* and *Allow merge or upsert* options, the Optimizer may be able to do a full push-down operation where the SQL statement is a MERGE into the target with a SELECT from the source.

In order for the *Allow merge or upsert* option to generate a MERGE statement, the primary key of the source table must be a subset of the primary key of the target table and the source row must be unique on the target key. In other words, there cannot be duplicate rows in the source data. If this condition is not met, the Optimizer pushes down the operation using a database-specific method to identify, update, and insert rows into the target table.

For example, suppose you have a data flow where the source and target tables are in the same datastore and the *Auto correct load* and *Allow merge or upsert* options are set to *Yes*.

The push-down operation passes the following statement to an Oracle database:

```
MERGE INTO "ODS"."TARGET" s
USING
SELECT "SOURCE"."A" A , "SOURCE"."B" B , "SOURCE"."C" C
                FROM "ODS"."SOURCE" "SOURCE"
                ) n
ON ((s.A = n.A))
WHEN MATCHED THEN
UPDATE SET s."B" = n.B,
                s."C" = n.C
WHEN NOT MATCHED THEN
INSERT /*+ APPEND */ (s."A", s."B", s."C" )
VALUES (n.A , n.B , n.C)
```

Similar statements are used for other supported databases.

6.5.2.4 Partial push down to the source example

If the data flow contains operations that cannot be passed to the DBMS, the software optimizes the transformation differently than the previous two scenarios. For example, if Query1 called `func(A) > 100`, where `func` is a SAP Data Services custom function, then the software generates two commands:

- The first query becomes the following command which the source DBMS executes:

  ```
  SELECT A, B, C
      FROM source
       WHERE B = C
  ```

- The second query becomes the following command which SAP Data Services executes because `func` cannot be pushed to the database:

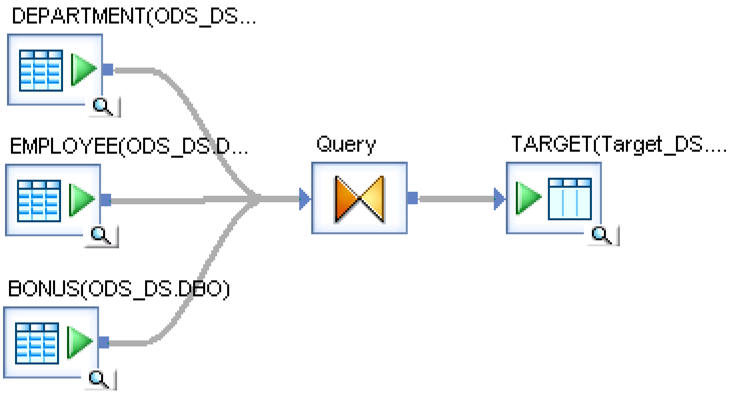
```
SELECT A, MAX(B), C
      FROM Query1
      WHERE func(A) > 100
    GROUP BY A, C
```

6.5.2.5 Push-down of SQL join example

If the tables to be joined in a query meet the requirements for a push-down operation, then the entire query is pushed down to the DBMS.

To confirm that the query will be pushed down, look at the Optimized SQL. If the query shows a single SELECT statement, then it will be pushed down.

For example, in the data flow shown below, the Department and Employee tables are joined with a inner join and then the result of that join is joined with left outer join to the Bonus table.



The resulting Optimized SQL contains a single select statement and the entire query is pushed down to the DBMS:

```
SELECT     DEPARTMENT.DEPTID, DEPARTMENT.DEPARTMENT, EMPLOYEE.LASTNAME,
BONUS.BONUS
FROM (DEPARTMENT INNER JOIN EMPLOYEE
(ON DEPARTMENT.DEPTID=EMPLOYEE.DEPTID))
LEFT OUTER JOIN BONUS
ON      (EMPLOYEE.EMPID = BONUS.EMPID)
```

Maximizing Push-Down Operations [page 2116]

Reference Guide: Transforms, Query, Joins in the Query transform [page 1455]

6.5.3 To view SQL

Before running a job, you can view the SQL code that SAP Data Services generates for table sources in data flows. By examining the SQL code, you can verify that the software generates the commands you expect. If necessary, you can alter your design to improve the data flow.

1. Validate and save data flows.
2. Open a data flow in the workspace.
3. Select *Display Optimized SQL* from the *Validation* menu.

   Alternately, you can right-click a data flow in the object library and select Display Optimized SQL.

   The *Optimized SQL* window opens and shows a list of datastores and the optimized SQL code for the selected datastore. By default, the *Optimized SQL* window selects the first datastore.

   The software only shows the SELECT generated for table sources and INSERT INTO... SELECT for targets. It does not show the SQL generated for SQL sources that are not table sources, such as:

   - Lookup function
   - Key_generation function
   - Key_Generation transform
   - Table_Comparison transform
4. Select a name from the list of datastores on the left to view the SQL that this data flow applies against the corresponding database or application.

   The following example shows the optimized SQL for the second datastore which illustrates a full push-down operation (INSERT INTO... SELECT). This data flows uses a Data_Transfer transform to create a transfer table that the software loads directly into the target.

   ```
   INSERT INTO "DBO"."ORDER_AGG" ("SHIPCOUNTRY","SHIPREGION", "SALES_AGG")
   SELECT "TS_Query_Lookup"."SHIPCOUNTRY" ,
   "TS_Query_Lookup"."SHIPREGION" ,sum("TS_Query_Lookup"."SALES")
   FROM"DBO"."TRANS2""TS_Query_Lookup"
   GROUP BY "TS_Query_Lookup"."SHIPCOUNTRY" , "TS_Query_Lookup"."SHIPREGION"
   ```

   In the *Optimized SQL* window you can:

   - Use the *Find* button to perform a search on the SQL displayed.
   - Use the *Save As* button to save the text as a .sql file.

If you try to use the *Display Optimized SQL* command when there are no SQL sources in your data flow, the software alerts you. Examples of non-SQL sources include:

- Message sources
- File sources
- IDoc sources

If a data flow is not valid when you click the *Display Optimized SQL* option, the software alerts you.

> Note
>
> The *Optimized SQL* window displays the existing SQL statement in the repository. If you changed your data flow, save it so that the *Optimized SQL* window displays your current SQL statement.

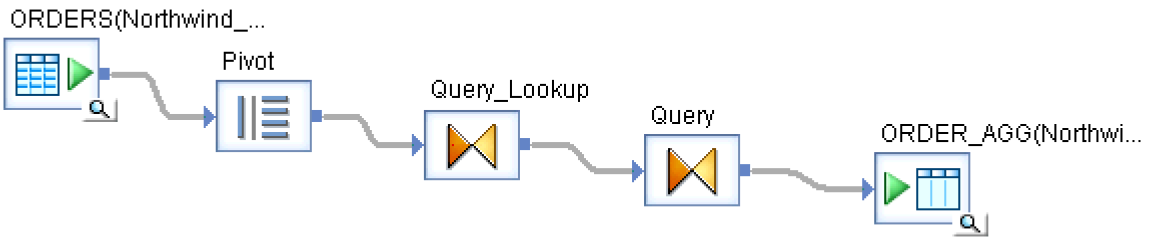
6.5.4 Data_Transfer transform for push-down operations

Use the Data_Transfer transform to move data from a source or from another transform into the target datastore and enable a full push-down operation (INSERT INTO... SELECT) to the target. You can use the Data_Transfer transform to push-down resource-intensive operations that occur anywhere within a data flow to the database. Resource-intensive operations include joins, GROUP BY, ORDER BY, and DISTINCT.

6.5.4.1 Push down an operation after a blocking operation example

You can place a Data_Transfer transform after a blocking operation to enable Data Services to push down a subsequent operation. A blocking operation is an operation that the software cannot push down to the database, and prevents ("blocks") operations after it from being pushed down.

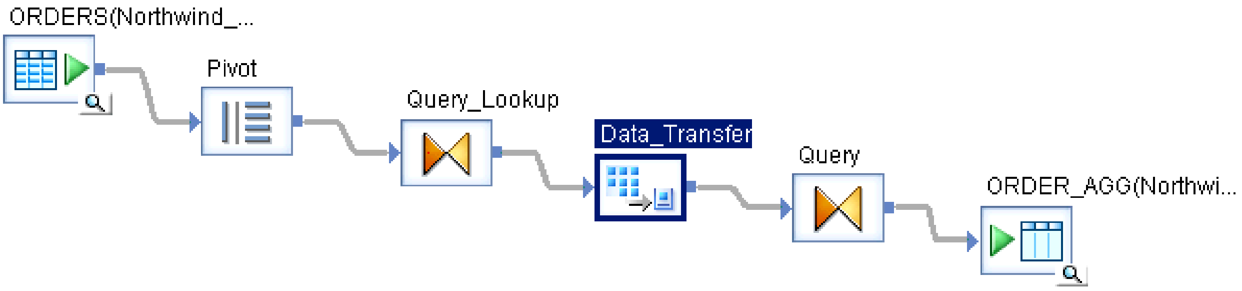
For example, you might have a data flow that groups sales order records by country and region, and sums the sales amounts to find which regions are generating the most revenue. The following diagram shows that the data flow contains a Pivot transform to obtain orders by Customer ID, a Query transform that contains a lookup_ext function to obtain sales subtotals, and another Query transform to group the results by country and region.



Because the Pivot transform and the lookup_ext function are before the query with the GROUP BY clause, the software cannot push down the GROUP BY operation. Here is how the *Optimized SQL* window would show the SELECT statement that the software pushes down to the source database:

```
SELECT "ORDERID", "CUSTOMERID", "EMPLOYEEID", "ORDERDATE", "REQUIREDDATE",
"SHIPPEDDATE",, "SHIPVIA"
"FREIGHT", "SHIPNAME", "SHIPADDRESS", "SHIPCITY", "SHIPREGION", "SHIPPOSTALCODE",
"SHIPCOUNTRY"
FROM "DBO"."ORDERS"
```

However, if you add a Data_Transfer transform before the second Query transform and specify a transfer table in the same datastore as the target table, the software can push down the GROUP BY operation.



The Data_Transfer Editor window shows that the transfer type is *Table* and the transfer table is in the same datastore as the target table (Northwind_DS.DBO.TRANS2).

Here's how the *Optimized SQL* window would show that the software pushed down the GROUP BY to the transfer table TRANS2.

```
INSTER INTO "DBO"."ORDER_AGG" ("SHIPCOUTNRY", "SHIPREGION", "SALES_AGG")
SELECT "TS_Query_Lookup"."SHIPCOUNTRY" , "TS_Query_Lookup"."SHIPREGION" ,
sum("TS_Query_Lookup"."SALES")
FROM "DBO"."TRANS2""TS_Query_Lookup"
GROUP BY "TS_Query_Lookup"."SHIPCOUNTRY" , "TS_Query_Lookup"."SHIPREGION"
```

Related Information

Reference Guide: Transforms, Data_Transfer [page 1071]

Operations that cannot be pushed down [page 2117]

6.5.4.2 Using Data_Transfer tables to speed up auto correct loads example

Auto correct loading ensures that the same row is not duplicated in a target table, which is useful for data recovery operations. However, an auto correct load prevents a full push-down operation from the source to the target when the source and target are in different datastores.

For large loads using database targets that support the *Allow merge or upsert* option for auto correct load, you can add a Data_Transfer transform before the target to enable a full push-down from the source to the target. In order for the *Allow merge or upsert* option to generate a MERGE statement:

- the primary key of the source table must be a subset of the primary key of the target table
- the source row must be unique on the target key

In other words, there cannot be duplicate rows in the source data. If this condition is not met, the Optimizer pushes down the operation using a database-specific method to identify, update, and insert rows into the target table.

If the MERGE statement can be used, SAP Data Services generates an SQL MERGE INTO **<target>** statement that implements the *Ignore columns with value* value (if a value is specified in the target transform editor) and the *Ignore columns with null* Yes/No setting.

For example, suppose you create a data flow that loads sales orders into an Oracle target table which is in a different datastore from the source.

For this data flow, the *Auto correct load* option is active and set to Yes, and the *Ignore columns with null* and *Allow merge or upsert* options are also active.

The SELECT statement that the software pushes down to the source database would look like the following (as it would appear in the *Optimized SQL* window).

```
SELECT "ODS_SALESORDER"."SALES_ORDER_NUMBER" , "ODS_SALESORDER"."ORDER_DATE" ,
"ODS_SALESORDER"."CUST_ID"
FROM "ODS"."ODS_SALESORDER""ODS_SALESORDER"
```

When you add a Data_Transfer transform before the target and specify a transfer table in the same datastore as the target, the software can push down the auto correct load operation.

The following MERGE statement is what the software pushes down to the Oracle target (as it appears in the *Optimized SQL* window).

```
MERGE INTO "TARGET"."AUTO_CORRECT_LOAD2_TARGET" s
USING
(SELECT "AUTOLOADTRANSFER"."SALES_ORDER_NUMBER" SALES_ORDER_NUMBER,
"AUTOLOADTRANSFER"."ORDER_DATE" ORDER_DATE, "AUTOLOADTRANSFER"."CUST_ID" CUST_ID
FROM "TARGET"."AUTOLOADTRANSFER" "AUTOLOADTRANSFER") n
ON ((s.SALES_ORDER_NUMBER=n.SALES_ORDRE_NUMBER00
WHEN MATCHED THEN
UPDATE SET s."ORDER_DATE"=nvl(n.ORDER_DATE,s."ORDER_DATE"),
s."CUST_ID"=nbl(n.CUST_ID,s."CUST_ID"
WHEN NOT MATCHED THEN
INSERT(s."SALES_ORDER_NUMBER",s."ORDER_DATE",s."CUST_ID")
VALUES(n.SALES_ORDRE_NUMBER,n.ORDRE_DATE,n.CUSTID)
```

Similar statements are used for other supported databases.

6.5.5 Database link and linked remote server support for push-down operations across datastores

Various database vendors support one-way communication paths from one database server to another. SAP Data Services refers to communication paths between databases as database links. The datastores in a database link relationship are called linked datastores, or, in the case of Sybase IQ, linked remote server.

The software uses linked datastores to enhance its performance by pushing down operations to a target database using a target datastore. Pushing down operations to a database not only reduces the amount of information that needs to be transferred between the databases and SAP Data Services but also allows the software to take advantage of the various DMBS capabilities, such as various join algorithms.

With support for database links, the software pushes processing down from different datastores, which can also refer to the same or different database type. Linked datastores allow a one-way path for data. For example, if you import a database link from target database B and link datastore B to datastore A, the software pushes the load operation down to database B, not to database A.

This section contains the following topics:

- Software support
- Example of push-down with linked datastores
- Example of push-down with linked remote servers
- Generated SQL statements
- Tuning performance at the data flow or Job Server level

Related Information

Designer Guide: Datastores, Linked datastores [page 231]

6.5.5.1 Software support

SAP Data Services supports push-down operations using linked datastores on all Windows and UNIX platforms. It supports DB2, Oracle, MS SQL server, and SAP Sybase SQL Anywhere databases.

Data Services supports push-down operations using linked remote server on all Windows and UNIX platforms. It supports Sybase IQ target and source datastore and Sybase ASE source datastore.

6.5.5.2 To take advantage of linked datastores

1. Create a database link on a database server that you intend to use as a target in a job.

   The following database software is required. See the Supported Platforms document for specific version numbers.

   - For DB2, use the DB2 Information Services (previously known as Relational Connect) software and make sure that the database user has privileges to create and drop a nickname.
     To end users and client applications, data sources appear as a single collective database in DB2. Users and applications interface with the database managed by the information server. Therefore, configure an information server and then add the external data sources. DB2 uses nicknames to identify remote tables and views.
     See the DB2 database manuals for more information about how to create links for DB2 and non-DB2 servers.
   - For Oracle, use the Transparent Gateway for DB2 and MS SQL Server.
     See the Oracle database manuals for more information about how to create database links for Oracle and non-Oracle servers.
   - For MS SQL Server, no special software is required.
     Microsoft SQL Server supports access to distributed data stored in multiple instances of SQL Server and heterogeneous data stored in various relational and non-relational data sources using an OLE database provider. SQL Server supports access to distributed or heterogeneous database sources in Transact-SQL statements by qualifying the data sources with the names of the linked server where the data sources exist.

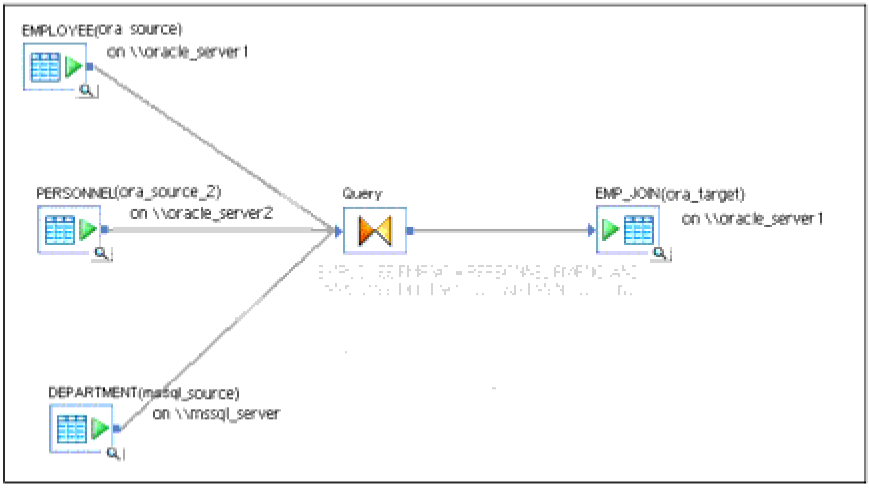
See the MS SQL Server database manuals for more information.

2. Create a database datastore connection to your target database.

6.5.5.2.1 Example of push-down with linked datastores

Linked datastores enable a full push-down operation (INSERT INTO... SELECT) to the target if all the sources are linked with the target. The sources and target can be in datastores that use the same database type or different database types.

The following diagram shows an example of a data flow that will take advantage of linked datastores:



The data flow joins three source tables from different database types:

- ora_source.HRUSER1.EMPLOYEE on \\oracle_server1
- ora_source_2.HRUSER2.PERSONNEL on \\oracle_server2
- mssql_source.DBO.DEPARTMENT on \\mssql_server3

The software loads the join result into the target table ora_target.HRUSER3.EMP_JOIN on \\oracle_server1.

In this data flow, the user (HRUSER3) created the following database links in the Oracle database oracle_server1.

Database Link Name	Local (to database link location) Connection Name	Remote (to database link location) Connection Name	Remote User
orasvr2	oracle_server1	oracle_server2	HRUSER2
tg4msql	oracle_server1	mssql_server	DBO

To enable a full push-down operation, database links must exist from the target database to all source databases and links must exist between the following datastores:

- ora_target and ora_source
- ora_target and ora_source2
- ora_target and mssql_source

The software executes this data flow query as one SQL statement in oracle_server1:

```
INSERT INTO HR_USER3.EMP_JOIN (FNAME, ENAME, DEPTNO, SAL, COMM)
SELECT psnl.FNAME, emp.ENAME, dept.DEPTNO, emp.SAL, emp.COMM
FROM HR_USER1.EMPLOYEE emp, HR_USER2.PERSONNEL@orasvr2 psnl,
oracle_server1.mssql_server.DBO.DEPARTMENT@tg4msql dept;
```

6.5.5.3 To take advantage of linked remote servers

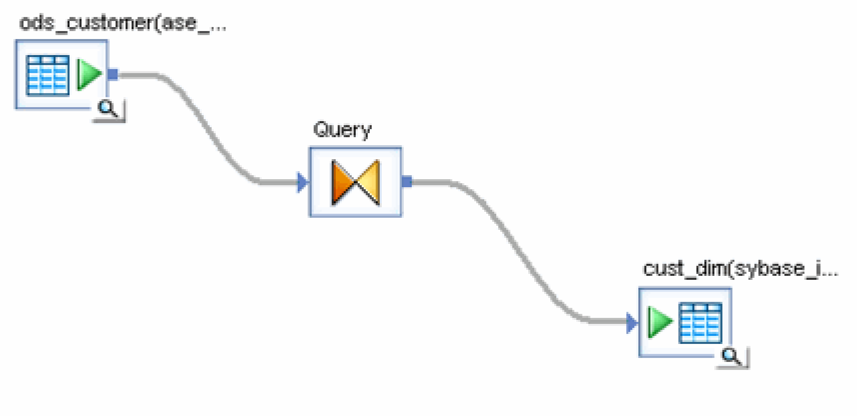
1. On the Sybase IQ server that you intend to use as a target for a job, create a remote server to the Sybase IQ or Sybase ASE server that you intend to use as a source for the job.
2. On the target server, create an external login to the same server that you configured the remote server for.
3. Refer to the Sybase documentation to set up the connectivity between the two servers that you want to communicate with.
4. Create a datastore connection to the target database and source database using the same server that you used to create the remote server.

Linked datastores enable a full push-down operation (INSERT INTO... SELECT) to a target if all of the sources are linked with the target. The sources and target can be in datastores that use the same database type or different database types.

6.5.5.3.1 Example of push-down with linked remote servers

Linked remote servers enable a full push-down operation (INSERT...LOCATION) to the target if all the target servers have remote links to the respective source server. Sources can be in Sybase IQ or Sybase ASE datastores and targets can be in Sybase IQ datastores.

The following diagram shows an example of a data flow that will take advantage of linked datastores. The source is a Sybase ASE datastore and the target is a Sybase IQ datastore with a remote server connection to Sybase ASE **<ase_remote>**.



The data flow selects data from a customer table and loads it to the cust_dim table using the INSERT...LOCATION SQL statement.

In this data flow, the user created a remote server link to the source table server Sybase_ase using the CREATE SERVER SQL statement in Sybase IQ. The user then configured a remote login for the server using the CREATE EXTERNLOGIN SQL statement. The remote login server name in the example is **`<ase_remote>`**.

The software executes the data flow query as one SQL statement in Sybase IQ:

```
INSERT INTO "DBA"."cust_dim" ( "Cust_ID" , "Cust_classf" , "Name1" , "Address" ,
"City" , "Region_ID" , "Zip" )
LOCATION 'ase_remote.cms57u05' PACKETSIZE 512 QUOTED IDENTIFIER ON ' SELECT
"ods_customer"."Cust_ID" , "ods_customer"."Cust_classf" , "ods_customer"."Name1" ,
"ods_customer"."Address" , "ods_customer"."City" , "ods_customer"."Region_ID" ,
"ods_customer"."Zip"
FROM "X9999"."ods_customer" "ods_customer"
```

6.5.5.4 Generated SQL statements

To see how SAP Data Services optimizes SQL statements, use *Display Optimized SQL* from the *Validation* menu when a data flow is open in the workspace.

- For DB2, it uses nicknames to refer to remote table references in the SQL display.
- For Oracle, it uses the following syntax to refer to remote table references: `<remote_table>@<dblink_name>`.
- For SQL Server, it uses the following syntax to refer to remote table references: `<linked_server>.<remote_database>.<remote_user>.<remote_table>`.

6.5.5.5 Tuning performance at the data flow or Job Server level

You might want to turn off linked-datastore push downs in cases where you do not notice performance improvements.

For example, the underlying database might not process operations from different data sources well. Data Services pushes down Oracle stored procedures and external functions. If these are in a job that uses database links, it will not impact expected performance gains. However, Data Services does not push down functions imported from other databases (such as DB2). In this case, although you may be using database links, Data Services cannot push the processing down.

Test your assumptions about individual job designs before committing to a large development effort using database links.

6.5.5.5.1 For a data flow

On the data flow properties dialog, this product enables the *Use database links* option by default to allow push-down operations using linked datastores. If you do not want to use linked datastores in a data flow to push down processing, deselect the check box.

This product can perform push downs using datastore links if the tables involved share the same database type and database connection name, or datasource name, even if the tables have different schema names. However, problems with enabling this feature could arise, for example, if the user of one datastore does not have access privileges to the tables of another datastore, causing a data access problem. In such a case, you can disable this feature.

6.5.5.5.2 For a Job Server

You can also disable linked datastores at the Job Server level. However, the *Use database links* option, at the data flow level, takes precedence.

Related Information

Designer Guide: Executing Jobs, Changing Job Server options [page 428]

6.6 Using Caches

6.6.1 Caching data

You can improve the performance of data transformations that occur in memory by caching as much data as possible. By caching data, you limit the number of times the system must access the database.

SAP Data Services provides the following types of caches that your data flow can use for all of the operations it contains:

- In-memory
  Use in-memory cache when your data flow processes a small amount of data that fits in memory.
- Pageable cache
  Use pageable cache when your data flow processes a very large amount of data that does not fit in memory. When memory-intensive operations (such as Group By and Order By) exceed available memory, the software uses pageable cache to complete the operation.

Pageable cache is the default cache type. To change the cache type, use the *Cache type* option on the data flow Properties window.

Note

If your data fits in memory, it is recommended that you use in-memory cache because pageable cache incurs an overhead cost.

6.6.1.1 Caching sources

By default, the *Cache* option is set to `Yes` in a source table or file editor to specify that data from the source is cached using memory on the Job Server computer. When sources are joined using the Query transform, the cache setting in the Query transform takes precedence over the setting in the source.

The default value for *Cache type* for data flows is `Pageable`.

It is recommended that you cache small tables in memory. Calculate the approximate size of a table with the following formula to determine if you should use a cache type of `Pageable` or `In-memory`.

```
table size = (in bytes)    # of rows *
                               # of columns *
                               20 bytes (average column size) *
                               1.3 (30% overhead)
```

Compute row count and table size on a regular basis, especially when:

- You are aware that a table has significantly changed in size.
- You experience decreased system performance.

If the table fits in memory, change the value of the *Cache type* option to `In-memory` in the Properties window of the data flow.

Related Information

Caching joins [page 2130]

6.6.1.2 Caching joins

The Cache setting indicates whether the software should read the required data from the source and load it into memory or pageable cache.

When sources are joined using the Query transform, the cache setting in the Query transform takes precedence over the setting in the source. In the Query editor, the cache setting is set to Automatic by default. The automatic setting carries forward the setting from the source table. The following table shows the relationship between cache settings in the source, Query editor, and whether the software will load the data in the source table into cache.

Cache Setting in Source	Cache Setting in Query Editor	Effective Cache Setting
Yes	Automatic	Yes
No	Automatic	No
Yes	Yes	Yes
No	Yes	Yes

Cache Setting in Source	Cache Setting in Query Editor	Effective Cache Setting
Yes	No	No
No	No	No

ℹ Note

If any one input schema has a cache setting other than Automatic specified in the Query editor, the Data Services Optimizer considers only Query editor cache settings and ignores all source editor cache settings.

ℹ Note

Best practice is to define the join rank and cache settings in the Query editor.

In the Query editor, cache a source only if it is being used as an inner source in a join.

When the cache setting is such that data will be cached if possible, a source is used as an inner source in a join under the following conditions:

- The source is specified as the inner source of a left outer join.
- In an inner join between two tables, the source has a lower join rank.

Caching does not affect the order in which tables are joined.

If optimization conditions are such that the software is pushing down operations to the underlying database, it ignores your cache setting.

If a table becomes too large to fit in the cache, ensure that the cache type is pageable.

Related Information

About join ordering [page 2201]

6.6.1.3 Changing cache type for a data flow

You can improve the performance of data transformations that occur in memory by caching as much data as possible. By caching data, you limit the number of times the system must access the database.

To change the cache type for a data flow:

1. In the object library, select the data flow name.
2. Right-click and choose *Properties*.
3. On the *General* tab of the *Properties* window, select the desired cache type in the drop-down list for the *Cache type* option.

6.6.1.4 Caching lookups

You can also improve performance by caching data when looking up individual values from tables and files.

6.6.1.4.1 Using a Lookup function in a query

SAP Data Services has three Lookup functions: `lookup`, `lookup_seq`, and `lookup_ext`. The `lookup` and `lookup_ext` functions have cache options. Caching lookup sources improves performance because the software avoids the expensive task of creating a database query or full file scan on each row.

You can set cache options when you specify a lookup function. There are three caching options:

Option	Description
NO_CACHE	Does not cache any values.
PRE_LOAD_CACHE	Preloads the result column and compare column into memory (it loads the values before executing the lookup).
DEMAND_LOAD_CACHE	Loads the result column and compare column into memory as the function executes. Use this option when looking up highly repetitive values that are a small subset of the data and when missing values are unlikely. Demand-load caching of lookup values is helpful when the lookup result is the same value multiple times. Each time the software cannot find the value in the cache, it must make a new request to the database for that value. Even if the value is invalid, the software has no way of knowing if it is missing or just has not been cached yet. When there are many values and some values might be missing, demand-load caching is significantly less efficient than caching the entire source.

6.6.1.4.2 Using a source table and setting it as the outer join

Although you can use lookup functions inside SAP Data Services queries, an alternative is to expose the translate (lookup) table as a source table in the data flow diagram, and use an outer join (if necessary) in the query to look up the required data. This technique has some advantages:

- You can graphically see the table the job will search on the diagram, making the data flow easier to maintain.
- The software can push the execution of the join down to the underlying RDBMS (even if you need an outer join).

This technique also has some disadvantages:

- You cannot specify default values in an outer join (default is always null), but you can specify a default value in lookup_ext.
- If an outer join returns multiple rows, you cannot specify what to return, (you can specify MIN or MAX in lookup_ext).

- The workspace can become cluttered if there are too many objects in the data flow.
- There is no option to use DEMAND_LOAD caching, which is useful when looking up only a few repetitive values in a very large table.

> ➜ Tip
>
> If you use the lookup table in multiple jobs, you can create a persistent cache that multiple data flows can access. For more information, see *Using persistent cache* [page 2134].

6.6.1.5 Caching table comparisons

You can improve the performance of a Table_Comparison transform by caching the comparison table. There are three modes of comparisons:

- Row-by-row select
- Cached comparison table
- Sorted input

Of the three, *Row-by-row select* will likely be the slowest and *Sorted input* the fastest.

> ➜ Tip
>
> If you want to sort the input to the table comparison transform, then choose the *Sorted input* option for comparison.

> ➜ Tip
>
> If the input is not sorted, then choose the *Cached comparison table* option.

6.6.1.6 Specifying a pageable cache directory

If the memory-consuming operations in your data flow exceed the available memory, SAP Data Services uses pageable cache to complete the operation. Memory-intensive operations include the following operations:

- Distinct
- Functions such as count_distinct and lookup_ext
- Group By
- Hierarchy_Flattening
- Order By

> i Note
>
> The default pageable cache directory is %LINKDIR\Log\PCache. If your data flows contain memory-consuming operations, change this value to a pageable cache directory that:

- Contains enough disk space for the amount of data you plan to profile.
- Is on a separate disk or file system from the SAP Data Services system.

Change the directory in the *Specify a directory with enough disk space for pageable cache* option in the Server Manager, under Runtime resources configured for this computer.

6.6.2 Using persistent cache

Persistent cache datastores provide the following benefits for data flows that process large volumes of data.

- You can store a large amount of data in persistent cache which SAP Data Services quickly pages into memory each time the job executes. For example, you can access a lookup table or comparison table locally (instead of reading from a remote database).
- You can create cache tables that multiple data flows can share (unlike a memory table which cannot be shared between different real-time jobs). For example, if a large lookup table used in a lookup_ext function rarely changes, you can create a cache once and subsequent jobs can use this cache instead of creating it each time.

Persistent cache tables can cache data from relational database tables and files.

> i Note
>
> You cannot cache data from hierarchical data files such as XML messages and SAP IDocs (both of which contain nested schemas). You cannot perform incremental inserts, deletes, or updates on a persistent cache table.

You create a persistent cache table by loading data into the persistent cache target table using one data flow. You can then subsequently read from the cache table in another data flow. When you load data into a persistent cache table, SAP Data Services always truncates and recreates the table.

6.6.2.1 Using persistent cache tables as sources

After you create a persistent cache table as a target in one data flow, you can use the persistent cache table as a source in any data flow. You can also use it as a lookup table or comparison table.

6.6.3 Monitoring and tuning caches

This section describes the following topics:

Related Information

Using statistics for cache self-tuning [page 2135]
To monitor and tune in-memory and pageable caches [page 2135]

6.6.3.1 Using statistics for cache self-tuning

SAP Data Services uses cache statistics collected from previous job runs to automatically determine which cache type to use for a data flow. Cache statistics include the number of rows processed.

The default cache type is pageable. The software can switch to in-memory cache when it determines that your data flow processes a small amount of data that fits in memory.

6.6.3.1.1 Choosing the cache type automatically

1. Run your job with options *Collect statistics for optimization*.
2. Run your job again with option *Use collected statistics* (this option is selected by default).

6.6.3.2 To monitor and tune in-memory and pageable caches

You can also monitor and choose the cache type to use for the data flow.

1. Test run your job with options *Collect statistics for optimization* and *Collect statistics for monitoring*.

   > Note
   >
   > The option *Collect statistics for monitoring* is costly to run because it determines the cache size for each row processed.

2. Run your job again with option *Use collected statistics* (this option is selected by default).
3. Look in the Trace Log to determine which cache type was used.
   - The first time you run the job or if you have not previously collected statistics, the following messages indicate that cache statistics are not available and the sub data flows use the default cache type, pageable.

     ```
     Cache statistics for sub data flow <GroupBy_DF_1_1> are not available to be
     used for optimization and need to be collected before they can be used.
     ```

     ```
     Sub data flow <GroupBy_DF_1_1> using PAGEABLE Cache with <1280 MB> buffer
     pool.
     ```

   - You might see the following message that indicates that the software is switching to In-memory cache:

     ```
     Cache statistics determined that sub data flow <GroupBy_DOP2_DF_1_4> uses <1>
     caches with a total size of <1920> bytes. This is less than (or equal to) the
     ```

```
virtual memory <1342177280> bytes available for caches. Statistics is
switching the cache type to IN MEMORY.
```

```
Sub data flow <GroupBy_DOP2_DF_1_4> using IN MEMORY Cache.
```

Because pageable cache is the default cache type for a data flow, you might want to permanently change the *Cache type* to In-Memory in the data flow *Properties* window.

- You might see the following messages that indicate on sub data flow uses IN MEMORY cache and the other sub data flow uses PAGEABLE cache:

```
Sub data flow <Orders_Group_DF_1> using IN MEMORY Cache.
```

```
...
```

```
Sub data flow <Orders_Group_DF_2> using PAGEABLE Cache with <1536 MB> buffer
pool.
```

4. Look in the Administrator Performance Monitor to view data flow statistics and see the cache size.
   a) On the Administrator, select ▶ *Batch* > **<repository name>** ◀.
   b) On the Batch Job Status page, find a job execution instance.
   c) Under *Job Information* for an instance, click *Performance Monitor*. The Administrator opens the Table tab of the Performance Monitor page. This tab shows a tabular view of the start time, stop time, and execution time for each work flow, data flow, and sub data flow within the job.
   d) To display statistics for each object within a data flow or sub data flow, click one of the data flow names on the Table tab. The Transform tab displays the following statistics.

Statistic	Description
Name	Name that you gave the object (source, transform, or target) in the Designer.
Type	Type of object within the data flow. Possible values include Source, Mapping, Target.
Start time	Date and time this object instance started execution.
End time	Date and time this object instance stopped execution.
Execution time (sec)	Time (in seconds) the object took to complete execution.
Row Count	Number of rows that this object processed.
Cache Size (KB)	Size (in kilobytes) of the cache that was used to process this object. Note This statistics displays only if you selected *Collect statistics for monitoring* for the job execution.

5. If the value in Cache Size is approaching the physical memory limit on the job server, consider changing the *Cache type* of a data flow from *In-memory* to *Pageable*.

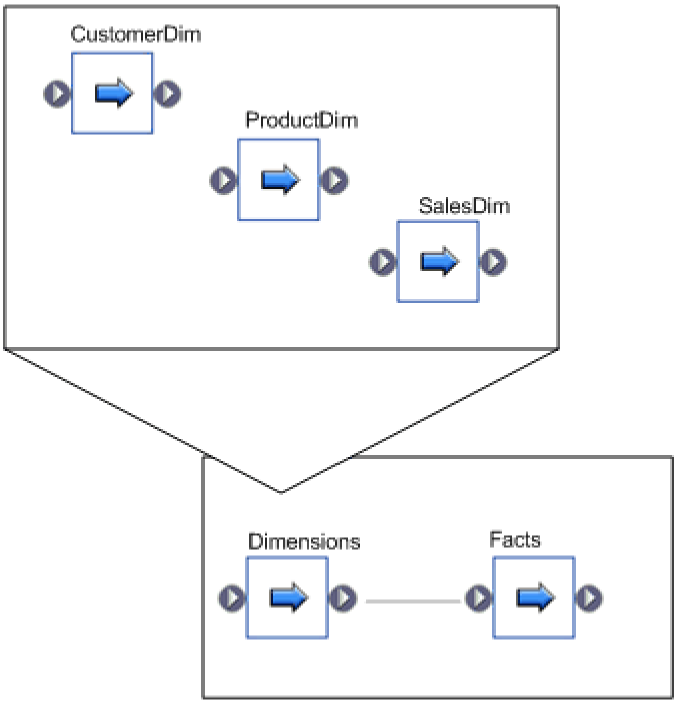
6.7 Using Parallel Execution

You can set SAP Data Services to perform data extraction, transformation, and loads in parallel by setting parallel options for sources, transforms, and targets. In addition, you can set individual data flows and work flows to run in parallel by simply not connecting them in the workspace. If the Job Server is running on a multi-processor computer, it takes full advantage of available CPUs.

6.7.1 Parallel data flows and work flows

You can explicitly execute different data flows and work flows in parallel by not connecting them in a work flow or job. SAP Data Services coordinates the parallel steps, then waits for all steps to complete before starting the next sequential step.

For example, use parallel processing to load dimension tables by calling work flows in parallel. Then specify that your job creates dimension tables before the fact table by moving it to the left of a second (parent) work flow and connecting the flows.



Parallel engine processes execute the parallel data flow processes. Note that if you have more than eight CPUs on your Job Server computer, you can increase *Maximum number of engine processes* to improve performance. To change the maximum number of parallel engine processes, use the Job Server options (*Tools* > *Options> Job Server* > *Environment*).

6.7.2 Parallel execution in data flows

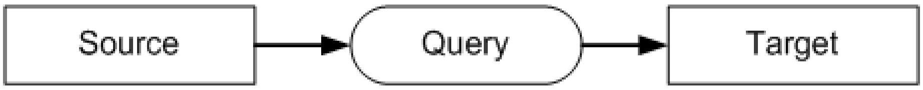
For batch jobs, SAP Data Services allows you to execute parallel threads in data flows.

6.7.2.1 Table partitioning

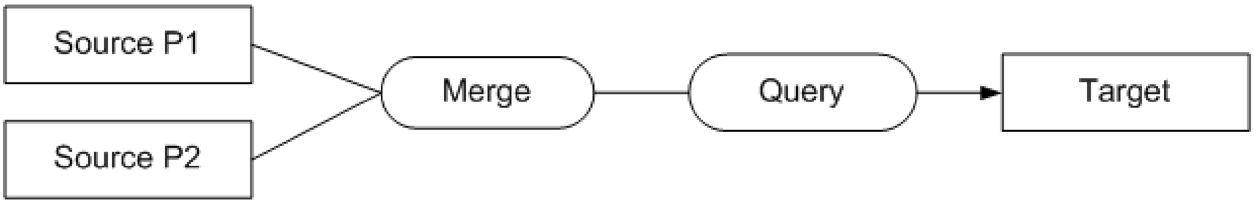
SAP Data Services processes data flows with partitioned tables based on the amount of partitioning defined.

6.7.2.1.1 Data flow with source partitions only

If you have a data flow with a source that has two partitions connected to a query and a target, it appears in the workspace as shown in the following diagram:



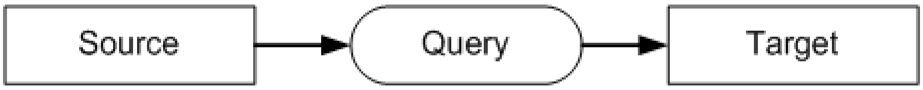
At runtime, the software translates this data flow to:



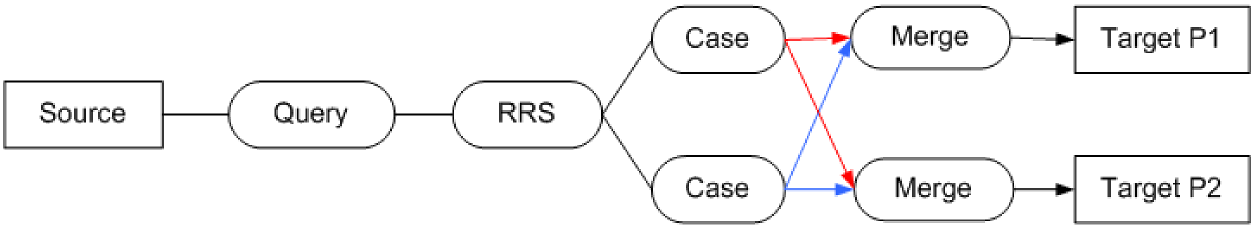
The software instantiates a source thread for each partition, and these threads run in parallel. The data from these threads later merges into a single stream by an internal merge transform before processing the query.

6.7.2.1.2 Data flow with target partitions only

If you have a data flow with a target that has two partitions connected to a query and a source, it appears in the workspace as shown in the following diagram:



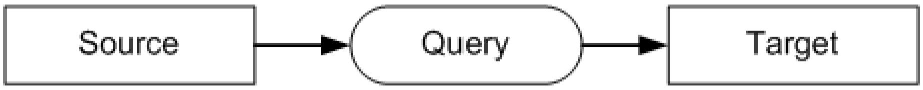
At runtime, the software translates this data flow to:



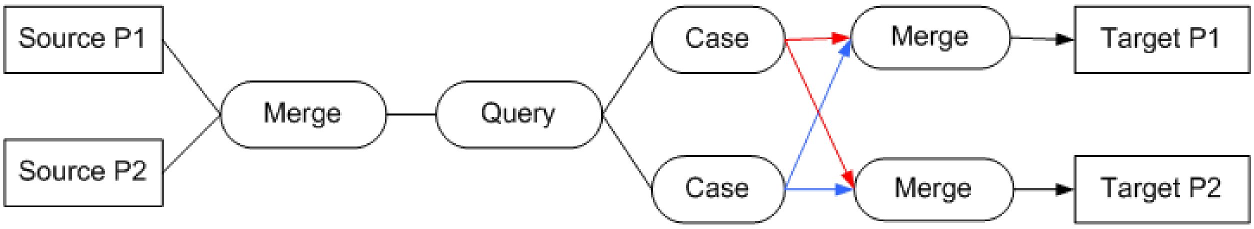
The software inserts an internal Round Robin Split (RRS) transform after the Query transform, which routes incoming rows in a round-robin fashion to internal Case transforms. The Case transforms evaluate the rows to determine the partition ranges. Finally, an internal Merge transform collects the incoming rows from different Case transforms and outputs a single stream of rows to the target threads. The Case transforms, Merge transform, and target threads execute in parallel.

6.7.2.1.3 data flow with source and target partitions

If you have a data flow with a source that has two partitions connected to a query and a target that has two partitions, it appears in the workspace as shown in the following diagram:



At runtime, the software translates this data flow to:



The source threads execute in parallel and the Case transforms, Merge transforms, and targets execute in parallel.

6.7.2.1.4 Viewing, creating, and enabling table partitions

Oracle databases support range, list, and hash partitioning. You can import this information as table metadata and use it to extract data in parallel. You can use range and list partitions to load data to Oracle targets. You can also specify logical range and list partitions using SAP Data Services metadata for Oracle tables.

In addition, it provides the ability to specify logical range and list partitions for DB2, Microsoft SQL Server, SAP R/3, SAP Sybase ASE, and SAP Sybase IQ tables by modifying imported table metadata.

SAP Data Services uses partition information by instantiating a thread at runtime for each partition. These threads execute in parallel. To maximize performance benefits, use a multi-processor environment.

6.7.2.1.4.1 Viewing partition information

1. Import a table into SAP Data Services.
2. In the *Datastores* tab of the object library, right-click the table name and select *Properties*.
3. Click the *Partitions* tab.

When you import partitioned tables from your database, you will find these partitions displayed on the Partitions tab of the table's Properties window. The partition name appears in the first column. The columns that are used for partitioning appear as column headings in the second row.

If you import a table that does not have partitions, you can create logical partitions using the Partitions tab of the table's Properties window.

6.7.2.1.4.2 Creating or editing table partition information

1. In the *Datastores* tab of the object library, right-click the table name and select *Properties*.
2. In the Properties window, click the *Partitions* tab.
3. Select a partition type.

Partition Type	Description
None	This table is not partitioned.
Range	Each partition contains a set of rows with column values less than those specified. For example, if the value of column one is `100,000`, then the data set for partition one will include rows with values less than `100,000` in column one.
List	Each partition contains a set of rows that contain the specified column values.

> **Note**
>
> If you imported an Oracle table with hash partitions, you cannot edit the hash settings in SAP Data Services. The Partitions tab displays the hash partition name and ID as read-only information. However, you can change the partition type to Range or List to create logical range or list partitions for an Oracle table imported with hash partitions.

4. Add, insert, or remove partitions and columns using the tool bar. (See the table at the end of this procedure.)
5. Select the name of a column from each column list box.
6. Enter column values for each partition.

   SAP Data Services validates the column values entered for each partition according to the following rules:

   - Values can be literal numbers and strings or datetime types.
   - Column values must match column data types.
   - Literal strings must include single quotes: `'Director'`.
   - For range partitions, the values for a partition must be greater than the values for the previous partition.
   - For the last partition, you can enter the value `MAXVALUE` to include all values.
7. Click *OK*.

   If the validation rules described in the previous step are not met, you will see an error message.

Icon	Description
	Add Partition
	Insert Partition
	Remove Partition
	Add Column
	Insert Column
	Remove Column

The number of partitions in a table equals the maximum number of parallel instances that the software can process for a source or target created from this table.

In addition to importing partitions or creating and editing partition metadata, enable the partition settings when you configure sources and targets.

6.7.2.1.4.3 Enabling partition settings in a source or target table

1. Drop a table into a data flow and select *Make Source* or *Make Target*.
2. Click the name of the table to open the source or target table editor.
3. Enable partitioning for the source or target:
   a) For a source table, click the *Enable Partitioning* check box.
   b) For a target table, click the *Options* tab, then click the *Enable Partitioning* check box.
4. Click *OK*.

   When the job executes, the softwarre generates parallel instances based on the partition information.

   > i Note
   >
   > If you are loading to partitioned tables, a job will execute the load in parallel according to the number of partitions in the table. If you set *Enable Partitioning* to Yes and *Include in transaction* to No, the *Include in transaction* setting overrides the *Enable Partitioning* option. For example, if your job is designed to load to a partitioned table but you set *Include in transaction* to Yes and enter a value for *Transaction order*, when the job executes, the software will include the table in a transaction load and does not parallel load to the partitioned table.

6.7.2.1.4.4 Tip

If the underlying database does not support range partitioning and if you are aware of a natural distribution of ranges, for example using an Employee Key column in an Employee table, then you can edit the imported table metadata and define table ranges. The software would then instantiate multiple reader threads, one for each defined range, and execute them in parallel to extract the data.

> **Note**
>
> Table metadata editing for partitioning is designed for source tables. If you use a partitioned table as a target, the physical table partitions in the database must match the metadata table partitions in SAP Data Services. If there is a mismatch, the software will not use the partition name to load partitions. Consequently, the whole table updates.

6.7.2.2 Degree of parallelism

T degree of parallelism (DOP) is a property of a data flow that defines how many times each transform defined in the data flow replicates for use on a parallel subset of data. If there are multiple transforms in a data flow, SAP Data Services chains them together until it reaches a merge point.

You can run transforms in parallel by entering a number in the *Degree of Parallelism* option on a data flow's Properties window. The number is used to replicate transforms in the data flow which run as separate threads when the Job Server processes the data flow.

6.7.2.2.1 Degree of parallelism and transforms

The Query transform always replicates when you set the DOP to a value greater than 1. SAP Data Services also replicates query operations such as Order By, Group By, join, and functions such as lookup_ext.

The Table Comparison replicates when you use the Row-by-row select and Cached comparison table comparison methods.

- Map_Operation
- History_Preserving
- Pivot

There are two basic scenarios:

- DOP and a data flow with a single transform
- DOP and a data flow with multiple transforms

DOP and a data flow with a single transform

The following figures show runtime instances of a data flow with a DOP of 1, and the same data flow with a DOP of 2.

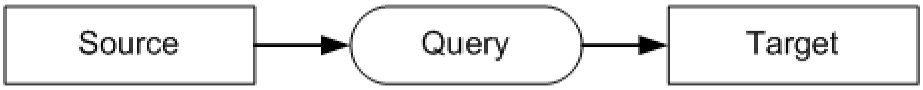


Figure 1: Runtime instance of a data flow where DOP =1

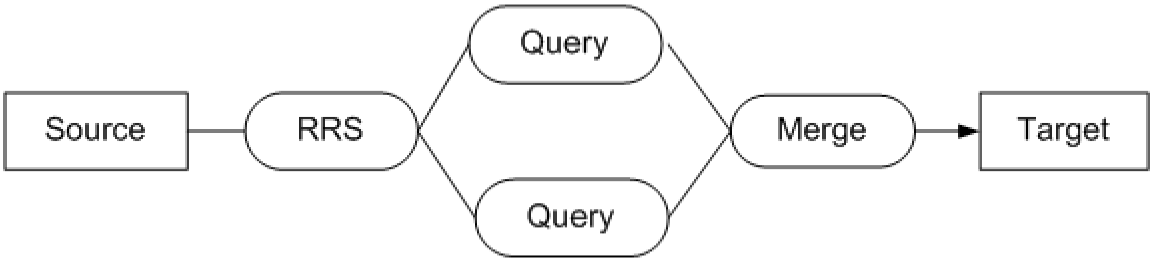

Figure 2: Runtime instance of a data flow where DOP = 2

With a DOP greater than 1, the software inserts an internal Round Robin Split (RRS) that transfers data to each of the replicated queries. The replicated queries execute in parallel, and the results merge into a single stream by an internal Merge transform.

DOP and a data flow with multiple transforms

The following figures show runtime instances of a data flow with a DOP of 1, and the same data flow with a DOP of 2. Notice multiple transforms in a data flow replicate and chain when the DOP is greater than 1.

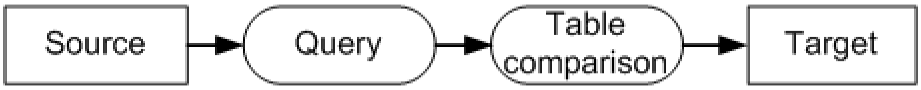

Figure 3: Runtime instance of a data flow where DOP =1

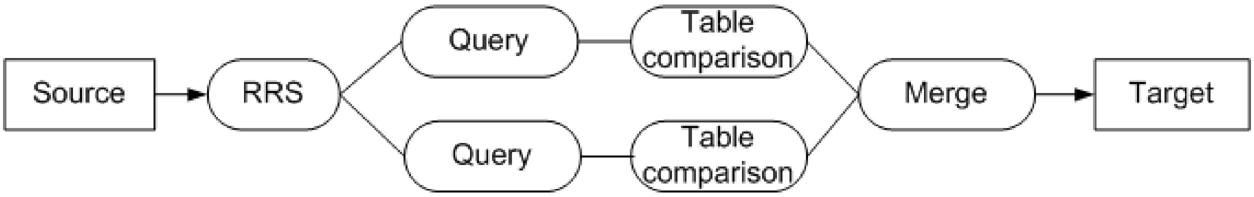

Figure 4: Runtime instance of a data flow where DOP = 2

When there are multiple transforms in a data flow and the DOP is greater than 1, the software carries the replicated stream as far as possible, then merges the data into a single stream.

6.7.2.2.2 To set the degree of parallelism for a data flow

The degree of parallelism (DOP) is a data flow property that acts on transforms added to the data flow.

1. In the object library, select the Data Flow tab.
2. Right-click the data flow icon and select *Properties*.

3. Enter a number in the *Degree of parallelism* option.

   The default value for degree of parallelism is 0. If you set an individual data flow's degree of parallelism to this default value, then you can control it using a Global_DOP value which affects all data flows run by a given Job Server. If you use any other value for a data flow's degree of parallelism, it overrides the Global_DOP value.

   You can use the local and global DOP options in different ways. For example:

   - If you want to globally set all data flow DOP values to 4, but one data flow is too complex and you do not want it to run in parallel, you can set the *Degree of parallelism* for this data flow locally. From the data flow's Properties window, set this data flow's *Degree of parallelism* to 1. All other data flows will replicate and run transforms in parallel after you set the Global_DOP value to 4. The default for the Global_DOP value is 2.
   - If you want to set the DOP on a case-by-case basis for each data flow, set the value for each data flow's *Degree of parallelism* to any value except zero.

   You set the Global_DOP value in the Job Server options.
4. Click *OK*.

Related Information

Designer Guide: Executing Jobs, Changing Job Server options [page 428]

6.7.2.2.3 Degree of parallelism and joins

If your Query transform joins sources, DOP determines the number of times the join replicates to process a parallel subset of data.

This section describes two scenarios:

- DOP and executing a join as a single process
- DOP and executing a join as multiple processes

DOP and executing a join as a single process

The following figures show runtime instances of a data flow that contains a join with a DOP of 1 and the same data flow with a DOP of 2. You use join ranks to define the outer source and inner source. In both data flows, the inner source is cached in memory.

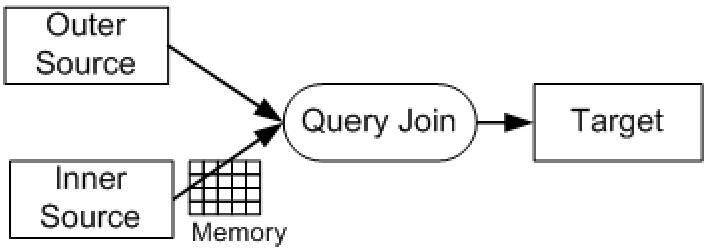

Figure 5: Runtime instance of a join where DOP =1

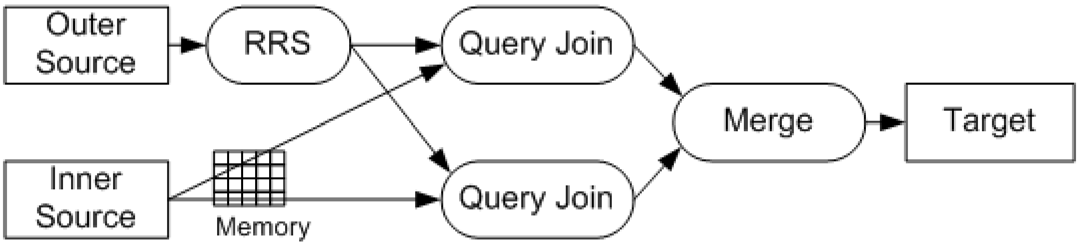

Figure 6: Runtime instance of a join where DOP = 2

With a DOP greater than one, the software inserts an internal Round Robin Split (RRS) that transfers data to each of the replicated joins. The inner source is cached once, and each half of the outer source joins with the cached data in the replicated joins. The replicated joins execute in parallel, and the results merge into a single stream by an internal Merge transform.

DOP and executing a join as multiple processes

When you select the *Run JOIN as a separate process* in the Query transform, you can split the execution of a join among multiple processes. the software creates a sub data flow for each separate process.

The following figure shows a runtime instance of a data flow that contains a join with a DOP of 2 and the *Run JOIN as a separate process* option selected.

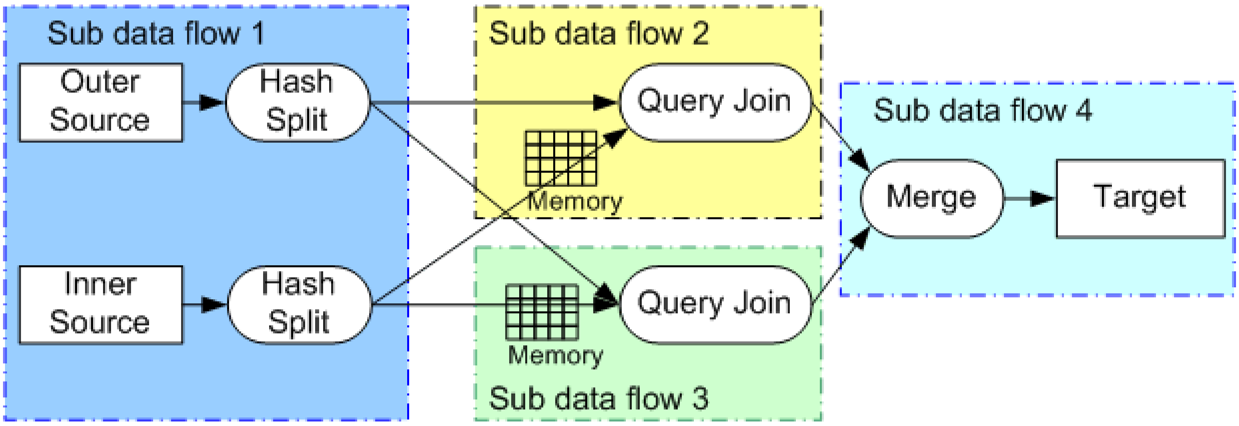

Figure 7: Runtime instance of a join that runs as multiple processes and DOP = 2

The data flow becomes four sub data flows (indicated by the blue dotted and dashed line in the figure):

- The first sub data flow uses an internal hash algorithm to split the data.
- The next two sub data flows are the replicated joins that run as separate processes.
- The last sub data flow merges the data and loads the target.

> ➔ Tip
>
> If DOP is greater than one, select either *job* or *data flow* for the *Distribution level* option when you execute the job. If you execute the job with the value *sub data flow* for *Distribution level*, the Hash Split sends data to the replicated queries that might be executing on different Job Servers. Because the data is sent on the network between different Job Servers, the entire data flow might be slower.

Related Information

About join ordering [page 2201]
Caching joins [page 2130]
Using grid computing to distribute data flow execution [page 2160]

6.7.2.2.4 Degree of parallelism and functions

You can set stored procedures and custom functions to replicate with the transforms in which they are used. To specify this option, select the *Enable parallel execution* check box on the function's Properties window. If this option is not selected and you add the function to a transform, the transform will not replicate and run in parallel even if its parent data flow has a *Degree of parallelism* value greater than `1`.

When enabling functions to run in parallel, verify that:

- Your database will allow a stored procedure to run in parallel.
- A custom function set to run in parallel will improve performance.

All built-in functions, except the following, replicate if the transform they are used in replicates due to the DOP value:

• `avg()`	• `min()`
• `count()`	• `previous_row_value()`
• `count_distinct()`	• `print()`
• `double_metaphone()`	• `raise_exception()`
• `exec()`	• `raise_exception_ext()`
• `get_domain_description()`	• `set_env()`
• `gen_row_num()`	• `sleep()`

- `gen_row_num_by_group()`	- `smtp_to()`
- `is_group_changed()`	- `soundex()`
- `key_generation()`	- `sql()`
- `mail_to()`	- `sum()`
- `max()`	- `total_rows()`

6.7.2.2.5 Enable stored procedures to run in parallel

Use the *Enable parallel execution* option to set functions to run in parallel when the transforms in which they are used execute in parallel.

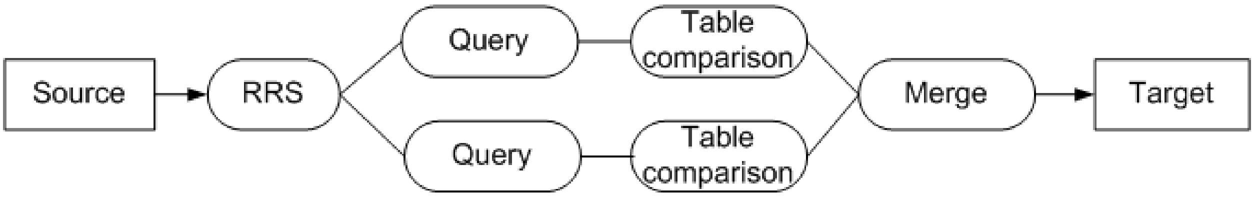
1. In the *Datastores* tab of the object library, expand a *Datastore* node.
2. Expand its *Function* node.
3. Right-click a function and select *Properties*.
4. In the Properties window, click the *Function* tab.
5. Click the *Enable Parallel Execution* check box.
6. Click *OK*.

6.7.2.2.5.1 To enable custom functions to run in parallel

1. In the *Custom Functions* tab of the object library, right-click a function name and select *Properties*.
2. In the Properties window, click the *Function* tab.
3. Click the *Enable Parallel Execution* check box.
4. Click *OK*.

6.7.2.2.6 Tips

DOP can degrade performance if you do not use it judiciously. The best value to choose depends on the complexity of the flow and number of CPUs available. For example, on a computer with four CPUs, setting a DOP greater than two for the following data flow will not improve performance but can potentially degrade it due to thread contention.



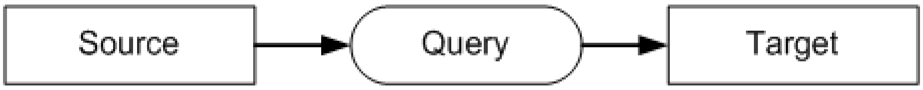
If your data flow contains an Order By or a Group By that is not pushed down to the database, put them at the end of a data flow. A sort node (Order By, Group By) is always a merge point, after which the engine proceeds as if the DOP value is 1.

Related Information

To view SQL [page 2121]

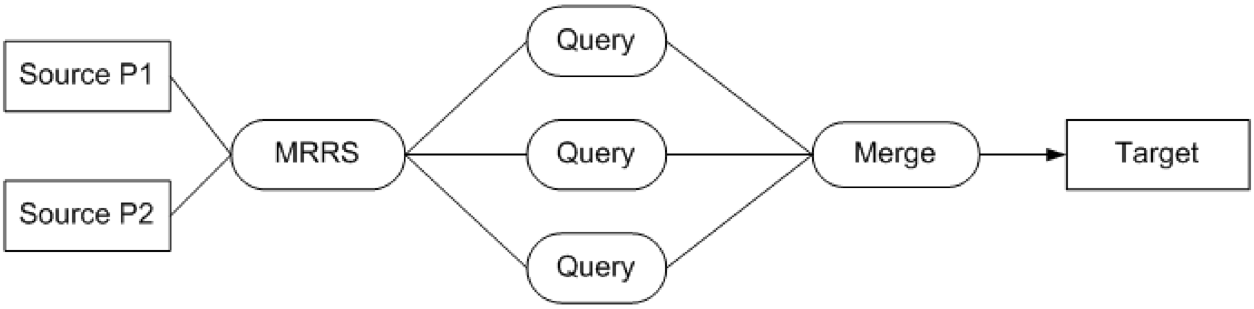
6.7.2.3 Combining table partitioning and a degree of parallelism

Different settings for source and target partitions and the degree of parallelism result in different behaviors in the SAP Data Services engine. The sections that follow show some examples. For all the following scenarios, the data flow appears as follows:



6.7.2.3.1 Two source partitions and a DOP of three

When a source has two partitions, it replicates twice. The input feeds into a merge-round-robin splitter (MRRS) that merges the input streams and splits them into a number equal to the value for DOP (in this case, three outputs to the query transform). The stream then merges and feeds into the target.

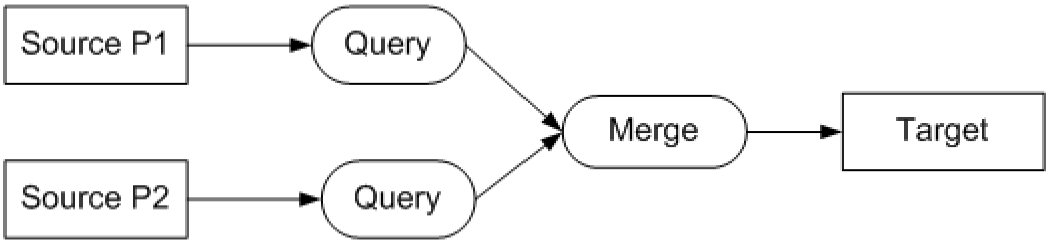


Tip

If the target is not partitioned, set the *Number of loaders* option equal to the DOP value. Depending on the number of CPUs available, set the DOP value equal to the number of source partitions as a general rule. This produces a data flow without the Merge Round Robin Split and each partition pipes the data directly into the consuming transform.

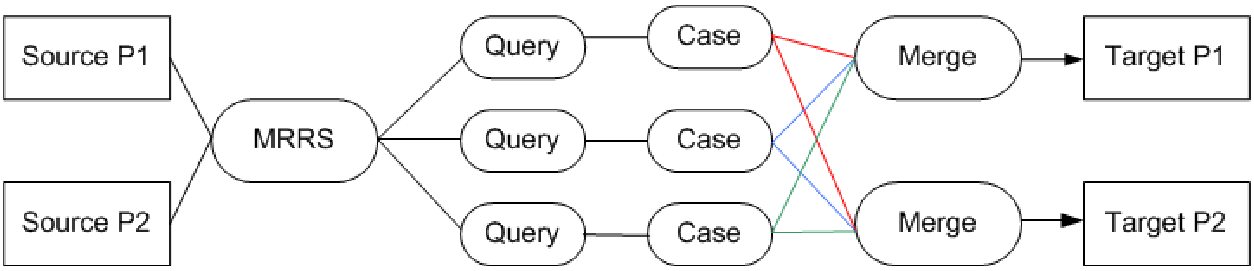
6.7.2.3.2 Two source partitions and a DOP of two

When the number of source partitions is the same as the value for DOP, the engine merges before the target (or before any operation that requires a merge, such as aggregation operations) and proceeds in a single stream to complete the flow.



6.7.2.3.3 Two source partitions, DOP of three, two target partitions

When the number of source partitions is less then the value for DOP, the input feeds into a merge-round-robin splitter (MRRS) that merges the input streams and splits them into a number equal to the value for DOP. The engine then merges the data before the target to equal the number of target partitions, then proceeds to complete the flow.



➜ Tip

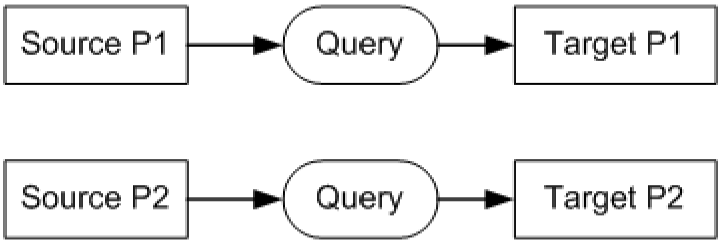
If the number of target partitions is not equal to the number of source partitions, set the *Number of loaders* option equal to the DOP value and do not enable partitioning for the target. Depending on the number of CPUs available, set the DOP value equal to the number of source partitions as a general rule. This produces a data flow without the Merge Round Robin Split and each partition pipes the data directly into the consuming transform.

6.7.2.3.4 Two source partitions, DOP of two, and two target partitions

The best case situation is when the following conditions exist:

- The source and target are partitioned the same way.
- The source and target have the same number of partitions.
- DOP is equal to the same number of partitions.

When a source has two partitions, it replicates twice. Because the DOP value is two, the Query transform replicates twice. When a target has two partitions, it replicates twice. The following figure shows that each source partition feeds directly into a replicated Query transform, and the output from each query feeds directly into a replicated target.



6.7.2.4 File multi-threading

You can set the number of threads used to process some sources and targets. The *Parallel process threads* option is available on the:

- File format editor
- Source file editor
- Target file editor
- Properties window of an ABAP data flow

Without multi-threading:

- With delimited file reading, the SAP Data Services reads a block of data from the file system and then scans each character to determine if it is a column delimiter, a row delimiter, or a text delimiter. Then it builds a row using an internal format.
- For positional file reading, the software does not scan character by character, but it still builds a row using an internal format.
- For file loading, processing involves building a character-based row from the internal row format.

You can set these time-consuming operations to run in parallel. You can use the *Parallel process threads* option to specify how many threads to execute in parallel to process the I/O blocks.

Note

Enabling CPU hyperthreading can negatively affect the performance of servers and is therefore not supported.

Related Information

Designer Guide: File Formats [page 254]
Reference Guide: Objects, Source [page 947]
Reference Guide: Objects, Target [page 960]

6.7.2.4.1 Flat file sources

To use the *Parallel process threads* option, the following conditions must be met:

- In the file format editor:
  - For delimited files, no text delimiters are defined.
    For fixed-width files, having a text delimiter defined does not prevent the file from being read by parallel process threads.
    You can set SAP Data Services to read flat file data in parallel in most cases because the majority of jobs use fixed-width or column-delimited source files that do not have text delimiters specified.
  - An end-of-file (EOF) marker for the file's input/output style is not specified.
  - The value of the row delimiter is not set to `{none}`. A row delimiter can be `{none}` only if the file is a fixed-width file.
  - If the file has a multi-byte locale and you want to take advantage of parallel process threads, set the row delimiter as follows:
    - The length of the row delimiter must be 1. If the codepage of the file is UTF-16, the length of the row delimiter can be 2.
    - The row delimiter hex value must be less than 0x40.
- In the Source File Editor, no number has been entered for *Rows to read*.
  The Rows to read option indicates the maximum number of rows that the software reads. It is normally used for debugging. Its default value is none.
- The maximum row size does not exceed 128 KB.

If a file source needs to read more than one file (for example, *.txt is specified for the *File(s)* option in the file format editor), the software processes the data in the first file before the data in the next file. It performs file multi-threading one file at a time.

6.7.2.4.2 Flat file targets

If you enter a positive value for *Parallel process threads*, Data Services parallel processes flat file targets when the maximum row size does not exceed 128KB.

6.7.2.4.3 Tuning performance

The *Parallel process threads* option is a performance enhancement for some sources and targets. Performance is defined as the total elapsed time used to read a file source.

A multi-threaded file source or target achieves high performance by maximizing the utilization of the CPUs on your Job Server computer. You will notice higher CPU usage when you use this feature. You might also notice higher memory usage because the number of process threads you set (each consisting of blocks of rows that use 128 kilobytes) reside in memory at the same time.

To tune performance, adjust the value for *Parallel process threads*. Ideally, have at least as many CPUs as process threads. For example, if you enter the value 4 for *Parallel process threads*, have at least four CPUs on your Job Server computer.

However, increasing the value for process threads does not necessarily improve performance. The file reads and loads achieve their best performance when the work load is distributed evenly among all the CPUs and the speed of the file's input/output (I/O) thread is comparable with the speed of the process threads.

The I/O thread for a file source reads data from a file and feeds it to process threads. The I/O thread for a file target takes data from process threads and loads it to a file. Therefore, if a source file's I/O thread is too slow to keep the process threads busy, there is no need to increase the number of process threads.

If there is more than one process thread on one CPU, that CPU will need to switch between the threads. There is an overhead incurred in creating these threads and switching the CPU between them.

6.7.2.4.4 Tips

The best value for *Parallel process threads* depends on the complexity of your data flow and the number of available processes. If your Job Server is on a computer with multiple CPUs, the values for file sources and targets should be set to at least two.

After that, experiment with different values to determine the best value for your environment.

Here are some additional guidelines:

- If *Parallel process threads* is set to `none`, then flat file reads and loads are not processed in parallel.
- If *Parallel process threads* is set to `1`, (meaning that one process thread will spawn) and your Job Server computer has one CPU, then reads and loads can occur faster than single-threaded file reads and loads because SAP Data Services reads the I/O thread separately and concurrently with the process thread.
- If *Parallel process threads* is set to `4`, four process threads will spawn. You can run these threads on a single CPU. However, using four CPUs would more likely maximize the performance of flat file reads and loads.

6.8 Distributing Data Flow Execution

The previous section describes how SAP Data Services can run a single process as multiple threads that run in parallel on a multiprocessor computer. Using degree of parallelism (DOP), it can execute each thread on a separate CPU on the computer.

This section describes how the software can split a process (data flow) into multiple processes (sub data flows) that can take advantage of more memory across multiple computers or on the same computer that has more than two gigabytes of memory. For example, if your computer has eight gigabytes of memory, you can have four sub data flows that each can use up to two gigabytes.

With this capability, the software can distribute CPU-intensive and memory-intensive operations (such as join, grouping, table comparison and lookups). This distribution of data flow execution provides the following potential benefits:

- Better memory management by taking advantage of more CPU power and physical memory.
- Better job performance and scalability by taking advantage of grid computing.

You can create sub data flows so that the software does not need to process the entire data flow in memory at one time. You can also distribute the sub data flows to different job servers within a server group to use additional memory and CPU resources.

6.8.1 Splitting a data flow into sub data flows

6.8.1.1 Run as a separate process option

If your data flow contains multiple resource-intensive operations, you can run each operation as a separate process (sub data flow) that uses separate resources (memory and computer) from each other to improve performance and throughput. When you specify multiple *Run as separate process* options in objects in a data flow, SAP Data Services splits the data flow into sub data flows that run in parallel.

The *Run as a separate process* option is available on resource-intensive operations that including the following:

- Hierarchy_Flattening transform
- Associate transform
- Country ID transform
- Global Address Cleanse transform
- Global Suggestion Lists transform
- Match Transform
- United States Regulatory Address Cleanse transform
- User-Defined transform
- Query operations that are CPU-intensive and memory-intensive:
  - Join
  - GROUP BY
  - ORDER BY
  - DISTINCT
- Table_Comparison transform
- Lookup_ext function
- Count_distinct function
- Search_replace function

6.8.1.2 Examples of multiple processes for a data flow

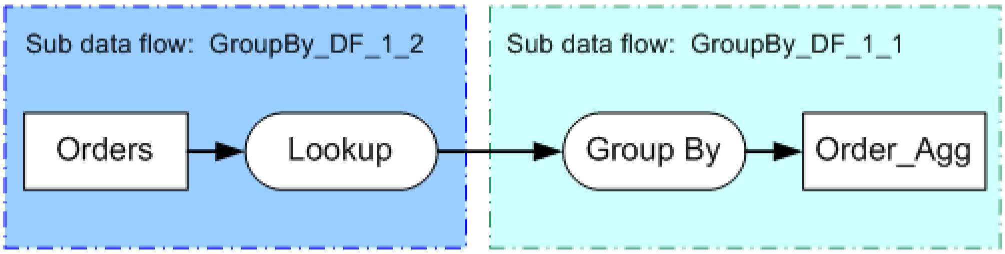
A data flow can contain multiple resource-intensive operations that each require large amounts of memory or CPU utilization. You can run each resource-intensive operation as a separate process that can use more memory on a different computer or on the same computer that has more than two gigabytes of memory. For example, you might have a data flow that sums sales amounts from a lookup table and groups the sales by country and region to find which regions are generating the most revenue. Other than the source and target, the data flow contains a Query transform for the lookup_ext function to obtains sales subtotals and another Query transform to group the results by country and region.

To define separate processes in this sample data flow, take one of the following actions:

- When you define the Lookup_ext function in the first query transform, select the *Run as a separate process* option.
- When you define the Group By operation in the second query transform, select the *Run GROUP BY as a separate process* option on the *Advanced* tab.

6.8.1.2.1 Scenario 1: Run multiple sub data flows with DOP set to 1

The following diagram shows how SAP Data Services splits this data flow into two sub data flows when you specify the *Run as a separate process* option for either the Lookup_ext function or the Group By.



The software generates sub data flow names that follow this format:

```
<DFName_executionGroupNumber_indexInExecutionGroup >
```

- `<DFName>` is the name of the data flow.
- `<executionGroupNumber>` is the order that the software executes a group of sub data flows
- `<indexInExecutionGroup>` is the sub data flow within an execution group.

When you execute the job, the trace log shows two sub data flows that execute in parallel and have different process IDs (Pids). For example, the following depiction of the trace log shows two sub data flows GroupBy_DF_1_1 and GroupBy_DF_1_2 that each start at the same time and have different Pids than the parent data flow GroupBy_DF.

Pid	Tid	Type	Message
...	...	...	...
964	5128	DATAFLOW	Process to execute data flow <GroupBy_DF> is started.
...	...	...	...
4512	5876	DATAFLOW	Process to execute sub data flow <GroupBy_DF_1_1> is started.

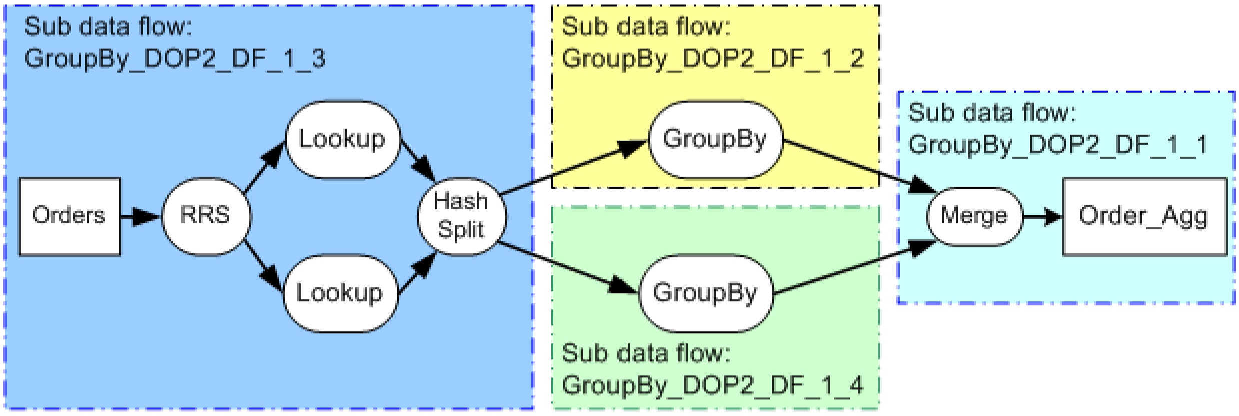
Pid	Tid	Type	Message
396	6128	DATAFLOW	Process to execute sub data flow <GroupBy_DF_1_2> is started.
...	...	...	...

6.8.1.2.2 Scenario 2: Run multiple sub data flows with DOP greater than 1

When the degree of parallelism (DOP) is set to a value greater than 1, each transform defined in the data flow replicates for use on a parallel subset of data.

Set DOP to a value greater than 1 on the data flow Properties window.

The following diagram shows the sub data flows that Data Services generates for GroupBy_DOP2_Job when the *Run GROUP BY as a separate process* is selected and DOP set to 2.



When you execute the job, the trace log shows that the software creates sub data flows that execute in parallel with different process IDs (Pids). For example, the following table shows what the trace log would display for the following four sub data flows that start concurrently, each with a different Pid than the parent data flow GroupBy_DOP2_DF:

- GroupBy_DOP2_DF_1_1
- GroupBy_DOP2_DF_1_2
- GroupBy_DOP2_DF_1_3
- GroupBy_DOP2_DF_1_4

Pid	Tid	Type	Message
...	...	...	...
4288	1960	DATAFLOW	Process to execute data flow <GroupBy_DOP2_DF> is started.

Pid	Tid	Type	Message
...	...	...	...
5548	3636	DATAFLOW	Process to execute sub data flow <GroupBy_DOP2_DF_1_1> is started.
4032	2868	DATAFLOW	Process to execute sub data flow <GroupBy_DOP2_DF_1_2> is started.
1800	5848	DATAFLOW	Process to execute sub data flow <GroupBy_DOP2_DF_1_3> is started.
4416	6128	DATAFLOW	Process to execute sub data flow <GroupBy_DOP2_DF_1_4> is started.
...	...	...	...

➜ Tip

When your data flow has a DOP of greater than one, select either `job` or `data flow` for the *Distribution level* option when you execute the job. If you execute the job with the value `sub data flow` for *Distribution level*, the Round-Robin Split or Hash Split sends data to the replicated queries that might be executing on different job servers. Because the data is sent on the network between different job servers, the entire data flow might be slower.

Related Information

Degree of parallelism [page 2142]

Using grid computing to distribute data flow execution [page 2160]

6.8.1.3 Data_Transfer transform

The Data_Transfer transform creates transfer tables in datastores to enable the software to push down operations to the database server. The Data_Transfer transform creates two sub data flows and uses the transfer table to distribute the data from one sub data flow to the other sub data flow. The sub data flows execute serially.

Related Information

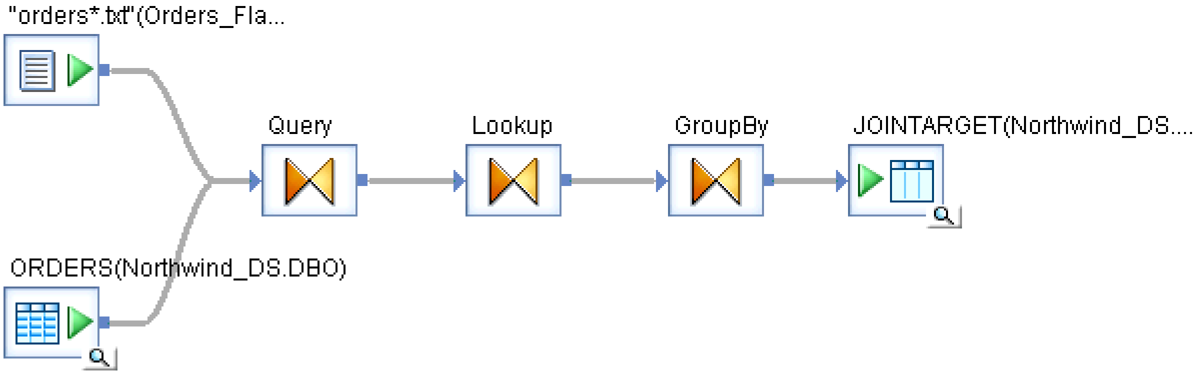
Reference Guide: Transforms, Data_Transfer [page 1071]

6.8.1.4 Examples of multiple processes with Data_Transfer

The following are typical scenarios of when you might use the Data_Transfer transform to split a data flow into sub data flows to push down operations to the database server.

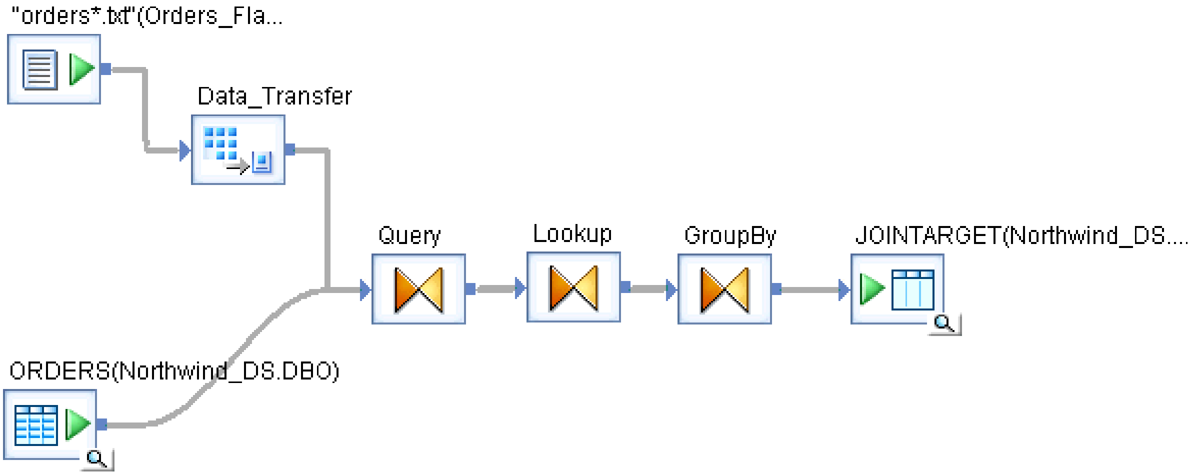
6.8.1.4.1 Scenario 1: Sub data flow to push down join of file and table sources

Your data flow might join an Orders flat file and a Orders table, perform a lookup_ext function to obtain sales subtotals, and another Query transform to group the results by country and region.



6.8.1.4.1.1 Define sub data flows to push down a join of a file and table

1. Add a Data_Transfer transform between the Orders file source and the Query transform.



2. Select the value `Table` from the drop-down list in the *Transfer type* option in the Data_Transfer editor.
3. For *Table name* in the Table options area, browse to the datastore that contains the source table that the Query joins to this file. Double-click the datastore name and enter a name for the transfer table on the Input table for Data_Transfer window.

   In this example, browse to the same datastore that contains the Orders table and enter Orders_FromFile in Table name.
4. After you save the data flow and click *ValidationDisplay Optimized SQL...*, the Optimized SQL window shows that the join between the transfer table and source Orders table is pushed down to the database.

   ```
   SELECT "Data_Transfer_Orders_Flatfile"."PRODUCTID" , "ORDERS"."SHIPCOUNTRY" ,
   "ORDERS"."SHIPREGION" , "Data_Transfer_Orders_Flatfile"."ORDERID"
   FROM "DBO"."ORDERS_FROMFILE"
   "Data_Transfer_Orders_Flatfile","DBO"."ORDERS""ORDERS"
   WHERE ("Data_Transfer_Orders_Flatfile"."ORDERID" = "ORDERS"."ORDERID")
   ```

   SAP Data Services can push down many operations without using the Data_Transfer transform.
5. When you execute the job, the Trace Log shows messages that indicate that the software created two sub data flows with different Pids to run the different operations serially.

Related Information

Push-down operations [page 2116]

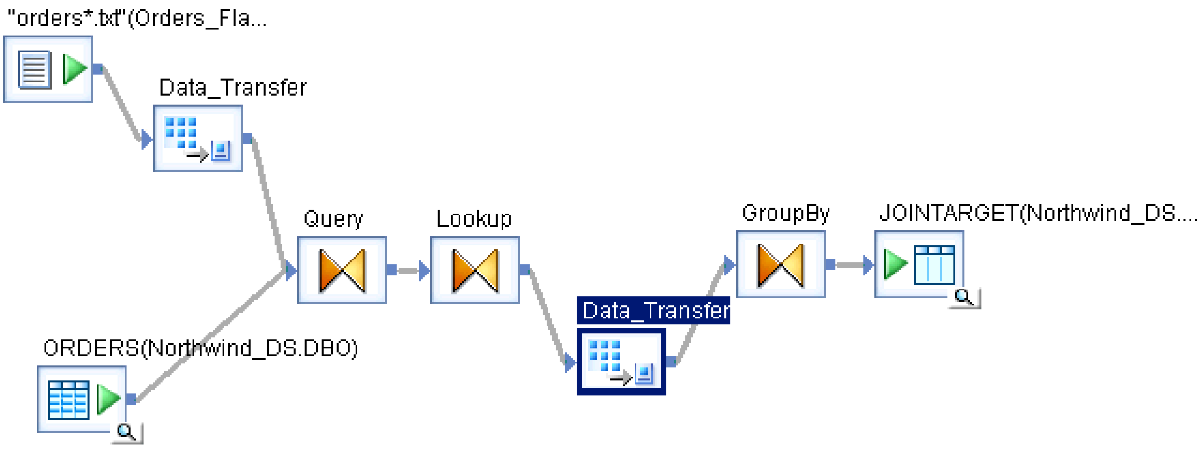
6.8.1.4.2 Scenario 2: Sub data flow to push down memory-intensive operations

You can use the Data_Transfer transform to push down memory-intensive operations such as Group By or Order By.

For the sample data flow in *Scenario 1: Sub data flow to push down join of file and table sources* [page 2157], you might want to push down the Group By operation.

6.8.1.4.2.1 Define sub data flows to push down another operation

1. Add a Data_Transfer transform between the Lookup and GroupBy Query transforms, as the following diagram shows.



2. Select the value `Table` from the drop-down list in the *Transfer type* option in the Data_Transfer editor.
3. For *Table name* in the Table options area, browse to the datastore that contains the target table. Double-click the datastore name and enter a name for the transfer table on the Input table for Data_Transfer window.
4. After you save the data flow and click ▶ *Validation* ▶ *Display Optimized SQL* ◀, the Optimized SQL window shows that the software pushes the GroupBy down to the target database.

```
INSERT INTO "DBO"."JOINTARGET"("PRODUCTID","SHIPCOUNTRY","SHIPREGION","SALES")

SELECT "Data_Transfer_1_Lookup"."PRODUCTID",
"Data_Transform_1_Lookup"."SHIPCOUNTRY",
"Data_Transfer_1_Lookup"."SHIPREGION",sum("Data_Transfer_1_Lookup"."SALES")
FROM "DBO"."GROUPTRANS""Data_Transfer_1_Lookup"
GROUP BY
"Data_Transfer_1_Lookup"."PRODUCTID","Data_Transfer_1_Lookup"."SHIPCOUNTRY",
"Data_Transfer_1_Lookup"."SHIPREGION"
```

   The software can push down many operations without using the Data_Transfer transform.
5. When you execute the job, the messages indicate that the software creates three sub data flows to run the different operations serially.

Related Information

Push-down operations [page 2116]

6.8.2 Using grid computing to distribute data flow execution

SAP Data Services takes advantage of grid computing when you:

- Define a group of Job Servers (called a *Server Group* [page 2160]) that acts as a server grid. The software leverages available CPU and memory on the computers where the Job Servers execute.
- Specify *Distribution levels for data flow execution* [page 2160] to process smaller data sets or fewer transforms on different Job Servers in a Server Group. Each data flow or sub data flow consumes less virtual memory.

6.8.2.1 Server Group

You can distribute the execution of a job or a part of a job across multiple Job Servers within a Server Group to better balance resource-intensive operations. A server group automatically measures resource availability on each Job Server in the group and distributes scheduled batch jobs to the Job Server with the lightest load at runtime.

Related Information

Management Console Guide: Server Groups [page 1885]

6.8.2.2 Distribution levels for data flow execution

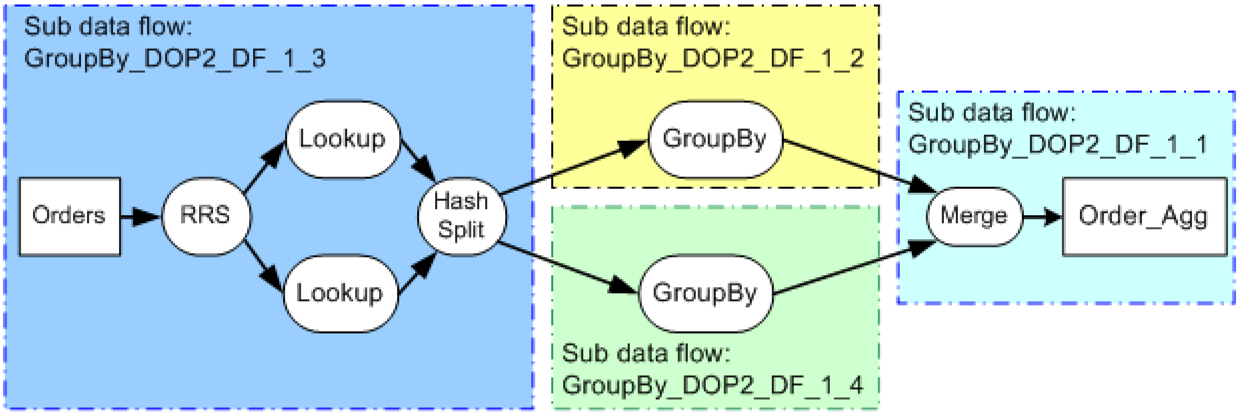
When you execute a job, you can specify the following values on the *Distribution level* option:

- Job level - An entire job can execute on an available Job Server.
- Data flow level - Each data flow within a job can execute on an available Job Server and can take advantage of additional memory (up to two gigabytes) for both in-memory and pageable cache on another computer.
- Sub data flow level - A resource-intensive operation (such as a sort, table comparison, or table lookup) within a data flow can execute on an available Job Server. Each operation can take advantage of up to two gigabytes additional memory for both in-memory and pageable cache on another computer.

6.8.2.2.1 Job level

When you choose a Server Group to execute your job, the default distribution level is Job.

When *Distribution level* has the value `Job`, all of the processes that belong to the job execute on the same computer. For example, section *Scenario 2: Run multiple sub data flows with DOP greater than 1* [page 2155] describes the data flow GroupBy_DOP2_DF which is designed to generate four sub data flows as follows.

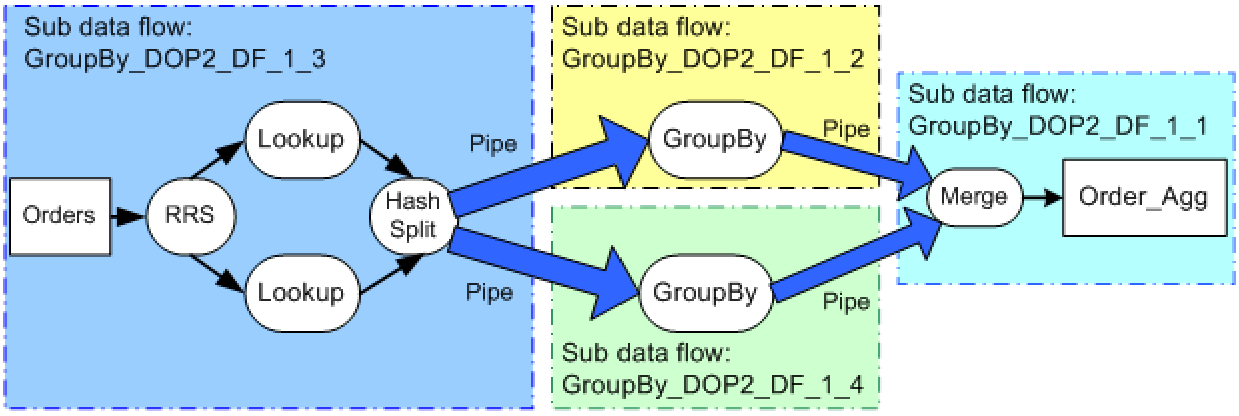


Sub data flow: GroupBy_DOP2_DF_1_3
Orders
RRS
Lookup
Lookup
Hash Split
Sub data flow: GroupBy_DOP2_DF_1_2
GroupBy
Sub data flow: GroupBy_DOP2_DF_1_4
GroupBy
Sub data flow: GroupBy_DOP2_DF_1_1
Merge
Order_Agg

When you execute the job, the following Trace log messages indicate the distribution level for each sub data flow:

```
Starting sub data flow <GroupBy_DOP2_DF_1_1> on job server host <SJ-C>, port
<3502>. Distribution level <Job>.
Starting sub data flow <GroupBy_DOP2_DF_1_2> on job server host <SJ-C>, port
<3502>. Distribution level <Job>.
Starting sub data flow <GroupBy_DOP2_DF_1_3> on job server host <SJ-C>, port
<3502>. Distribution level <Job>.
Starting sub data flow <GroupBy_DOP2_DF_1_4> on job server host <SJ-C>, port
<3502>. Distribution level <Job>.
```

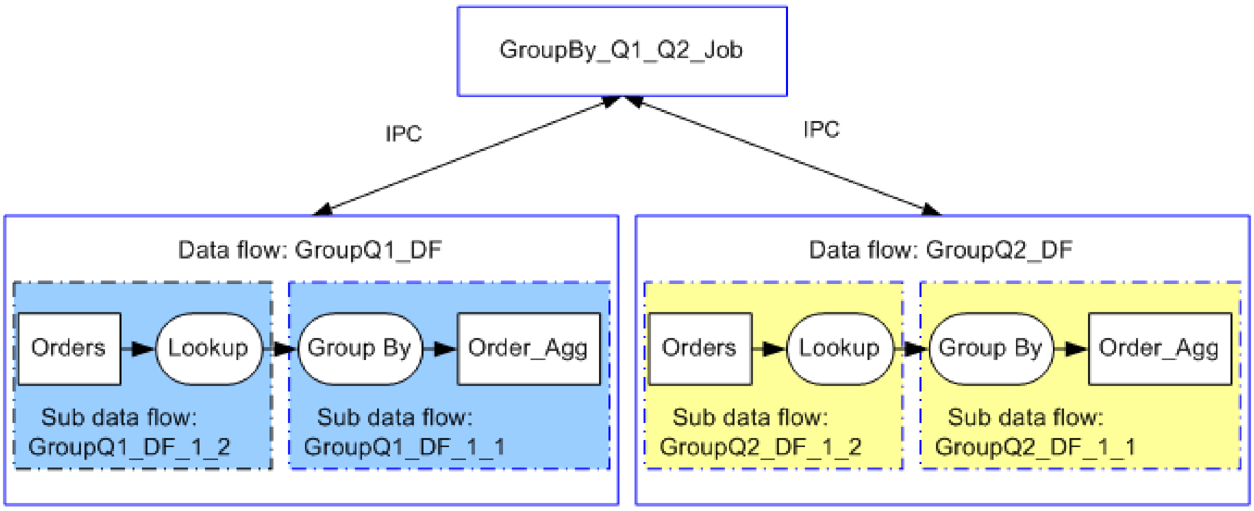
When *Distribution level* is `Job`, the software uses named pipes to send data between the sub data flow processes on the same computer, as the following diagram indicates with the blue arrows.



Sub data flow: GroupBy_DOP2_DF_1_3
Orders
RRS
Lookup
Lookup
Hash Split
Pipe
Pipe
Sub data flow: GroupBy_DOP2_DF_1_2
GroupBy
Pipe
Sub data flow: GroupBy_DOP2_DF_1_4
GroupBy
Pipe
Sub data flow: GroupBy_DOP2_DF_1_1
Merge
Order_Agg

6.8.2.2.2 Data flow level

When *Distribution level* has the value `Data flow`, all of the processes that belong to each data flow can execute on a different computer. For example, the following GroupBy_Q1_Q2_Job has two data flows: GroupQ1_DF and GroupQ1_DF that process orders for the first quarter and second quarter, respectively.



- The solid blue lines enclose each process that can execute on a separate Job Server. In this example, each data flow can execute on a different computer than the computer where the job started.
- SAP Data Services uses Inter-Process Communications (IPC) to send data between the job and data flows on the different computers. IPC uses the peer-to-peer port numbers specified on the *Start port* and *End port* options in the Server Manager.

Note

The default values for *Start port* and *End port* are `1025` and `32767`, respectively. Change these values if you want to restrict the number of ports or if some of the ports are already in use.

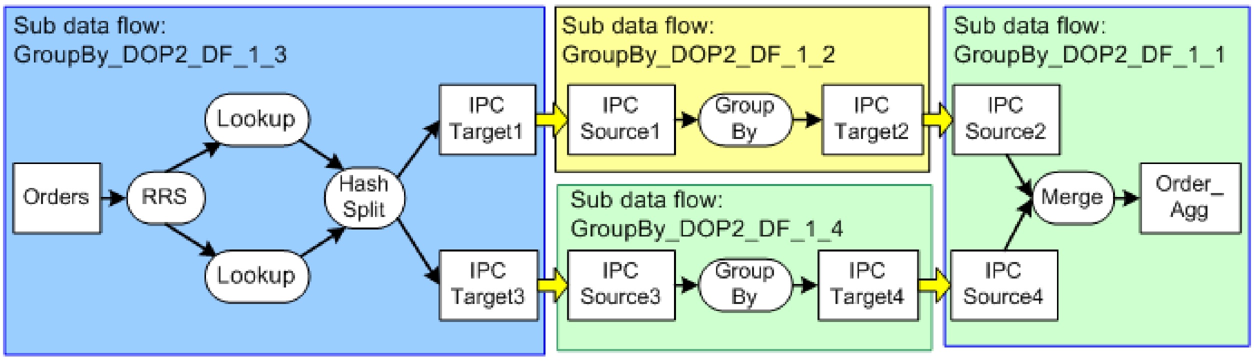
When you execute the job, the Trace log displays messages such as the following that indicate the communication port for the data flow and the distribution level for each data flow. All of the sub data flows within a data flow run on the same computer.

```
Data flow communication using peer-to-peer method with the port range <1025> to
<32767>.
...
Peer-to-peer connection server for session process is listening at host <SJ-C>,
port <1025>.
Job <GroupBy_Q1_Q2_Job> is started.
Starting data flow </GroupBy_Q1_Q2_Job/GroupBy_Q1_DF> on job server host <SJ-C>,
port <3502>. Distribution level <Data
flow>. Data flow submitted to server group <sg_direpo>. Load balancing algorithm
<Least load>. Server group load statistics
from job server <mssql_lap_js SJ-C 3502>:
<mssql_lap_js SJ-C 3502> System Load <47%> Number of CPUs <1>
<MSSQL2005_JS SJ-W-C 3500> System Load <70%> Number of CPUs <2>
Process to execute data flow <GroupBy_Q1_DF> is started.
Starting sub data flow <GroupBy_Q1_DF_1_1> on job server host <SJ-C>, port <3502>.
Distribution level <Data flow>.
Starting sub data flow <GroupBy_Q1_DF_1_2> on job server host <SJ-C>, port <3502>.
Distribution level <Data flow>.
Starting sub data flow <GroupBy_Q1_DF_1_3> on job server host <SJ-C>, port <3502>.
```

```
Distribution level <Data flow>.
Starting sub data flow <GroupBy_Q1_DF_1_4> on job server host <SJ-C>, port <3502>.
Distribution level <Data flow>.
```

6.8.2.2.3 Sub data flow level

When *Distribution level* has the value `Sub data flow`, each sub data flow within a data flow can execute on a different computer. In the example that section *Scenario 2: Run multiple sub data flows with DOP greater than 1* [page 2155] describes, the GroupBy_DOP2_Job has four sub data flows as follows.



- The solid blue lines enclose each process that can execute on a separate Job Server. In this example, each sub data flow can execute on a different computer than the computer where the job started.
- The yellow arrows indicate the Inter-Process Communications (IPC) that SAP Data Services uses to send data between the job and sub data flows on the different computers. IPC the peer-to-peer port numbers specified on the *Start port* and *End port* options in the Server Manager.
  The default values for Start port and End port are 1025 and 32767, respectively. Change these values if you want to restrict the number of ports or if some of the ports are already in use.

> i Note
>
> If you find that sending data across the network is causing your data flow to execute longer, you might want to change *Distribution level* from `Sub data flow` to `Data flow` or `Job`.

When you execute the job, the Trace log displays messages such as the following that indicate that the software selects a job server for each sub data flow based on the system load on each computer:

```
Starting sub data flow <GroupBy_DOP2_DF_1_1> on job server host <SJ-C>, port
<3502>. Distribution level <Sub data flow>. Sub data
flow submitted to server group <sg_direpo>. Load balancing algorithm <Least load>.
Server group load statistics
from job server <mssql_lap_js SJ-C 3502>:
<mssql_lap_js SJ-C 3502> System Load <21%> Number of CPUs <1>
<MSSQL2005_JS SJ-W-C 3500> System Load <70> Number of CPUs <1>
Starting sub data flow <GroupBy_DOP2_DF_1_2> on job server host <SJ-C>, port
<3502>. Distribution level <Sub data
flow>. Sub data flow submitted to server group <sg_direpo>. Load balancing
algorithm <Least load>. Server group load statistics
from job server <mssql_lap_js SJ-C 3502>:
<mssql_lap_js SJ-C 3502> System Load <21%> Number of CPUs <1>
<MSSQL2005_JS SJ-W-C 3500> System Load <70> Number of CPUs <2>
```

The following messages show the communication port that each sub data flow uses:

```
Peer-to-peer connection server for sub data flow <GroupBy_DOP2_DF_1_1> is listening
at host <SJ-C>, port <1027>.
Process to execute sub data flow <GroupBy_DOP2_DF_1_4> is started.
Peer-to-peer connection server for sub data flow <GroupBy_DOP2_DF_1_2> is listening
at host <SJ-C>, port <1028>.
Peer-to-peer connection server for sub data flow <GroupBy_DOP2_DF_1_3> is listening
at host <SJ-C>, port <1029>.
Peer-to-peer connection server for sub data flow <GroupBy_DOP2_DF_1_4> is listening
at host <SJ-C>, port <1030>.
```

6.9 Bulk Loading and Reading

SAP Data Services supports capabilities present in most supported databases that enable you to load and in some cases read data in bulk rather than using SQL statements. Some general considerations when using bulk loading and reading are:

- Specify bulk-loading options on the Data Services target table editor on the *Options* and *Bulk Loader Options* tabs.
- Specify Teradata reading options on the source table editor *Teradata options* tab.
- Most databases do not support bulk loading with a template table.

For details on the options for each database type, see the *Reference Guide*.

Related Information

Reference Guide: Objects, Target tables [page 963]

Reference Guide: Objects, Teradata source [page 952]

6.9.1 Bulk loading in DB2 Universal Database

SAP Data Services supports bulk loading to the DB2 Universal Database.

6.9.1.1 When to use each DB2 bulk-loading method

SAP Data Services supports multiple bulk-loading methods for DB2 Universal Database (UDB) on Windows and UNIX. The following table lists the methods that you can select depending on your requirements.

Note

You cannot bulk load data to DB2 databases that run on AS/400 or z/OS (MVS) systems.

Load method	Description	Advantages	Restrictions
CLI Load	Loads a large volume of data at high speed by passing it directly from memory to the table on the DB2 UDB server.	• Provides the fastest way to bulk load. • Eliminates some parameters because no intermediate data file is required. • Can put rows that violate the unique key constraint into an exception table.	• Must specify *Recoverable* and *Copy target directory* options to enable recovery because DB2 logging is not enabled for CLI Load. • The DB2 UDB server and client must be Version 8.0 or later. • Stops loading when it encounters the first rejected row.
Import	Loads a large volume of data by using a SQL INSERT statement to write data from an input file into a table or view.	• Recovery is enabled automatically because DB2 logging occurs during import. • Performs referential integrity or table constraint checking in addition to unique key constraint checking.	• Because DB2 logs each INSERT statement, this method is the slowest way to bulk load data. • The Data Services Job Server and DB2 UDB server must be on the same computer.

6.9.1.2 Using the DB2 CLI load method

The DB2 Call Level Interface (CLI) load method performs faster than the bulk load or import utilities because it does not write the data to an intermediate file. Instead, the CLI load method writes the data from memory (where SAP Data Services extracted or transformed the data) directly to the table on the DB2 server.

6.9.1.2.1 Configuring your system to use the CLI load method

1. Enter the appropriate information in the datastore editor, on the *DB2 Properties* tab.

   Fields include:

   ○ *Bulk loader user name*: The user name SAP Data Services uses when loading data with the CLI load option. For bulk loading, you might specify a different user name, for example one with import and load permissions.

   ○ *Bulk loader password*: The password SAP Data Services uses when loading with the CLI load option.
2. To use a different bulk loader working directory than the default (`<DS_COMMON_DIR>\log\bulkloader`), specify the directory name in the datastore editor on the *Connections* tab.

6.9.1.2.2 Using the CLI load method in a job

1. Open the DB2 target table editor in the Designer workspace.
2. Select the *Bulk Loader Options* tab below the table schema area.
3. In the *Bulk loader* list, select *CLI load*.

   The window updates to show all CLI load options. CLI load options include these existing bulk load options:

   - Mode
   - Warning row count
   - Exception table name
   - Recoverable
   - Copy target directory

Additional or changed CLI load options include:

- *Maximum bind array*: Defines the maximum number of rows extracted or transformed before the software sends the data to the DB2 table or view. If you do not enter a value, Data Services uses the CLI load default value of 10000 rows.
- *Clean up bulk loader directory after load*: If you select this option, the software deletes the message file when the CLI load completes successfully. Because the CLI load obtains the data from memory, Data Services creates no control or data files.

Related Information

Reference Guide: Objects, Target tables [page 963]

6.9.1.3 Using the import utility

SAP Data Services also supports bulk loading in the DB2 Universal Database 5.2 environment using the import utility. For the software to initiate DB2 bulk loading by this method directly, the Job Server and DB2 must be located on the same system. If they are not, use the following procedure to initiate bulk loading:

1. Generate a control file and data file. Check *Generate files only* in the target table editor on the Bulk Loader Options tab.
2. Manually move the control file and data file to the system where the target database is located.
3. Start the execution of the bulk loader manually.

6.9.2 Bulk loading in HP Neoview

SAP Data Services supports bulk loading to HP Neoview via Neoview Transporter.

For detailed information about HP Neoview loading options and their behavior, see the relevant HP Neoview product documentation.

To use Neoview Transporter, you must also install the following components:

- Neoview Transporter Java Client
- Java JRE version 1.5 or newer
- Neoview JDBC Type 4 Driver
- Neoview ODBC Windows Driver (for Windows)
- Neoview UNIX Drivers (for connecting to a database on UNIX)
- Neoview Command Interface

Note

If you are using multibyte data on Windows, you must change the Windows regional settings to the multibyte language, for example, Japanese.

Note

When you install the Java Client, an environment variable called NVTHOME is created and will point to the location of the Neoview Transporter base directory. You may receive an error in SAP Data Services if NVTHOME is not defined.

HP Neoview recommends that you use the bulk-loading method to load data for faster performance. The SAP Data Services bulk loader for HP Neoview supports UPDATE and UPSERT as well as INSERT operations, which allows for more flexibility and performance.

SAP Data Services generates a control file as input into Neoview Transporter. The control file specifies the data files and the target tables to be loaded. Being in UTF-8, the control file supports multibyte data.

By default, HP Neoview uses the SQL insert operation. For SQL update and upsert options, the control file specifies the columns used in the WHERE clause and the columns to be updated in the UPDATE clause. By default, SAP Data Services uses the primary key columns in the WHERE clause.

To bulk load to a HP Neoview target table, the software:

- Creates a control file in UTF-8
- Loads data from the source into the file or named pipe in UTF-8
- Invokes Neoview Transporter

6.9.2.1 How Data Services and HP Neoview use the file options to load

You can choose to use either named pipes or data files as staging for loading the data. Choose from the following file options:

- Data file (for Windows and UNIX)
- Named pipe (for UNIX only)

Data file

SAP Data Services runs bulk-loading jobs using a staging data file as follows:

1. The software generates staging data file(s) containing data to be loaded into a HP Neoview table.
2. The software generates a control file to be used by Neoview Transporter.

Named pipe

SAP Data Services runs bulk-loading jobs using named pipes as follows:

1. The software generates a control file that Neoview Transporter uses to manipulate the database.
2. The software creates a pipe to contain the data to apply into an HP Neoview table.
   On UNIX, the pipe is a FIFO (first in, first out) file that has name of this format:

   ```
   /temp/<filename>.dat
   ```
3. The software invokes Neoview Transporter with the control file as input.
4. The software writes data to the pipes.
5. Neoview Transporter reads data from the pip and applies data to the HP Neoview table.

6.9.2.2 Using the UPSERT bulk operation

The purpose of the HP Neoview Upsert operation is to update a row, but if no row matches the update, the row is inserted.

In SAP Data Services, you enable Upsert on the target table editor's *Bulk Loader Options* tab. In the *Data Services options* section, for *Bulk Operation*, select *Upsert* (the default is *Insert*) in the SQL Operation list.

After selecting *Upsert*, notice you can also enable the *Use input keys* option on the target editor's *Options* tab. The *Use input keys option* will assign the input primary keys as primary keys in the target table.

Related Information

Reference Guide: Objects, Target tables [page 963]

6.9.3 Bulk loading in Informix

SAP Data Services supports Informix bulk loading. For detailed information about Informix bulk-loading utility options and their behavior in the Informix DBMS environment, see the relevant Informix product documentation.

Setting up Informix for bulk-loading requires that you set the `INFORMIXDIR`, `INFORMIXSERVER`, and `PATH` environment variables.

For the software to initiate Informix bulk loading directly, the Job Server and the target database must be located on the same system.

> Note
>
> SAP Data Services provides Informix bulk-loading support only for single-byte character ASCII delimited files (not for fixed-width files).

6.9.3.1 Setting Informix server variables

For Windows platforms, configure the environment variables in the `$LINK_DIR\bin\dbloadIfmx.bat` script.

```
set INFORMIXDIR=<C:\path\to\informix\installation>
set INFORMIXSERVER=ol_svr_custom
set PATH=%INFORMIXDIR%\bin;%PATH%
```

For UNIX platforms, configure the environment variables in the `$LINK_DIR/bin/dbloadIfmx.sh` script.

```
export INFORMIXDIR=</path/to/informix/installation>
export INFORMIXSERVER=ol_svr_custom
export PATH=$INFORMIXDIR/bin:$PATH
```

6.9.4 Bulk loading in Microsoft SQL Server

SAP Data Services supports Microsoft SQL Server bulk loading through the SQL Server ODBC bulk copy API. For detailed information about the SQL Server ODBC bulk copy API options and their behavior in the Microsoft SQL Server DBMS environment, see the relevant Microsoft SQL Server product documentation.

6.9.4.1 To use the SQL Server ODBC bulk copy API

To enable bulk loading on the default job server, do the following:

1. From the *Tools* menu, select *Options* > *Job Server* > *General*.
2. For *Section*, enter `AL_Engine`.
3. For *Key*, enter `UseSQLServerBulkCopy`.
4. Select TRUE (default) or FALSE. If you leave the default, the software uses the SQL Server ODBC bulk copy API. If you set this parameter to FALSE, the software overrides the default and uses the SQLBulkOperations API (this method is slower than the default).

6.9.4.2 Network packet size option

When loading to SQL Server, the client caches rows until it either fills a network packet or reaches the commit size (regardless of whether the packet is full). Then the client sends the packet to the server. You can affect performance by tuning commit size and network packet size. You can change these sizes on the Bulk Loader Options tab for SQL Server:

- Rows per commit
  This option lets you specify the number of rows to put in the cache before issuing a commit.
- Network packet size
  This option lets you specify network packet size in kilobytes. The default packet size is 4 kilobytes.

Note

It is recommended that you set the *Rows per commit* and *Network packet size* parameters to avoid sending many partially filled packets over the network and ensure that the packet size contains all rows in the commit.

6.9.4.3 Maximum rejects option

The *Maximum rejects* parameter (on the Bulk Loader Options page) can also affect your SQL Server bulk-loading performance. When you set *Maximum rejects* to 0, SAP Data Services stops at the first error it encounters and does not cache rows in the transaction (caching rows in a transaction allows the software to process each row even if an error occurs during the transaction commit process.)

When you do not specify a value for *Maximum rejects*, the software ignores the rejected rows, logs warnings, and continues processing.

6.9.5 Bulk loading in Netezza

SAP Data Services supports bulk loading to Netezza Performance Servers.

For detailed information about Netezza loading options and their behavior in the Netezza environment, see the relevant Netezza product documentation.

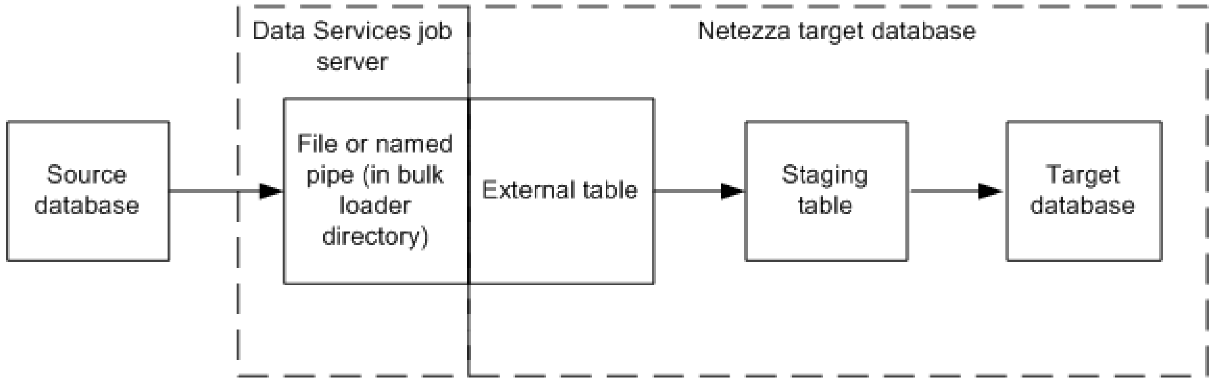
Netezza recommends using the bulk-loading method to load data for faster performance. Unlike some other bulk loaders, the SAP Data Services bulk loader for Netezza supports UPDATE and DELETE as well as INSERT operations, which allows for more flexibility and performance.

6.9.5.1 Netezza bulk-loading process

To bulk load to a Netezza target table, SAP Data Services:

- Creates an external table that is associated with a local file or named pipe.
- Loads data from the source into the file or named pipe.

- Loads data from the external table into a staging table by executing an INSERT statement.
- Loads data from the staging table to the target table by executing a set of INSERT/UPDATE/DELETE statements.



6.9.5.2 Options overview

From the *Bulk Loader Options* tab of your Netezza target table editor, select one of these methods depending on your Netezza environment:

- *Named pipe*—SAP Data Services streams data as it is written to the named pipe through the external table to the staging table. For files that are larger than 4 GB in size, select this option for faster performance.
- *File*—SAP Data Services writes the data to a file before loading through the external table to the staging table. For files that are smaller than 4 GB in size, select this option for faster performance.
- *None*—SAP Data Services does not use bulk loading.

Because the bulk loader for Netezza also supports UPDATE and DELETE operations, the following options (on the target table editor *Options* tab) are also available for Netezza bulk loading.

- Column comparison
- Number of loaders
- Use input keys
- Update key columns
- Auto correct load

Related Information

Reference Guide: Objects, Target tables [page 963]

6.9.5.3 Configuring bulk loading for Netezza

First configure the bulk loader and log directories in the datastore editor, then enable and configure bulk loading in the target table editor:

1. In the Netezza datastore editor, click *Advanced*.
2. Click in the field to the right of *Bulk loader directory* and type the directory path or click *Browse* to where the software should write SQL and data files for bulk loading.
3. In the *FTP* category, enter the FTP host name, login user name, login password, and host working directory.

   These options are used to transfer the Netezza nzlog and nzbad files.

   > Note
   >
   > If this datastore is not being used specifically for Netezza bulk loading, the software ignores any FTP option entries.

4. If you are loading non-ASCII character data, set the *Code page* to *latin-9*.

   If you are loading mulitbyte data, set the *Code page* to *utf-8*.
5. Click *OK* or *Apply*.
6. Open the data flow and open the target table editor by clicking its name.
7. On the *Bulk Loader Options* tab, select a bulk-loading method and configure the remaining options there and on the *Options* tab.
8. Save the data flow.

Related Information

Reference Guide: Objects, Database datastores (ODBC) [page 885]

Designer Guide: Datastores, Defining a database datastore [page 213]

Reference Guide: Objects, Target tables [page 963]

6.9.5.4 Netezza log files

When writing from the external table to the staging table, Netezza generates logs (nzlog and nzbad files) and writes them to a database server working directory. You can use these logs to troubleshoot your jobs. (If you do not enter a *Database server working directory* in the datastore editor, Netezza uses the temp directory on its server, /tmp, to store the nzlog and nzbad files.)

For SAP Data Services to access and manage these logs, configure the FTP parameters in the datastore editor. After a load, trhe software copies these files from the specified Netezza *Database server working directory* to the specified *Bulk loader directory* and deletes them from the Netezza server.

For successful loads, SAP Data Services then deletes these log files from the *Bulk loader directory* (assuming the *Clean up bulk loader directory after load* option is checked in the target table editor).

For failed loads, the software does not delete the log files from the *Bulk loader directory* even if the *Clean up bulk loader directory after load* option is checked in the target table editor.

6.9.6 Bulk loading in Oracle

SAP Data Services supports Oracle bulk loading.

6.9.6.1 Bulk-loading methods

You can bulk load to Oracle using an API or a staging file:

- If you select the *API* method, SAP Data Services accesses the direct path engine of Oracle's database server associated with the target table and connected to the target database. Using Oracle's Direct-Path Load API, input data feeds directly into database files. To use this option, you must have Oracle version 8.1 or later.
- If you select the *File* method, Data Services writes an intermediate staging file, control file, and log files to the local disk and invokes the Oracle SQL*Loader. This method requires more processing time than the API method.
  For detailed information about the Oracle SQL*Loader options, see the relevant Oracle product documentation.

6.9.6.2 Bulk-loading modes

Bulk loading in Oracle supports two modes of data loading: conventional-path and direct-path. Conventional-path loading is implicit for the *File* option if you do not select *Direct-path* on the *Bulk Loader Options* tab in the target table editor. SAP Data Services always uses direct-path loading for the *API* option.

- Conventional-path loading: Conventional-path loads use the SQL INSERT statements to load data to tables.
- Direct-path loading:Direct-path loads use multiple buffers for a number of formatted blocks that load data directly to database files associated with tables.

6.9.6.3 Bulk-loading parallel-execution options

Parallel-execution options for bulk loading are on the *Options* tab.

For the API method, you can choose to select the *Enable partitioning* check box. If selected, SAP Data Services generates the number of target parallel instances based on the number of partitions in the target table. If not selected or if your table target is not partitioned, Data Services uses one loader by default.

For the File method, enter a value in the *Number of loaders* box or select the *Enable partitioning* check box.

> Note
>
> The *Enable partitioning* check box does not appear on the *Options* tab if the target table is not partitioned.

6.9.6.4 Bulk-loading scenarios

With two bulk-loading methods, two load modes, and two parallel load options, there are several scenarios you can configure:

Scenario	Method	Load Mode	Parallel Load Options
1	API	Direct-path	Enable partitions is not selected (One loader is used by default)
2	API	Direct-path	Enable partitions is selected
3	File	Direct-path	Number of loaders = 1
4	File	Direct-path	Number of loaders > 1
5	File	Direct-path	Enable partitions is selected
6	File	Conventional	Number of loaders = 1
7	File	Conventional	Number of loaders > 1
8	File	Conventional	Enable partitions is selected

Here are some tips for using these scenarios:

- The API method always uses the direct-path load type, and when it is used with a partitioned target table, SAP Data Services processes loads in parallel. The software instantiates multiple loaders based on the number of partitions in a table. Each loader receives rows that meet the conditions specified by the partition.
- With the File method, direct-path is faster than conventional load, but the File method is slower than using an API because of the need to generate a staging file, logs, and invoke Oracle's SQL*Loader.
- With the File method, when you use a value of greater than one for either the *Number of Loaders* or the *Enable partitioning* option, loads cannot truly run in parallel. The creation of a staging file and log for each loader is serialized.

6.9.6.5 Using bulk-loading options

As seen in the table on the previous page, there are many ways to set up bulk loading for an Oracle database. The following sections describe two scenarios in detail.

6.9.6.5.1 Direct-path loads using Number of Loaders and File method

In the *Options* tab of the target table editor, when you enter a value for *Number of loaders*, SAP Data Services instantiates multiple loaders. Each loader receives rows equal to the amount specified in the *Rows per commit* box on the *Bulk Loader Options* tab. The loaders pipe rows to a staging file, then call the SQL*Loader to load the staging file contents into the table.

This process occurs in "round-robin" fashion. For example, if you set *Rows per commit* to `5000` and *Number of loaders* to `2`, then the first loader receives 5000 rows, writes them to the staging file, and then invokes the SQL*Loader to load the data into the table.

Meanwhile, the second loader receives the second batch of 5000 rows, writes them to a staging file, and then waits for the first loader to complete the loading. When the first loader completes the bulk load, the second loader starts, and while the second loader is loading, the first loader receives the third batch of 5000 rows. This process continues until all the data loads.

The SQL*Loader uses a control file to read staging files and load data. The software either creates this control file at runtime or uses one that is specified on the *Bulk Loader Options* tab at design time.

For parallel loading, the generated control files, data files, and log files are named as follows:

```
<TableNameTIDPID_LDNUM_BATCHNUM >
```

Where:

<TableName:> The name of the table into which data loads.

<TID> : The thread ID.

<PID> : The process ID.

<LDNUM> : The loader number, which ranges from `0` to number of loaders minus 1. For single loaders, `LDNUM` is always `0`.

<BATCHNUM> : The batch number the loader is processing. For single loaders the **<BATCHNUM>** is always `0`.

> Note
>
> Product performance during this type of parallel loading depends on a number of factors such as distribution of incoming data and underlying DBMS capabilities. Under some circumstances it is possible that specifying parallel loaders can be detrimental to performance. Always test the parallel loading process before moving to production.

6.9.6.5.2 Direct-path loads using partitioned tables and API method

You can import partitioned tables as SAP Data Services metadata.

In the *Options* tab of the target table editor, when you select *Enable partitioning*, the software instantiates multiple loaders based on the number of partitions in a table. Each loader receives rows that meet the conditions specified by the partition. In addition, commits occur based on the number specified in the *Rows per commit* box on the *Bulk Loader Options* tab.

For example:

- If you *Rows per commit* to 5000, the number of partitions is set `2`, and your first partition includes 2500 rows, then the first loader commits after receiving all possible rows (2500) while concurrently processing the second loader.
- If you *Rows per commit* to 5000, the number of partitions is set `2`, and your first partition includes 10,000 rows, then the first loader commits twice. Once after receiving 5000 rows and again after receiving the second batch of 5000 rows. Meanwhile, the second loader is processing its rows.

The loaders pipe rows directly to Oracle database files by using Oracle direct-path load APIs (installed with the Oracle client) that are associated with the target database.

The API method allows the software to bypass the use of the SQL* Loader (and the control and staging files it needs). In addition, by using table partitioning, bulk loaders can pass data to different partitions in the same target table at the same time. Using the API method with partitioned tables fully optimizes performance.

> Note
>
> If you plan to use a partitioned table as a target, the physical table partitions in the database must match the metadata table partitions in SAP Data Services. If there is a mismatch, Data Services will not use the partition name to load partitions, which impacts processing time.

For the API method, the software records and displays error and trace logs as it does for any job. A monitor log records connection activity between components; however, it does not record activity while the API is handling the data.

6.9.7 Bulk loading in SAP HANA

SAP Data Services supports bulk loading to the SAP HANA database.

For improved performance when using changed-data capture or auto correct load, Data Services uses a temporary staging table to load the target table. Data Services first loads the data to the staging table, then it applies the operation codes (INSERT, UPDATE, and DELETE) to update the target table. With the *Bulk load* option selected in the target table editor, any one of the following conditions triggers the staging mechanism:

- The data flow contains a Map_CDC_Operation transform.
- The data flow contains a Map_Operation transform that outputs UPDATE or DELETE rows.
- The data flow contains a Table_Comparison transform.
- The *Auto correct load* option in the target table editor is set to *Yes*.

If none of these conditions are met, that means the input data contains only INSERT rows. Therefore Data Services does only a bulk insert operation, which does not require a staging table or the need to execute any additional SQL.

By default, Data Services automatically detects the SAP HANA target table type and updates the table accordingly for optimal performance.

Because the bulk loader for SAP HANA is scalable and supports UPDATE and DELETE operations, the following options (target table editor ▶ *Options* ▶ *Advanced* ▶ *Update control* ◀) are also available for bulk loading:

- Use input keys
- Auto correct load

Related Information

Reference Guide: Objects, SAP HANA target table options [page 986]

6.9.8 Bulk loading in SAP Sybase ASE

SAP Data Services supports bulk loading of SAP Sybase ASE databases through the SAP Sybase ASE bulk copy utility. For detailed information about the SAP Sybase ASE bulk loader options and their behavior in the SAP Sybase ASE DBMS environment, see the relevant SAP Sybase ASE product documentation.

6.9.9 Bulk loading in SAP Sybase IQ

SAP Data Services supports bulk loading to SAP Sybase IQ databases via the SAP Sybase IQ LOAD TABLE SQL command. For detailed information about the SAP Sybase IQ LOAD TABLE parameters and their behavior in the SAP Sybase IQ database environment, see the relevant SAP Sybase IQ product documentation.

For improved performance when using changed-data capture or auto correct load, Data Services uses a termporary staging table to load the target table. Data Services first loads the data to the staging table, then it applies the operation codes (INSERT, UPDATE, and DELETE) to update the target table. With the *Bulk load* option selected in the target table editor, any one of the following conditions triggers the staging mechanism:

- The data flow contains a Map_CDC_Operation transform.
- The data flow contains a Map_Operation transform that outputs UPDATE or DELETE rows.
- The *Auto correct load* option in the target table editor is set to *Yes*.

If none of these conditions are met, that means the input data contains only INSERT rows. Therefore, Data Services does only a bulk INSERT operation, which does not require a staging table or the need to execute any additional SQL.

Note that because the bulk loader for SAP Sybase IQ also supports UPDATE and DELETE operations, the following options (target table editor *Options* > *Advanced* > *Update control*) are also available for bulk loading:

- Use input keys
- Auto correct load

Related Information

Reference Guide: Objects, SAP Sybase IQ target table options [page 988]

6.9.9.1 Configuring bulk loading for SAP Sybase IQ

First configure the bulk loader and log directories in the datastore editor, then enable and configure bulk loading in the target table editor:

1. In the SAP Sybase IQ datastore editor, click *Advanced*.
2. Click in the field next to *Bulk loader directory* and type the directory path or click *Browse* to navigate to where Data Services should write command and data files for bulk loading.
3. Depending on the version of SAP Sybase IQ to which this datastore connects, configure *Bulk Loader* and/or *FTP* options.
4. Click *OK* or *Apply*.
5. Open the data flow and open the target table editor by clicking its name.
6. On the *Bulk Loader Options* tab, select a bulk-loading method and configure the remaining options there and on the *Options* tab.
7. Save the data flow.

Related Information

Reference Guide: Objects, Database datastores, SAP Sybase IQ [page 898]
Reference Guide: Objects, Target tables, SAP Sybase IQ target table options [page 988]

6.9.9.2 SAP Sybase IQ log files

After a job executes, Data Services stores the SAP Sybase IQ message and row logs in the *Bulk loader directory* specified in the datastore editor (regardless of the setting for the *JS and DB on same machine* option). A data file will also be present if you do not use the named pipe option. If you do not specify a Bulk loader directory, Data Services by default writes the files to the directory `<DS_COMMON_DIR>\log\bulkloader`.

The logs include:

- message log—Records constraint violations specified in the *Error handling* section of the target table *Bulk Loader Options* tab.
- row log—Contains the data from the violating row. The data in the row log is delimited by the *Field delimiter* character specified on the *Bulk Loader Options* tab.

If you select *Clean up bulk loader directory after load*, Data Services deletes the data file and log files after loading completes. If you choose not to clean up the bulk loader directory or if your job results in errors captured in the logs, the software does not delete the data file and log files.

6.9.10 Bulk loading and reading in Teradata

SAP Data Services supports the following bulk loading and reading tools:

- Parallel Transporter
- FastLoad
- MultiLoad
- TPump
- Load Utility
- None (use ODBC)

> Note
>
> If your Job Server is on a UNIX platform, to take advantage of bulk loading on Teradata 13 databases you must set the required environment parameters in the file $LINK_DIR/bin/td_env.config. Instructions are documented inside the file.

For detailed information about Teradata options and their behavior in the Teradata environment, see the relevant Teradata product documentation.

Related Information

Reference Guide: Objects, Teradata source [page 952]

Reference Guide: Objects, Teradata target table options [page 989]

6.9.10.1 Bulk loader file options

For all bulk loader methods, you can use staging data files or named pipes. These *File option* types are on the *Bulk Loader Options* tab of the target table editor. This section describes how each file option works.

6.9.10.1.1 Data file

The Data file option loads a large volume of data by writing to a data file that it passes to the Teradata server. SAP Data Services runs bulk-loading jobs using a staging data file as follows:

1. It generates staging data file(s) containing data to be loaded into a Teradata table.
2. It generates a loading script to be used by Teradata Parallel Transporter. The script defines read and load operators.
3. If you use Teradata Parallel Transporter, the read operator reads the staging data file, then passes the data to the load operator, which loads data into the Teradata table.

6.9.10.1.2 Generic named pipe

The *Generic named pipe* file option loads a large volume of data by writing to a pipe from which Teradata reads. SAP Data Services runs bulk-loading jobs using a generic named pipe as follows:

1. It generates a script that Teradata Parallel Transporter uses to load the database.
2. It creates a pipe to contain the data to load into a Teradata table.
   On UNIX, the pipe is a FIFO (first in, first out) file that has a name of this format:

   ```
   /temp/<filename>.dat
   ```

   On Windows, the name has this format:

   ```
   \\.\pipe\<datastorename_ownername_tablename_loadernum>.dat
   ```
3. It executes the loading script. If you use Teradata Parallel Transporter, the script starts Teradata Parallel Transporter and defines read and load operators.
4. It writes data to the pipes.
5. Teradata Parallel Transporter connects to the pipes. Then the read operator reads the named pipe and passes the data to the load operator, which loads the data into the Teradata table.

6.9.10.1.3 Named pipes access module

The *Named pipes access module* file option loads a large volume of data by writing to a pipe from which Teradata reads. SAP Data Services runs bulk-loading jobs using a named pipe access module as follows:

1. Data Services generates a script that Teradata Parallel Transporter uses to load the database. The script starts Teradata Parallel Transporter and defines read and load operators.
2. Teradata (Parallel Transporter or non-Parallel Transporter utility) creates named pipes to contain the data to load into a Teradata table.
   On UNIX, the pipe is a FIFO (first in, first out) file that has name of this format:

   ```
   /temp/<filename>.dat
   ```

   On Windows, the name has this format:

   ```
   \\.\pipe\<datastorename_ownername_tablename_loadernum>.dat
   ```
3. Data Services connects to the pipes and writes data to them.

   > **Note**
   >
   > When Data Services tries to connect to the pipes, Teradata Parallel Transporter might not have yet created them. Data Services tries to connect every second for up to 30 seconds. You can increase the 30-second connection time to up to 100 seconds as follows: In the Designer, select ▶ *Tools* › *Options* › *Job Server* › *General* ◀ and enter the following:

   Section: **al_engine**
   Key: **NamedPipeWaitTime**
   Value: **<nn>**
   (**<nn>** is from 30 to 100)
4. The Teradata Parallel Transporter read operator reads the named pipe and passes the data to the load operator, which loads the data into the Teradata table.

6.9.10.2 When to use each Teradata bulk-loading method

SAP Data Services supports multiple bulk-loading methods for Teradata on Windows and UNIX. The following table lists the methods and file options that you can select, depending on your requirements.

Bulk loader method	File Option	Advantages	Restrictions
Parallel Transporter	Data file	• Can use Data Services parallel processing. • Data Services creates the loading script.	• The Teradata Server Tools and Utilities must be Version 7.0 or later. • If you use TTU 7.0 or 7.1, see the *Release Notes*.
	Generic named pipe	• Provides a fast way to bulk load because: ○ As soon as Data Services writes to a pipe, Teradata can read from the pipe. ○ Can use Data Services parallel processing. ○ On Windows, no I/O to an intermediate data file occurs because a pipe is in memory • Data Services creates the loading script.	• A job that uses a generic pipe is not restartable. • The Teradata Server Tools and Utilities must be Version 7.0 or later. • If you use TTU 7.0 or 7.1, see the *Release Notes*.
	Named pipe access module	• The job is restartable. • Provides a fast way to bulk load because: ○ As soon as Data Services writes to a pipe, Teradata can read from the pipe. ○ Can use Data Services parallel processing. ○ On Windows, no I/O to an intermediate data file occurs because a pipe is in memory. • Data Services creates the loading script.	• The Teradata Server Tools and Utilities must be Version 7.0 or later. • If you use TTU 7.0 or 7.1, see the *Release Notes*.

Bulk loader method	File Option	Advantages	Restrictions
Load utility	Data file	Load utilities are faster than INSERT statements through the ODBC driver.	● User must provide the loading script. ● Cannot use Data Services parallel processing
	Generic named pipe	● Load utilities are faster than INSERT statements through the ODBC driver. ● Named pipes are faster than data files because: ○ As soon as Data Services writes to a pipe, Teradata can read from the pipe. ○ On Windows, no I/O to an intermediate data file occurs because a pipe is in memory.	● User must provide the loading script. ● Cannot use Data Services parallel processing ● A job that uses a generic pipe is not restartable.
	Named pipes access module	● Load utilities are faster than INSERT statements through the ODBC driver. ● Named pipes should be faster than data files because: ○ As soon as Data Services writes to a pipe, Teradata can read from the pipe. ○ On Windows, no I/O to an intermediate data file occurs because a pipe is in memory ● The job is restartable.	● User must provide the loading script. ● Cannot use Data Services parallel processing.
FastLoad, MultiLoad, and TPump	Data file	Load utilities are faster than INSERT or UPSERT statements through the ODBC driver. Data Services creates the loading script.	Cannot use Data Services parallel processing
	Generic named pipe	● Load utilities are faster than INSERT or UPSERT statements through the ODBC driver.	● Cannot use Data Services parallel processing

Bulk loader method	File Option	Advantages	Restrictions
		• Named pipes are faster than data files because: ○ As soon as Data Services writes to a pipe, Teradata can read from the pipe. ○ On Windows, no I/O to an intermediate data file occurs because a pipe is in memory. • Data Services creates the loading script.	• A job that uses a generic pipe is not restartable.
	Named pipes access module	• Load utilities are faster than INSERT or UPSERT statements through the ODBC driver. • Named pipes should be faster than data files because: ○ As soon as Data Services writes to a pipe, Teradata can read from the pipe. ○ On Windows, no I/O to an intermediate data file occurs because a pipe is in memory. • The job is restartable. • Data Services creates the loading script.	Cannot use Data Services parallel processing.
None (use ODBC)	Uses Teradata ODBC driver to send separate SQL INSERT statements to load data.	INSERT statements through the ODBC driver are simpler to use than a data file or pipe.	This method does not bulk-load data.

Related Information

Designer Guide: Recovery Mechanisms, Automatically recovering jobs [page 721]

6.9.10.3 Parallel Transporter method

SAP Data Services supports Teradata's Parallel Transporter, an ETL tool that consolidates bulk-loading utilities into a single interface.

When you use the Parallel Transporter method, you can leverage Data Services' powerful parallel processing capabilities to specify a number of source and target options including the number of files or pipes for the software to use when processing large quantities of data.

6.9.10.3.1 Source performance tuning

Teradata source options are on the *Teradata options* tab in the source table editor. Here you can select the reading mode plus a number of advanced options.

You can tune the following options in the Teradata source editor to improve performance:

Option	Description
Maximum number of sessions	For large volumes of data, more sessions allows Data Services to read more data parallel. Ideally this number should equal the number of AMPs.
Number of export operator instances	When reading data in parallel, it can be consumed by multiple export instances for better performance. Ideally this value should equal the number of CPUs.
Parallel process threads	These internal threads break buffered data into rows and columns, which can improve performance by maximizing CPU usage on the Job Server computer. Ideally this number should equal the number of CPUs.

Related Information

Reference Guide: Teradata source [page 952]

6.9.10.3.1.1 Special considerations

Be aware of the following limitations when using the Teradata Parallel Transporter.

- It is not always possible to use the Parallel Transporter method to read from a source. In certain situations, Teradata does not support certain SQL constructs and you must use the ODBC method instead. In the following scenarios, Data Services will automatically switch the source mode to ODBC regardless of the actual mode selected on the *Teradata options* tab in the source editor:
  - The WHERE clause of a Query contains `<primary key>=<value>` predicate(s). Such a primary key can be a single column or a composite key.
  - The input schema contains columns of the LOB (CLOB or BLOB) data type.

- Unique secondary index columns are not allowed in the WHERE clause of a Query. However, because Data Services does not have the information as to whether a WHERE clause predicate is part of a unique secondary index, the WHERE clause gets pushed down to the Parallel Transporter reader. In this situation, a run-time error will occur, and you can manually set the source mode to *None* (ODBC).
- Database functions that are pushed down for ODBC readers are also pushed down for Parallel Transporter except for the functions Year and Month.
- Parallel Transporter does not accept parameterized SQL. As a result of this restriction, if a Teradata table is the inner loop of a join, the table will always be cached.
- Readers generated from Table Comparison transform and Lookup function families do not use Parallel Transporter.
- When multiple Teradata readers are optimized by Data Services by collapsing into one, Data Services uses Parallel Transporter whenever possible. When not possible, ODBC is used instead.

6.9.10.3.2 Target performance tuning

SAP Data Services provides the option for parallel processing when you bulk load data using the Parallel Transporter method.

In the target table editor using a combination of choices from the *Options* and *Bulk Loader Options* tabs, you can specify the number of data files or named pipes as well as the number of read and load Operator Instances. The *Number of Loaders* option distributes the workload while the Operators perform parallel processing.

In the target table *Options* tab, specify the *Number of Loaders* to control the number of data files or named pipes that Data Services or Parallel Transporter generates. Data Services writes data to these files in batches of 999 rows. For example, if you set *Number of Loaders* to 2, the software would generate two data files, writing 999 rows to the first file, then writing the next 999 rows to the second file. If there are more rows to process, the software continues, writing to the first file again, then the second, and so forth.

On the *Bulk Loader Options* tab, specify the number of instances in the loading scripts. If you set *Number of DataConnector instances* to 2 and *Number of instances* to 2, Parallel Transporter will assign the first read operator instance to read one data file and the other instance to read another data file in parallel. The DataConnector (read operator) instances then pass the data to the load operator instances for parallel loading into Teradata.

The Parallel Transporter uses a control file to read staging files or pipes and load data.

> **Note**
>
> Performance uaing this type of parallel loading depends on a number of factors such as distribution of incoming data and underlying DBMS capabilities. Under some circumstances, it is possible that specifying parallel loaders can be detrimental to performance. Always test the parallel loading process before moving to production.

6.9.10.3.2.1 Configuring the bulk loader for parallel processing

1. On the target table *Options* tab, specify the *Number of loaders* to control the number of data files or named pipes. Data Services will write data to these files in batches of 999 rows.

2. On the *Bulk Loader Options* tab, for *Bulk loader* choose *Parallel Transporter*.
3. For *File Option*, choose the type of file (*Data file*, *Generic named pipe*, or *Named pipes access module*) to contain the data to bulk load.
4. If you chose *Data file* or *Generic named pipe* in *File Option*, specify the number of read and load instances in the loading scripts.

   If you set *Number of instances* to 2 (load operators) and *Number of DataConnector instances* to 2 (read operators), Parallel Transporter will assign the first read operator instance to read one data file and the other instance to read another data file in parallel. The read operator instances then pass the data to the load operator instances for parallel loading into Teradata.

   > Note
   >
   > If you chose *Data file*, the value you specify for DataConnector instances (read operators) should be less than or equal to the number of data files.

5. If you chose *Named pipes access module* for *File Option*, specify *Number of instances* (load operators) in the loading scripts.

   Teradata uses the value you specify in *Number of loaders* to determine the number of read operator instances, as well as the number of named pipes. The DataConnector instances is not applicable when you use Named Pipes Access Module.

   For example, if you set *Number of loaders* to 2, Parallel Transporter generates two named pipes and assigns one read operator instance to read from one pipe and the other instance to read the other pipe in parallel. If you set *Number of instances* to 2 (load operators), the read operator instances pass the data to the load operator instances for parallel loading into Teradata.
6. If you specified *Named pipes access module* for *File Option*, you can override the default settings for the following Teradata Access Module parameters: Log directory, Log level, Block size, Fallback file name, Fallback directory, Signature checking.

   The Teradata Access Module creates a log file to record the load status and writes information to fallback data files. If the job fails, the Teradata Access Module uses the fallback data files to restart the load. The Access Module log file differs from the build log that you specify in the *Log directory* option in the Teradata datastore.

   > Note
   >
   > Data Services sets the bulk loader directory as the default value for both Log Directory and Fallback Directory.

   For more information about these parameters, see the relevant Teradata tools and utilities documentation.

6.9.10.4 Teradata standalone utilities

In addition to the Parallel Transporter interface, SAP Data Services supports several Teradata utilities that load to and extract from the Teradata database. Each load utility is a separate executable designed to move data into a Teradata database. Choose from the following bulk loader utilities:

Utility	Description
FastLoad	Loads unpopulated tables only. Both the client and server environments support FastLoad. Provides a high-performance load (inserts only) to one empty table each session.
MultiLoad	Loads large quantities of data into populated tables. MultiLoad also supports bulk inserts, updates, upserts, and deletions against populated tables.
TPump	Uses standard SQL/DML to maintain data in tables. It also contains a method that you can use to specify the percentage of system resources necessary for operations on tables. Allows background maintenance for insert, update, upsert, and delete operations to take place at any time you specify. Used with small data volumes.
Load Utility	Invokes one of the above utilities (MultiLoad, FastLoad, or TPump) with the interface prior to Data Services version 11.5.1.

6.9.10.4.1 FastLoad

This procedure describes how to bulk load a table using the Teradata FastLoad utility.

1. Ensure that your Teradata datastore specifies a value in *TdpId* (Teradata Director Program Identifier). This option identifies the name of the Teradata database to load and is mandatory for bulk loading.
2. In the Bulk Loader Options tab of the target table editor, choose *FastLoad* in the *Bulk loader* drop-down list.
3. For *File option*, choose the type of file (*Data file*, *Generic named pipe*, or *Named pipes access module*) to contain the data to bulk load.
4. You can specify the following FastLoad parameters:

FastLoad parameter	Description
Data encryption	Encrypt data and requests in all sessions used by the job. The default is not to encrypt all sessions.
Print all requests	Prints every request sent to the Teradata database. The default is not to reduce print output.
Buffer size	Number of kilobytes for the output buffer that FastLoad uses for messages to the Teradata database. The default is 63 kilobytes which is also the maximum size.
Character set	Particular mapping between characters and byte strings (such as ASCII or UTF-8).

For more information about these parameters, see the Teradata FastLoad Reference.

5. In *Attributes*, you can usually use the default settings for the following attributes in the FastLoad script that SAP Data Services generates.

Script attribute	Description
AccountId	Identifier, of up to 30 characters, associated with the user name that will logon to the Teradata database.
CheckpointRate	The number of rows sent to the Teradata database between checkpoint operations. The default is not to checkpoint.
ErrorLimit	Maximum number of rejected records that Teradata can write to the error table 1 while inserting into a FastLoad table.
ErrorTable1	FastLoad uses this table to store records that were rejected for errors other than unique primary index or duplicate row violation.
ErrorTable2	FastLoad uses this table to store records that violated the unique primary index constraint.
MaxSessions	Maximum number of FastLoad sessions for the load job.
MinSessions	Minimum number of FastLoad sessions required for the load job to continue.
TenacityHours	Number of hours that the FastLoad utility continues trying to logon when the maximum number of load jobs are already running on the Teradata database.
TenacitySleep	Number of minutes that the FastLoad utility waits before it retries a logon operation. The default is six minutes.

> i Note
>
> By default, Data Services uses the bulk loader directory to store the script, data, error, log, and command (bat) files.

For more information about these parameters, see the Teradata FastLoad Reference.

6. If you specified *Data file* for *File Option*, you can increase the *Number of loaders* on the *Options* tab, which increases the number of data files. The software can use parallel processing to write data to multiple data files in batches of 999 rows.

   If you specified *Generic named pipe* or *Named pipes access module*, Data Services supports only one loader and disables the *Number of loaders* option.

Related Information

Reference Guide: Objects, Database datastores (Teradata) [page 868]

6.9.10.4.2 MultiLoad

This procedure describes how to bulk load a table using the Teradata MultiLoad utility.

1. Ensure that your Teradata datastore specifies a value in *TdpId* (Teradata Director Program Identifier). This option identifies the name of the Teradata database to load and is mandatory for bulk loading.
2. In the Bulk Loader Options tab of your target table editor, choose *MultiLoad* in the *Bulk loader* drop-down list.
3. In *File Option*, choose the type of file (*Data File*, *Generic named pipe*, or *Named pipes access module*) to contain the data to bulk load. The default is *Data File*.
4. You can specify the following MultiLoad parameters:

MultiLoad parameter	Short description
Reduced print output	The default is not to reduce print output.
Data Encryption	The default is not to encrypt all sessions.
Character set	Particular mapping between characters and byte strings (such as ASCII or UTF-8).

For more information about these parameters, see the Teradata MultiLoad Reference.

5. In *Attributes*, you can usually use the default settings for the following attributes in the MultiLoad script that SAP Data Services generates.

Script attribute	Short description
LogTable	Table in which Teradata stores the load job status. Specify the restart log table that will maintain the checkpoint information for your MultiLoad job.
AccountId	Identifier, of up to 30 characters, associated with the user name that will logon to the Teradata database.
WorkTable	Teradata uses this table to stage input data.
ErrorTable1	Teradata uses this table to store errors that it detects during the acquisition phase of the MultiLoad import task.
ErrorTable2	Teradata uses this table to store errors that it detects during the application phase of the MultiLoad import task.
ErrorLimit	Maximum number of rejected records that Teradata can write to the error table 1 during the acquisition phase of the MultiLoad import task. If used with ErrorPercentage, *ErrorLimit* specifies the number of records that must be sent to the Teradata database before *ErrorPercentage* takes effect.
ErrorPercentage	Approximate percentage (expressed as an integer) of total records sent so far (*ErrorLimit*) to the Teradata database that the acquisition phase might reject.
CheckpointRate	Interval between checkpoint operations during the acquisition phase. Express this value as either: ○ The number of rows read from your client system or sent to the Teradata database. ○ An amount of time in minutes.
MaxSessions	Maximum number of MultiLoad sessions for the load job.
MinSessions	Minimum number of MultiLoad sessions required for the load job to continue.
TenacityHours	Number of hours that the MultiLoad utility continues trying to logon when the maximum number of load jobs are already running on the Teradata database.

Script attribute	Short description
TenacitySleep	Number of minutes that the MultiLoad utility waits before it retries a logon operation. The default is six minutes.
TableWait	Number of hours that MultiLoad continues trying to start when one of the target tables is being loaded by some other job.
AmpCheck	Specifies how MultiLoad should respond when an Access Module Processor (AMP) is down.
IgnoreDuplicate	Select IgnoreDuplicate to not place duplicate rows in error table 2. The default is to load the duplicate rows.

Note

By default, Data Services uses the bulk loader directory to store the script, data, error, log, and command (bat) files.

For more information about these parameters, see the Teradata MultiLoad Reference.

6. If you specified *Data file* in *File Option*, you can increase the *Number of loaders* in the *Options* tab which increase the number of data files. Data Services can use parallel processing to write data to multiple data files in batches of 999 rows.

   If you specified *Generic named pipe* or *Named pipes access module*, Data Services supports only one loader and disables the *Number of loaders* option.

Reference Guide: Objects, Target tables (Teradata target table options) [page 963]

6.9.10.4.3 TPump

This procedure describes how to bulk load a table using the Teradata TPump utility.

1. Ensure that your Teradata datastore specifies a value in *TdpId* (Teradata Director Program Identifier). This option identifies the name of the Teradata database to load and is mandatory for bulk loading.
2. On the *Bulk Loader Options* tab of the target table editor, choose *TPump* in the *Bulk loader* drop-down list.
3. For *File Option*, choose the type of file (*Data file*, *Generic named pipe*, or *Named pipes access module*) to contain the data to bulk load.
4. You can specify the following TPump parameters:

FastLoad parameter	Short description
Reduced print output	Reduce the print output of TPump to the minimal information required to determine the success of the job. The default is not to reduce print output.

FastLoad parameter	Short description
Retain Macros	Keep macros that were created during the job run. You can use these macros as predefined macros for subsequent runs of the same job.
Data Encryption	Encrypt data and requests in all sessions used by the job. The default is not to encrypt all sessions.
Number of buffers	Number of request buffers that TPump uses for SQL statements to maintain the Teradata database.
Character set	Particular mapping between characters and byte strings (such as ASCII or UTF-8).
Configuration file	Configuration file for the TPump job.
Periodicity value	Controls the rate at which TPump transfers SQL statements to the Teradata database. Value can be between 1 and 600, which specifies the number of periods per minute. The default value is 4 15-second periods per minute.
Print all requests	Turns on verbose mode which provides additional statistical data in addition to the regular statistics.

For more information about these parameters, see the Teradata Parallel Data Pump Reference.

5. In *Attributes*, you specify Data Services parameters that correspond to Teradata parameters in TPump commands. You can usually use the default settings for the following parameters in the TPump script that the software generates.

TPump command	Data Services parameter in Attributes pane	Description
NAME	AccountId	Identifier, of up to 30 characters, associated with the user name that will logon to the Teradata database.
BEGIN LOAD	Append	Use the error table specified in ErrorTable. If the table does not exist, TPump creates it. If the structure of the existing error table is not compatible with the error table TPump creates, the job will run into an error when TPump tries to insert or update the error table.
BEGIN LOAD	CheckpointRate	Number of minutes between checkpoint operations. Value must be an unsigned integer from 0 through 60, inclusive. The default is to checkpoint every 15 minutes.
BEGIN LOAD	ErrorLimit	Maximum number of rejected records that TPump can write to the error table while maintaining a table. The default is no limit. If you specify ErrorPercentage , *ErrorLimit* specifies the number of records that must be sent to the Teradata database before *ErrorPercentage* takes effect. For example, if ErrorLimit is 100 and ErrorPercentage is 5, 100 records must be sent to the Teradata database before the approximate 5% rejection limit is applied. If only 5 records were rejected when the 100th record is sent, the limit is not ex-

TPump command	Data Services parameter in Attributes pane	Description
		ceeded. However, if six records were rejected when the 100th record is sent, TPump stops processing because the limit is exceeded.
BEGIN LOAD	ErrorPercentage	Integer value that represents the approximate percent of the total number of records sent to the Teradata Database that might be rejected during the TPump task. You cannot specify this parameter without ErrorLimit.
BEGIN LOAD	ErrorTable	Name of the table in which TPump stores information about errors and the rejected records.
EXECUTE	ExecuteMacro	Name of macro to execute. Using predefined macros saves time because TPump does not need to create and drop new macros each time you run a TPump job script.
DML LABEL	Ignore duplicate inserts	Select *Ignore duplicate inserts* to not place duplicate rows in the error table.
NAME	JobName	Character string that identifies the name of a job. The maximum length is 16 characters.
BEGIN LOAD	Latency	Number of seconds that the oldest record resides in the buffer before TPump flushes it to the Teradata database. Value cannot be less than one second. If the *SerializeOn* is not specified, only the current buffer can possibly be stale. If you specify *SerializeOn*, the number of stale buffers can range from zero to the number of sessions.
Other TPump commands	LogTable	Name of the table to use to write checkpoint information that is required for the safe and automatic restart of a TPump job. The default name has the following format: `<owner>.<table>_LT`
BEGIN LOAD	MacroDatabase	Name of database to contain any macros TPump uses or builds. The default is to place macros in the same database that contains the TPump target table.
BEGIN LOAD	MaxSessions	Maximum number of sessions for TPump to use to update the Teradata database. SAP Data Services uses a default of 3.
BEGIN LOAD	MinSessions	Minimum number of sessions for TPump to use to update the Teradata database.
BEGIN LOAD	NoDrop	Do not drop the error table, even if it is empty, at the end of a job. You can use *NoDrop* with *Append* to persist the error table, or you can use it alone.

TPump command	Data Services parameter in Attributes pane	Description
BEGIN LOAD	NoMonitor	Prevents TPump from checking for statement rate changes from, or update status information for, the TPump Monitor.
IMPORT INFILE	NoStop	Prevents TPump from terminating because of an error associated with a variable-length record.
BEGIN LOAD	Pack	Number of SQL statements to pack into a multiple-statement request. The default is 20 statements per request. The maximum value is 600.
BEGIN LOAD	PackMaximum	Select PackMaximum to have TPump dynamically determine the number of records to pack within one request. The maximum value is 600.
BEGIN LOAD	Rate	Initial maximum rate at which TPump sends SQL statements to the Teradata database. Value must be a positive integer. If unspecified, Rate is unlimited.
BEGIN LOAD	Robust	Specifies whether or not to use robust restart logic. Value can be *YES* or *NO*. ○ *NO* specifies simple restart logic, which cause TPump to begin where the last checkpoint occurred in the job. TPump redoes any processing that occurred after the checkpoint. ○ *YES* specifies robust restart logic, which you would use for DML statements that change the results when you repeat the operation. Examples of such statements include the following: INSERTs into tables which allow duplicate rows `UPDATE foo SET A=A+1...`
BEGIN LOAD	SerializeOn	Specify a comma separated list of columns to use as the key for rows and guarantee that operations on these rows occur serially.
BEGIN LOAD	TenacityHours	Number of hours that the utility tries to log on sessions required to perform the TPump job. The default is four hours.
BEGIN LOAD	TenacitySleep	Number of minutes that TPump waits before it retries a logon operation. The default is six minutes.

Note

By default, SAP Data Services uses the bulk loader directory to store the script, data, error, log, and command (bat) files.

For more information about these parameters, see the Teradata Parallel Data Pump Reference.

6. If you specified *Data file* in *File Option*, you can increase the *Number of loaders* in the Options tab which increase the number of data files. The software can use parallel processing to write data to multiple data files in batches of 999 rows.

   If you specified Generic named pipe or Named pipe access module, Data Services supports only one loader and disables the Number of loaders option.

Related Information

Reference Guide: Objects, Database datastores (Teradata) [page 868]

6.9.10.4.4 Load Utility

To bulk load a Teradata table using the Load Utility:

1. On the *Bulk Loader Options* tab of your target table editor, choose *Load* in the *Bulk loader* drop-down list.
2. For *File Option*, choose the type of file (*Data File*, *Generic named pipe*, or *Named pipes access module*) to contain the data to bulk load.
3. Enter a command to be invoked by Data Services in the *Command line* text box. For example, `fastload<C:\tera_script\float.ctl`.
4. If you chose *Data file* for *File Option*, enter (or browse to) the directory path where you want the software to place your data file.
5. If you chose *Generic named pipe* or *Named pipes access module* for *File Option*, enter the pipe name.

6.9.10.5 Using the UPSERT bulk-loading operation

The purpose of the Teradata UPSERT operation is to update a row, but if no row matches the update, the row is inserted.

In SAP Data Services, you can only use the Teradata UPSERT operation with the following *Bulk loader* methods:

- MultiLoad
- TPump
- Parallel Transporter
  The UPSERT operation is available only with the following Operators:
  - Stream
  - Update

In Data Services, you enable UPSERT on the target table editor's *Bulk Loader Options* tab. In the *Data Services options* section, for *Bulk Operation*, select *Upsert* (the default is *Insert*).

The additional *Attributes* available when you select *Upsert* include:

- *Ignore missing updates*: Select whether or not to write the missing update rows into the error table. The default is *yes*.

- *Ignore duplicate updates*: Select whether or not to write an updated duplicate row into the error table. The default is *no*.

After selecting *Upsert*, note that you can also enable the *Use input keys* option on the target editor's *Options* tab.

Reference Guide: Objects, Target tables [page 963]

6.9.11 Bulk loading using DataDirect's Wire Protocol SQL Server ODBC driver

Use the DataDirect's Wire Protocol SQL Server ODBC driver bulk load feature to quickly insert and update a large number of records into a database. You don't need to use a separate database load utility because the bulk load feature is built into the driver. DataDirect drivers are included in the Data Services installation.

For more detailed information about the Wire Protocol SQL Server ODBC driver, see the DataDirect documentation.

Some general considerations when using the bulk load feature:

- Enable the bulk load option only when you want to optimize load performance. Leaving the bulk load option enabled at all times could lead to undesired results or even corrupt data.
- Do not select the *Enable Bulk Load* option if any of the following Data Services loader options are enabled:
  - Include in Transaction
  - Use Overflow File
  - Auto Correct Load
  - Load Triggers
- You should create a different DSN and datastore when you are:
  - using the same SQL Server database server in different datastores.
  - using loaders that have different bulk load options.

6.9.11.1 Enabling the DataDirect bulk load feature in Windows

To enable the DataDirect bulk load feature for MS SQL Server on Windows, do the following:

1. Open the ODBC Data Source Administrator and go to the *Use DSN* tab. Click *Add*.
2. In the *Create New Data Source* window, select the DataDirect SQL Server Wire Protocol driver and click *Finish*. The *ODBC SQL Server Wire Protocol Driver Setup* window opens.
3. Enter driver setup information, such as the name of the data source, the host number, and so on.
4. On the Bulk tab, select the *Enable Bulk Loading* option.
5. Set the Bulk Options.

Option	Description
Keep Identity	Keeps source identity values.
Check Constraints	Checks constraints while data is being inserted into the database.
Keep Nulls	Keeps null values in the destination table.
Table Lock	Locks the table while the bulk copy operation is taking place. This option is checked by default.
Fire Triggers	Executes a trigger each time a row is being inserted into the database.
Bulk Binary Threshold (KB)	Maximum amount of data that you want exported to the bulk data file.
Batch Size	Number of rows you want the driver to send to the database at one time.
Bulk Character Threshhold (KB)	Maximum amount of character data that you want exported to the bulk data file.

6.9.11.2 Enabling the DataDirect bulk load feature in UNIX

To enable the DataDirect bulk load feature for MS SQL Server on UNIX, do the following:

1. Using a text editor, open the `odbc.ini` file associated with the DSN for which you are bulk loading.
2. Set the EnableBulkLoad option to 1.
3. Enter a BulkLoadOptions value. The value you enter depends on what options you enable.

Option	Description
Keep Identity	A value of 1 keeps source identity values.
Check Constraints	A value of 16 checks constraints while data is being inserted into the database.
Keep Nulls	A value of 64 keeps null values in the destination table.
Table Lock	A value of 2 locks the table while the bulk copy operation is taking place.
Fire Triggers	A value of 32 executes triggers when a row is being inserted into the database.

   Add the option values together and use the total as the BulkLoadOption value. For example, 16 (Check Constraints) + 32 (Fire Triggers) + 1 (Keep Identity) = 49.

   `BulkLoadOptions=49`.

4. Set the BulkLoadBatchSize option. This option sets the number of rows you want the driver to send to the database at one time. The default value is 1024.

Example

odbc.ini file

6.10 Other Tuning Techniques

The previous chapters describe the following tuning techniques:

- Maximizing push-down operations
- Using Caches
- Using Parallel Execution
- Distributing Data Flow Execution
- Using Bulk Loading

This section describes other tuning techniques that you can use to adjust performance:

- Source-based performance options
    - Join ordering
    - Minimizing extracted data
    - Using array fetch size

- Target-based performance options
  - Loading method
  - Rows per commit
- Job design performance options
  - Loading only changed data
  - Minimizing data type conversion
  - Minimizing locale conversion
  - Precision in operations

These techniques require that you monitor the change in performance carefully as you make small adjustments.

6.10.1 Source-based performance options

6.10.1.1 Join ordering

6.10.1.1.1 Join rank settings

You can use join rank to control the order in which sources are joined. Join rank indicates the rank of a source relative to other tables and files joined in a data flow. When considering join rank, the Data Services Optimizer joins sources with higher join ranks before joining sources with lower join ranks.

Join rank must be a non-negative integer. The default value is 0.

Although it is possible to set join rank in the Query editor FROM tab or in a source editor, the best practice is to specify the join rank directly in the Query editor.

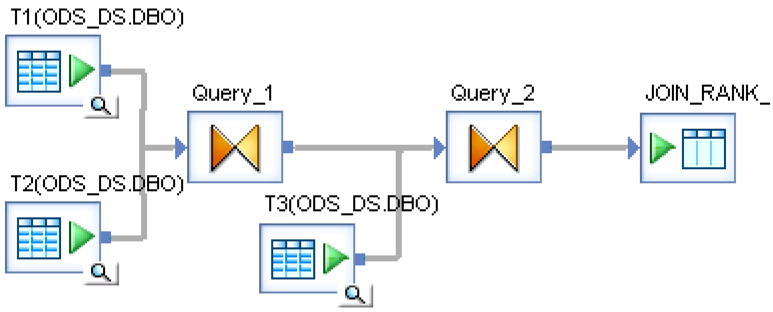
> i Note
>
> Join ranks set in sources are not displayed in the Query editor. If a join rank value is specified in the source, to find the value you must open the source editor.

The Data Services Optimizer gives preference to settings entered in the Query editor over settings entered in a source editor. If any one input schema has a join rank specified in the Query editor, then the Data Services Optimizer considers only Query editor join rank settings and ignores all source editor join rank settings.

Additionally, in a data flow containing multiple adjacent Query transforms, upstream join rank settings may be considered.

The join rank determination for multiple adjacent Query transforms can be complex because the Data Services Optimizer may combine these Query transforms into a single Query transform.

Consider a case where there is a join T1 inner join T2 in a query, Query_1; and the result of that join is used in another join in a downstream query, Query_2, as Query_1 inner join T3. The Optimizer would combine these two inner joins into a new Query, Query_2'.



Scenario 1

If the join rank values are set as follows:

Query editor	Table	Join rank
Query_1	T1	30
	T2	40
Query_2	Query_1 result set	10
	T3	20

The combined query, Query_2', would have the following join rank values:

Query editor	Table	Join rank
Query_2'	T1	30
	T2	40
	T3	41

The join rank value for T3 is adjusted to 41 because in the original Query_2 T3 has a higher join rank value than the result of T1 join T2 (Query_1 result set).

Scenario 2

In Query_2, if no join rank value is specified, then the default join rank of 0 is applied to both the Query_1 result set and T3. The join rank values are set as follows:

Query editor	Table	Join rank
Query_1	T1	30
	T2	40

Query editor	Table	Join rank
Query_2	Query_1 result set	not set (default=0)
	T3	not set (default=0)

The combined query, Query_2', would have the following join rank values:

Query editor	Table	Join rank
Query_2'	T1	30
	T2	40
	T3	40

The join rank value for T3 is adjusted to 40 because in the original Query_2 T3 has the same join rank value as the result of T1 join T2 (Query_1 result set).

Scenario 3

Assume join ranks are not set in the source tables. In Query_1, if no join rank value is specified, then the default join rank of 0 is applied to both T1 and T2. Values are set in the Query_2 Query editor as follows:

Query editor	Table	Join rank
Query_1	T1	not set (default=0)
	T2	not set (default=0)
Query_2	Query_1 result set	10
	T3	20

The combined query, Query_2', would have the following join rank values:

Query editor	Table	Join rank
Query_2'	T1	10
	T2	10
	T3	20

Scenario 4

If join rank values are not specified in the Query_1 and Query_2 Query editors, then the combined query, Query_2', would have no join rank values specified (default=0).

6.10.1.1.2 Join rank tips

For an inner join between two tables, in the Query editor assign a higher join rank value to the larger table and, if possible, cache the smaller table.

For a join between a table and file:

- If the file is small and can be cached, then assign it a lower join rank value and cache it.
- If you cannot cache the file, then assign it a higher join rank value so that it becomes the "outer table" in the join.

For a join between two files, assign a higher rank value to the larger file and, if possible, cache the smaller file.

6.10.1.1.3 About join ordering

The Data Services Optimizer determines the order it joins two or more tables based on the type of join and, where applicable, join rank. Although the join order has no effect on the actual result produced, controlling join order can often have a profound effect on the performance of producing the join result.

Join ordering is relevant only in cases where the Data Services engine performs the join. In cases where the query is pushed down to the database, the database determines how a join is done.

Join order in left outer joins

The result of a left outer join depends on the order of the sources. When considering left outer joins, the Data Services Optimizer does not change the join order from that specified in the Query editor. Since join order is not changed, join rank is not considered in the current query. However in a downstream query that uses the results of the left outer join as one of the sources, the join rank may be considered. Caching is implemented based on the cache settings specified in the Query editor.

Join order in inner joins

The result of an inner join is not dependent on the order of the sources. The Data Services Optimizer considers join rank and uses the source with the highest join rank as the left source. The Data Services Optimizer may choose to join tables in a different order than the order defined in the Query editor.

Viewing optimized join order

You can print a trace message to the Monitor log file which allows you to see the order in which the Data Services Optimizer performs the joins. This information may help you identify ways to improve performance.

To add the trace, select *Optimized Data Flow* from the list of traces in the *Trace* tab of the *Execution Properties* dialog.

View the results of the trace in the Trace log. The message begins `Join Order is:`.

Join order in real-time jobs

Using a left outer join is often preferable with real-time jobs because often you want the whole message passed on whether or not conditions a join looks for in the inner source exist.

In fact, if you do not use a left outer join to order joins for a message, the software will still process the message as if it has the highest join rank. The message source editor lacks a Join rank option because the software automatically gives it the highest join rank.

Related Information

Maximizing Push-Down Operations [page 2116]

6.10.1.1.4 Inner join example

When performing inner joins, the results of the join are identical no matter what order the joins are performed.

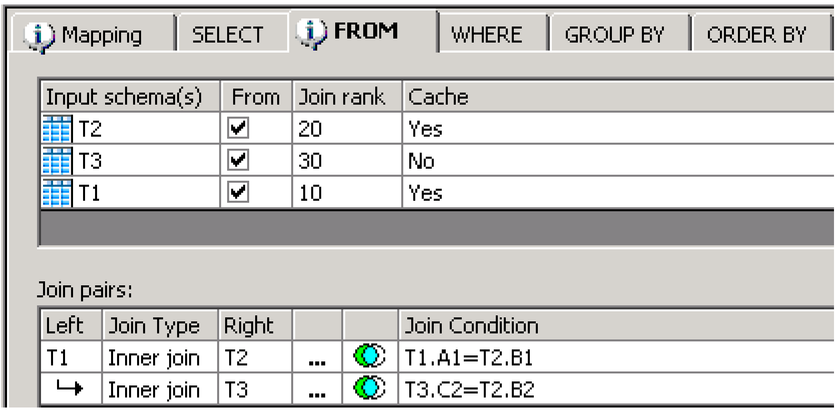
Because join rank is considered, for inner joins, the Data Services Optimizer may choose to join tables in a different order than the order defined in the Query editor.

When assigning join rank, also consider the effect of cache. If you assign a high join rank to a source, it will likely become the left (outer) source for the join. Generally, right (inner) tables are cached. When choosing to cache a source, ensure that you have sufficient memory or pageable cache.

Consider the following information:

Table	Column (data type)	Column (data type)	Number of Rows
T1	A1 (int)	A2 (int)	1,000,000
T2	B1 (int)	B2 (int)	1000
T3	C1 (int)	C2 (int)	1000

Suppose you wanted to create inner joins between T1, T2, and T3. Taking the number of rows in each table into consideration, in the Query editor you might specify join rank, cache, and join pairs as shown in the following screenshot:



Input schema(s)	From	Join rank	Cache
T2	☑	20	Yes
T3	☑	30	No
T1	☑	10	Yes

Join pairs:

Left	Join Type	Right			Join Condition
T1	Inner join	T2	...		T1.A1=T2.B1
↳	Inner join	T3	...		T3.C2=T2.B2

Although the join order is expressed as `T1 INNER JOIN T2 ON T1.A1=T2.B1 INNER JOIN T3 ON T3.C2=T2.B2`, the Data Services Optimizer determines the join order for inner joins. For the first join, the Optimizer takes source with the largest join rank, T3, as the left source and the table with the next highest join rank, T2, as the right source. The result of that inner join would then be joined with the remaining table, T1. The optimized SQL would appear as follows:

```
SELECT T1.A1, T3.C2
FROM (T3 INNER JOIN T2 ON (T3.C2=T2.B2))
INNER JOIN T1 ON (T1.A1=T2.B1)
```

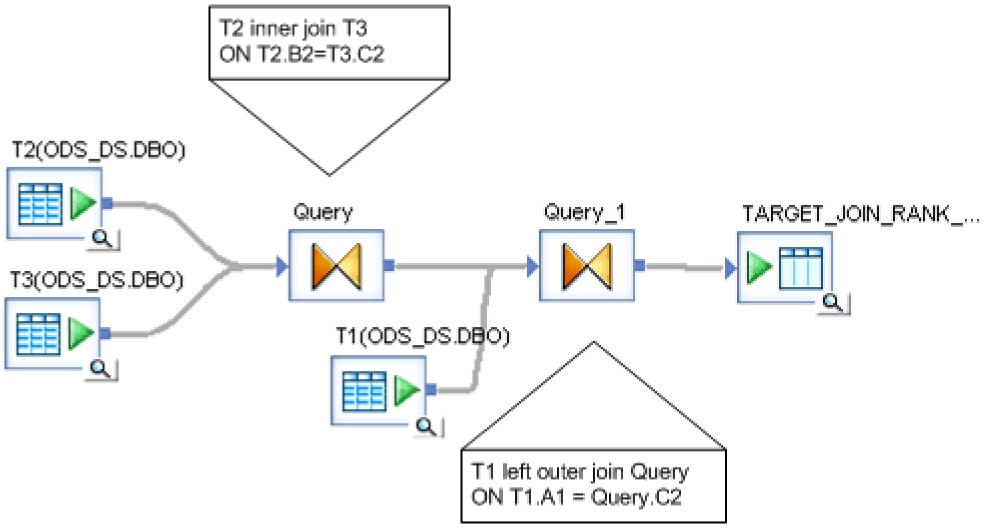
6.10.1.1.5 Join order with mixed joins example

Consider a case where you want to join T1 with the result of an inner join between T2 and T3.

```
FROM T1 LEFT OUTER JOIN (T2 INNER
          JOIN T3 ON T2.B2=T3.C2)
 ON T1.A1=T3.C2
```

Although you can specify mixed joins within the Query editor, you may specify the left table only for the first join. Subsequent joins take the result of the previous join as the left source. The data flow for this case must contain two queries. The first query will inner join T2 and T3; the second query is a left outer join with T1 as the left source and the result of the first query as the right source.

The data flow would look as follows:



In the Query_1 transform, C2 originates in T3.

Assume the source information in the following table:

Table	Column (data type)	Column (data type)	Number of Rows	Join Rank	Cache
T1	A1 (int)	A2 (int)	1,000,000	10	Yes
T2	B1 (int)	B2 (int)	1000	20	No
T3	C1 (int)	C2 (int)	1000	30	No

In the first query, T3 has the higher join rank so the Data Services Optimizer would perform the inner join as `T3 INNER JOIN T2 ON T3.C2 = T2.B2` even if the outer table specified in the Query editor is T2. In this case the cache setting for T2 is No, so the table would not be cached.

In the second query, T1 is left outer joined with the results of the first query. Join rank is not considered because this is a left outer join. In a scenario where join rank is relevant, the maximum join rank from the previous join is inherited. Additionally the result of the join T2 and T3 would be cached if either T2 or T3 has a cache setting of Yes.

6.10.1.2 Minimizing extracted data

The best way to minimize the amount of data extracted from the source systems is to retrieve only the data that has changed since the last time you performed the extraction. This technique is called changed-data capture.

Related Information

Designer Guide: Capturing Changed Data [page 738]

6.10.1.3 Using array fetch size

SAP Data Services provides an easy way to request and obtain multiple data rows from source databases. The array fetch size feature allows you to retrieve data using fewer requests, thereby significantly reducing traffic on your network. Tuning array fetch size can also reduce the amount of CPU use on the Job Server computer.

The array fetch feature lowers the number of database requests by "fetching" multiple rows (an array) of data with each request. Enter the number of rows to fetch per request in the *Array fetch size* option on any source table editor or SQL transform editor. The default setting is 1000, meaning that with each database request, The software will automatically fetch 1000 rows of data from your source database. The maximum array fetch size that you can specify is 5000 bytes.

It is recommended that you set the array fetch size based on network speed.

> i Note
>
> Higher array fetch settings will consume more processing memory proportionally to the length of the data in each row and the number of rows in each fetch.

Regardless of the array fetch setting, sources reading columns with an Oracle LONG data type cannot take advantage of this feature. If a selected data column is of type LONG, the array fetch size internally defaults to `1` row per request.

6.10.1.3.1 Setting the Array fetch size parameter

1. Use either a source table editor or an SQL transform editor.

   To use a source table editor:

   a) Double-click a source table in the Designer's workspace.

   b) In the *Performance* section of the *Source* tab, enter a number in the *Array fetch size* text box.

   To use an SQL transform editor:

   a) Double-click an SQL transform in the Designer's workspace.

   b) In the SQL transform editor, enter a number in the *Array fetch size* text box.

   Array Fetch Size indicates the number of rows returned in a single fetch call to a source table. The default value is 1000. This value reduces the number of round-trips to the database and can improve performance for table reads.

   The Array Fetch Size option does not support long column data types. If the *SELECT* list contains a long column, the software sets the *Array Fetch Size* to 1 and reads one row of data at a time from the database.
2. Click *OK*.

6.10.1.3.2 Tip

The optimal number for *Array fetch size* depends on the size of your table rows (the number and type of columns involved) as well as the network round-trip time involved in the database requests and responses. If your computing environment is very powerful, (meaning that the computers running the Job Server, related databases, and connections are extremely fast), then try higher values for *Array fetch size* and test the performance of your jobs to find the best setting.

6.10.2 Target-based performance options

6.10.2.1 Loading method

You can choose to use regular loading or bulk loading. For a regular load, the *Parameterized SQL* option is automatically selected when generating, parsing, and compiling the statement. By using parameterized SQL, the software can minimize these efforts by using one handle for a set of values instead of one handle per value.

Many databases do not support bulk loading with the following options; see the specific options for your target database in the *Reference Guide*.

- Auto-correct load
- Enable Partitioning
- Number of Loaders
- Full push down to a database
  The software automatically selects this optimizer process when the following conditions are met:
  - The source and target in a data flow are on the same database.
  - The database supports the operations in the data flow.

  If the optimizer pushes down source or target operations, then it ignores the performance options set for sources (Array fetch size, Caching, and Join rank) because it is not solely processing the data flow.
- Overflow file
- Transactional loading

To improve performance for a regular load (parameterized SQL), you can select the following options from the target table editor. Note that if you use one, you cannot use the others for the same target.

- Enable Partitioning
  Parallel loading option. The number of parallel loads is determined by the number of partitions in the target table.
- Number of Loaders
  Parallel loading option. The number of parallel loads is determined by the number you enter for this option.

Related Information

Table partitioning [page 2138]
Bulk Loading and Reading [page 2164]
Reference Guide: Objects, Target tables [page 963]

6.10.2.2 Rows per commit

Rows per commit for regular loading defaults to 1000 rows. Setting the *Rows per commit* value significantly affects job performance. Adjust the rows per commit value in the target table editor's *Options* tab, noting the following rules:

- Do not use negative number signs and other non-numeric characters.
- If you enter nothing or `0`, the text box will automatically display `1000`.
- If you enter a number larger than `5000`, the text box automatically displays `5000`.

It is recommended that you set rows per commit between `500` and `2000` for best performance. You might also want to calculate a value. To do this, use the following formula:

`max_IO_size/row size` (in bytes)

For most platforms, `max_IO_size` is 64K. For Solaris, `max_IO_size` is 1024K.

Note that even with a value greater than one set for *Rows per commit*, SAP Data Services will submit data one row at a time if the following conditions exist:

- You are loading into a database (this scenario does not apply to Oracle databases), and have a column with a LONG datatype attribute.
- You are using an overflow file where the transaction failed. However, once all the rows are loaded successfully, the commit size reverts to the number you entered. In this case, depending on how often a load error happens, performance might be come worse than setting *Rows per commit* to `1`.

Related Information

Caching sources [page 2130]

6.10.3 Job design performance options

6.10.3.1 Loading only changed data

Identifying and loading only changed data is called changed-data capture (CDC), which includes only incremental data that has changed since the last refresh cycle. Performance improves because with less data to extract, transform, and load, the job typically takes less time.

Related Information

Designer Guide: Capturing Changed Data [page 738]

6.10.3.2 Minimizing data type conversion

SAP Data Services offers very robust and easy-to-use data type conversions via column mappings of different data types. It is recommended that you:

- Avoid unnecessary data conversions.
- Verify that Data Services is performing the implicit conversions (selected when you drag and drop columns from input to output schemas in the query transform) as expected. This can be done by looking at the warnings generated during job validation.

6.10.3.3 Minimizing locale conversion

If your jobs do not require the use of different or multi-byte locales, you can increase performance by ensuring that locales are single-byte and not mismatched.

6.10.3.4 Precision in operations

SAP Data Services supports the following precision ranges: 0-28, 29-38, 39-67, 68-96. Note that as you decrease precision, performance increases for arithmetic operations and comparison operations. In addition, when processing an arithmetic or boolean operation that includes decimals in different precision ranges, the software converts all to the highest precision range value because it cannot process more than one decimal data type precision range for a single operation. For example, if the software must perform an arithmetic operation for decimals with precision 28 and 38, it converts both to precision 38 before completing the operation.

7 Integrator Guide

7.1 Welcome to SAP Data Services

7.1.1 Welcome

SAP Data Services delivers a single enterprise-class solution for data integration, data quality, data profiling, and text data processing that allows you to integrate, transform, improve, and deliver trusted data to critical business processes. It provides one development UI, metadata repository, data connectivity layer, run-time environment, and management console—enabling IT organizations to lower total cost of ownership and accelerate time to value. With SAP Data Services, IT organizations can maximize operational efficiency with a single solution to improve data quality and gain access to heterogeneous sources and applications.

7.1.2 Documentation set for SAP Data Services

You should become familiar with all the pieces of documentation that relate to your SAP Data Services product. The latest Data Services documentation can be found on the *SAP Help Portal*.

Document	What this document provides
Adapter SDK Guide	Information about installing, configuring, and running the Data Services Adapter SDK
Administrator Guide	Information about administrative tasks such as monitoring, lifecycle management, security, and so on.
Customer Issues Fixed	Information about customer issues fixed in this release. ℹ Note In some releases, this information is displayed the Release Notes.
Designer Guide	Information about how to use Data Services Designer.
Documentation Map	Information about available Data Services books, languages, and locations.
Installation Guide for Windows	Information about and procedures for installing Data Services in a Windows environment.
Installation Guide for UNIX	Information about and procedures for installing Data Services in a UNIX environment.
Integrator Guide	Information for third-party developers to access Data Services functionality using web services and APIs.
Master Guide	Information about the application, its components and scenarios for planning and designing your system landscape. Information about SAP Information Steward is also provided in this guide.

Document	What this document provides
Management Console Guide	Information about how to use Data Services Administrator and Data Services Metadata Reports.
Performance Optimization Guide	Information about how to improve the performance of Data Services.
Reference Guide	Detailed reference material for Data Services Designer.
Release Notes	Important information you need before installing and deploying this version of Data Services.

7.1.3 Accessing documentation

You can access the complete documentation set for SAP Data Services in several places.

7.1.3.1 Accessing documentation on Windows

After you install SAP Data Services, you can access the documentation from the Start menu.

1. Choose *Start* > *Programs* > *SAP Data Services 4.2* > *Data Services Documentation* > *All Guides*.
2. Click the appropriate shortcut for the document that you want to view.

7.1.3.2 Accessing documentation on UNIX

After you install SAP Data Services, you can access the documentation by going to the directory where the printable PDF files were installed.

1. Go to `<LINK_DIR>/doc/book/en/`.

2. Using Adobe Reader, open the PDF file of the document that you want to view.

7.1.3.3 Accessing documentation from the Web

You can access the complete documentation set for SAP Data Services from the SAP Business Users Support site.

To do this, go to *http://help.sap.com/bods*.

You can view the PDFs online or save them to your computer.

7.1.4 SAP information resources

A global network of SAP technology experts provides customer support, education, and consulting to ensure maximum information management benefit to your business.

Useful addresses at a glance:

Address	Content
Customer Support, Consulting, and Education services *http://service.sap.com/*	Information about SAP support programs, as well as links to technical articles, downloads, and online forums. Consulting services can provide you with information about how SAP can help maximize your information management investment. Education services can provide information about training options and modules. From traditional classroom learning to targeted e-learning seminars, SAP can offer a training package to suit your learning needs and preferred learning style.
Product documentation *http://help.sap.com/bods/*	SAP product documentation.
Supported Platforms (Product Availability Matrix) *https://service.sap.com/PAM*	Get information about supported platforms for SAP Data Services. Use the search function to search for Data Services. Click the link for the version of Data Services you are searching for.
SAP Data Services Community Network *http://scn.sap.com/community/data-services*	Get online and timely information about SAP Data Services, including forums, tips and tricks, additional downloads, samples, and much more. All content is to and from the community, so feel free to join in and contact us if you have a submission.
Blueprints *http://scn.sap.com/docs/DOC-8820*	Blueprints for you to download and modify to fit your needs. Each blueprint contains the necessary SAP Data Services project, jobs, data flows, file formats, sample data, template tables, and custom functions to run the data flows in your environment with only a few modifications.

Address	Content
SAPTerm *https://portal.wdf.sap.corp/go/sapterm*	SAP’s terminology database, the central repository for defining and standardizing the use of specialist terms.

7.2 Web service support

This section discusses both how an administrator can configure SAP Data Services through the Administrator to publish jobs as callable web services, and how an application developer can access those web services.

The software publishes web services from the Management Console Administrator. To use SAP Data Services as a web service, select the Web Services node in the Administrator's navigation tree. For general information on using the Administrator, see the *Management Console Guide*.

7.2.1 Overview

Web services are modular business applications based on open standards (WSDL, REST, SOAP, and XML Schema primarily) that allow integration among different applications and environments through the Internet. Web services allow parts of existing applications to be used by other applications.

For business intelligence (BI), you can use web services to accomplish the following:

- Access legacy systems
- Conduct computer-to-computer interaction over an internal or external web
- Allow applications constructed in different languages on different platforms to communicate with each other in an enterprise environment

SAP Data Services can:

- Publish any job as a callable web service (server functionality)
- Call published web services from within its jobs using the built-in web services datastore (client functionality)

If you have an application that also supports web services, you can use that application to run batch and real-time jobs or to publish your application's functionality to be called by data flows.

After you install the software, you can immediately start working with its client functionality because the built-in web services datastore is a web services client that provides access to a web services server from a data flow.

Related Information

Using SAP Data Services as a web service provider [page 2218]

Consuming external web services in SAP Data Services [page 2257]

7.2.2 Web services technologies

SAP Data Services web services are fully compliant with Web Services Interoperability (WS-I) Basic Profile 1.0, and support three Java Web Services technologies.

Web service technology	Description
SOAP	Connection protocol (envelope for XML messages).
WSDL	Language used to request a service and return replies (subset of XML).
XML Schema	Format used for the WSDL file.

The software supports SOAP 1.1, WSDL version 1.1, 2.0 and 2.1, and Apache Axis 1.1 (an industry-standard SOAP message handler and WSDL parser).

SAP Data Services is also compliant with the Microsoft .NET environment for web services. You can import the WSDL that the software generates into Visual Studio .NET and the web services datastore can call the WSDL that Visual Studio .Net generates.

SAP Data Services also supports the following for REST web services:

Web service technology	Description
REST	Design pattern based on HTTP connection protocol.
WADL	Language used to describe the request and response for a web provider.
XML Schema	Schema used to describe the input and output for a web service operation.
JSON/XML	Message format used by web services to communicate with a client.

ℹ Note

Currently, SAP Data Services only supports consuming external REST web service providers (for example, outbound web calls allowing you to call a provider). The software does not expose REST web service operations (for example, inbound web calls allowing you to access SAP Data Services).

Related Information

SOAP [page 2214]
REST web services [page 2216]

7.2.2.1 SOAP

SAP Data Services allows you to invoke real-time services using the following:

- Message Client API (which supports C++ and Java connections)
- TCP/IP
- proprietary XML using HTTP

In addition, the software supports the Simple Object Access Protocol (SOAP). SOAP is the industry standard from the World Wide Web Consortium (WC3.org) used to invoke network resources using XML over HTTP, HTTPS, and other standard protocols.

A SOAP gateway is built in to the Administrator. The software supports SOAP over HTTP and HTTPS protocols.

7.2.2.1.1 WSDL

Web Services Description Language (WSDL) is a subset of XML. It is used as a transport mechanism for XML messages. SAP Data Services publishes its jobs in WSDL based on configuration settings applied in the Administrator, and then developers can create a web services client based on the software's WSDL.

The software also publishes all comments entered into the Designer's *Job Descriptions* box with each job that is added to the WSDL file.

The WSDL file generated by the software includes tags (such as services, bindings, ports, and operations) that support the use of the SOAP protocol. Each tag uses a name that the software provides. For example:

- You select which jobs to publish in the web service named `DataServices_server`. In WSDL, a service is a set of business operations with connection endpoints.
- Binding names include `Connection_Operations`, `Batch_Jobs`, `Real-time_Services`, and `Batch_Job_Admin`. WSDL uses bindings to associate operations with ports.
- Operation names have a one-to-one relationship with the names of batch jobs or real-time services.

7.2.2.1.2 XML Schema

WSDL uses XML Schemas to define input and output message formats.

- For server functionality, if a real-time service was defined with DTDs, you will need to translate the DTD format into the XML Schema format.
- For client functionality, the web services datastore imports metadata into SAP Data Services using the XML Schema format only.

XML Schema formats are defined in the *types* element of the WSDL file.

> i Note
>
> When you import an XML schema for a real-time web service job, you should use a unique target namespace for the schema. When Data Services generates the WSDL file for a real-time job with a source or target schema that has no target namespace, it adds an automatically generated target namespace to the types section of the XML schema. This can reduce performance because Data Services must suppress the namespace information from the web service request during processing, and then reattach the proper namespace information before returning the response to the client.

7.2.2.1.3 UDDI

UDDI is a method of publishing comments and other reference information about jobs to an external web site. SAP Data Services does not publish information to a UDDI web site because most web service users work behind enterprise firewalls.

7.2.2.2 REST web services

Representational State Transfer (REST or RESTful) web service is a design pattern for the World Wide Web. Data Services allows you to call the REST server and then browse through and use the data the server returns. Unlike SOAP, which exposes functions, REST exposes resources (data). The REST web services supports JSON and XML data types.

Each function in REST web services uses a unique endpoint uniform resource identifier (URI). Data Services strictly requires each function to have a fixed schema defined by XSD (XML Schema Definition). Based on HTTP verbs, Data Services is then able to get or modify resources. Some of the more common HTTP verbs include GET (retrieves data), PUT (updates data), POST (creates new data), and DELETE (deletes data).

> **Note**
>
> Data Services does not support the HEAD HTTP verb. It does not expose header outputs in the Query transform.

In order to call the REST web service through Data Services, you need to provide a Web Application Description Language (WADL) file. This XML file describes methods and input and output schemas and provides Data Services with all the required parameters it needs to call REST functions.

Data Services allows you to do the following:

- Create a Web Services REST datastore. The datastore exposes functions that Data Services uses to call the server through HTTP communication.
- Parse the WADL file to expose REST functions.
- Browse a Web Services REST datastore to find and import functions.
- Use REST functions in a Query transform.
- Use JSON or XML as input and output for REST functions.
- Consume REST web services (outbound only) from the engine.

For more information, see "Web service datastores" in the *Designer Guide*.

Authorization schemas

Data Services supports the following authorization schemas. You must have knowledge of the provider to which you are connecting in order to obtain some configuration information, such as the consumer key.

- Basic
- Basic + CSRF (Cross-Site Request Forgery protection)

- Authorization Header (Custom Token, API key, and so on)
- OAuth 1.0 (2-legged)
- OAuth 2.0 (2-legged)

> **Note**
>
> For OAuth 2.0 based authentication, Data Services only supports client_credentials and password-based grant types. Data Services does not support the 3-legged model.

Related Information

WADL [page 2217]

7.2.2.2.1 WADL

You must provide Data Services with a well-organized WADL file. This file should follow the schema provided by the World Wide Web Consortium (WC3.org) at *http://www.w3.org/Submission/wadl/wadl.xsd* . There are various third party tools that you can use to create and edit this file.

The file should contain a Grammars element, which provides the location for input and output schemas. Data Services can then parse elements and store them in an internal repository for browsing and exposing operations.

A WADL file contains many components. The following table explains some of the more common elements of the schema:

Element	Description
Application	Forms the root of the WADL file and contains all the resources.
Doc	Describes an element. If provided in the param element, this information will be displayed as the function description in the Designer user interface.
Grammars	Provides the external location for input and output schemas.
Resources	Contains a list of resources.
Resource	Defines a unique URI.
Method	Defines the HTTP verb for selected resource.
Representation	Indicates the content type and respective element defined in grammar.
Param	Contains parameters that form a part of the URI or header.

Related Information

Designer Guide: To define a web services datastore [page 237]

7.2.2.2.2 HTTP Status Codes

HTTP Status Codes are standard response codes that a server returns to help you identify the cause of a problem.

An HTTP Status Code of 200 OK is the correct response (for example, the XML/JSON document matches the schema output schema) and is considered a success. An HTTP Status Code greater than or equal to 400 is considered an error and Data Services populates the AL_ERROR_MSG column with a server error message.

- AL_ERROR_NUM — returns error codes: 0 for success and a non-zero integer for failures
- AL_ERROR_MSG — returns an error message if AL_ERROR_NUM is not 0. Returns NULL if AL_ERROR_NUM is 0

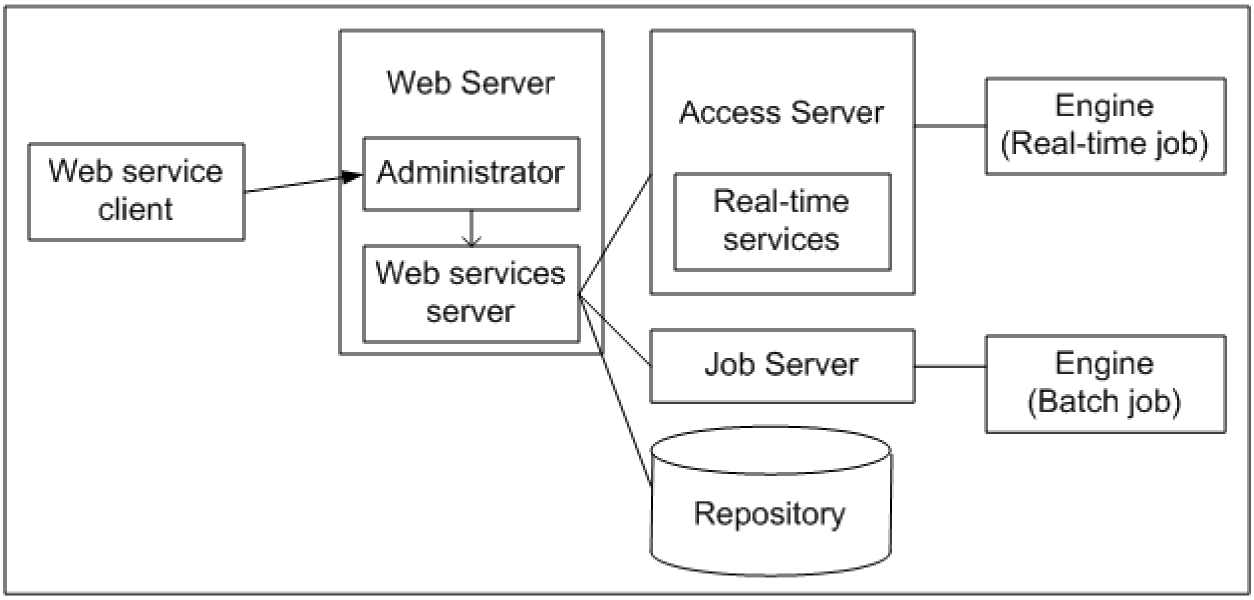
Table 183: Error codes for AL_ERROR_NUM column

Error code	Description
0	The call was successful and the server returned a 200 OK status.
1	NRDM to XML/JSON conversion failed. The engine was unable to successfully create the message payload. This can be caused by an invalid character in the input, and so on.
2	XML/JSON to NRDM conversion failed. Engine was unable to successfully convert the response payload. Possible causes include: • invalid XML/JSON • server did not return a document that matches the schema (the engine requires the XML/JSON document to exactly match the schema) • invalid characters (for example, control characters)
3	The call to the server failed. Possible causes include: • invalid URL • malformed URL • server does not exist • SSL certificate is missing • proxy or firewall does not allow Data Services to communicate with the URL • no internet communication • resource can't be found • lack of privileges to access the resource
4	An OAuth communication error. This error can be caused by all the items listed for error code 3, but are related to only OAuth and OAuth errors.

7.3 Using SAP Data Services as a web service provider

After the Administrator publishes batch or real-time jobs as web services, the web application hosts those web services. When an external application calls into SAP Data Services through web services, the application acts as a web services client accessing a web services server.

Web service clients call the published web services, pass in the appropriate parameters, and receive the results. The software routes calls to the appropriate Job Server and job for processing.



Web services might be used in the following example scenarios:

- Dynamically update an internal web site
  Suppose you have an internal web site that manages foreign exchange rate status worldwide for the Finance department. When foreign exchange rates change more than a certain percentage, a batch job updates exchange rates in your financial data mart. The rate change initiates a call to a web service that starts the appropriate batch ETL job.
- Solve a processing issue
  Suppose you have an existing Enterprise Application Integration (EAI) bus infrastructure and want to manage batch processes and EAI transactional processes from within the same infrastructure. The transactional processes are complex. Their staging is laid out in the order process. However, EAI work flows do not have the ability to run batch processes.
  The software can publish Web services that allow you to leverage EAI process management category tools (for example, webMethods Business Process Manager) to control and stage batch processes alongside its transactional processes.
  The work flows might call the software to:
  - Perform an initial load of a data mart for real-time reporting
  - Refresh the data cache depending on specified business criteria
  - Perform complex transforms on hierarchical objects for mapping data between ERP systems

7.3.1 WSDL basics

WSDL is a subset of XML that you can use to describe network services as a collection of endpoints capable of exchanging messages.

This table shows the elements in a WSDL file, and describes how those elements are used in the SAP Data Services-generated WSDL file.

Element Name	Description
definition	Root element
service	Used to group a set of related ports or endpoints to which a client application will connect. The software publishes a single service in the WSDL file it generates.
port	Defines a specific web service endpoint that a client can access. Each port has a unique name and a specific address used for binding. The software defines ports for web services as: ● `Connection_Operations`: used for authentication and ping ● `Real-time_Services`: used for real-time jobs exposed as web services ● `Batch_Jobs`: used for batch jobs exposed as web services (each batch jobs has its own operation) ● `Batch_Job_Admin`: used for administrative operations for batch jobs
portType	Defines a set of operations that a web service publishes. A portType is bound to a particular port. The binding specifies the protocol and data formation for the operations defined by a portType.
operation	Defines a specific function call. The software publishes each batch job and real-time service as an operation. It also publishes connection operations.
message	Defines the data to transmit. There is an input (request) message, which the web service receives from the client, and there is an output (response) message, which the web service sends back to the client.
type	Defines the data types used in messages sent to/from a web service.

SoapAction element [page 2247]

7.3.1.1 Building a WSDL file

Use the information in the WSDL file produced by SAP Data Services to create an application that can access batch jobs and real-time services. Access the WSDL file by making web service client calls to it using a reference URL.

To view the WSDL file so that you can create your application, use the *Web Services* node of the Management Console Administrator, or open a browser window and search for:

http://**`<hostname:port>`**/DataServices/servlet/webservices?ver=2.0&wsdlxml

7.3.1.1.1 To configure web service information using the Administrator

1. Open the Administrator.
2. Log in with Administrator-level privileges. Users with Monitor-level privileges cannot configure web services.

   > i Note
   >
   > If you enable security for the WSDL file, SAP Data Services requires that web services clients use the user name and password of any user with Administrator-level privileges to access all published web services.

3. Add connections from Access Servers and repositories to view jobs in the Administrator.
4. If you plan to publish real-time jobs as web services, configure real-time jobs as real-time services.

   The software publishes the following as web services:

   - Real-time services enabled as web service operations in the Administrator
   - Batch jobs enabled as web service operations in the Administrator
   - Connection Operations
     - Ping - Used to ping Web services
     - Logon and Logout - Security operations that provide controlled access to Web service operations (if enabled).
5. In the Administrator's navigation tree, select *Web Services*.

   The *Web Services Status* page opens. This page lists Web service operations that are published in the WSDL. By default, only the Ping operation is automatically published.
6. Click the *Web Services Configuration* tab.

   Use the *Configuration* tab to open the *Web Services Configuration* page. Use this page to select jobs and real-time services to be published, enable/disable security for the WSDL file, and to enable/disable access to full batch job attributes.
7. From the pull-down menu, use *Add Real-time Service* or *Add Batch Job* to add jobs or services to the WSDL, and click *Apply*.

   On the *Add Real-time Service* page, real-time services are grouped by the Access Server for which the service is configured. To add a real-time service to the WSDL, select an Access Server or select *All*, select the check box in front of a real-time service name, and click *Add*.

   On the *Add Batch Job* page, jobs are grouped by the repository on which the job is stored. To add a job to the WSDL, select a repository or select *All*, select the check box in front of a job name, and click *Add*.
8. (Optional) On the *Web Services Configuration* page, select *Enable Session Security* and click *Apply* to enable security for the WSDL.

   Security for published operations is disabled by default.

   With security enabled, instead of making a single call to the Administrator to start a batch job or trigger a real-time service from an external application, clients must make at least three calls:

   - The first call logs in to the Administrator and gets a session ID.
   - The second call accesses a job or service using the session ID as an input parameter. Create a call for each job or service you want to access.
   - The final call logs out of the session.

9. (Optional) On the *Web Services Configuration* page, from the drop-down menu, select *Enable Job Attributes* to allow the input message for all the batch jobs you publish to include all options supported for submitting batch jobs from the Administrator. The following table lists elements added to the message:

Element	Description
job_system_profile	System profile used to run the job.
sampling_rate	Monitor sample rate (# of seconds).
auditing	Enable auditing (true or false).
recovery	Enable recovery (true or false).
job_server	Job Server or Server Group.
trace	Trace option to be enabled. You must specify an option to enable tracing. This element can be repeated for as many trace options as you require. The WSDL defines values for the trace option and includes the following (all options on the batch job submit page of the administrator): ○ job_trace_all ○ job_trace_row ○ job_trace_session ○ job_trace_workflow ○ job_trace_dataflow ○ job_trace_transform ○ job_trace_usertransform ○ job_trace_userfunction ○ job_trace_abapquery ○ job_trace_sqlfunctions ○ job_trace_sqlreaders ○ job_trace_sqlloaders ○ job_trace_optimized_dataflow ○ job_trace_table ○ job_trace_script ○ job_trace_ascomm ○ job_trace_rfc_function ○ job_trace_table_reader ○ job_trace_idoc_file ○ job_trace_adapter ○ job_trace_communication ○ job_trace_parallel_execution ○ job_trace_audit
distribution_level	You can distribute the execution of a job or a part of a job across multiple Job Servers within a Server Group to better balance resource-intensive operations.

Element	Description
	You can specify the following values on the distribution level option when you execute a job: ○ Job: A job can execute on an available Job Server. ○ Data flow: Each data flow within a job can execute on an available Job Server. ○ Sub data flow: A resource-intensive operation (such as a sort, table comparison, or table lookup) within a data flow can execute on an available Job Server. Note Casing and spacing are important for these values.

10. Navigate back to the *Web Services Status* page, choose the WSDL version you want to create, and click *View WSDL*.

    A new browser window opens with the WSDL displayed. Use the information in this file to perform the following:

    - Confirm that the software updated the WSDL file with all jobs and services without error.
    - Create calls to the software.
      Use the information in the WSDL file to configure your application to access batch jobs and real-time services.
      To ensure that your application calls the latest version of the job, update the WSDL when the metadata imported into the software changes for a job or real-time service by removing then re-adding a job or service from the *Web Services Configuration* page.

11. After your web service clients are accessing jobs, you can monitor the status of web service operations on the server by viewing the data on the *Web Services Status* page.

Column name	Description
Operation Name	Same as job or real-time service name.
Web Services Port	For jobs, the port name is Batch_jobs. For services, the port name is Real-Time_Service. For built-in operations, the port name is Connection_Operations. For administrative operations for batch jobs, the port name is Batch_Job_Admin.
Repository/ Access Server	For jobs, the repository name. For services, the Access Server name.
Job Information	For jobs, a link to the Batch Job History page. For services, a link to the Real-time Services History page.

Column name	Description
Requests Processed	Number of client requests successfully processed.
Requests Failed	Number of client requests that failed somewhere between the time that the Web Server receives the request and the Job Server receives it.
Requests Pending	Number of requests in a queue for Job Server.
Jobs Failed	Number of requests that failed due to a problem with the Job Server.

7.3.1.2 Tips for using the WSDL file

The WSDL file:

- Appears in the View WSDL window or any browser window by searching for the following URL: http://**<hostname:port>**/DataServices/servlet/webservices?ver=2.0&wsdlxml

  > Note
  >
  > To support previously-created datastores using a WSDL file with XML schema simple types, manually delete "ver=2.0&" from the default URL of Web Service and Apply to save as follows:

  http://**<hostname:port>**/DataServices/servlet/webservices?wsdlxml
- Displays all real-time services and jobs enabled for web services in the Administrator.
- Only displays log on, log off, and session ID information when security is enabled.
- Displays XML Schema formats in the *types* element.

7.3.1.3 WSDL versions

From time to time, the WSDL version used by SAP Data Services may change for a variety of reasons. For example, the syntax may change in order to operate more efficiently, or to add support for new technologies.

Although we typically maintain backward compatibility between WSDL versions, we recommend that you move to the newest WSDL version available in your Data Services installation. The latest version often includes improvements in web service execution, and older versions may be deprecated and no longer supported over time.

For more information about the changes between specific WSDL versions, see the *Upgrade Guide*.

Version history

In general, a WSDL version is deprecated when the version of Data Services in which it was introduced is no longer supported.

WSDL Version	Introduced	Deprecated
1.0	Original WSDL release	n/a
1.1	Data Integrator 11.5.0.0	n/a
2.0	Data Integrator 11.7.0.0	n/a
2.1	Data Services 12.2.1	n/a

7.3.2 Creating a client to use web services

To use a published web service, you must know the URL of the target WSDL. The Administrator produces a WSDL file with this URL: `http://<hostname:port>/DataServices/servlet/webservices?ver=2.0&wsdlxml`

The batch or real-time jobs must have previously been exposed as web services.

This section discusses general steps for using a published SAP Data Services web service. The tools you use to develop your web services client are your choice and the exact steps in using those tools vary, but these basic steps apply as a simple overview to all development projects for web services clients.

1. Import the software's WSDL into your development environment to create a web services client application.
   The incorporated web services appear in the hierarchy of your development environment.
2. Open the web service.
   Each available port for the web service is made visible in the IDE.
3. Write the code to call any of the jobs or services provided by the ports.
4. Run the project to execute the code.
   Executing the code initiates the web services job. A connection is made to the web services tier of the Access Server.

The Access Server then sends information to various job servers, which then executes the al_engine process to run the job, and results are sent back to the Web services client application.

7.3.2.1 Design choices

SAP Data Services provides different ways that you can call jobs using web services, each with benefits and drawbacks:

- Individually published job-specific web services (Batch_Jobs and Real-time_Services ports)
  These web services have their schema published directly in the WSDL, and web service development tools can automatically create classes that serialize and deserialize the input and output XML messages. However, you need to create a separate operation for each published job.
- Generalized web services (Batch_Jobs_Admin and Realtime_Service_Admin ports)

These web services take a job name as input, but do not directly expose the input schema of the job. This allows an application to dynamically call different jobs with one web service, but the schema must be known in advance or generated dynamically with another web service call.

7.3.3 Supported web service operations

SAP Data Services creates a WSDL file with a single service definition. It is possible to create multiple service definitions in a WSDL, but many web service implementations do not support more than one service definition. To avoid that limitation, the software creates only one service.

Within the service definition, the software defines ports for:

- `Connection_Operations`
- `Batch_Job_Admin`
- `Real-time_Services`
- `Batch_Jobs`
- `Repo_Operations`

7.3.3.1 Connection port

SAP Data Services generates WSDL that defines connection operations that belong to web services. The software supports the following Connection operations.

Operation	Description
Ping	Verifies the connection to web services
Logon	Verifies secure access before establishing a session
Logout	Terminates a session

Note

The software generates Logon and Logout operations only if you enable security for published jobs.

7.3.3.1.1 Ping

The Ping operation is an empty input message with a ping operation request. The output message is a text string that returns the current SAP Data Services version, which indicates that a connection has been established.

7.3.3.1.2 Logon

The Logon operation is required when you enable SAP Data Services to provide secure communication. To access web services, provide an Administrator login name and password (with Administrator-level privileges). When the software validates them, the logon operation returns an Administrator session ID that you must include in all subsequent calls to the web services.

Input message

Element	Type	Description
cms_authentication	String	Specifies the type of authentication to use for logging on to a Data Services web service. Values include: • `secEnterprise`: Use for Enterprise authentication • `secLDAP`: Use for LDAP authentication • `secWinAD`: Use for Windows Active Directory authentication • `secSAPR3`: Use for SAP authentication
cms_system	String	The CMS server name. If the CMS server is listening on the default 6400 port, then pass only the CMS server name. If the server is listening on any other port, then also pass the port number.
password	String	Password for the CMS user.
username	String	CMS user name.

Output message

Element	Type	Description
SessionId	String	A unique session ID is returned. Use this session ID in subsequent Data Services operations for which session security is enabled.

7.3.3.1.3 Logout

The Logout operation is required when you enable SAP Data Services to provide secure communication. When web service communication is complete, call the Logout operation to terminate the session.

7.3.3.2 Realtime_Service_Admin port

7.3.3.2.1 Get_RTMsg_Format

Use Get_RTMsg_Format to retrieve the input/output format for a real-time service as an XML Schema. The real-time service does not need to be published as a web service.

Input message

Element	Type	Description
serviceName	string	The name of the real-time service as displayed in the Administrator.
selector	string	A selector that determines whether the input or output schema for the service is returned. Valid strings include: • in - Returns the input schema. • out - Returns the output schema.

Output message

Element	Type	Description
schema	string	The input or output XML Schema for the real-time service.
rootElement	string	The root element of the returned XML Schema.
rootElementNS	string	The root element namespace of the returned XML Schema.
schemaName	string	The name of a dependent schema used in the returned XML Schema, if applicable. This element may be returned multiple times.
schema	string	A dependent schema used in the returned XML Schema, if applicable. This element may be returned multiple times.
errorMessage	string	Any error message that resulted while retrieving the XML Schema for the real-time service.

7.3.3.2.2 Get_RTService_List

Use the Get_RTService_List operation to retrieve a list of the names of published real-time services.

Input message

Get_RTService_List takes no input message.

Output message

Element	Type	Description
serviceName	string	The list of published real-time services.

Element	Type	Description
errorMessage	string	Any error message that occurred while retrieving the list of real-time services.

7.3.3.2.3 Run_Realtime_Service

Use Run_Realtime_Service to call a published real-time service. The real-time service must be running and published as a web service in the Administrator, and the XML input content must match the input format defined for the real-time service.

Input message

Element	Type	Description
serviceName	string	The name of the real-time service as displayed in the Administrator.
xmlInput	string	The XML input content used to start the real-time service. This content must match the input format required by the real-time service.

Output message

Element	Type	Description
xmlOutput	string	The XML output content returned by the real-time service. This content is formatted according to the output schema of the real-time service called.
errorMessage	string	Any error message that resulted while attempting to call the real-time service.

7.3.3.3 Batch_Job_Admin port

7.3.3.3.1 Get_BatchJob_ExeDetail

Use Get_BatchJob_ExeDetail to retrieve a list of all job executions for the selected repository and job. You can also filter the list by time range.

> Note
>
> When the StartTime and EndTime elements are empty, this operation returns all the batch job details. When one field is empty, this operation returns the current date as the default value.

Input message

Element	Type	Description
jobName	String	The name of the batch job.
repoName	String	The name of the repository.
startTime	String	The date the job started (**<YYYY-MM-DD HH:mm:ss>**). For example, `2013-06-08 10:10:10`. This element is optional. When it is empty, the software returns the current date as default value.
endTime	String	The date the job stopped (**<YYYY-MM-DD HH:mm:ss>**). For example, `2013-06-08 10:10:10`. This element is optional. When it is empty, the software returns the current date as default value.

Output message

Element	Type	Description
ObjID	String	The job's unique identifier.
RunID	String	The unique ID for the batch job run.
JobName	String	The name of the batch job.
StartTime	String	The date and time the job started (**<yyyy-MM-dd HH:mm:ss am>**).
EndTime	String	The time the job stopped (**<yyyy-MM-dd HH:mm:ss am>**).
ExecutionTime	String	The length of time (in seconds) the job ran.
Status	String	The status code for the batch job run. Valid strings include: ● Succeed ● Recovered ● Failed
JobServerUsed	String	The name of the job server and the port number. The format is **<jobserver name:jobserver port>**.

Example

SOAP request XML

```
<soapenv:Envelope xmlns:soapenv="http://schemas.xmlsoap.org/soap/envelope/"
xmlns:ser="http://www.businessobjects.com/DataServices/ServerX.xsd">
   <soapenv:Header>
      <ser:session>
         <SessionID>D19C201F-074C-B5FE-70A4-2F3436AC04E8</SessionID>
      </ser:session>
   </soapenv:Header>
   <soapenv:Body>
      <ser:jobExcutionDetailsRequest>
         <jobName>Job1_Query</jobName>
         <repoName>echo_oracle</repoName>
         <!--Optional:-->
         <startTime>2013-06-18</startTime>
         <!--Optional:-->
         <endTime>2013-06-19</endTime>
      </ser:jobExcutionDetailsRequest>
   </soapenv:Body>
</soapenv:Envelope>
```

Example

SOAP response XML

```
<soapenv:Envelope xmlns:soapenv="http://schemas.xmlsoap.org/soap/envelope/">
   <soapenv:Body>
      <localtypes:jobExcutionDetailsResponse xmlns:localtypes="http://
www.businessobjects.com/DataServices/ServerX.xsd">
         <jobDetail>
            <ObjID>146</ObjID>
            <RunID>37</RunID>
            <JobName>Job1_Query</JobName>
            <StartTime>2013-06-18 12:22:41 PM</StartTime>
            <EndTime>2013-06-18 12:22:55 PM</EndTime>
            <ExecutionTime>14</ExecutionTime>
            <Status>error</Status>
            <JobServerUsed>echo_orc:3500</JobServerUsed>
         </jobDetail>
         <jobDetail>
            <ObjID>146</ObjID>
            <RunID>38</RunID>
            <JobName>Job1_Query</JobName>
            <StartTime>2013-06-18 12:23:18 PM</StartTime>
            <EndTime>2013-06-18 12:23:32 PM</EndTime>
            <ExecutionTime>14</ExecutionTime>
            <Status>succeeded</Status>
            <JobServerUsed>echo_orc:3500</JobServerUsed>
         </jobDetail>
         <StatusCode>0</StatusCode>
      </localtypes:jobExcutionDetailsResponse>
   </soapenv:Body>
</soapenv:Envelope>
```

7.3.3.3.2 Get_BatchJob_FlowDetails

Use Get_BatchJob_FlowDetails to get details about the tasks included in a job.

Input message

Element	Type	Description
repoName	String	The name of the repository to access.
runID	String	The unique ID for the batch job.

Output message

Element	Type	Description
ObjectName	String	The name of the object used in the job.
ObjectType	String	The type of object. For example, workflow, dataflow, and so on.
ParentObject	String	The name of the main or base object.
ParentType	String	The type of parent object. For example, workflow, dataflow, and so on.
StartTime	String	The date and time that the job execution instance started (**<yyyy-MM-dd HH:mm:ss am/pm>**). For example, 2013-06-18 10:05:38 AM.
EndTime	String	The date and time that this job execution instance stopped (**<yyyy-MM-dd HH:mm:ss am/pm>**). For example, 2013-06-18 12:05:38 PM.
Duration	Integer	The time (in seconds) that the job took to complete.
RowsRead	Integer	The number of rows read.
JobserverUsed	String	The name of the job server used to run the job. The format is **<jobserver name:jobserver port>**.
hasAuditData	String	Specifies if there is audit data. Valid strings include: • Yes • No

Example

SOAP request XML

```
<soapenv:Envelope xmlns:soapenv="http://schemas.xmlsoap.org/soap/envelope/"
xmlns:ser="http://www.businessobjects.com/DataServices/ServerX.xsd">
   <soapenv:Header>
      <ser:session>
         <SessionID>D19C201F-074C-B5FE-70A4-2F3436AC04E8</SessionID>
      </ser:session>
   </soapenv:Header>
   <soapenv:Body>
      <ser:jobFlowDetailsRequest>
         <repoName>echo_oracle</repoName>
         <runID>29</runID>
      </ser:jobFlowDetailsRequest>
   </soapenv:Body>
</soapenv:Envelope>
```

Example

SOAP response XML

```
<soapenv:Envelope xmlns:soapenv="http://schemas.xmlsoap.org/soap/envelope/">
   <soapenv:Body>
      <localtypes:jobExcutionDetailsResponse xmlns:localtypes="http://
www.businessobjects.com/DataServices/ServerX.xsd">
         <flowDetail>
            <ObjectName>New_DataFlow10</ObjectName>
            <ObjectType>Dataflow</ObjectType>
            <ParentObject>audit008</ParentObject>
            <ParentType>Job</ParentType>
            <StartTime>2013-06-18 12:05:38 PM</StartTime>
            <EndTime>2013-06-18 12:05:38 PM</EndTime>
            <Duration>0</Duration>
            <RowsRead>0</RowsRead>
            <JobserverUsed>echo_orc:3500</JobserverUsed>
            <hasAuditData>yes</hasAuditData>
         </flowDetail>
         <StatusCode>0</StatusCode>
      </localtypes:jobExcutionDetailsResponse>
   </soapenv:Body>
</soapenv:Envelope>
```

7.3.3.3.3 Get_BatchJob_List

Use Get_BatchJob_List to retrieve a list of the names of published batch jobs.

Input message

Element	Type	Description
repoName	String	The name of the repository to access. This element is optional.
allBatchJobs	Boolean	Includes all batch jobs in the repository, not only those published as web services. This parameter is optional.

Output message

Element	Type	Description
jobName	String	The list of published batch jobs. This element has an additional attribute, repo, which specifies the name of the repository that contains the job.
errorMessage	String	Any error message that occurred while retrieving the list of batch jobs.

7.3.3.3.4 Get_BatchJob_RunIDs

Each individual run of an SAP Data Services batch job is assigned a unique run ID.

Use Get_BatchJob_RunIDs to retrieve a list of run IDs associated with a particular batch job.

Input message

Element	Type	Description
jobName	String	The name of the batch job.
status	String	The status code for the type of run IDs requested. Valid codes include: running, succeeded, error, warning, and all.
repoName	String	The name of the repository to access. When specified, the operation returns only run IDs from this repository. This element is optional.

Output message

The response of the Get_BatchJobs_RunIDs operation contains one or more run element. Each run element contains the following sub-elements:

Element	Type	Description
runID	Integer	The unique ID for the batch job run.
status	String	The status code for the batch job run. Valid codes include: running, succeeded, error, warning, and all.
repoName	String	The repository name associated with the batch job.
errorMessage	String	Any error message that occurred while retrieving the list of batch jobs.

7.3.3.3.5 Get_BatchJob_Status

Use Get_BatchJob_Status to retrieve the status of a particular batch job run.

Input message

Element	Type	Description
runID	Integer	The run ID for the particular batch job status desired.
repoName	String	The name of the repository to access.

Output message

Element	Type	Description
returnCode	Integer	The status for the operation. Valid values include: ● 0 - The operation completed successfully. ● 1 - The operation encountered an error. For example, the repoName specified is invalid.
status	String	The status of the batch job run. Valid values include: ● Running - The job is currently running. ● Succeeded - The job completed with no errors. ● Warning - The job completed, but warnings occurred. ● Error - The job completed with an error.

7.3.3.3.6 Get_DF_Auditdata

Use Get_DF_Auditdata to show audit information for a data flow. To retrieve audit information, you need to enable the audit point in your data flow object.

Input message

Element	Type	Description
runID	String	The unique ID for the batch job.
repoName	String	The name of the repository to access.
dataflow	String	The name of the data flow for which you want audit information.

Output message

Element	Type	Description
auditPoint	String	The name of the object in a data flow from which you are collecting audit statistics.
auditValue	String	The value of the audit function in the audit point.

Example

SOAP request XML

```
<soapenv:Envelope xmlns:soapenv="http://schemas.xmlsoap.org/soap/envelope/"
xmlns:ser="http://www.businessobjects.com/DataServices/ServerX.xsd">
   <soapenv:Header>
      <ser:session>
         <SessionID>D19C201F-074C-B5FE-70A4-2F3436AC04E8</SessionID>
      </ser:session>
   </soapenv:Header>
   <soapenv:Body>
      <ser:dataflowAuditRequest>
         <runID>34</runID>
         <repoName>echo_oracle</repoName>
         <dataflow>New_DataFlow10</dataflow>
      </ser:dataflowAuditRequest>
   </soapenv:Body>
</soapenv:Envelope>
```

Example

SOAP response XML

```
<soapenv:Envelope xmlns:soapenv="http://schemas.xmlsoap.org/soap/envelope/">
   <soapenv:Body>
      <localtypes:dataflowAuditResponse xmlns:localtypes="http://
www.businessobjects.com/DataServices/ServerX.xsd">
         <audit>
            <auditPoint>$Count_Query_1</auditPoint>
            <auditValue>6</auditValue>
         </audit>
         <audit>
            <auditPoint>$CountError_Query</auditPoint>
            <auditValue>0</auditValue>
         </audit>
         <audit>
            <auditPoint>$Count_Query</auditPoint>
            <auditValue>6</auditValue>
         </audit>
         <audit>
            <auditPoint>$CountError_Row_Generation</auditPoint>
            <auditValue>0</auditValue>
         </audit>
         <StatusCode>0</StatusCode>
      </localtypes:dataflowAuditResponse>
   </soapenv:Body>
</soapenv:Envelope>
```

7.3.3.3.7 Get_DF_Monitor_Log

Use Get_DF_Monitor_Log to show the runtime statistics for a single data flow execution.

> i Note
>
> The Job Server must be running in order to use this operation.

Input message

Element	Type	Description
repoName	String	The name of the repository to access.
runID	Integer	The unique ID for the batch job.
dataflow	String	The name of the dataflow which contains the batch job.
stoponly	String	Indicates if the process ended without error. You can use a Yes or No string for this element. If it is set to Yes, the output will have only Stop rows, meaning the transform object status is in a Stop state.

Output message

Element	Type	Description
threadName	String	The name of the thread.
state	String	The status of each process in the execution of the data flow. Valid strings include: • Initializing - Indicates that the job is initializing. • Optimizing - Indicates that the job is optimizing. • Proceed - Indicates that the process is executing. • Stop - Indicates that the process ended without error.
absoluteTime	Integer	The amount of time (in seconds) since the execution of the data flow began.

Element	Type	Description
counter	Integer	The number given to each monitor log file to which the software writes information.
rowProcessed	Long	The number of rows processed through the object.
bufferSize	Long	The output buffer size (in kilobytes). This is the amount of time allotted for processing.
bufferUsed	String	The output buffer size used.
CPUUtilization	String	The percent of CPU uses per thread.
jobServerUsed	String	The name of the job server used to execute the data flow.

Example

SOAP request XML

```
<soapenv:Envelope xmlns:soapenv="http://schemas.xmlsoap.org/soap/envelope/"
xmlns:ser="http://www.businessobjects.com/DataServices/ServerX.xsd">
   <soapenv:Header>
      <ser:session>
         <SessionID>D19C201F-074C-B5FE-70A4-2F3436AC04E8</SessionID>
      </ser:session>
   </soapenv:Header>
   <soapenv:Body>
      <ser:DataFlowMonitorLogRequest>
         <runID>29</runID>
         <repoName>echo_oracle</repoName>
         <dataflow>New_DataFlow10</dataflow>
         <stoponly>yes</stoponly>
      </ser:DataFlowMonitorLogRequest>
   </soapenv:Body>
</soapenv:Envelope>
```

Example

SOAP response XML

```
<soapenv:Envelope xmlns:soapenv="http://schemas.xmlsoap.org/soap/envelope/">
   <soapenv:Body>
      <localtypes:DataFlowMonitorLogResponse xmlns:localtypes="http://
www.businessobjects.com/DataServices/ServerX.xsd">
         <Row>
            <threadName>/New_DataFlow10/Row_Generation</threadName>
            <state>STOP</state>
            <absoluteTime>2.906</absoluteTime>
            <counter>1</counter>
            <rowProcessed>6</rowProcessed>
            <bufferSize>0</bufferSize>
            <bufferUsed>0</bufferUsed>
            <CPUUtilization>0.0</CPUUtilization>
            <jobServerUsed>echo_orc:3500</jobServerUsed>
         </Row>
         <Row>
            <threadName>/New_DataFlow10/Query-Mapping1</threadName>
            <state>STOP</state>
            <absoluteTime>2.906</absoluteTime>
            <counter>1</counter>
            <rowProcessed>0</rowProcessed>
            <bufferSize>0</bufferSize>
            <bufferUsed>0</bufferUsed>
            <CPUUtilization>0.0</CPUUtilization>
            <jobServerUsed>echo_orc:3500</jobServerUsed>
         </Row>
         <Row>
            <threadName>/New_DataFlow10/Audit[3]</threadName>
            <state>STOP</state>
            <absoluteTime>2.906</absoluteTime>
            <counter>1</counter>
            <rowProcessed>0</rowProcessed>
            <bufferSize>0</bufferSize>
            <bufferUsed>0</bufferUsed>
            <CPUUtilization>0.0</CPUUtilization>
            <jobServerUsed>echo_orc:3500</jobServerUsed>
         </Row>
         <Row>
            <threadName>/New_DataFlow10/Merge: 0</threadName>
            <state>STOP</state>
            <absoluteTime>2.906</absoluteTime>
            <counter>1</counter>
            <rowProcessed>6</rowProcessed>
            <bufferSize>0</bufferSize>
            <bufferUsed>0</bufferUsed>
            <CPUUtilization>0.0</CPUUtilization>
            <jobServerUsed>echo_orc:3500</jobServerUsed>
         </Row>
         <Row>
            <threadName>-New_DataFlow10/output8.txt</threadName>
            <state>STOP</state>
            <absoluteTime>2.906</absoluteTime>
            <counter>1</counter>
            <rowProcessed>6</rowProcessed>
            <bufferSize>0</bufferSize>
            <bufferUsed>0</bufferUsed>
            <CPUUtilization>0.0</CPUUtilization>
            <jobServerUsed>echo_orc:3500</jobServerUsed>
         </Row>
         <returnCode>0</returnCode>
      </localtypes:DataFlowMonitorLogResponse>
   </soapenv:Body>
</soapenv:Envelope>
```

7.3.3.3.8 Get_DF_Monitor_Log_Pivot

Use Get_DF_Monitor_Log_Pivot to show the runtime statistics as pivoted for a single data flow execution.

i Note

The Job Server must be running in order to use this operation.

Input message

Element	Type	Description
repoName	String	The name of the repository to access.
runID	Integer	The unique ID for the batch job.
dataflow	String	The name of the data flow for which you want audit information.
threadName	String	Filters the output based on the thread name. This element is optional.
measure	String	Filters the output based on the measure type. This element is optional. Valid strings include: ● rows processed ● buffer used ● thread CPU %

Output message

Element	Type	Description
threadName	String	The name of the thread.
measure	String	The measure type. Valid strings include: ● rows processed ● buffer used ● thread CPU %
sample<x>	Integer	The software writes information to log files at assigned intervals. The sample number corresponds to the monitor sample counter, which is a number that is assigned to each monitor log file. The sample output consists of measure type statistics for a thread. Output is limited to 500 sample columns (sample1 through sample500).

Example

SOAP request XML

```
<soapenv:Envelope xmlns:soapenv="http://schemas.xmlsoap.org/soap/envelope/"
xmlns:ser="http://www.businessobjects.com/DataServices/ServerX.xsd">
   <soapenv:Header>
      <ser:session>
         <SessionID>D19C201F-074C-B5FE-70A4-2F3436AC04E8</SessionID>
      </ser:session>
   </soapenv:Header>
   <soapenv:Body>
      <ser:DataFlowMonitorLogPivotRequest>
```

```
         <runID>29</runID>
         <repoName>echo_oracle</repoName>
         <dataflow>New_DataFlow10</dataflow>
         <!--Optional:-->
         <threadName></threadName>
         <!--Optional:-->
         <measure>thread CPU %</measure>
      </ser:DataFlowMonitorLogPivotRequest>
   </soapenv:Body>
</soapenv:Envelope>
```

Example

SOAP response XML

```
<soapenv:Envelope xmlns:soapenv="http://schemas.xmlsoap.org/soap/envelope/">
   <soapenv:Body>
      <localtypes:DataFlowMonitorLogPivotResponse xmlns:localtypes="http://
www.businessobjects.com/DataServices/ServerX.xsd">
         <Row>
            <threadName>/New_DataFlow10/Row_Generation</threadName>
            <measure>thread CPU %</measure>
            <Sample1>0.0</Sample1>
            <Sample2>0.0</Sample2>
            <Sample3>0.0</Sample3>
            <Sample4/>
            <Sample5/>
            <Sample6/>
            <Sample7/>
            <Sample8/>
            <Sample9/>
            <Sample10/>
            <Sample11/>
                                                ...
                                                <Sample496/>
            <Sample497/>
            <Sample498/>
            <Sample499/>
            <Sample500/>
         </Row>
         <returnCode>0</returnCode>
      </localtypes:DataFlowMonitorLogPivotResponse>
   </soapenv:Body>
</soapenv:Envelope>
```

7.3.3.3.9 Get_Error_Log

SAP Data Services produces several types of log information for a batch job published as a web service.

Use the Get_Error_Log operation to retrieve the error log for a batch job.

Input message

Element	Type	Description
runID	integer	The batch job run ID for the particular log desired.
repoName	string	The name of the repository to access.
page	integer	The page number of the error log to return. This element is optional.

Output message

Element	Type	Description
returnCode	integer	The status for the operation. Valid values include: • 0 - The operation completed successfully. • 1 - The operation failed to retrieve the error log.
error	string	The error log associated with the input batch job run ID.

7.3.3.3.10 Get_Job_Input_Format

Use Get_Job_Input_Format to retrieve the input format for a batch job as an XML Schema.

Input message

Element	Type	Description
jobName	string	The name of the batch job as displayed in the Administrator.
repoName	string	The name of the repository to access.

Output message

Element	Type	Description
format	string	The input format for the batch job, as an XML Schema.
errorMessage	string	Any error message that resulted while retrieving the input format for the batch job.

7.3.3.3.11 Get_Monitor_Log

SAP Data Services produces several types of log information for a batch job published as a web service.

Use the Get_Monitor_Log operation to retrieve the monitor log for a batch job.

Input message

Element	Type	Description
runID	integer	The batch job run ID for the particular log desired.
repoName	string	The name of the repository to access.
page	integer	The page number of the monitor log to return. This element is optional.

Output message

Element	Type	Description
returnCode	integer	The status for the operation. Valid values include: • 0 - The operation completed successfully. • 1 - The operation failed to retrieve the monitor log.
monitor	string	The monitor log associated with the input batch job run ID.

7.3.3.3.12 Get_Trace_Log

SAP Data Services produces several types of log information for a batch job published as a web service.

Use the Get_Trace_Log operation to retrieve the trace log for a batch job.

Input message

Element	Type	Description
runID	integer	The batch job run ID for the particular log desired.
repoName	string	The name of the repository to access.
page	integer	The page number of the trace log to return. This element is optional.

Output message

Element	Type	Description
returnCode	integer	The status for the operation. Valid values include: • 0 - The operation completed successfully. • 1 - The operation failed to retrieve the trace log.
trace	string	The trace log associated with the input batch job run ID.

7.3.3.3.13 Run_Batch_Job

Use Run_Batch_Job to call a batch job with the ability to specify job parameters and global variables.

Input message

Element	Type	Description
jobName	string	The name of the batch job as displayed in the Administrator.
repoName	string	The name of the repository to access.
jobServer	string	The name of the job server to use to execute the job. This element is optional, but cannot be specified if serverGroup is also specified.
serverGroup	string	The name of the server group to use to execute the job. This element is optional, but cannot be specified if jobServer is also specified.
jobParameters	complex	A complex XML element that sets specific job execution parameters.
globalVariables	complex	A complex XML element that defines global job execution variables.

> Note
>
> If you do not specify a serverGroup or jobServer, the operation attempts to find an available job server that is attached to the repository by first checking the server group list, and then the job server list.

> Note
>
> For detailed information about the jobParameters and globalVariables elements, view the WSDL from the Administrator. For more information about available job parameters and global variables, see the *Reference Guide*.

Output message

Element	Type	Description
pid	int	The process ID number for the batch job execution. Process IDs can be reused.
cid	int	The counter ID number for the batch job excecution. You can use a counter ID together with a process ID to uniquely identify a specific instance of the job execution.
rid	int	The run ID associated with the specific execution of the batch job.
repoName	string	The repository name associated with the batch job execution.
errorMessage	string	Any error message that resulted while attempting to call the batch job.

7.3.3.3.14 Stop_Batch_Job

Use the Stop_Batch_Job operation to stop a particular batch job run.

Input message

Element	Type	Description
runID	integer	The run ID for the particular batch job run to stop.
repoName	string	The name of the repository to access.

Output message

Element	Type	Description
returnCode	integer	The success code for the batch job stop attempt. Valid codes include: • 0 - The operation successfully stopped the specified batch job. • 1 - The operation failed to stop the specified batch job in the specified repository.
errorMessage	string	The error message associated with a failure to stop a batch job run.

7.3.3.4 Real-time_Services port

SAP Data Services generates WSDL that defines how to invoke real-time services enabled as web service operations. Each real-time service name is represented as an operation name in the WSDL file.

Each real-time service operation has a set of messages that it uses to communicate with the real-time service. Real-time services use a defined XML message as input and a defined XML message as output. Real-time services obtain the format of these messages from the repository and provide the format in the WSDL.

The software supports XML Schemas as its message format for real-time services. A web service provides only XML Schemas in the WSDL. You will need to convert any DTDs to XML schemas as necessary.

The repository stores XML Schemas that define the input and output messages as independent definitions. The WSDL file includes these definitions in the *types* element.

The messages that an XML Schema defines for each real-time service operation are:

- Header message
  If security is enabled for the message, the software defines a secure session identifier in the message header.
- Input message
  When an external web services client invokes it, the input message passes information to a real-time service. The name of the input message is the name of the operation that the software publishes followed by the suffix `_Input`. The input message contains the message source defined by the real-time service.
- Output message
  The software returns the output message when the real-time service completes. The output message contains the output generated by the real-time service. The name of the output message is the name of the operation followed by the suffix `_Output`. The output message contains the message target defined by the real-time service.
- Fault message
  The software returns a fault message when it cannot invoke the real-time service.

7.3.3.4.1 Message formats

The following segment shows the syntax that Data Services generates in a WSDL file to define an operation's messages. In this example:

- `RTService` represents the name of the real-time service as defined in the Administrator.
- `XMLSchemaName` represents the name of the XML Schema that was used to create an XML message source or XML message target in the Designer.
- `RootElement` represents the root element of the XML Schema.

The software publishes a WSDL that includes input and output XML Schema message formats in the *types* element.

> **i Note**
>
> Server support for real-time services requires that you use a valid URL for locating XML Schema (.xsd) files in an import statement. A local file name cannot be used. For example, the .xsd must be either self-contained when imported into the software or it must use a network reference (URL), not a file or relative path reference, as an identifier.

The WSDL file displays the operations for real-time services within a `portType` tag.

7.3.3.5 Batch_Jobs port

SAP Data Services generates WSDL that defines how to start batch jobs. The WSDL file represents each batch job name as an operation.

In addition, the WSDL file defines an input and output message for each operation. An input message communicates the input needed by the job at startup (such as the global variables needed to start the job). An output message either confirms that the job started or presents the errors that prevent the job from starting.

WSDL defines the following messages for each operation:

Message	Description
Header message	When security is enabled for the message, the software defines a secure session identifier in the message header.
Input message	The input message passes information needed by the batch job at startup. The name assigned to the input message is the name of the operation followed by the suffix `_Input`. The input message contains global variables. When security is enabled for the message, the software defines a secure session identifier in the message header.
Output message	The software returns the output message when the batch job starts. The output message contains the job identification. The name of the output message is the name of the operation followed by the suffix `_Output`. The output message contains the following IDs: ● OS process ID of the started job ● Job Server Counter ID of the started job
Fault message	The software returns a fault message if the batch job fails to start. It returns a text description of the error that prevents the job from starting.

7.3.3.5.1 SoapAction element

The definition of each batch job operation uses the `soapAction` element to define the batch job name needed to launch the job.

The WSDL file displays the `soapAction` element in the service and port section.

7.3.3.5.2 Security

When publishing a job as a web service, the Administrator can enable secure access, requiring that web services clients provide authentication and authorization (an Administrator username and password) for access to the web service operations. Administrator-level (not Monitor-level) privileges must be used. That is, you cannot limit access to users based on role. This authentication is SSL-compliant.

If you do not enable secure access and you are using HTTP, web services clients have open access to all published batch jobs and real-time services.

Related Information

To configure web service information using the Administrator [page 2221]

7.3.3.6 Repo_Operations port

SAP Data Services generates WSDL that defines operations that belong to web services. The software supports the following operations on the Repo_Operations port.

Operation	Description
Delete_Repo_Objects	Deletes objects from the repository.
Import_Repo_Object	Imports an object to the repository.
Validate_Repo_Object	Validates an object contained in the repository.
Export_DQReport	Exports reports to a specified location at runtime.
Get_Repository_List	Retrieves the entire repository list based on the user's permissions. This operation also returns a list of the repositories that the user is currently logged into.

7.3.3.6.1 Delete_Repo_Objects

Use the Delete_Repo_Objects operation to delete objects from the SAP Data Services repository.

Input message

Element	Type	Description
objName	string	The name of the object to delete from the repository. This element requires the attribute objType and can occur multiple times. The objType attribute specifies the type of the object: • BATCH_JOB • REALTIME_JOB • WORKFLOW • DATAFLOW

Element	Type	Description
		- ABAP_DATAFLOW - DATA_QUALITY_TRANSFORM_CONFIGURATION - DATASTORE - FILE_FORMAT - XML_SCHEMA - DTD - CUSTOM_FUNCTION - EXCEL_WORKBOOK - COBOL_COPYBOOK - SYSTEM_PROFILE - SUBSITUTION_CONFIGURATION - PROJECT - TABLE - TEMPLATE_TABLE - DOMAIN - HIERARCHY - STORED_PROCEDURE - IDOC - BW_MASTER_TRANSFER_STRUCTURES - BW_MASTER_TEXT_TRANSFER_STRUCTURES - BW_TRANSACTION_TRANSFER_STRUCTURES - BW_HIERARCHY_TRANSFER
repoName	string	The name of the repository that contains the objects to delete.
jobServer	string	The name of the job server associated with the repository. This element is optional, but cannot be specified if serverGroup is also specified.
serverGroup	string	The name of the server group associated with the repository. This element is optional, but cannot be specified if jobServer is also specified.
traceOn	string	Enables tracing for the operation. This element is optional.

Note

If you do not specify a serverGroup or jobServer, the operation attempts to find an available job server that is attached to the repository by first checking the server group list, and then the job server list.

Output message

Element	Type	Description
returnCode	int	The status of the operation: - 0 - The operation completed successfully.

Element	Type	Description
		- 1 - The operation failed to complete successfully.
errorMessage	string	The error message associated with the operation. This element is output only if the operation fails to complete successfully.
traceMessage	string	The trace message associated with the operation. This element is output only if the traceOn element is specified on input.

7.3.3.6.2 Import_Repo_Object

Use the Import_Repo_Object operation to save an XML object definition to the SAP Data Services repository.

Input message

Element	Type	Description
definition	string	The object to import to the repository. The object must be defined in XML format.
repoName	string	The name of the repository in which to import the object.
jobServer	string	The name of the job server associated with the repository. This element is optional, but cannot be specified if serverGroup is also specified.
serverGroup	string	The name of the server group associated with the repository. This element is optional, but cannot be specified if jobServer is also specified.
traceOn	string	Enables tracing for the operation. This element is optional.
passphrase	string	The passphrase that was used to encode any passwords in the XML object definition. Note If the passphrase you specify is incorrect, the operation will still save the XML objects to the repository, but any passwords in the definition will be removed.

> Note
>
> If you do not specify a serverGroup or jobServer, the operation attempts to find an available job server that is attached to the repository by first checking the server group list, and then the job server list.

Output message

Element	Type	Description
returnCode	int	The status of the operation: • 0 - The operation completed successfully. • 1 - The operation failed to complete successfully.
errorMessage	string	The error message associated with the operation. This element is output only if the operation fails to complete successfully.
traceMessage	string	The trace message associated with the operation. This element is output only if the traceOn element is specified on input.

7.3.3.6.3 Validate_Repo_Object

Use the Validate_Repo_Object operation to validate an object stored in the SAP Data Services repository.

Input message

Element	Type	Description
objName	string	The name of the object to validate.
objType	string	The type of the object to validate: • BATCH_JOB • REALTIME_JOB • WORKFLOW • DATAFLOW • ABAP_DATAFLOW • DATA_QUALITY_TRANSFORM_CONFIGURATION • CUSTOM_FUNCTION
repoName	string	The name of the repository that contains the object to validate.
systemProfile	string	The name of the job system profile to use while validating the object. This element is optional.
jobServer	string	The name of the job server associated with the repository. This element is optional, but cannot be specified if serverGroup is also specified.
serverGroup	string	The name of the server group associated with the repository. This element is optional, but cannot be specified if jobServer is also specified.
substitutionParameters	complex	Substitution parameters to override while validating the object. This element is optional and contains one or more parameter child elements.
parameter	string	An individual substitution parameter.
traceOn	string	Enables tracing for the operation. This element is optional.

i Note

If you do not specify a serverGroup or jobServer, the operation attempts to find an available job server that is attached to the repository by first checking the server group list, and then the job server list.

Output message

Element	Type	Description
returnCode	int	The status of the operation: • 0 - The operation completed successfully. • 1 - The operation failed to complete successfully.
errorMessage	string	The error message associated with the operation. This element is output only if the operation fails to complete successfully.
traceMessage	string	The trace message associated with the operation. This element is output only if the traceOn element is specified on input.

7.3.3.6.4 Export_DQReport

Use the Export_DQReport operation to export reports to a specified location at runtime.

Input message

Element	Type	Description
runID	integer	The unique ID for the batch job run.
repoName	string	The name of the repository to that contains the batch job.

Output message

Element	Type	Description
exportFileName	string	The name of the file that is exported; for example, `matchcriteriasummary_Set1.pdf`.
exportPath	string	The path where the reports will be exported to. The default path is <**<DS_COMMON_DIR>**>`\DataQuality\reports\`. Upon execution, the repository name and job name folders are appended to the path. If the Overwrite option is not selected, a run ID folder is also appended to the path.

Element	Type	Description
		Note If you export reports to a location other than a local drive, such as a network drive, before you execute the job you must start the web application server with an account that has access rights to that location.
exportStatus	boolean	The status of the overall export operation: ● 0 - The operation completed successfully. ● Negative integer - The operation failed to complete successfully.
processMessage	string	Informational messages about the overall export process.
reportName	string	The name of the report that is displayed in the Management Console; for example, Match Criteria Summary.
reportStatus	integer	The status of the export operation for each report: ● 0 - The operation completed successfully. ● Negative integer - The operation failed to complete successfully.
statusMessage	string	Informational message about the export status for each report.

7.3.3.6.5 Get_Repository_List

Use Get_Repository_List to retrieve the entire repository list based on the user's permissions. This operation also returns a list of the repositories that the user is currently logged into.

Input message

No input parameter is needed. You only need to log into the system.

Output message

Element	Type	Description
repoName	String	The name of the repository that is configured in the Management Console.
repoType	String	The repository database type. This element is optional. Valid strings include: ● local ● central

Element	Type	Description
		• secure central • profiler
dbType	String	The repository database type. For example, Oracle, DB2, HANA, and so on.
dbHost	String	The host name of the database server.
connectionStatus	String	Indicates whether the connection is active or inactive.
username	String	The user name used to log into the database.
permissions	String	The user's permission level for the repository. If you don't have rights to view a repository, the repository name will not be returned. Valid strings include, READ, EDIT, and DELETE.

Example

SOAP request XML

```
<soapenv:Envelope xmlns:soapenv="http://schemas.xmlsoap.org/soap/envelope/"
xmlns:ser="http://www.businessobjects.com/DataServices/ServerX.xsd">
   <soapenv:Header>
      <ser:session>
         <SessionID>D19C201F-074C-B5FE-70A4-2F3436AC04E8</SessionID>
      </ser:session>
   </soapenv:Header>
   <soapenv:Body>
      <ser:GetListOfRepositoriesRequest/>
   </soapenv:Body>
</soapenv:Envelope>
```

Example

SOAP response XML

```
<soapenv:Envelope xmlns:soapenv="http://schemas.xmlsoap.org/soap/envelope/">
   <soapenv:Body>
      <localtypes:GetListOfRepositoriesResponse xmlns:localtypes="http://
www.businessobjects.com/DataServices/ServerX.xsd">
         <repository>
            <repoName>echo_oracle</repoName>
            <repoType>local</repoType>
            <dbType>Oracle</dbType>
            <dbHost>shg-v-imdb02</dbHost>
            <connectionStatus>active</connectionStatus>
            <username>echo</username>
            <permissions>READ,EDIT,DELETE</permissions>
         </repository>
         <repository>
            <repoName>echo_sqlany</repoName>
            <repoType>local</repoType>
            <dbType>SQL_Anywhere</dbType>
            <dbHost>shg-v-imdb03</dbHost>
            <connectionStatus>active</connectionStatus>
            <username>dba</username>
            <permissions>READ,EDIT,DELETE</permissions>
         </repository>
      </localtypes:GetListOfRepositoriesResponse>
   </soapenv:Body>
</soapenv:Envelope>
```

7.3.4 Enabling SSL support

7.3.4.1 To configure SSL on the web application server

For SAP Data Services web services to work with SSL, the web application server must be configured to support SSL connections. The `server.xml` file can be used to configure the packaged Tomcat application server.

> Note
>
> For other web application servers, refer to the product documentation about how to configure SSL support.

1. Open `server.xml` in a text editor. This file is located in the `Tomcat55\conf` directory at the same level as `LINK_DIR`.
2. Locate the commented `connector` element in the XML:

   ```
   <!-- Define a SSL HTTP/1.1 Connector on port 8443 -->
   <!--
   <Connector port="8443" maxHttpHeaderSize="8192"
     maxThreads="150" minSpareThreads="25" maxSpareThreads="75"
     enableLookups="false" disableUploadTimeout="true"
     acceptCount="100" scheme="https" secure="true"
     clientAuth="false" sslProtocol="TLS" />
    -->
   ```

3. Remove the comment (`<!-- -->`) tags around the `connector` element.
4. Add the `keystoreFile` and `keystorePath` attributes into the `connector` element.

   ```
   keystoreFile="<path/to/keystore/file>"
   keystorePass="<keystore_password>"
   ```

5. Restart the Tomcat application server.

7.3.5 Error reporting

SAP Data Services uses web services to define every operation with both an input and output message. In addition to the output message, the software returns a fault message when an error occurs.

7.3.5.1 Administrator log

In addition to the fault message, SAP Data Services writes log and debug messages to the Administrator's log file (`webadmin.log`). Fault messages include a short description of a failure. For detailed information about an error, use the Administrator's log file.

All Administrator components share the Administrator's log. The software prefixes these messages with the name of the component that issues the error message. For web services, the component name is the name of the Java class issuing the error. All web service classes start with `com.acta.adapter.webservice`.

The software creates the Administrator's log file in: **`<DS_COMMON_DIR>`**`\log\webadmin.log`.

To control the level of detail in the `webadmin.log` file, you must edit the `log4j.properties` file. The properties file is located in:

`<LINK_DIR>``\ext\webserver\webapps\acta_web_admin\WEB-INF`

To obtain a debug trace of events, change the log level from the default of `INFO` to `DEBUG`. For example, `log4j.rootLogger=DEBUG, A`

7.3.5.2 Web service log

In addition to the shared Administrator log, web service messages are also written to a separate log file. The `WebService.log` file is in **`<DS_COMMON_DIR>`**`\log`.

7.3.5.3 Error messages

The following are error messages that you might encounter if you are using SAP Data Services as a web service provider to accept inbound calls:

- A web service is unable to process a request due to an unknown function in the soapAction element.
  The server returns this error message if the soapAction header in the HTTP request is not recognized. Every web service call expects a soapAction header that indicates an action. The WSDL publishes a soapAction for each operation. When the web services server cannot determine what action to take, it is unable to call the software.
  To find extended error information, use the `WebService.log` file in **`<DS_COMMON_DIR>`**`/log`. To use extended diagnostics, use debug tracing in the `webadmin.log` file.
- A web service is unable to process a request to call real-time service **`<ServiceName>`** using Access Server **`<AccessServerName>`**.
  The server returns this error message when it recognizes a request to call a real-time service but is unable to extract the XML message from the SOAP Envelope that is supposed to be sent to the real-time service. To find extended error information, use the `WebService.log` file in **`<DS_COMMON_DIR>`**`/log`.
  To use extended diagnostics, use debug tracing in the `webadmin.log` file.
- A web service sent a request to invoke real-time service **`<ServiceName>`** to Access Server **`<AccessServerName>`**. The request failed with error = **`<access-server generated error message>`**

The server returns this error message if it recognizes a request to call a real-time service, data was extracted from the incoming SOAP Envelope, and data was passed to the Access Server, which refused to service the request.

To locate where the error occurred use the Access Server log file (*Real-time* > **<AccessServerName>** > *Logs - Current*).

If the Access Server passed the request on to the Job Server, use the following logs to diagnose the problem:

  - Job Server log (**<DS_COMMON_DIR>**`/log/`**<JobServerName>**`/server_eventlog.txt`)
  - Real-time service provider log (*Real-time* > **<AccessServerName>** > **<Real-timeServiceName>** > **<ProcessID>**)

- A web service operation is unable to process the request to start batch job **<JobName>** on server **<JobServerName>**. Error = **<web services generated error message>**
  The server returns this error message if it recognizes a request to start a batch job but is unable get the information it needs to start the job.
  To find extended error information, use the `WebService.log` file in **<DS_COMMON_DIR>**`/log`. To use extended diagnostics, use debug tracing in the `webadmin.log` file.
- A web service sent a request to start batch job **<JobName>** on server **<JobServerName>**. The Job Server refused the request with error: **<job server generated error message>**
  The server returns this error message if it recognizes a request to start a batch job and has passed the request to the Job Server to start the job. The Job Server is unable to start the job. To find extended error information, use the Job Server log (**<DS_COMMON_DIR>**`/log/`**<JobServerName>**`/server_eventlog.txt`).

Related Information

Administrator log [page 2256]

7.4 Consuming external web services in SAP Data Services

You can add functionality to SAP Data Services to invoke web services in external applications from data flows. This functionality requires configuring the software's built-in web services datastore type. The web services datastore provides support for locating and importing metadata for a web services server as well as invoking web service operations.

The web services datastore works by sending a request and waiting until it receives a reply from a web services server.

For example, you might create a web services server as a front-end to a legacy application. You could call the web services server daily from a data flow to access inventory and update an inventory data mart.

The interaction between the web services datastore and an external web service has these parts:

- Creating a web services datastore that identifies the WSDL, which describes the web services server.
- Importing metadata to extract the information form the WSDL needed to access the web service server.

- Creating a data flow that uses the imported function call to call the web services server.

7.4.1 To access a web service using the Designer

To configure access to a specific web services, use the Designer to create a web service datastore. SAP Data Services provides access to web services as stream-oriented function calls, which it configures when you import metadata.

1. Create a web service datastore.

   The following parameters are available when creating a Web Service SOAP datastore:

Parameter	Details
Datastore type	Choose Web Service SOAP.
Web Service URL	Specify the URL of the web services server for a data flow to access. It must be the same URL that accepts a web service connection and returns the WSDL. The datastore connects to the web services server using the URL to locate the definition of published services.
User name	Enter the user name for HTTP basic authentication. Required only if basic authentication is needed to connect to the web service provider.
Password	Enter the password for HTTP basic authentication. Required only if basic authentication is needed to connect to the web service provider.
XML Recursion Level	Enter the number of passes the software should run through the XSD to resolve names. The default is 0.
Keystore path	If the web service provider uses an SSL connection, specify the location of the keystore used to establish the connection.
Socket timeout	Enter the maximum number of milliseconds the web service client will wait to receive the response from the web service provider.
Axis2/c config file path	Enter the path to your Axis2/c configuration file (`axis2.xml`). If a path is not specified, the default path is **`<LINK_DIR>`**`/ext/webservice-c/axis2.xml`.
Proxy host	Enter the host name for the HTTP proxy server. Required only if a proxy server is needed to connect to the web service provider.
Proxy port	Enter the port number for the HTTP proxy server. Required only if a proxy server is needed to connect to the web service provider.
Proxy username	Enter the user name for the HTTP proxy server. Required only if a proxy server that uses authentication is needed to connect to the web service provider.
Proxy password	Enter the password for the HTTP proxy server. Required only if a proxy server that uses authentication is needed to connect to the web service provider.

   The following parameters are available, depending on the Authorization Schema you select, when creating a Web Service REST datastore:

Parameter	Details
Datastore type	Choose Web Service REST.
Web Service URL	Specify the location of the WADL. You can enter the URL or the path to a local WADL file.
Authorization schema	Choose one of the following options:

Parameter	Details
	○ Basic ○ Basic + CSRF ○ Authorization Header ○ OAuth 1.0 (2-legged) ○ OAuth 2.0 (2-legged) Data Services does not support the 3-legged model.
User name	Enter the user name for HTTP basic authentication. Required only if basic authentication is needed to connect to the web service provider.
Password	Enter the password for HTTP basic authentication. Required only if basic authentication is needed to connect to the web service provider.
Password Type	Options include Plain and Digest.
CSRF Fetch URL CSRF Fetch URL Method CSRF Header Key CSRF Header Value	Enter the location (URL) to fetch the CSRF token. Tokens can be retrieved via a service call to the server. To retrieve the token, set *CSRF Fetch URL Method* to GET or POST, *CSRF Header Key* (case sensitive) to X-CSRF-Token or the server required header key, and *CSRF Header Value* to Fetch or the server required value.
Header based api key or token	Enter the api key or token. For example, Token token=SECRET.
Proxy host	Enter the host name for the HTTP proxy server. Required only if a proxy server is needed to connect to the web service provider.
Proxy port	Enter the port number for the HTTP proxy server. Required only if a proxy server is needed to connect to the web service provider.
Proxy username	Enter the user name for the HTTP proxy server. Required only if a proxy server that uses authentication is needed to connect to the web service provider.
Proxy password	Enter the password for the HTTP proxy server. Required only if a proxy server that uses authentication is needed to connect to the web service provider.
Standard HTTP Header Fields	Enter a header field. Header fields generally contain the operating parameters of an HTTP request or response.
SSL Pem File	Enter the path and name of the `.pem` file (private key or certificate).
Dynamic Base URL	Enter the base URL. The base URL is comprised of the protocol, server name, port number, and path of the service that listens to RESTful web service requests. You can obtain ths URL from the WADL file under the element resource and attribute base. This is useful when you have multiple servers serving the same resources and you want to dynamically create the URL during the call.
Preferred Mediatype	The following options are available: ○ Application/XML ○ Application/JSON
Consumer Key for Oauth Consumer Key Secret for Oauth	Enter the Consumer Key and Consumer Key Secret for Oauth (equivalent to role account user names and passwords). You can obtain this information through the web service provider (for example, Google Apps or Twitter).

Parameter	Details
Oauth Token Key Oauth Token Key Secret	If the server supports 2-legged OAuth, Data Services does the authentication using the Consumer key and secret, otherwise, enter the Token Key and Token Key Secret for the Oauth. This information allows single user authorization. You can obtain this information through the web service provider (for example, Google Apps or Twitter).
Signature method	Select the signature method for HTTP requests. Options include: ○ HMAC-SHA1 (default) ○ Plain text
Client ID Client Secret	Enter the Client ID (represents your application) and Client Secret (security key). You can obtain this information through the web service provider (for example, Google Apps or Twitter).
Access token	Enter the location (API endpoint) of the temporary token. This allows you to access protected resources.
Refresh token	Enter the Refresh Token.
Request token URL Access token URL	Enter the URL for requesting a temporary token and a URL for getting the final token. Note Leave these parameters empty if the server uses only consumer key and secret to access the protected resource.
Grant type	Enter the type of grant access you want to use to obtain an access token. Options include: ○ Client credentials (default): Use your own credentials in order to obtain an access token. ○ Password: Use the resource owner's password to obtain an access token.
Default configuration	Indicates if you want to use the default configuration (the default is Yes).
Preferred method	Select the method you want to use to test trusted authentication. Options include: ○ Header String (POST) (default) ○ Query String (GET)

2. Import metadata from the web service datastore
   a) From the object library, open the web service datastore.
   The Designer calls the web service server at the indicated WSDL or WADL URL and obtains a list of the published services and ports.
   b) Expand the ports to see published operations available for import.
   c) Right-click an operation and select *Import*.
   The software imports web service operations as function calls and lists them under the web service datastore in the object library. Each function call includes a definition for both the input and output messages required for communication with a web service operation. The Designer extracts the details about the request and reply messages and generates XML Schema that describes the messages.
3. From the Designer, add a web service function call to a job.

   As a web services client, the software calls a web services server twice:

- ○ During design time to import metadata for the functions and data types that a particular web service supports.
- ○ During run time to call the web service and invoke its functionality.

For more information, see “Defining a web service datastore” in the *Designer Guide*.

Related Information

Configuring HTTP header fields [page 2261]

7.4.2 To add web service calls to a job

Once a web service datastore is created and metadata is imported, you can add web service function calls to an SAP Data Services job.

1. Add a Query transform to the data flow.
2. Open the Query editor, right-click the target schema and select *New function call*.
   The Function Editor opens listing the operation metadata that you imported under the datastore name.
3. Select a datastore to view the metadata that you want to add to your job.
4. Select the metadata name and click *Next*.
5. Map the input schema to the output schema.

   > **Note**
   >
   > If you want to nest data in the target schema, use this first Query transform to place the schema in your job and additional Query transforms to perform the nesting. The Function Editor does not allow complex schema configuration.
6. Click *OK*.
   The imported schema appears in the query.
7. Configure the rest of the data flow by supplying input to the function call and extracting the response information obtained from the web service.

7.4.3 Configuring HTTP header fields

In the HyperText Transfer Protocol (HTTP), header fields generally contain the operating parameters of an HTTP request or response. The header fields define various characteristics of the the data transfer that is requested or the data that is provided in the message body.

An HTTP header field always starts with a field name, then a colon (`:`), and ends with the field value. A core set of header fields is standardized by the Internet Engineering Task force. These standard headers are commonly understood by all compliant protocol implementations. Header field names may also be any application-specific strings, known as customary headers.

7.4.3.1 To configure standard HTTP header fields

Standard HTTP header fields have specified values that are the same and fixed for all web service functions in the web service datastore. The values for standard fields also remain the same for all web service calls in a data flow.

1. In the Designer, open the web service datastore configuration and click *Advanced*.
2. Select *Standard HTTP header fields* and click *...*.
   The *Edit HTTP Header Fields* screen appears.
3. Enter each field name and its corresponding default value and click *OK*.
   A semicolon-separated list of the header fields appears in the column for *Standard HTTP header fields*.
4. Click *OK* to accept the datastore configuration.

7.4.3.2 To configure dynamic HTTP header fields

Dynamic HTTP header fields have values that may be different for each function in the web service datastore. The values for dynamic fields can also change for each web service call in a data flow.

1. In the Designer, open the web service datastore configuration and click *Advanced*.
2. Select *Dynamic HTTP header fields* and click *...*.
   The *Edit HTTP Header Fields* screen appears.
3. Enter each field name and the maximum length for its value and click *OK*.
   A semicolon-separated list of the header fields appears in the column for *Dynamic HTTP header fields*.
4. Click *OK* to accept the datastore configuration.

When you import a function into the web service datastore, the dynamic HTTP headers are available for mapping in the HTTPHeader schema.

7.4.4 Enabling SSL support

7.4.4.1 To configure SSL on the native web service datastore

To configure SSL support on the native web service datastore, add the path to your keystore to the datastore configuration.

> Note
>
> The keystore path is only used while importing WSDL operations into the datastore, and is not used at runtime.

For more information about configuring web service datastores, see the *Designer Guide*.

7.4.4.2 To configure SSL in the runtime execution file

1. Obtain a certification authority (CA) certificate for the client.
2. Open `LINK_DIR\ext\webservice-c\axis2.xml` in a text editor.
3. Locate the commented `transportReciever` and `transportSender` elements in the XML:

```
<transportReceiver name="https" class="axis2_http_receiver">
  <parameter name="port" locked="false">6060</parameter>
  <parameter name="exposeHeaders" locked="true">false</parameter>
</transportReceiver>

<transportSender name="https" class="axis2_http_sender">
  <parameter name="PROTOCOL" locked="false">HTTP/1.1</parameter>
</transportSender>
```

4. Remove the comment (`<!-- -->`) tags around the `transportReciever` and `transportSender` elements.
5. Provide the path to the CA certificate as the `SERVER_CERT` parameter.

```
<parameter name="SERVER_CERT"></path/to/ca/certificate></parameter>
```

6. If you need client authentication, additionally provide the private key and keystore passphrase.

```
<parameter name="KEY_FILE"></path/to/client/certificate/chain/file></parameter>
<parameter name="SSL_PASSPHRASE"><passphrase></parameter>
```

7.4.5 Enabling WS-Security support

WS-Security is a communications protocol that applies security to web services at the message level. The protocol defines how integrity and confidentiality can be enforced on web service messaging, as well as how to attach signatures and encryption headers to SOAP messages. In addition, it defines how to attach security tokens such as X.509 certificates or Kerberos tickets to messages.

SAP Data Services implements WS-Security support through the Apache open source project rampart/c and can be configured through the web service datastore and an external policy file.

7.4.5.1 To configure WS-Security on the native web service datastore

1. Create a security policy file (`policy.xml`) based on the WS-Security policy specification that satisfies your security requirements.

   You can see sample policy files by downloading a copy of rampart/c and opening the `samples/secpolicy` folder.
2. Place your security policy file in the `LINK_DIR/ext/webservice-c` folder or another location.
3. If your policy file is not named `policy.xml` or is located in a folder other than the default location, specify the path using the WSS Policy file path parameter in the datastore configuration.

4. Enable the rampart/c module in your `axis2.xml` file.

   Within `axis2.xml`, uncomment the `<!-- module ref="rampart" /-->` line. By default, `axis2.xml` is installed to `LINK_DIR/ext/webservice-c/`.

You can also make more changes in the Advanced section of the native web service datastore configuration:

Parameter	Details
WSS Username	Enter the username to use for WS-Security.
WSS Password	Enter the password to use for WS-Security.
WSS Password type	Enter the password type to use for WS-Security. The available options are **`PlainText`** and **`Digest`**.
WSS Time to live	Enter the time for WS-Security protected messages to live. The default is 0. Any positive number will add a timestamp to the message.
WSS Policy file path	Enter the path to your WS-Security policy file. The default path is `LINK_DIR/ext/webservice-c/policy.xml`.

For more information about configuring web service datastores, see the *Designer Guide*.

WS-Security policy specification

7.5 Using the operational statistics API

Use the operational statistics as web services API to retrieve job execution data from the Data Services repository and local log files.

You can use the following operations to generate dashboards to further analyze and review operational statistics:

Operation	Description
Get_Repository_List	Use the Get_Repository_List operation to get the entire repository list based on the user's permissions. This operation also returns a list of the repositories that the user is currently logged into. This operation is part of the Repo_Operations port.
Get_BatchJob_ExeDetail	Retrieves a list of all job executions for the selected repository and job. You can also filter the list by time range. This operation is part of the Batch_Job_Admin port.
Get_BatchJob_FlowDetails	Retrieves details about the tasks included in a job. This operation is part of the Batch_Job_Admin port.
Get_DF_Auditdata	Shows audit information for a data flow. This operation is part of the Batch_Job_Admin port.

Operation	Description
Get_DF_Monitor_Log	Shows the runtime statistics for single data flow execution. This operation is part of the Batch_Job_Admin port.
Get_DF_Monitor_Log_Pivot	Shows the runtime statistics as pivoted for a single data flow execution. This operation is part of the Batch_Job_Admin port.

Related Information

Get_Repository_List [page 2253]
Get_BatchJob_ExeDetail [page 2229]
Get_BatchJob_FlowDetails [page 2231]
Get_DF_Auditdata [page 2235]
Get_DF_Monitor_Log [page 2237]
Get_DF_Monitor_Log_Pivot [page 2239]

7.5.1 Prerequisites

The operations you use to retrieve operational statistics data are session security enabled.

Before you can call the functions, you need to log onto the system by using the Logon operation.

To disable session security, do the following:

1. Open Data Services Management Console.
2. Open the *Administrator* and then click *Web Services*.
3. Click the *Web Services Configuration* tab and select the operations for which you want to disable session security.
4. Choose the *Disable Session Security* option from the drop-down box at the bottom of the page and click *Apply*.

Endpoints

The WSDL URL depends on your web server host and port. You can obtain the endpoint URL from the Data Services Management Console.

Note

WSDL file version 2.1 supports the operations used to retrieve operational statistics data. Earlier versions do not support these operations.

The basic format for the URL is as follows:

```
http://<serverhost>:<port>/DataServices/servlet/webservices?ver=2.1
```

For example:

`http://localhost:8080/DataServices/servlet/webservices?ver=2.1`

To get the WSDL file, you need to add "&wsdlxml" to your endpoint. For example:

`http://localhost:8080/DataServices/servlet/webservices?ver=2.1&wsdlxml`

Related Information

Logon [page 2226]

7.6 Using the Message Client API

You can integrate SAP Data Services' real-time services by using the C++ or Java API. Either of these interfaces allows you to connect to the real-time service with a persistent connection to the server, send and receive data from it, and close the connection.

> i Note
>
> The Message Client API supports the creation of reports, similar to any job you run with the software.

In the execution of real-time jobs with real-time services APIs, these steps take place:

1. An administrator logs into the Management Console and chooses which real-time jobs to expose as real-time services. Those job names are stored in the local repository.
2. An administrator chooses which Access Server to run the services on and starts the real-time services.
3. A developer accesses a real-time service through Java and C++ libraries.
4. A C++ or Java application client makes a connection to the Access Server, which then sends information to various job servers.
5. The job servers route requests to an engine to process the real-time job.

File location

The Message Client API files for each supported platform are installed to **<LINK_DIR>**`\SDK\RTSDK`. When the software is installed on a Windows server, the Message Client API files for both C++ and Java for each UNIX platform are provided in a `.tar.gz` archive.

To use the UNIX Message Client API files with a Windows installation, copy the appropriate Message Client API package file for your UNIX platform from `LINK_DIR\SDK\RTSDK\platform` to your UNIX system, and then unzip and extract the archive to the desired installation location. For example, on Solaris:

```
gunzip MessageClient_Solaris_64bit.tar.gz
tar -xvf MessageClient_Solaris_64bit.tar
```

7.6.1 Interface components

The interface between the Access Server and your application includes these components:

- Connection definition (Connection)
  A class that defines the connection that your application uses to send and receive messages from the Access Server. Initialize the class (using the connect method) each time you initialize your application.
- Connection initialization (Connect)
  A method that creates the connection using host and port information supplied by the client.
- Request (Invoke)
  A method that indicates the request message for the specified real-time service. This method is a synchronous call that waits for a return.
- Exception handlers (Error message)
  A class that returns exceptions thrown by the connection object and system exceptions, if available.

7.6.2 Creating the connection

The Connection object creates an active connection to the Access Server.

Creating a Connection (calling the Connect method) does the following:

- Authenticates the client as secure
- Produces an open TCP/IP socket between the client and the Access Server
- Encapsulates the connection information into a client identifier (Connection ID)

As soon as you create the Connection object, you can use it to send messages to the Access Server. Typically, you would create a single Connection per client. If you attempt to call the Connect method for a Connection that already exists, the Access Server ignores the call.

7.6.3 Sending messages

Send requests from the client application using the Invoke method and the Connection ID.

Each business operation implemented by your web application can result in a call to the Access Server with a message. The Access Server uses the name of the business operation to determine the path for the message. When you use SAP Data Services to process real time jobs, you pair this business operation name, called a service, with the job and data flow names you defined in the software to process the message. There is a one-to-one correlation between business operation, service, job, and XML source.

Call the Invoke method with a string return value to process a synchronous response.

7.6.4 Closing the connection

The library provides a method (Disconnect) with the Connection object that allows you to systematically close the TCP/IP socket between the client and the Access Server.

7.6.5 Pseudo code example

```
// Login and authenticate the client connection =
connect(     accessServerAddress,

// TCP/HTTP address
clientName,
// matches Access Server
clientPassword);
// IP & Client
// security settings
// Invoke Service String xmlOut =
connection.invoke(     serviceName,

// has mapping to RT job     xmlIn);
// according to the RT job DTD
// In case of an error returns the error code
// and error message
```

7.6.6 C++ API reference

7.6.6.1 Class RTServiceClient

RTServiceClient

Contains C++ methods for allowing a client to connect to real-time services.

Method summary	
`virtual void`	connect (char* **`<hostname>`** unsigned short **`<port>`** bool **`<use_SSL>`** char* **`<trusted_certs_filename>`**)
`virtual char*`	invoke (char* serviceName char* inData)
`virtual void`	disconnect ( )

Constructor detail

RTServiceClient

```
RTServiceClient(){}
```

Method detail

connect

```
virtual void    connect(char* hostname, unsigned short port)
```

Establishes a connection between a client and the Access Server. You must establish a connection before a message can be exchanged.

Option	Description
hostname	The name or IP address of the machine that hosts the Access server.
port	The port number used for the connection.

setUseSSL

```
void setUseSSL(const char* certificate_dir)
```

Uses SSL when communicating with the Access Server.

`certificate_dir` – the folder that contains the certificate files. Files with `.crt`, `.pem`, and `.cer` extensions are used as trusted certificates.

invoke

```
virtual char* invoke(char* serviceName, char* inData)
```

Sends the input data to the real-time service and returns the output data.

Option	Description
serviceName	The name of the real-time service to invoke.
inData	The input data to send to the real-time service.

disconnect

```
virtual void disconnect ()
```

Stops the connection between a client and the Access Server.

7.6.6.2 Class RTServiceClientError

RTServiceClientError

Represents an error object thrown by the C++ class RTServiceClient.

Method summary
RTServiceClientError(const char*, int=0)
RTServiceClientError(const char*, const char*, const char*)

Method summary
RTServiceClientError(const RTServiceClientError&)

Method detail

RTServiceClientError

```
RTServiceClientError(const char*, int=0)
```

```
RTServiceClientError(const char*, const char*, const char*)
```

```
RTServiceClientError(const RTServiceClientError&)
```

Represents an error object thrown by the client library.

7.6.7 Java API reference

7.6.7.1 Class RTServiceClient

```
com.businessobjects.rtsclient.RTServiceClient
```

Contains Java methods for allowing a client a connection to real-time services.

Method Summary	
`public void`	connect (char * **`<machineName>`** int **`<port>`** bool **`<use_SSL>`** char* **`<trusted_certs_filename>`**) throws RTServiceExceptionThrows:
`public java.lang.String`	invoke (java.lang.String **`<serviceName>`** java.lang.String **`<inData>`**) throws RTServiceExceptionThrows:
`public void`	disconnect ( ) throws RTServiceExceptionThrows:

Method detail

connect

```
public void    connect (java.lang.String machineName, int port, bool use_SSL, char*
trusted_certs_filename) throws RTServiceExceptionThrows:
```

Establishes a connection between a client and the Access Server. You must establish a connection before a message can be exchanged.

Option	Description
machineName	The name or IP address of the machine that hosts the Access Server
port	The port number used for the connection.
use_SSL	Indicates that SSL should be used for the connection to the Access Server.
trusted_certs_filename	The path to the file that contains the trusted SSL certificates.

invoke

```
public java.lang.String invoke(java.lang.String serviceName, java.lang.String
inData) throws RTServiceExceptionThrows:
```

Sends the input data to the real-time service and returns the output data.

Option	Description
serviceName	The name of the real time service to invoke.
inData	The input data to send to the real time service.

disconnect

```
public void disconnect ()throws RTServiceExceptionThrows:
```

Stops the connection between a client and SAP Data Services.

7.7 Using the JMS adapter

7.7.1 Introduction

7.7.1.1 About this section

This section provides a detailed step-by-step method of installing and configuring the SAP Data Services JMS adapter. It includes a description of required support software, including supported versions, details of the adapter components, environment setup both for the software and external applications, and instructions for executing the adapter.

7.7.1.1.1 Who should read this section?

This section assumes the following:

- You understand how to use Designer to design and run real-time data flows (RTDFs) and batch jobs.
- You have a basic understanding of how to use Administrator to administer SAP Data Services processes. (You administer adapters from the Administrator.)

- You have a working knowledge of the environment this adapter is targeting.
- You know the role an adapter plays in business systems integration.
- You have some familiarity with XML and XML configuration schemas.
- Also, to integrate the software with an external system, it's recommended that you be familiar with systems administration and systems integration issues.

General SAP Data Services product documentation assumes the following:

- You are an application developer, consultant or database administrator working on data extraction, data warehousing, or data integration.
- You understand your source and target data systems, DBMS, legacy systems, business intelligence, and messaging concepts.
- You understand your organization's data needs.
- If you are interested in using this product to design real-time processing you are familiar with:
    - DTD and XML Schema formats for XML files
    - Publishing Web Services (WSDL, HTTP/S and SOAP protocols, etc.)
- You are familiar with the software's installation environments: Microsoft Windows or UNIX.

7.7.1.2 Adapter overview

Typical enterprise infrastructure is a complex mix of off-the-shelf and custom applications, databases, ERP applications etc. SAP Data Services combines and extends critical Extraction Transformation Loading (ETL) and Enterprise Application Integration (EAI) technology components required for true enterprise data integration.

Integrating disparate applications with the software's platform requires adapters. These adapters help facilitate otherwise incompatible applications and systems work together, thereby sharing data.

7.7.1.2.1 About Java Messaging Service (JMS)

Enterprise-messaging or Message Oriented Middleware (MOM) products are fast becoming an essential component for integrating intra-company operations. They allow separate business components to be combined into a reliable, yet flexible, system. In addition to the traditional MOM vendors, several database vendors and Internet-related companies also provide enterprise-messaging products.

Java language clients and Java language middle-tier services must be capable of using these messaging systems. Java Messaging Service (JMS) provides a common way for Java language programs to access these systems.

JMS is a set of interfaces and associated semantics that define how a JMS client accesses the facilities of an enterprise-messaging product. Since messaging is peer-to-peer, all users of JMS are generically referred to as clients. A JMS application is composed of a set of application-defined messages and a set of clients that exchange them. Products that implement JMS do this by supplying a provider that implements the JMS interfaces.

7.7.1.2.2 Scope of the JMS adapter

- SAP Data Services initiates Request/Reply
  The software initiates the request by sending the message on a pre-configured request queue and gets the reply on a pre-configured reply queue.
- The software initiates Request/Acknowledgment
  The software initiates the request by sending the message on a pre-configured target queue or by publishing a message to a JMS topic. In this case, only the acknowledgment is sent back to the software.
- IR initiates Request/Acknowledgment & Request/Reply
  In this case, an external Information Resource (IR is a JMS compatible application) sends the requests to the software and gets the reply or acknowledgment.
  Alternatively, the IR publishes a message to a JMS topic to which the JMS adapter has subscribed.

7.7.2 Installation and configuration

7.7.2.1 JMS adapter installation

This section details the components of the Adapter for JMS as well as system requirements.

The Adapter for JMS is automatically installed when you install SAP Data Services version 12.0.0 or later.

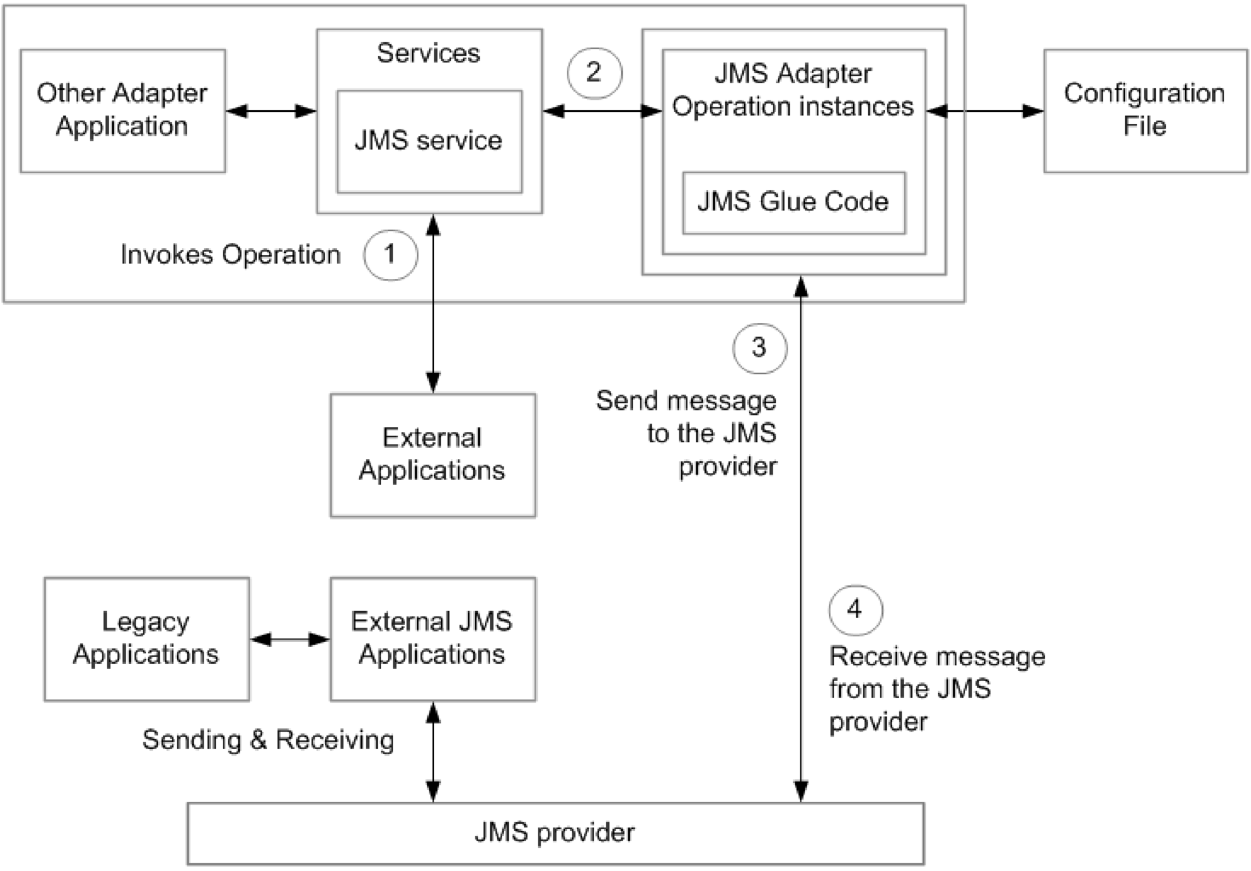
7.7.2.1.1 System prerequisites

Before you install your SAP Data Services Adapter for JMS, ensure that the following software is installed. For specific installation instructions, see the technical documentation for each product.

Software	Version	Comment
JMS Provider		For example, Weblogic Application Server
SAP Data Services	11.7.0 or later	Use the software to configure the services and adapter
SAP Data Services Adapter SDK	2.0.0.0 or later	

7.7.2.1.2 Adapter product components

The following diagram shows a functional overview of the SAP Data Services Adapter for JMS with other components and their potential interrelationships:



Other Adapter Application
Services
JMS service
2
JMS Adapter Operation instances
JMS Glue Code
Configuration File
Invokes Operation
1
3
Send message to the JMS provider
External Applications
Legacy Applications
External JMS Applications
4
Receive message from the JMS provider
Sending & Receiving
JMS provider

The diagram shows the architecture and functionality of the SAP Data Services Adapter for JMS as well as how the adapter interacts with the external JMS application through the JMS Provider. The adapter sends or receives data on queues using the Point to Point (P2P) mode of communication, or publishes or subscribes to a JMS topic using the Publish/Subscribe mode of communication.

The flow of control in the previous diagram is as follows:

1. External application invokes a service on the software.
2. Based on the service invoked on the software, its respective real-time data flow (RTDF) invokes the Operation instance with XML data sent by the external application as input.
3. This operation instance sends the message to the configured queue or topic in the JMS provider. Based on the type of operation (such as Request/Reply or Request/Acknowledge), the JMS provider sends the Reply/Acknowledgment message back to the software.
4. External JMS application sends messages to the JMS Provider on a request queue or publishes the message to a topic. The JMS Adapter receives these messages after polling them from the JMS Provider and for P2P, sends the reply back to external JMS application on a configured reply queue. No reply is sent if the message was from a topic.

7.7.2.2 JMS adapter configuration

Before the Adapter for JMS can begin integrating the JMS Provider with the SAP Data Services system you must create and configure at least one adapter instance and at least one operation for each instance. Adapter instances identify the JMS Application used in the integration. Adapter operations identify the integration operations to be used with the configured adapter instance.

Operations provided with Adapter for JMS include the following:

- PutGet Operation (Request/Reply): The software initiates a request, sending a message on a pre-configured request queue. Simultaneously, the software listens on a pre-configured reply queue. An external JMS-compatible application listens on the request queue, processes the request, and returns an XML response message to the reply queue. The adapter sends the message to the Job service.
- Put Operation (Request/Acknowledgment): The software initiates a request, sending a message on a pre-configured target queue. If the message was sent successfully, the adapter sends an acknowledgement to the Job service. The adapter raises an exception if it was unable to send the message.
- Get Operation (Request/Acknowledgment and Request/Reply from Information Resource): An external information resource (IR) sends a request XML message to a JMS queue. The adapter polls the JMS queue at a time interval you specify in the configuration. When the adapter receives a message from the JMS queue, it sends the message to the pre-configured Job service.
  After processing the XML message, the Job service may send a response message to the adapter. When this happens, the adapter puts the message in a pre-configured response queue. If the response queue is not configured, it becomes a request/acknowledgment operation and no reply is sent. If there is any error in invoking another service from the Job service, the original message is sent to the undelivered queue for reference by the IR.
- PutTopic Operation (Request/Acknowledgment): A software service initiates a request, publishing an XML message to a pre-configured target topic. If the message was sent successfully, the adapter sends an acknowledgement to the Job service. The adapter raises an exception if it was unable to send the message.
- GetTopic Operation (Request/Acknowledgment): An external information resource (IR) publishes an XML message to a JMS topic. The adapter polls the topic at the time intervals specified in the configuration. When the adapter receives the message from the topic, it sends the message to the service that handles the message.

7.7.2.2.1 To configure the JMS adapter

All SAP Data Services adapters communicate with the software through a designated Adapter Manager Job Server. Install adapters on the computer containing your designated Adapter Manager Job Server. This special Job Server integrates adapters with the software using the Administrator and Designer. After you install your adapter:

1. Use the Server Manager utility to configure adapter connections with the Adapter Manager Job Server.
2. From the Administrator, perform the following tasks:
   - Add at least one instance of the adapter to system.
   - Add at least one operation for each adapter instance.
   - Start the adapter instance (operations are started automatically).
3. Open the Designer and create an adapter datastore. Use metadata accessed through the adapter to create batch and/or real-time jobs.

For more information, see “To configure Job Servers” in the *Installation Guide* and “Adapter Considerations” in the *Management Console Guide*.

7.7.2.2.2 To configure an adapter instance in the Administrator

From the Administrator you can add a JMS adapter to the SAP Data Services system as well as edit existing adapter configurations. Add the adapter in the Administrator before you run jobs that use information from that adapter.

1. Select *Adapter Instances* › *Job Server*.
2. Select the *Configuration* tab.
3. Click *Add*.
4. Select *JMSAdapter* from the list of adapters available on this Job Server and click *Apply*.
5. Enter the required information to create a JMS Adapter instance and click *Apply*.

The Administrator makes the adapter instance available to the software.

7.7.2.2.2.1 Adapter instance configuration information

To configure a JMS adapter instance in SAP Data Services, you need to complete the fields in the Administrator under Adapter instance startup configuration.

Field	Description
Adapter Instance Name	Enter a unique name that identifies this instance of the adapter.
Access Server Host	Enter the host ID of the computer running the Access Server that connects to this adapter instance. To run a real-time job, you must configure a service that the Access Server will use to run the job. When a job uses adapter-based data, the Access Server must be able to connect to the adapter instance.
Access Server Port	The message broker port of the Access Server host. After you log into the Administrator for this Access Server, select *Configuration* › *Client Interfaces* to view message broker port information.
Adapter Retry Count	Applies if adapter instance fails or crashes. Enter 0 for no retries; enter a negative number for indefinite retries.
Adapter Retry Interval	Wait in msec. between adapter retry attempts.
Classpath	The adapter is a Java program, so you must configure the jar files required by the adapter `CLASSPATH`. The adapter is pre-configured with most of the necessary jar files, except for the vendor-specific JMS provider jar files and the `j2ee.jar` file. Add these jar files to the `CLASSPATH`. For example: • **`<LINK_DIR>`**`/lib/acta_adapter_sdk.jar` • **`<LINK_DIR>`**`/lib/acta_broker_client.jar` • **`<LINK_DIR>`**`/lib/acta_tool.jar`

Field	Description
	• <LINK_DIR>/ext/lib/xerces.jar • <LINK_DIR>/lib/acta_jms_adapter.jar • <LINK_DIR>/ext/lib/jms/<JMS Provider Jar File> • <LINK_DIR>/ext/lib/jms/j2ee.jar Note Specify the jar file provided with the JMS provider that you are using. For Weblogic, the name of jar file is weblogic.jar. Note The j2ee.jar file is required. You can get the j2ee.jar file from Java EE 1.6 and copy it to the adapter job server machine. You then need to add the j2ee.jar to the JMS adapter CLASSPATH.
Autostart	When set to True, the adapter interface automatically starts when the Administrator starts.
Trace Mode	Set this flag to control the number of trace messages the adapter produces. There are two settings: • True: The adapter interface writes information and error messages to help debug problems. The adapter writes information and error messages to the <adapter_instance_name>_trace.txt file in the <DS_COMMON_DIR>\adapters\logs directory. • False: The adapter interface writes only error information messages. The adapter writes error messages to the <adapter_instance_name>_error.txt file in the <DS_COMMON_DIR>\adapters\logs directory.
Additional Java Launcher Options	Additional command line parameters used for the javaw.exe command line and for the adapter itself. (See specific adapter documentation for details.)
Adapter Type Name	(Read-only) Name of the adapter used to create this instance.
Adapter Version	(Read-only) Version of the adapter used to create this instance.
Adapter Class	(Read-only) Name that identifies the adapter class. The name depends on the type of adapter.

In the JMS Adapter section, select a Configuration Type and enter Configuration parameters.

Parameter	Description
Configuration Type	Uses only the configuration parameters associated with the selected configuration type. ● JNDI configuration type ● MQ configuration type

For the JNDI configuration type, use the following configuration parameters.

Parameter	Description
Server URL	Represents the URL of the JMS Provider. For example: `t3://`**`<JMS Provider IP Address>`**`:`**`<port number>`**.
JNDI Context Factory	JNDI context factory name is JMS Provider specific. You can choose the context factory from a list that includes common context factories. If you require a context factory that is not listed, you can add it to the list by editing file **`<DS_COMMON_DIR>`**`/adapters/config/templates/JMSAdapter.xml` and updating the `<jndiFactory>` element. For Weblogic as a JMS Provider, the JNDI Factory name is: `weblogic.jndi.WLInitialContextFactory`.
Queue Connection Factory	Queue connection factory name. For example: `JMSConnections.AdapterConnectionFactory`.
Topic Connection Factory	Topic connection factory name. For example: `JMSConnections.AdapterTopicConnectionFactory`.

For the MQ configuration type, use the following configuration parameters.

Parameter	Description
MQ Queue Manager Name	(Optional) Specify if not using the default MQ Queue Manager on the system running MQ.
MQ Channel Name	(Optional) Specify if not using the default MQ Channel on the system running the adapter.
MQ Computer Name	(Optional) Specify if not using the MQ Queue Manager on the same system running the adapter.
MQ Port	(Optional) Specify if not using the default MQ port (1414).
MQ User ID	(Optional) Specify if required to login to the MQ Queue Manager.
MQ Password	(Optional) Specify if required to login to the MQ Queue Manager.

7.7.2.2.3 To add an operation instance to an adapter instance

1. Select *Configuration* > *Adapter instances* .
2. Click *Operations* under Dependent Objects.
3. Click *Add* to configure a new operation. Or, you can click the link of an existing operation instance to edit its configuration.
4. Select an operation type from the list and click *Apply*. The options that appear on this page vary based on operation-specific design.

Complete the operation instance configuration form and click *Apply*.

7.7.2.2.3.1 Operation instance configuration options

Each operation type contains different configuration options. Operations include:

- Put Operation (request/acknowledgment) options
- PutTopic Operation (request/acknowledgment) options
- PutGet Operation (request/reply) options
- Get Operation (request/reply and request/acknowledgment) options
- GetTopic Operation (request/acknowledgment only) options

Note

When specifying a queue or topic, you must provide the JNDI queue name or the MQ queue name as indicated by the Adapter Configuration Type property.

7.7.2.2.3.1.1 Put Operation (request/acknowledgement) options

To set up an operation instance of type Put Operation in SAP Data Services, complete the following fields in the Administrator.

Field	Description
Operation instance	The unique operation instance name. In the Designer, your operation metadata object is imported with this name.
Thread count	The number of copies of Request/Reply operation to run in parallel. For parallel (asynchronous) processing of messages coming from real-time service, more than one copy should be used. But if the sequence of messages is important (synchronous processing), more than one thread should not be used. (Multiple copies of real-time services must be

FIeld	Description
	supported by multiple instances of Request/Reply.) The default is 1.
Operation retry count	The number of times to retry this operation if it fails. Enter 0 to indicate no retries are to be attempted. Enter a negative number to indicate the operation should be retried indefinitely.
Operation retry interval	The time (in milliseconds) to wait between operation retry attempts.
Display name	The display name of the operation instance. This display name is visible in the Designer's metadata browsing window.
Description	The description of the operation instance. This description is visible in the Designer's metadata browsing window.
Enable	Whether to enable the operation to start at the same time as the adapter instance. Valid values are true and false. ● When true, the operation starts when the adapter instance starts. ● When false, the operation needs to be started manually from *Adapter Operations Status* window of the adapter administrator.
Destination Queue	The name of the destination queue where the message will be sent.
Request Format	The DTD or XSD file name that defines the XML message used in the operation.
Request XML Root Element	The name of the XML root element.

7.7.2.2.3.1.2 PutTopic Operation (request/ acknowledgement) options

To set up an operation instance of type PutTopic in the SAP Data Services, complete the following fields in the Administrator.

Field	Description
Operation instance	The unique operation instance name. In the Designer, your operation metadata object is imported with this name.
Thread count	The number of copies of Request/Reply operation to run in parallel. For parallel (asynchronous) processing of messages coming from real-time service, more than one copy should be used. But if the sequence of messages is important (synchronous processing), more than one thread should not be used. (Multiple copies of real-time services must be supported by multiple instances of Request/Reply.) The default is 1.

Field	Description
Operation retry count	The number of times to retry this operation if it fails. Enter 0 to indicate no retries are to be attempted. Enter a negative number to indicate the operation should be retried indefinitely.
Operation retry interval	The time (in milliseconds) to wait between operation retry attempts.
Display name	The display name of the operation instance. This display name is visible in the Designer's metadata browsing window.
Description	The description of the operation instance. This description is visible in the Designer's metadata browsing window.
Enable	Whether to enable the operation to start at the same time as the adapter instance. Valid values are true and false. ● When true, the operation starts when the adapter instance starts. ● When false, the operation needs to be started manually from *Adapter Operations Status* window of the adapter administrator.
Destination Topic	The topic to which the operation is published. Use JNDI or MQ name as specified by Adapter Configuration Type.
Message Format	The DTD or XSD file name defining the XML message used in this operation.
Request XML Root Element	The name of the XML root element.
Persistent Message	Whether to make published messages available to durable subscribers. Valid values are true and false. When true, published messages are available to durable subscribers.

7.7.2.2.3.1.3 PutGet Operation (request/reply) options

To set up an operation instance of type PutGet Operation in SAP Data Services, complete the following fields in the Administrator.

Field	Description
Operation instance	The unique operation instance name. In the Designer, your operation metadata object is imported with this name.
Thread count	The number of copies of Request/Reply operation to run in parallel. For parallel (asynchronous) processing of messages coming from real-time service, more than one copy is used. If the sequence of messages is important (synchronous processing), more than one thread should not be used. (Multiple copies of real-time services must be supported by multiple instances of Request/Reply.) The default is 1.
Operation retry count	The number of times to retry this operation if it fails. Enter 0 to indicate no retries are to be attempted. Enter a negative

Field	Description
	number to indicate the operation should be retried indefinitely.
Operation retry interval	The amount of time (in milliseconds) to wait between operation retry attempts.
Display name	The display name of the operation instance. This display name is visible in the Designer's metadata browsing window.
Description	The description of the operation instance. This description is visible in the Designer's metadata browsing window.
Enable	Whether to enable the operation to start at the same time as the adapter instance. Valid values are true and false. ● When true, the operation starts when the adapter instance starts. ● When false, the operation needs to be started manually from *Adapter Operations Status* window of the adapter administrator.
Request Queue	The name of the destination queue where the message will be sent.
Reply Queue	The name of the destination queue where the message will be sent.
Timeout	The maximum time (in milliseconds) the operation should wait for the reply message.
Continue After Error	Whether to continue after encountering an error. Valid values are true and false. ● When true, the operation instance remains in start stage even after the error. ● When false, the operation instance stops after the error occurs during the process.
Request Format	The DTD or XSD file name that defines the Request XML message used in this operation.
Request XML Root Element	The name of the XML root element in the Request DTD or XSD.
Reply Format	The DTD or XSD file name that defines the Reply XML message used in the operation.
Reply XML Root Element	The name of the XML root element in the Reply DTD or XSD.

7.7.2.2.3.1.4 Get Operation (request/reply and request/acknowledgement) options

To set up an operation instance of type Get Operation in SAP Data Services, complete the following fields in the Administrator.

Field	Description
Operation instance	The unique operation instance name. In the Designer, your operation metadata object is imported with this name.
Polling interval	The time interval (in milliseconds) for polling the source queue by this operation instance. For example, If the polling interval is 1000, then it polls the source queue after every one second.
Operation retry count	The number of times to retry this operation if it fails. Enter 0 to indicate no retries are to be attempted. Enter a negative number to indicate the operation should be retried indefinitely.
Operation retry interval	The time (in milliseconds) to wait between operation retry attempts.
Enable	Whether to enable the operation to start at the same time as the adapter instance. Valid values are true and false. ● When true, the operation starts when the adapter instance starts. ● When false, the operation needs to be started manually from *Adapter Operations Status* window of the adapter administrator.
Source Queue	The name of the queue where the message is sent by the IR and received by the adapter. Use JNDI or MQ name as specified by the Adapter Configuration Type.
Service	The name of the real-time service invoked by the operation when it receives a new message from the Source Queue.
Timeout	The maximum time (in milliseconds) that the Service takes to process a message. If the operation instance is unable to invoke the service within the Timeout limit, it sends the error message to the undelivered queue.
Continue After Error	Whether to continue after encountering an error. Valid values are true and false. ● When true, the operation instance remains in start stage even after the error. ● When false, the operation instance stops after the error occurs during the process.
Default Response Queue	[optional]: Used only for Request/Reply operation. In case of Request/Acknowledgment operation, it remains blank. The application sends the reply back to external JMS application (IR) on this queue. Use JNDI or MQ name as specified by the Adapter Configuration Type.
Undelivered Queue	[optional]: The undelivered queue for receiving the error messages, if any. Use JNDI or MQ name as specified by the Adapter Configuration Type.
Request DTD Root Element	The name of the root element for the input DTD for this operation.

7.7.2.2.3.1.5 GetTopic Operation (request/ acknowledgement only) options

To set up an operation instance of type GetTopic in SAP Data Services, complete the following fields in the Administrator.

Field	Description
Operation instance	The unique operation instance name. In the Designer, your operation metadata object is imported with this name.
Polling interval	The time interval (in milliseconds) for polling the source topic by this operation instance. For example, if the polling interval is 1000, then it polls the source topic after every one second.
Operation retry count	The number of times to retry this operation if it fails. Enter 0 to indicate no retries are to be attempted. Enter a negative number to indicate the operation should be retried indefinitely.
Operation retry interval	The time (in milliseconds) to wait between operation retry attempts.
Enable	Whether to enable the operation to start at the same time as the adapter instance. Valid values are true and false. ● When true, the operation starts when the adapter instance starts. ● When false, the operation needs to be started manually from *Adapter Operations Status* window of the adapter administrator.
Source Topic	The topic to which the operation subscribes. Use JNDI or MQ name as specified by Adapter Configuration Type.
Durable subscriber	The subscription name of Durable subscriber. If not applicable, leave this field blank.
Service	The name of the real-time service invoked by the operation when it receives a new message from the source topic.
Timeout	The maximum time (in milliseconds) that the service takes to process a message.
Continue After Error	Whether to continue after encountering an error. Valid values are true and false. ● When true, the operation instance remains in start stage even after the error. ● When false, the operation instance stops after the error occurs during the process.

7.7.2.2.4 Defining a JMS adapter datastore

Use the SAP Data Services Adapter for JMS with a batch job or real-time data flow (RTDF) when the batch job or RTDF passes a message to an operation instance, using either:

- An Outbound message (for Request/Acknowledge operations)
- A Message Function (for Request/Reply operations)

You must first define an adapter datastore in the Designer. Then, the batch job or RTDF can pass a message to one of the adapter operation instances defined in that datastore. To define an adapter, you must:

- Define a datastore object for each adapter instance
- Define one function or one outbound message for each operation instance to which you want to pass a message.

For each adapter instance, define a corresponding datastore object in the Datastore Editor window of the Designer object library.

7.7.2.2.4.1 To define a JMS adapter datastore

1. From the Datastore Editor:
   a) Select the *Job Server* configured to manage your JMS adapter.
   b) Select the *Adapter instance name* you configured in the Administrator.
2. Select the Adapter Properties tab and enter values for each property.
3. Click *OK* to save values and create the datastore.

7.7.2.2.5 Importing message functions and outbound messages to the datastore

You can pass messages from a batch job or RTDF to an operation instance. Import either a function or an outbound message (depends on the type of operation involved) in the Designer Datastore library for each operation instance.

Real-time data flows use following methods.

Method	Description
Message functions	Pass messages to an operation instance if the RTDF waits for a return XML message from the IR.
Outbound messages	Outbound messages Pass messages to an operation instance if the RTDF waits for a confirmation only (not a return XML message) from the IR.

Operation types in the SAP Data Services Adapter for JMS have the following invocation types.

Operation type	Invocation type
Request/Reply Operation	Message Function
Request/Acknowledge Operation	Outbound Message

7.7.2.2.5.1 To import message functions and outbound messages

1. In Designer, double-click the datastore associated with your JMS Adapter Instance to display the Adapter metadata browser window.
2. Right-click the operation instance to be imported and select Import.
   The selected operation instance is added to the datastore.

These message functions and outbound message functions can be used for creating Batch Jobs or RTDFs in SAP Data Services.

7.7.3 Using the JMS adapter

7.7.3.1 To start an instance of the JMS adapter

1. From the Administrator go to *Adapter Instance* > *Job Server* and select the *Status* tab.
2. Select the check-box next to the previously configured adapter instance.
3. Click *Start*.

When the adapter instance and its operations start, the message “Started” appears in the Status column.

7.7.3.1.1 Operations from SAP Data Services to the JMS adapter

7.7.3.1.1.1 Request/Reply - PutGet operation

SAP Data Services initiates the request by sending a message on a pre-configured request queue. Simultaneously, the software also listens on a pre-configured reply queue. An external JMS-compatible application listening on this request queue, after processing, sends back the response on response queue. This response, in the form of the reply XML message, is returned back to the software.

Related Information

Testing PutGet: Request/Reply [page 2290]

7.7.3.1.1.2 Request/Acknowledge - Put operation

SAP Data Services initiates the request by sending the message on a pre-configured target queue.

Related Information

Testing Put: Request/Acknowledge [page 2296]

7.7.3.1.1.3 Request/Acknowledge - PutTopic operation

SAP Data Services initiates the request by publishing the message to a pre-configured target topic.

Related Information

Testing PutTopic: Request/Acknowledge [page 2291]

7.7.3.1.2 Operations from Information Resource (IR) to Data Services

7.7.3.1.2.1 Request/Reply - Get operation

IR initiates the request by putting a message in the source queue of the Get operation. The Get operation receives the message from the source queue during a polling cycle and sends the message to the configured Job service. The service sends a reply message to the Get operation, which then puts the message in the response queue. The IR then gets the message from the response queue.

Related Information

Testing Get: Request/Reply [page 2292]

7.7.3.1.2.2 Request/Acknowledge - Get operation

IR initiates the request by putting a message in the source queue of the Get operation. The Get operation receives the message from the source queue during a polling cycle and sends the message to the configured Job service.

Related Information

Testing Get: Request/Acknowledge [page 2294]

7.7.3.1.2.3 Request/Acknowledge - GetTopic operation

IR initiates the request by publishing a message to the source topic of the GetTopic operation. The GetTopic operation receives the message from the source queue during a polling cycle and sends the message to the configured Job service.

Related Information

Testing GetTopic: Request/Acknowledge [page 2294]

7.7.3.2 To run the sample

This section details the JMS adapter operations.

1. Import the `JMSAdapter.atl` file into the Designer. Find the `.atl` file in **`<DS_COMMON_DIR>`**`/adapters/jms/samples`. The imported project name is Acta_JMSAdapter_Sample.
2. Change the input and output XML files path for all the batch jobs depending on your location of your **`<DS_COMMON_DIR>`** environment variable.
3. Use the Administrator Real-Time Services Configuration tab to create the service Queue.TestService referencing job TestService_Job and Topic.TestService referencing job TestServiceTopic_Job.
4. Open Web Administrator and configure a JMS adapter. Define the operations detailed in the following tests.
5. Use the Designer to edit the JMSAdapter datastore and rename it to the name of the adapter you just created.

Before running the sample, create the following queues and topic using your JMS provider utilities:

- Queue.MyQueue
- Queue.ActaQueuePutGet
- Queue.ActaQueuePutGet1
- Queue.ActaQueueGet
- Queue.ActaReplyQueueGet
- Queue.ActaUndeliveredQueue
- Topic.MyTopic

> Note
>
> The `JMSAdapterTest.properties` file and the scripts to execute the samples are located in the **`<DS_COMMON_DIR>`**`/adapters/jms/samples` directory.

The `JMSAdapterTest.properties` file `TopicConnectionFactoryName` property value is **`Tcf`** and the `QueueConnectionFactoryName` property value is **`Qcf`**. You must edit this file and change the property values if the adapter was configured using different factory names.

The `JMSAdapterTest.properties` file `MessageSource` property refers to the file **`<DS_COMMON_DIR>`**`/adapters/jms/samples/xml/JMSSource.xml`. You must edit this file and change the property value if this is not where your `JMSSource.xml` file is located.

You must edit `setTestEnv.bat` on Windows or `setTestEnv.sh` on UNIX to set the JMS Provider jar files in the class path used by the sample test programs.

7.7.3.2.1 Configuring the JMS provider

Create a JMS Server, Connection Factory and configure JMS queues to run SAP Data Services Adapter for JMS. For testing the adapter, using sample applications, configure the following queues and topic:

- Queue.MyQueue
- Queue.ActaQueuePutGet
- Queue.ActaQueuePutGet1
- Queue.ActaQueueGet
- Queue.ActaReplyQueueGet
- Queue.ActaUndeliveredQueue
- Topic.MyTopic

Refer to the “Appendix” section for instructions on using Weblogic as the JMS Provider. Steps for JMS Provider may differ from the example provided in this section.

7.7.3.2.2 To use MQ instead of JNDI configuration

The properties file used by the samples, `JMSAdapterTest.properties`, is set up to use the JNDI configuration. You can edit this file to use MQ configuration parameters.

1. Open the `JMSAdapterTest.properties` file.
2. Set ConfigType = MQ.
3. Set any of the following properties as required by your system:
    - MqQueueManager
    - MqChannel
    - MqComputerName
    - MqPort
    - MqUserID
    - MqPassword
4. For the queue and topic names, use MQ names instead of the JNDI names for the following properties:
    - TopicGetName
    - TopicPutName
    - QueueSourceGetName
    - QueueResponseGetName
    - QueuePutName
    - QueueRequestPutGetName
    - QueueReplyPutGetName

7.7.3.3 Testing PutGet: Request/Reply

To configure the operation type PutGet (Request/Reply), enter the following information in the operation instance configuration page in Administrator.

Option	Value
Operation instance	JMSPutGetOperation
Thread count	1
Display name	JMSPutGetOperation
Description	This operation instance represents the PutGet Request/Reply operation. It sends the request message to the request queue and receives the reply message from the reply queue.
Enable	true
Request queue	Queue.ActaQueuePutGet
Reply queue	Queue.ActaQueuePutGet1
Timeout	200000
Continue after error	true
Request format	**<DS_COMMON_DIR>**`/adapters/JMS/samples/dtd/JMSPUTGET_SOURCE.dtd`
Request XML root element	source
Reply format	**<DS_COMMON_DIR>**`/adapters/JMS/samples/dtd/JMSPUTGET_RESPONSE1.dtd`
Reply XML root element	source

After entering this information, click *Apply* and restart the JMS Adapter instance. When the JMS Adapter starts running, the operation instance also starts running.

Testing on Windows

Open a command prompt window and change directory to **<DS_COMMON_DIR>**`\adapters\jms\samples`. Run the sample application (external IR) by running `sampleTest_PutGet.bat`. The application displays the message:

```
Ready to receive message from queue Queue.ActaQueuePutGet
```

Execute the batch Job JMSPutGetOperation_BatchJob from the Designer. This sends the message to the request queue.

The sample application (external IR) listens for a message to arrive at the request queue of the JMSPutGetOperation instance. When it receives the message, it prints a message to the command prompt window such as:

```
Message received:  <?xml version="1.0" encoding="UTF-8"?>  <!-- Data Services
generated XML -->  <!-- 2005-05-05.16:41:57(539,223)[1] -->  <source>  <age>18</
age>  <salary>200000000</salary>  <acno>2356376438743</acno>  </source>
```

The sample test program then sends a reply message to the reply queue configured for the JMSPutGetOperation instance. It echoes a message to the command prompt window such as:

```
Message sent:  <?xml version="1.0" encoding="UTF-8"?>  <source>
<age>ReplyFromJMSIR1</age>  <salary>ReplyFromJMSIR2</salary>
<acno>ReplyFromJMSIR3</acno>  </source>
```

After the adapter operation receives the reply from the reply queue, it sends the message to the job which then generates the output file `JMSSourceOutput_PutGet.xml` under the directory **<DS_COMMON_DIR>**`/adapters/JMS/samples/xml`. The contents of the file should be similar to the message sent from the sample test with the addition of a timestamp and error information.

Testing on UNIX

Run the sample application (external IR) by running `sampleTest_PutGet.sh` file from the command prompt.

Execute the batch Job JMSPutGetOperation_BatchJob from Designer. This sends the message at the request queue.

Sample application (external IR) listens for the message at the request queue of JMSPutGetOperation instance and sends the message to the reply queue configured for the JMSPutGetOperation instance. After receiving the reply from the reply queue an output file `JMSSourceOutput_PutGet.xml` is generated under the directory **<DS_COMMON_DIR>**`/adapters/JMS/samples/xml`.

7.7.3.4 Testing PutTopic: Request/Acknowledge

To configure the operation type Put topic (Request/Acknowledge), enter the following information in the operation instance configuration page in the Web Administrator.

Option	Value
Operation instance	JMSPutTopicOperation
Thread count	1
Operation retry count	5
Operation retry interval	15000
Display name	JMSPutTopicOperation Display Name
Description	JMSPutTopicOperation Display Name
Enable	true
Destination queue	Topic
Message format	`C:\ProgramFiles\SAP BusinessObjects\Data Services`
Request XML root element	source
Persistent message	true

After entering this information, click *Apply* and restart JMS Adapter instance. When the JMS Adapter starts running, the operation instance also starts running.

Add the testing sections:

Testing on Windows

Open a command prompt window and change directory to **<DS_COMMON_DIR>**\adapters\jms\samples. Run the sample application (external IR) by running sampleTest_PutTopic.bat. The application should display the message:

```
Ready to receive message from topic Topic.MyTopic
```

If you do not see this message, then start the JMS publish/subscribe broker. The message should appear after you start the broker.

Execute the batch Job JMSPutTopicOperation_BatchJob from the Designer.

The sample application (external IR) listens for a message to be published by the JMSPutTopicOperation instance. When it receives the message, it will print a message to the command prompt window such as:

```
Received message:  <?xml version="1.0" encoding="UTF-8"?>  <source>  <age>18</age>
<salary>200000000</salary>  <acno>2356376438743</acno>  </source>
```

After the adapter operation acknowledges sending the message to the IR, the job then generates the output file JMSSourceOutput_PutTopic.xml under the directory **<DS_COMMON_DIR>**/adapters/JMS/samples/xml. The contents of the file should be similar to the message received by the sample test with the addition of a timestamp. Note that this file is created as a result of the design of the job, not as a result of the adapter operation sending a reply message to the job.

Testing on UNIX

Run the sample application by running sampleTest_Put.sh file from the command prompt. This sample application listens at the destination queue configured for the Put operation instance.

Execute the batch Job JMSPutOperation_BatchJob from the Designer.

7.7.3.5 Testing Get: Request/Reply

To configure the operation type Get (Request/Reply), enter the following information in the operation instance configuration page in the Web Administrator.

Option	Value
Operation instance	JMSGetOperation

Option	Value
Polling interval	1000
Thread count	1
Enable	true
Source queue	Queue.ActaQueueGet
Service	Queue.TestService
Timeout	2000
Continue after error	true
Default response queue	Queue.ActaReplyQueueGet
Undelivered queue (optional)	Queue.ActaUndeliveredQueue

After entering this information, click *Apply* and restart the JMS Adapter instance. When the JMS Adapter starts running, the operation instance also starts running.

Testing on Windows

Run the sample application (external IR) by running `sampleTest_Send.bat` file from the command prompt. This sample application sends the message at the source queue of the Get operation instance configured in the software.

Also, run another sample application (external IR) by running the batch file `sampleTest_Get.bat` file, which receives the reply from SAP Data Services on a default response queue.

The sample application `sampleTest_Send.bat` (external IR) sends the message as a request on a source queue configured for JMSGetOperation instance. JMSGetOperation instance invokes the real-time batch job and also sends the reply back at the default response queue. The sample application `sampleTest_Get.bat` (external IR) receives the reply on this default response queue. If any error occurs while invoking another service from this Job service, then the original message is sent to the undelivered queue, for reference by the IR.

Testing on UNIX

Run the sample application (external IR) by running `sampleTest_Send.sh` file from the command prompt. This sample application sends the message at the request queue of the operation instance configured in the software.

Also, run another sample application (external IR) by running the batch file `sampleTest_Get.sh` file. This receives the reply from the software on a default response queue.

The sample application `sampleTest_Send.sh` (external IR) sends the message as a request on a source queue configured for JMSGetOperation instance. JMSGetOperation instance will invoke the real-time batch job and also sends the reply back at the default response queue. The sample application `sampleTest_Get.sh` (external IR) receives the reply on this default response queue. If any error occurs while invoking another service from this Job service, then the error message is sent to the undelivered queue, for reference by the IR.

7.7.3.6 Testing GetTopic: Request/Acknowledge

To configure the operation type Get topic (Request/Acknowledge), enter the following information in the operation instance configuration page in the Web Administrator.

Option	Value
Operation instance	JMSGetTopicOperation
Polling interval	1000
Thread count	1
Enable	true
Source topic	Topic.MyTopic
Service	Topic.TestService
Timeout	2000
Continue after error	true

After entering this information, click *Apply* and restart the JMS Adapter instance. When the JMS Adapter starts running, the operation instance also starts running.

Testing on Windows

Run the sample application (external IR) by running the `sampleTest_GetTopic.bat` file from the command prompt. This sample application publishes a message to the source topic of the GetTopic operation instance.

JMSGetTopicOperation, which has subscribed to the topic, receives the message and sends it to the real-time service. The service then puts the message into file `JMSFileTarget_GetTopic.xml` in directory **`<DS_COMMON_DIR>`**`/adapters/jms/samples/xml`.

Testing on UNIX

Run the sample application (external IR) by running the `sampleTest_GetTopic.sh` file from the command prompt. This sample application publishes a message to the source topic of the GetTopic operation instance.

JMSGetTopicOperation, which has subscribed to the topic, receives the message and sends it to the real-time service. The service then puts the message into file `JMSFileTarget_GetTopic.xml` in directory **`<DS_COMMON_DIR>`**`/adapters/jms/samples/xml`.

7.7.3.7 Testing Get: Request/Acknowledge

To configure the operation type Get (Request/Acknowledgment), enter the following information in the operation instance configuration page in the Web Administrator.

Option	Value
Operation instance	JMSGetOperation
Polling interval	1000
Thread count	1
Enable	true
Source queue	Queue.ActaQueueGet
Service	Queue.TestService
Timeout	2000
Continue after error	true
Default response queue	ℹ Note When you specify a value, this operation changes from Request/Acknowledgement to Request/Reply.
Undelivered queue	ℹ Note When you specify a value, this operation changes from Request/Acknowledgement to Request/Reply.

After entering this information, click *Apply* and restart the JMS Adapter instance. When the JMS Adapter starts running, the operation instance also starts running.

Testing on Windows

Run the sample application by running `sampleTest_Send.bat` file from the command prompt.

This sample application (external IR) sends the message as a request on a source queue configured for JMSGetOperation instance. JMSGetOperation instance invokes the real-time batch job. This creates an output file `JMSSourceOutput_Get.xml` as an acknowledgement at the location **`<DS_COMMON_DIR>`**`/adapters/JMS/samples/xml`. No response is sent to the default response queue since it is not configured for this type of operation.

Testing on UNIX

Run the sample application by running `sampleTest_Send.sh` file from the command prompt.

This sample application (external IR) sends the message as a request on a source queue configured for JMSGetOperation instance. JMSGetOperation instance invokes the real-time batch job. This creates an output file `JMSSourceOutput_Get.xml` as an acknowledgement at the location **`<DS_COMMON_DIR>`**`/adapters/JMS/samples/xml`. No response is sent to the default response queue since it is not configured for this type of operation.

7.7.3.8 Testing Put: Request/Acknowledge

To configure the operation type Put (Request/Acknowledge), enter the following information in the operation instance configuration page in the Web Administrator.

Option	Value
Operation instance	JMSPutOperation
Thread count	1
Display name	JMSPutOperation
Description	This operation instance represents the Put Request/ Acknowledge operation. It queues the message to the configured destination queue.
Enable	true
Destination queue	Queue.MyQueue
Request format	**<DS_COMMON_DIR>**/adapters/JMS/samples/dtd/JMSPUT_SOURCE.dtd
Request XML root element	source

Click *Apply* after entering this information, then restart the adapter instance.

When the JMS Adapter is running, the operation instance is also running.

Testing on Windows

Open a command prompt window and change directory to **<DS_COMMON_DIR>**\adapters\jms\samples. Run the sample application (external IR) by running sampleTest_Put.bat. The application should display the message:

```
Ready to receive message from queue Queue.MyQueue.
```

Execute the batch Job JMSPutOperation_BatchJob from the Designer.

The sample application (external IR) listens for a message to arrive at the request queue of the JMSPutOperation instance. When it receives the message, it will print a message to the command prompt window such as:

```
Received message:  <?xml version="1.0" encoding="UTF-8"?>  <source>  <age>18</age>
<salary>200000000</salary>  <acno>2356376438743</acno>  </source>
```

After the adapter operation acknowledges sending the message to the IR, the job then generates the output file JMSSourceOutput_Put.xml under the directory **<DS_COMMON_DIR>**/adapters/JMS/samples/xml. The contents of the file should be similar to the message received by the sample test with the addition of a timestamp. Note that this file is created as a result of the design of the job, not as a result of the adapter operation sending a reply message to the job.

Testing on UNIX

Run the sample application by running `sampleTest_Put.sh` file from the command prompt. This sample application listens at the destination queue configured for the Put operation instance.

Execute the batch Job JMSPutOperation_BatchJob from the Designer.

The sample application receives the message from the destination queue and an output file `JMSSourceOutput_Put.xml` as an acknowledgment gets created under the directory **`<DS_COMMON_DIR>`**`/adapters/JMS/samples/xml`.

7.7.3.9 Technical implementation

7.7.3.9.1 Design considerations

In the current design:

- JMS queues and topics used in the Operation instances must be pre-configured in the Messaging System.
- Only XML messages are handled.
- GetTopic operations should be configured to specify a Thread Count of 1. Since each thread would be a subscriber to the topic, each thread would receive the same message and send it to the service, resulting in multiple copies of the same message going to the service.

7.7.3.9.2 Error handling and tracing

Error messages are logged in error log file under the **`<DS_COMMON_DIR>`**`/adapters/log` directory before throwing any exception. The name of the error log file is same as the name of the adapter configured in the Administrator.

For tracing, the trace messages are logged in the trace file under the **`<DS_COMMON_DIR>`**`/adapters/log` directory. The name of the trace file is same as the name of the adapter configured in the Administrator. You can enable the trace option in the Administrator for this adapter. Trace message shows the execution flow of the adapter and contain useful information on finding the cause of an error. The output in this trace file is of great help for SAP Business User Support.

7.7.4 Appendix

7.7.4.1 Weblogic as JMS provider

Before you run the SAP Data Services Adapter for JMS, you need to create a JMSServer, Connection Factory and configure JMS queues.

- Create a JMS Server
- Start the BEA Weblogic server.
- Open the Weblogic console.
- Under services\JMS, click *Servers*.
- Click Create a new JMS Server button.

Create the instance of JMS server. Then, click *Create*.

Click the Target link on the screen and select the server from available block to a chosen block. Click *Apply* to create the server instance.

7.7.4.1.1 To create a JMS Connection Factory

1. Start the BEA Weblogic server
2. Open the Weblogic console
3. Under services\JMS, click *Connection Factories*.

Configure the Connection Factory. For testing purposes, “JMSConnections.AdapterConnectionFactory” must be configured.

Click the Target link on the screen. Select the server from available block to chosen block.

7.7.4.1.2 To configure the JMS Connection Factory

For testing purposes, “JMSConnections.AdapterConnectionFactory” must be configured.

1. Click the Target link on the screen.
2. Select the server from available block to chosen block.
3. Click *Apply* to create the connection factory.

7.7.4.1.3 To create a JMS queue

1. Start the BEA Weblogic server.
2. Open the Weblogic console
3. Under services\JMS\Servers\ConfigJMSServer\Destinations, click *Create a New JMS Queue*.

For testing purposes, configure the following queues in the server:

- Queue.MyQueue
- Queue.ActaQueuePutGet
- Queue.ActaQueuePutGet1
- Queue.ActaQueueGet
- Queue.ActaReplyQueueGet

- Queue.ActaUndeliveredQueue

7.8 Using the HTTP adapter

7.8.1 Introduction

7.8.1.1 Audience and assumptions

This section assumes the following:

- You understand how to use the Designer to design and run Data Services data flows.
- You have a basic understanding of how to use the Administrator to administer Data Services processes. (To use an adapter, you administer it from the Administrator.)
- You have a working knowledge of the environment this adapter is targeting.
- You know the role an adapter plays in business systems integration
- You have some familiarity with the XML markup language and XML configuration schemas.
- Because you will integrate Data Services and an external system, some familiarity with systems administration and systems integration issues is recommended.

7.8.1.2 About this section

This section tells you how to use the HTTP Adapter for integrating SAP Data Services with external applications using the HTTP protocol.

This section provides a detailed description of installing the HTTP Adapter. This includes the descriptions of the pre-requisite software along with their supported versions, the details of the adapter components, the environment setup for both Data Services and Tomcat and instructions for executing the adapter.

7.8.2 Overview

What does the HTTP Adapter provide?

The HTTP Adapter provides data transfer using HTTP and HTTPS protocols.

What is HTTP protocol?

The Hypertext Transfer Protocol (HTTP) is an application-level protocol for distributed, collaborative, hypermedia information systems. HTTP has been in use by the World-Wide Web global information initiative since 1990 and its use has increased steadily over the years, mainly because it has proven useful as a generic middleware protocol.

The HTTP protocol is a request/response protocol. A client sends a request to the server in the form of a request method, URI, and protocol version, followed by a MIME-like message containing request modifiers, client information, and possible body content over a connection with a server.

The server responds with a status line, including the message's protocol version and a success or error code, followed by a MIME-like message containing server information, entity meta information, and possible entity-body content.

HTTP communication usually takes place over TCP/IP connections. The default port is TCP 80 [19], but other ports can be used. This does not preclude HTTP from being implemented on top of any other protocol on the Internet, or on other networks. HTTP only presumes a reliable transport; any protocol that provides such guarantees can be used.

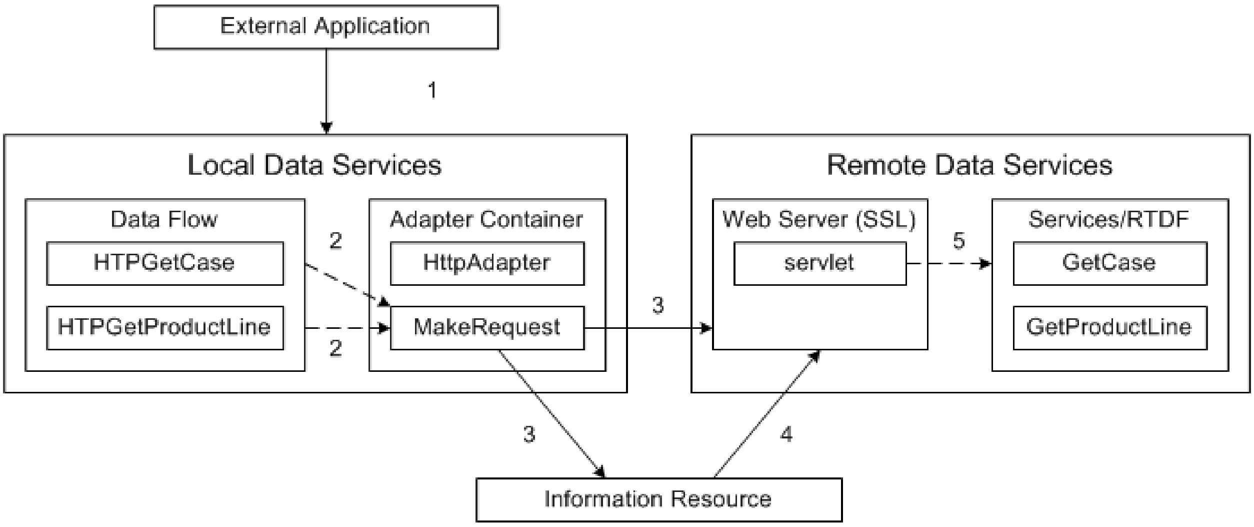
Scope of the HTTP Adapter

The major scope of the HTTP Adapter is:

- To ensure rapid integration of diverse systems and applications by making use of HTTP protocol with the SAP Data Services platform to meet unique business process requirements saving valuable time and effort.
- The HTTP Adapter supports SSL (Secure Socket Layer) to implement security over the HTTP protocol. Using HTTPS protocol, the data will be protected from any unscrupulous elements.
- The HTTP Adapter supports compress type data encoding while sending and receiving the information and thus saves network traffic.
- Request/Reply and Request/Acknowledge services by SAP Data Services can be initiated through this adapter.

7.8.3 Architecture

The following diagram shows the functional overview of the HTTP Adapter. It depicts two remote SAP Data Services installations using the HTTP Adapter to exchange information. The same diagram applies for interaction between SAP Data Services and any other third-party software supporting the HTTP protocol.



The flow of control is explained below. Refer to the above diagram.

1. External application invokes a service on SAP Data Services.
2. A data flow makes a call to the adapter operation instance.
3. The operation instance receives the XML data from RTDF and makes a request on the remote Data Services server. The operation instance forms the request URL by reading its configuration file. The URL contains servlet name and the service name, which are configured as part of the operation instance configuration. In the case of requesting to the information resource, a resource-specific URL will be configured as part of the operation instance configuration.
4. The information resource (for example, Siebel) can make a request on the remote Data Services server by using HTTP or HTTPS protocol. The information resource forms the URL, which contains the servlet name and service name.
5. The servlet runs on the HTTP server (Tomcat) that is a part of Data Services. This HTTP server can be SSL enabled, depending on user requirements. The servlet processes the request to get the service name and XML data. It will then invoke that service running locally in Data Services and send the reply back to the client.

7.8.4 Installation and configuration

The HTTP Adapter is installed with every SAP Data Services Job Server.

You need to create and configure an adapter instance and necessary adapter operations of the HTTP Adapter. Adapter operations identify the integration options available for the configured adapter instance. The HTTP Adapter servlet is also installed while installing the HTTP Adapter.

The operations provided with the HTTP Adapter include the following:

- Request/Reply operation
  This operation is used to execute a remote Data Services service in the Request/Reply mode. It makes the request to the remote Data Services machine where the HTTP Adapter servlet is running and waits for the reply. The service name to be executed can be configured as part of the URL while configuring the operation instance.
- Request/Acknowledge operation

This operation is used to execute a remote Data Services service in the Request/Acknowledge mode. It makes the request to the remote Data Services machine where the HTTP Adapter servlet is running and does not wait for the reply. Instead, it sends acknowledgement if the operation is successful. The service name to be executed can be configured as part of the URL while configuring the operation instance.

7.8.4.1 To configure the HTTP Adapter

To use the HTTP Adapter, create an instance of the adapter together with a real-time data flow (RTDF) or data flow that you define using the Designer. Before using an HTTP Adapter instance, you must first configure it as explained in this section. To configure the HTTP Adapter means to configure one or more instances of the adapter and one or more operation instances for each adapter instance.

All SAP Data Services adapters communicate with Data Services through a designated Adapter Manager Job Server. An adapter must first be installed on the same computer as this Job Server before you can integrate the adapter with Data Services using the Administrator and Designer. After the adapter is installed:

1. Use the Server Manager utility to configure adapter connections with the Adapter Manager Job Server. For details, see the “To configure Job Servers” section of the *Administrator Guide*.
2. Open the Administrator and:
   a) Add at least one instance of the adapter to the Data Services system.
   b) If the adapter instance includes operations, add at least one operation for each adapter instance.
   c) Start the adapter instance.

      Operations are started automatically.
3. Open the Designer and create an adapter datastore. Use metadata accessed through the adapter to create batch and/or real-time jobs. For details, see the “Adapter datastores” section of the *Designer Guide*.

7.8.4.2 To configure an HTTP Adapter instance

Use the Administrator to add an HTTP Adapter to the SAP Data Services system and to edit existing adapter configurations. Until you add the adapter in the Administrator, you cannot run jobs using information from that adapter.

To add an adapter instance in the administrator:

1. Select *Adapter Instances* › *Job Server*.
2. Click the *Configuration* tab.
3. Click *Add*.
4. Select the HTTP Adapter from the list of those available on the Job Server.
5. Enter the required information to create an HTTP Adapter instance.
   For details, see “Adapter instance configuration information”.
6. Click *Apply*.

The Administrator adds the adapter instance to the list of those available to the Data Services system.

7.8.4.2.1 Adapter instance configuration information

Complete the following fields in the Administrator to set up an HTTP Adapter instance in the SAP Data Services system:

Field	Configuration information
Adapter instance name	Enter a unique name that identifies this instance of the HTTP Adapter.
Access Server host	Enter the host ID of the computer running the Access Server that connects to this adapter instance.
Access Server connection port	The Access Server host's message broker port. After you log into the Administrator for this Access Server, select *Configuration* > *Interfaces* to view message broker port information.
Classpath	All adapter Java programs require specific JAR files in the CLASSPATH to use when starting `javaw.exe`. For example: • **`<LINK_DIR>`**`/lib/acta_adapter_sdk.jar` • **`<LINK_DIR>`**`/lib/acta_broker_client.jar` • **`<LINK_DIR>`**`/lib/acta_tool.jar` • **`<LINK_DIR>`**`/ext/lib/xerces.jar` • **`<LINK_DIR>`**`/lib/acta_http_adapter.jar` • **`<LINK_DIR>`**`/lib/jcert.jar` • **`<LINK_DIR>`**`/lib/jnet.jar` • **`<LINK_DIR>`**`/lib/jsse.jar`
Autostart	When set to True, the adapter interface automatically starts when the Administrator starts.
Trace mode	Set this flag to control the number of trace messages the adapter writes. There are two settings: • True: The adapter interface writes additional information messages to help debug problems. • False: The adapter interface writes minimal information messages. The adapter writes trace messages to the **`<adapter_instance_name>`**`_trace.txt` file in the **`<DS_COMMON_DIR>`**`/adapters/logs` directory.
Application command line parameters	Additional command line parameters used for the `javaw.exe` command line and for the adapter itself. See specific adapter documentation for details.
Adapter type name	The name of the adapter used to create this instance. (Read-only)
Adapter version	The version of the adapter used to create this instance. (Read-only)
Adapter class	A name that identifies the adapter class. The name depends on the type of adapter. (Read-only)
Keystore password	Required if requests are made using the HTTPS protocol. If a password is given, it is used to check the integrity of the

Field	Configuration information
	keystore data. Otherwise, the integrity of the keystore is not checked.

7.8.4.3 To configure an operation instance

Use the Administrator to add an operation instance to an adapter instance.

1. Select *Adapter Instance* › *Job Server*
2. Click the *Configuration* tab.
3. Click *Operations* under Dependent Objects.
4. Click *Add* to configure a new operation or click the link of an existing operation to edit its configuration.
5. Select an operation type from the list and click *Apply*. The options that appear on this page depend on the operation-specific design.
6. Complete the operation instance configuration form. For details, see “Operation instance configuration information”.
7. Click *Apply*.

7.8.4.3.1 Operation instance configuration information

Request/Reply operation configuration

Complete the following fields in the Administrator to set up a Request/Reply operation instance:

Field	Configuration information
Operation instance	Enter the unique operation instance name. In the Designer, Request/Reply operation metadata object will be imported with this name.
Thread count	The number of copies of the Request/Reply operation to run in parallel. For parallel (asynchronous) processing of messages coming from a real-time service, use more than one copy. If the sequency of messages is important (synchronous processing), you should not use more than one thread. The default is 1. Note Multiple copies of real-time services must be supported by multiple copies of Request/Reply.
Display name	Enter the operation instance display name. This display name will be visible in the Designer's metadata browsing window.

Field	Configuration information
Description	Enter the operation instance description. This description will be visible in the Designer's metadata browsing window.
Enable	True if the Adapter SDK will start this operation instance when the adapter starts, otherwise false.
Target URL	URL where you want to send the HTTP request. Data Services uses the following server URL format: `http://<host>:<port>/admin/servlet/com.acta.adapter.http.server.HTTPActaServlet?ServiceName=<ServiceName>` - Host: The IP address or host name of the Access Server. - Port: The port number of the Access Server. - ServiceName: The name of the service.
Request method	The HTTP request method to be used for submitting the request. The possible values are POST and GET.
Content-Type	This is used to set the content type header of the request. It specifies the nature of the data by giving type and subtype identifiers.
Content-Language	The ISO code for the language in which the request's document is written. For example, `en` means that the language is English in one of its forms.
Content-Encoding	Specifies the encoding mechanism used for sending the request. Currently only x-compress and x-gzip are used.
Continue if untrusted	Specifies whether to continue the operation if the HTTP server is untrusted when using the HTTPS protocol. - True: The operation instance will continue for untrusted servers. - False: The operation instance will be terminated for untrusted servers.
Request DTD	The DTD file name that defines the request XML message used in this operation.
Request XML root element	The name of the XML root element in the request DTD.
Reply DTD	The DTD file name that defines the reply XML message used in this operation.
Reply XML root element	The name of the XML root element in the reply DTD.

Note

Restart the HTTP Adapter instance so that all configuration changes take effect.

Request/Acknowledge operation configuration

Complete the following fields in the Administrator to configure a Request/Acknowledge operation instance:

Field	Configuration information
Operation instance	Enter the unique operation instance name. In the Designer, Request/Acknowledge operation metadata object will be imported with this name.
Thread count	The number of copies of the Request/Acknowledge operation to run in parallel. For parallel (asynchronous) processing of messages coming from a real-time service, use more than one copy. If the sequency of messages is important (synchronous processing), you should not use more than one thread. The default is 1. Note Multiple copies of real-time services must be supported by multiple copies of Request/Acknowledge.
Display name	Enter the operation instance display name. This display name will be visible in the Designer's metadata browsing window.
Description	Enter the operation instance description. This description will be visible in the Designer's metadata browsing window.
Enable	True if the Adapter SDK will start this operation instance when the adapter starts, otherwise false.
Target URL	URL where you want to send the HTTP request. Data Services uses the following server URL format: `http://<host>:<port>/admin/servlet/com.acta.adapter.http.server.HTTPActaServlet?ServiceName=<ServiceName>` ● Host: The IP address or host name of the Access Server. ● Port: The port number of the Access Server. ● ServiceName: The name of the service.
Request method	The HTTP request method to be used for submitting the request. The possible values are POST and GET.
Content-Type	This is used to set the content type header of the request. It specifies the nature of the data by giving type and subtype identifiers.
Content-Language	The ISO code for the language in which the request document is written. For example, `en` means that the language is English in one of its forms.
Content-Encoding	Specifies the encoding mechanism used for sending the request. Currently only x-compress and x-gzip are used.
Continue if untrusted	Specifies whether to continue the operation if the HTTP server is untrusted when using the HTTPS protocol. ● True: The operation instance will continue for untrusted servers. ● False: The operation instance will be terminated for untrusted servers.

Field	Configuration information
Request DTD	The DTD file name that defines the request XML message used in this operation.
Request XML root element	The name of the XML root element in the request DTD.

i Note

Restart the HTTP Adapter instance so that all configuration changes take effect.

7.8.4.4 Defining the adapter datastore

Use the HTTP Adapter with an RTDF/data flow when the the RTDF/data flow passes a message to an operation instance, using either:

- An outbound message (for Request/Acknowledge operations)
- A message function (for Request/Reply operations)

You must define an adapter datastore in the Designer. An RTDF/data flow can then pass a message to one of the adapter's operation instances defined in the datastore.

To define an adapter datastore, you must:

- Define a datastore object for each adapter instance.
- Define one function or one outbound message for each operation instance to which you want to pass a message.

The following sections summarize the Designer tasks involved. For complete information, see the *Designer Guide*.

7.8.4.4.1 To define an adapter datastore

For each adapter instance, define a corresponding datastore object in the Designer object library, in the *Datastore Editor* window.

1. In the *Job Server* box, select the Job server that is configured to handle your HTTP adapter.
2. For *Adapter instance name*, choose the instance name you configured in the Administrator.
3. Click to select the Adapter Properties tab and enter values for each property.
4. Click *OK* to save values and create the datastore.

7.8.4.4.2 To import message functions and outbound messages

Messages can be passed from a real-time data flow (RTDF) to an operation instance. You must import either a function or an outbound message (depending on the type of operation involved) in the Designer Datastore library for each operation instance.

Real-time data flows use:

Method	Description
Message functions	Pass messages to an operation instance if the RTDF waits for a return XML message from the information resource.
Outbound messages	Outbound messages pass messages to an operation instance if the RTDF waits for a confirmation only (not a return XML message) from the information resource.

The operation types in the HTTP Adapter have the following invocation types:

Operation type	Invocation type
Request/Reply	Message function
Request/Acknowledge	Outbound message

To import the message functions and outbound messages:

1. In the Designer, double click on the datastore that has an associated HTTP Adapter instance.
2. In the *Adapter Metadata Browser* window, right-click on the operation instance to import and select *Import*.

The selected operation instance will be added to the datastore. These message functions and outbound messages can be used for creating the RTDF/data flow in Data Services.

7.8.4.5 Configuring SSL with the HTTP adapter

With Secure Sockets Layer (SSL), the HTTP Adapter can use secure transport over the TCP/IP network.

Server-side configuration

To use SSL with the HTTP adapter, you must properly configure your web application server for SSL support.

If you are using the default web application server bundled with SAP BusinessObjects BI platform, see the *SAP BusinessObjects BI Platform Administrator Guide* for information on how to configure SSL.

If you are using a different third-party web application server, see the web application server's documentation.

Client-side configuration

On the client side, the HTTP Adapter client internally handles the details of certificate authentication by implementin the X509TrustManager interface and using SSLSocketFactory classes from the HttpsURLConnection class.

Whenever an HTTPS request is made to the SSL-enabled web server, the client requests the server's certificate, which may be issued by a standard authority, such as VeriSign. If the HTTP client finds the certificate to be one that is trusted by comparing it to the certificate store in **<LINK_DIR>**`/ext/jre/lib/security`, it retrieves all data from the web server. In the case of an un-trusted certificate, the HTTP client throws an SSLException to the caller.

The HTTP client requires the password for querying the local keystore for verification. This password can be supplied through the `keystorePassword` parameter specified as a part of the adapter configuration.

The operation instance will read the configurable *Continue if untrusted* flag and, based on its value, trust the unknown server and its certificate. If the parameter is set to **`False`**, then the SSLException is shown to the user with a friendly message and logged in Data Services' trace files and the client does not retrieve any data from the server. If the parameter is set to **`True`**, then the SSLException is logged in Data Services' error and trace files and the client proceeds to retrieve data from the server. The certificate file `untrust.cer` is downloaded to the user's current working directory or to the **`<LINK_DIR>`**`/bin` directory. This certificate file can later be imported into the JDK certificate keystore by using the `keytool` command-line utility:

```
keytool -import -alias <description> -file untrust.cer -keystore
<full_path_of_cacerts_file> cacerts -storepass changeit
```

7.8.5 Using the HTTP Adapter

To start the adapter instance:

1. Select the *Status* tab under *Adapter Instances* in the Administrator.
2. Check the *Select* box next to the adapter instance that you configured previously.
3. Click *Start*.

When your adapter instance and its operations start, the message “Started” appears in the status column. To confirm that all operations are started, click *Operations* in the *Dependent Objects* column.

If you have a real-time service set up on your system, you can invoke it through the HTTP interface:

`http://localhost:8080/admin/jsp/InvokeService.jsp`

Using this interface, you can invoke the selected service by sending the input XML to the HTTP Adapter servlet running on the remote machine where the service is configured.

> Note
>
> For information about how to set up a test service, see the “Verifying real-time connectivity” section in the *Installation Guide*.

Request/Reply from Data Services

The Request/Reply operation instance sends the request to the remote SAP Data Services machine and waits for the reply.

To check the sample Request/Reply operation, see the “Testing the Request/Reply operation” section.

Request/Acknowledge from Data Services

The Request/Acknowledge operation instance sends the message to the remote SAP Data Services machine and gives an acknowledgement.

To check the sample Request/Acknowledge operation, see the "Testing the Request/Acknowledge operation" section.

7.8.5.1 Testing the Request/Reply operation

To configure the Request/Reply operation for testing, use the following information to configure the operation instance in the Administrator:

Field	Configuration information
Operation instance	`HTTP_ReqReply_Function`
Thread count	`1`
Display name	`HTTP_ReqReply_Function`
Description	`Performs the Request/Reply operation`
Enable	`true`

Target URL	For HTTP operation, use:
	`http://<ds_host_name>:<access_server_port>/admin/servlet/com.acta.adapter.http.server.HTTPActaServlet?ServiceName=Test`
	For HTTPS operation, use:
	`https://<ds_host_name>:<tomcat_https_port>/admin/servlet/com.acta.adapter.http.server.HTTPActaServlet?ServiceName=Test`
	Note
	By default, the HTTPS port of the Tomcat server is 8443. This can be changed in the Tomcat configuration file (`acta-server.xml` on Windows, and `acta-server1.xml` on UNIX)

Request method	`Post`
Content-Type	`text/xml`
Content-Language	`en`

Field	Configuration information
Content-Encoding	**application/nocompress**
Continue if untrusted	**true**
Request DTD	**<DS_COMMON_DIR>**/adapters/Http/samples/dtd/HTTPTestIn.dtd
Request XML root element	**test**
Reply DTD	**<DS_COMMON_DIR>**/adapters/Http/samples/dtd/HTTPTestOut.dtd
Reply XML root element	**test**

After configuring the operation instance, click *Apply* and then restart the HTTP Adapter instance. After the HTTP Adapter is running, the operation instance will also be in a running state.

Execute the HTTP_ReqRep_BatchJob job in the Designer.

After the batch job executes successfully, an output file OutputRep.xml will be created in the **<DS_COMMON_DIR>**/adapters/Http/samples/xml directory.

7.8.5.2 Testing the Request/Acknowledge operation

To configure the Request/Acknowledge operation for testing, use the following information to configure the operation instance in the Administrator:

Field	Configuration information
Operation instance	**HTTP_ReqAck_Outbound**
Thread count	**1**
Display name	**HTTP_ReqAck_Outbound**
Description	**Performs the Request/Acknowledge operation**
Enable	**true**
Target URL	For HTTP operation, use: **http://<ds_host_name>:<access_server_port>/admin/servlet/com.acta.adapter.http.server.HTTPActaServlet?ServiceName=Test** For HTTPS operation, use: **https://<ds_host_name>:<tomcat_https_port>/admin/servlet/**

Field	Configuration information
	com.acta.adapter.http.server.HTTPActaServlet?ServiceName=Test Note By default, the HTTPS port of the Tomcat server is 8443. This can be changed in the Tomcat configuration file (acta-server.xml on Windows, and acta-server1.xml on UNIX)
Request method	**Post**
Content-Type	**text/xml**
Content-Language	**en**
Content-Encoding	**application/nocompress**
Continue if untrusted	**true**
Request DTD	**<DS_COMMON_DIR>**/adapters/Http/samples/dtd/HTTPTestIn.dtd
Request XML root element	**test**

After configuring the operation instance, click *Apply* and then restart the HTTP Adapter instance. After the HTTP Adapter is running, the operation instance will also be in a running state.

Execute the HTTP_ReqAck_BatchJob job in the Designer.

After the batch job executes successfully, an output file OutputAck.xml will be created in the **<DS_COMMON_DIR>**/adapters/Http/samples/xml directory.

7.8.6 Error handling and tracing

All error and trace messages are logged to the log files in the **<DS_COMMON_DIR>**/adapters/log directory. The names of the error and trace log files match the names of the adapter instance as configured in the Administrator, and appended with _error.txt for error logs and _trace.txt for trace logs.

For example, if the name of the HTTP Adapter instance is “HTTPAdapter”, the name of the error file will be HTTPAdapter_error.txt and the name of the trace file will be HTTPAdapter_trace.txt.

7.9 Object creation XML toolkit

7.9.1 Overview

The object creation XML toolkit is a collection of utilities and features that enable you to programmatically create objects such as jobs, data flows, and work flows from your own application and then import, validate, and execute them in SAP Data Services.

The toolkit consists of several primary components:

Component	Purpose
XML schema	Used to defines Data Services objects
Designer import and export tools	Used to create template or example XML of objects
Web services	Used to send externally generated objects to Data Services and import, validate, or execute them
Auxiliary utilities	Used to perform specific tasks required by some jobs, such as datastore password encryption

7.9.2 Using the toolkit

In general, the object creation XML toolkit is suitable for two scenarios:

- Exporting Designer-created object definitions for use as templates that are customized with substitution variables
- Exporting Designer-created object definitions for use as a guideline for creating new object definitions from scratch

For both scenarios, we recommend that you use the Designer and its import and export capabilities heavily until you have the object definition to generate from within your own application. After you have suitable object defintions, you can use web services to import, validate, and execute jobs within Data Services.

The recommended work flow for using the toolkit is:

1. Create templates of your objects in the Designer.
2. Export your objects from the Designer to the XML format.
3. Customize the exported XML objects for generation in your external application.
4. Import, validate, and execute the XML objects generated by your application through Data Services' web services.

7.9.2.1 Templating objects

A key feature of the object creation XML toolkit is the ability to use the Designer to template your objects. You can use the Designer to create and debug objects, and then export them to an XML format for customization and use in your own external application. To create a template object for use in the object creation XML toolkit, the process is the same as creating any other normal object in the Designer.

> ➜ Tip
>
> Although it is possible to use only the XML schema to write complete repository objects from scratch, we strongly recommend that you use the Designer to create your objects due to complex interactions between many parts of the XML structure.

For more information about using the Designer to create and configure jobs, data flows, transforms, and other objects, see the *Designer Guide*.

For more information about configuration options available for specific objects, see the *Reference Guide*.

7.9.2.2 Exporting objects

The Designer allows you to export SAP Data Services objects in a standardized, reproducible XML format. When exporting objects, you can choose to export an entire job or individual objects. Each export option produces a single XML file that contains all exported objects. If you want to create separate XML files for each object, use the export editor to individually export each object.

For more information about using the export editor, see the “Export/Import” section of the *Administrator Guide*.

7.9.2.3 Adapting objects

Because the options of many XML objects, such as transforms, have complex interactions and do not always match the way the configuration appears in the Designer, it's strongly recommended that you adapt exported versions of these objects that have already been mostly configured how you want. By adapting existing objects, you can be more confident that the objects generated by your application will be free of problems, and function as you expect.

For example, you can configure several transforms using the Designer and then export them to XML files. In your application, you can assemble the pre-configured transforms into working data flows, and use web services to import and run them with Data Services.

Exported objects can still be customized through the use of parameters, as well as simply modifying the XML directly.

Related Information

Parameters and variables [page 2339]

7.9.2.4 Using web services

After generating custom objects in your application, you can use web service operations provided with SAP Data Services to import, validate, and execute them.

The general process for using the object creation XML toolkit with web service operations has several steps:

1. Log in

   If web service security is enabled, use the Logon operation and get a session object.
2. Import objects

   Use the Import_Repo_Object operation to import objects to the repository. You can import single or multiple objects at a time. However, for large XML, you may need to import objects one at a time.

   If an error occurs during importing, the operation returns the error message.
3. Validate objects

   After the objects have been imported successfully, use the Validate_Repo_Object to perform a semantic validation. You can also perform the validation on only the highest level object to recursively validate all dependent objects.

   If an error occurs during validation, the operation returns the error message.
4. Execute objects

   After the objects have been validated successfully, use the Run_Batch_Job operation to execute the job now stored in the repository. Use the job name as the parameter for the execution request.

   If an error occurs during execution, use the returned runID code and the Get_Error_Log and Get_Trace_Log operations to retrieve messages specific to this execution of the job.
5. Retrieve operational metadata

   Use the runID code returned by Run_Batch_Job along with the Get_Error_Log, Get_Trace_Log, and Get_Monitor_Log operations to retrieve errors, warnings, trace messages, and performance statistics for this execution of the job.
6. Remove objects (optional)

   If you don't want the objects to persist in the repository after execution, use the Delete_Repo_Objects operation to remove them. Because the operation does not remove dependencies automatically, you need to call it once for each object you want to remove.
7. Remove operational metadata

   Error and trace logs for non-execution requests are automatically cleared at the completion of each request. However, execution logs are not automatically cleared, and must be cleaned up manually. You can schedule the cleanup of execution logs by setting an appropriate log retention period in the Administrator.

   For more information, see the *Management Console Guide*.
8. Log out

   If you used the Login operation to take advantage of web services security, use the Logout operation to log out and end the session.

7.9.2.5 Encrypting passwords

For security, passwords for things such as datastore connections are encrypted when stored in the repository. However, when importing objects, SAP Data Services does not perform the encryption operation. Because of this, in order to use passwords in externally generated objects, you must use the encrypted form of the password in the generated XML.

To encrypt passwords outside of Data Services, use the `al_encrypt` utility included with the object creation XML toolkit. You can use `al_encrypt` with parameters for either an existing keyfile or a plain-text passphrase.

By default, `al_encrypt` outputs the encrypted password to the screen. However, you can use output redirection to store the encrypted password to a file, and then read the password from that file when generating the XML for your object. For example:

```
al_encrypt -e mypassword -p thepassphrase > c:\password.txt
```

For complete syntax information for `al_encrypt`, see the *Administrator Guide*: Command line administration, Password encryption.

7.9.2.6 Best practices

When using the object creation XML toolkit, there are a number of best practices that you can follow to simplify your work flow and minimize any problems that you may encounter.

Importing objects

- While you are allowed to import multiple objects at once, you may need to import objects individually when the XML syntax is large.
- Objects should be imported into the repository in order. That is, lower level objects in the dependency chain should be imported before higher level objects. For example, if you have a job that contains a data flow that uses a file format, you should import the file format, followed by the data flow, and then the job. By properly maintaining the correct import order, you can avoid cross-referencing issues.
- You can avoid import problems by validating your generated XML before importing. That is, ensuring that elements are closed correctly, and so on.

Validating objects

- Validate your objects using the Designer during your design phase. The validation web service performs only a runtime validation that is not as comprehensive as the Designer's validation. Validating in the Designer can provide you with more detailed information that may be helpful in resolving issues.
- You can validate objects individually or recursively by validating a high level object.

Other

- All object definitions must be placed within the correct container element, DataIntegratorExport. You can place one or more object definitions into the DataIntegratorExport element.

  ```
  <?xml version="1.0" encoding="UTF-8" ?>
  <DataIntegratorExport repositoryVersion="12.2.0.0000" productVersion="12.1.0.0">

     <!-- One or more object definitions -->

  </DataIntegratorExport>
  ```
- Some Data Services objects support expressions. For example, you can assign a query to the output field of a query transform. In addition, scripts and custom functions are defined as expressions. The expressions used in these objects are represented twice in exported XML:

  1. As an expr attribute with the same format as shown in the Designer
  2. As a complex XML hierarchy

  When importing these objects, only the format contained in the expr attribute is required.
- For Data Quality transform custom configurations, it is not required to have best practice input and output fields defined.

7.9.2.7 Limitations

General limitations

You should be aware of several general limitations when using the object creation XML toolkit:

- Some parts of object validation can only be performed in the Designer user interface.
  To more quickly identify and fix validation problems, you can import and validate your objects in the Designer when you are developing custom objects.
- The web service operations do not support import or bulk loading of Data Cleanse dictionaries.
  Before using other web services with the Data Cleanse transform, you must configure the appropriate dictionaries with the Designer.

Concurrent use issues

When multiple users access the same repository concurrently, the Data Services engine locks appropriate tables and serializes requests so that the repository is always in a structurally valid state. However, you should be aware of other issues that can arise due to concurrent repository access:

- Referential integrity violation due to object removal
  The Delete_Repo_Objects web service operation does not enforce the rule that an object cannot be deleted if it is being used by other objects. The exception is a datastore, which cannot be deleted if it contains any child objects.
  You should maintain referential object integrity in your application outside Data Services.
- Interference between web service operations
  Some available web service operations have the potential to interfere with others if they are currently running. For example, a job could fail if the job is deleted with the Delete_Repo_Objects operation at the same time it is being executed with the Run_Batch_Job operation.
  You should be careful to synchronize web service operations so that conflicts do not occur.

One way to avoid most concurrent use issues is by maintaining good naming conventions. For example, by using unique names for objects created in different instances of your application, you can effectively create a segregated domain for each application instance. As a result, the application instances will not interfere with each other when performing operations such as creating, modifying, or reading repository objects.

7.9.3 XML schema reference

The object creation XML toolkit supports the creation and usage of all objects available in Data Services. This section provides information about the structure and usage of some of the most common objects. For objects not covered in detail, use the export function of the Designer and the “Objects” section in the *Reference Guide* as a guide for creating and using your own objects.

Caution

All examples provided in this section are for reference only. Do not attempt to run them.

Enclosing objects to import

To import XML content into the Data Services repository, it must be enclosed in a DataIntegratorExport element. Specify the repository and product versions using the repositoryVersion and productVersion attributes.

```
<?xml version="1.0" encoding="UTF-8" ?>
<DataIntegratorExport repositoryVersion="12.2.0.0000"
  productVersion="12.2.0.0">

</DataIntegratorExport>
```

The DataIntegratorExport element is required only once per XML file, and should contain all objects that you want to import.

7.9.3.1 Batch job

➜ Tip

It's strongly recommended that you use the Designer to create and export your objects, and then use your application to adapt them as required. Many object options and parameters interact in complex ways, and do not always match the way they appear in the Designer.

Creating the object definition

Open the batch job definition with the DIJob element.

```
<DIJob name="<JobName>" typeId="2">
```

Specify steps within the job using the DISteps and DICallStep elements.

```
<DISteps>
  <DICallStep typeID="1" calledObjectType="Dataflow"
    name="<DataflowName>"></DICallStep>
</DISteps>
```

Apply job-specific attributes with a DIAttribute block.

```
<DIAttributes>
  <DIAttribute name="job_checkpoint_enabled" value="no" />
  <DIAttribute name="job_collect_statistics" value="no" />
  <DIAttribute name="job_collect_statistics_monitor"
    value="no" />
  <DIAttribute name="job_enable_assemblers" value="yes" />
  ...
</DIAttributes>
```

End the job definition with the closing tag of the DIJob element.

```
</DIJob>
```

Available DIAttribute names

The available DIAttribute names correspond to object parameters and properties, but do not necessarily match the wording used in the Designer. For a complete description of each attribute, see the “Descriptions of objects” section in the *Designer Guide*.

DIAttribute name	Designer
job_checkpoint_enabled	
job_collect_statistics	▶ *Job properties* ▶ *Execution options* ▶ *Collect statistics for optimization* ▶

7.9.3.2 work flow

➜ Tip

It's strongly recommended that you use the Designer to create and export your objects, and then use your application to adapt them as required. Many object options and parameters interact in complex ways, and do not always match the way they appear in the Designer.

Creating the object definition

Open the work flow definition with the DIWorkflow element.

```
<DIWorkflow name="<WorkflowName>" typeId="2">
```

Specify steps within the work flow using the DISteps, DICallStep, and DIScript elements.

```
<DISteps>
  <DIScript>
```

```
    <DIUIOptions>
      <DIAttribute name="ui_display_name"
        value="<ScriptName>" />
    </DUIOptions>
    ...
  </DIScript>
  <DICallStep typeID="1" calledObjectType="Dataflow"
    name="<DataflowName>"></DICallStep>
  <DIScript>
    <DIUIOptions>
      <DIAttribute name="ui_display_name"
        value="<ScriptName>" />
    </DUIOptions>
    ...
  </DIScript>
</DISteps>
```

Apply workflow-specific attributes with a DIAttribute block.

```
<DIAttributes>
  <DIAttribute name="run_once" value="no" />
  <DIAttribute name="unit_of_recovery" value="no" />
</DIAttributes>
```

End the work flow definition with the closing tag of the DIWorkflow element.

```
</DIWorkflow>
```

Available DIAttribute names

The available DIAttribute names correspond to work flow parameters and properties, but do not necessarily match the wording used in the Designer. For a complete description of each attribute, see the “Descriptions of objects” section in the *Designer Guide*.

DIAttribute name	Designer
run_once	*Properties* > *General* > *Execute only once*
unit_of_recovery	*Properties* > *General* > *Recover as a unit*

7.9.3.3 data flow

➡ Tip

It's strongly recommended that you use the Designer to create and export your objects, and then use your application to adapt them as required. Many object options and parameters interact in complex ways, and do not always match the way they appear in the Designer.

Creating the object definition

Open the data flow definition with the DIDataflow element.

```
<DIDataflow name="<DataflowName>" typeId="1">
```

Invoke transforms within DIDataflow by using the DITransforms element.

```
<DITransforms>
  <DIFileSource typeId="33" formatName="<FileFormatName>"
    filename="<filename.txt>"/>
  <DIQuery typeId="22"/>
  <DIFileTarget typeId="3"/>
  ...
</DITransforms>
```

Apply dataflow-specific attributes with a DIAttribute block.

```
<DIAttributes>
  <DIAttribute name="Cache_type" value="pageable_cache" />
  <DIAttribute name="Parallelism_degree" value="0" />
  <DIAttribute name="allows_both_input_and_output"
    value="yes" />
  <DIAttribute name="run_once" value="no" />
  <DIAttribute name="use_dataflow_links" value="no" />
  <DIAttribute name="use_datastore_links" value="yes" />
  <DIAttribute name="validation_xform_exists" value="no" />
  <DIAttribute name="validation_xform_stats" value="no" />
</DIAttributes>
```

End the data flow definition with the closing tag of the DIDataflow element.

```
</DIDataflow>
```

Available DIAttribute names

The available DIAttribute names correspond to object parameters and properties, but do not necessarily match the wording used in the Designer. For a complete description of each attribute, see the “Descriptions of objects” section in the *Designer Guide*.

DIAttribute name	Designer
Cache_type	*Properties* > *General* > *Cache type*
Parallelism_degree	*Properties* > *General* > *Degree of parallelism*
allows_both_input_and_output	
run_once	*Properties* > *General* > *Execute only once*
use_dataflow_links	
use_datastore_links	*Properties* > *General* > *Use database links*
validation_xform_exists	

DIAttribute name	Designer
validation_xform_stats	

7.9.3.4 Script

🡆 Tip

It's strongly recommended that you use the Designer to create and export your objects, and then use your application to adapt them as required. Many object options and parameters interact in complex ways, and do not always match the way they appear in the Designer.

Creating the object definition

Open the script definition with the DIScript element.

```
<DIScript>
```

Specify the name of the script with a DIAttribute element in the DIOptions block.

```
<DIOptions>
  <DIAttribute name="ui_display_name" value="<script_name>" />
</DIOptions>
```

Include expressions with the DIExpression element. In exported objects, additional XML syntax may be present. However, this additional syntax is optional; only the expr attribute of DIExpression is required.

```
<DIExpression isString="true" expr="<script_expression>">
  <<Additional optional XML syntax>/>
</DIExpression>
```

Include functions with the DIFunctionCallStep element. Define the function using a DIExpression element. In exported objects, additional XML syntax may be present. However, this additional syntax is optional.

```
<DIFunctionCallStep typeId="23">
  <DIExpression isString="true" expr="<function_call>">
    <<Additional optional XML syntax>/>
        </DIExpression>
</DIFunctionCallStep>
```

End the script definition with the closing tag of the DIScript element.

```
</DIScript>
```

Available DIAttribute names

The available DIAttribute names correspond to object parameters and properties, but do not necessarily match the wording or location used in the Designer. For a complete description of each attribute, see the "Descriptions of objects" section in the *Designer Guide*.

DIAttribute name	Designer
ui_display_name	*Properties* › *General* › *Name*

For more information about scripts, see the "Objects, Script" section in the *Reference Guide*.

7.9.3.5 File format

Tip

It's strongly recommended that you use the Designer to create and export your objects, and then use your application to adapt them as required. Many object options and parameters interact in complex ways, and do not always match the way they appear in the Designer.

Creating the object definition

Open the file format definition with the DIFlatFileDatastore element.

```
<DIFlatFileDatastore name="<FileFormatName>" typeId="3">
```

Specify field names, types, and sizes with DIElement elements in the DISchema block.

```
<DISchema>
  <DIElement name="<FieldName1>" datatype="VARCHAR" size="7">
  </DIElement>
  <DIElement name="<FieldName2>" datatype="VARCHAR" size="7">
  </DIElement>
  ...
</DISchema>
```

Apply file format-specific attributes with a DIAttribute block.

```
<DIAttributes>
  <DIAttribute name="abap_file_format" value="no" />
  <DIAttribute name="blank_pad" value="leading" />
  <DIAttribute name="cache" value="yes" />
  <DIAttribute name="column_delimiter" value=", " />
  ...
</DIAttributes>
```

End the file format definition with the closing tag of the DIFlatFileDatastore element.

```
</DIFlatFileDatastore>
```

Available DIAttribute names

The available DIAttribute names correspond to object parameters and properties, but do not necessarily match the wording used in the Designer. For a complete description of each attribute, see the "Descriptions of objects" section in the *Designer Guide*.

7.9.3.5.1 To use as a source

To use a file format as a source within a data flow, invoke the format with the DIFileSource element. The DIFileSource element must be placed within the DITransforms section of a data flow.

```
<DIFileSource typeId="33" formatName="<FormatName>"
  filename="<FileName>">
```

Define the name of the source with a DIAttribute element.

```
<DIUIOptions>
<DIAttribute name="ui_display_name" value="<SourceName>" />
</DIUIOptions>
```

Specify a name for the output schema with the DIOutputView element. By default, it is set to the format name. However, you can change it to any unique string, and use it in all downstream transforms.

```
<DIOutputView name="<SchemaName>" />
```

Apply source-specific attributes with a DIAttribute block.

```
<DIAttributes>
  <DIAttribute name="adaptable" value="no" />
  <DIAttribute name="cache" value="yes" />
  <DIAttribute name="connection_port" value="no" />
  <DIAttribute name="file_location" value="local" />
  ...
</DIAttributes>
```

End the source definition, with the closing tag of the DIFileSource element.

```
</DIFileSource>
```

Available DIAttribute names

The available DIAttribute names correspond to object parameters and properties, but do not necessarily match the wording or location used in the Designer. For a complete description of each attribute, see the “Descriptions of objects” section in the *Designer Guide*.

7.9.3.5.2 To use as a target

To use a file format as a target within a data flow, invoke the format with the DIFileTarget element. The DIFileTarget element must be placed within the DITransforms section of a data flow.

```
<DIFileTarget typeId="3" formatName="<FormatName>"
  filename="<FileName>">
```

Define the name of the target with a DIAttribute element.

```
<DIUIOptions>
<DIAttribute name="ui_display_name" value="<TargetName>" />
</DIUIOptions>
```

Specify a name for the input schema with the DIInputView element. By default, it is set to the format name. However, you can change it to any unique string, and use it in all downstream transforms.

```
<DIInputView name="<SchemaName>" />
```

Apply target-specific attributes with a DIAttribute block.

```
<DIAttributes>
  <DIAttribute name="connection_port" value="no" />
  <DIAttribute name="file_location" value="local" />
  <DIAttribute name="isstreamdebugfile" value="no" />
  <DIAttribute name="loader_load_choice" value="replace" />
  ...
</DIAttributes>
```

End the target definition, with the closing tag of the DIFileTarget element.

```
</DIFileTarget>
```

Available DIAttribute names

The available DIAttribute names correspond to object parameters and properties, but do not necessarily match the wording or location used in the Designer. For a complete description of each attribute, see the "Descriptions of objects" section in the *Designer Guide*.

7.9.3.6 Database datastore

> ➜ Tip
>
> It's strongly recommended that you use the Designer to create and export your objects, and then use your application to adapt them as required. Many object options and parameters interact in complex ways, and do not always match the way they appear in the Designer.

Creating the object definition

Open the database datastore definition with the DIDatabaseDatastore element.

```
<DIDatabaseDatastore name="<datastore_name>" typeId="3">
```

Apply database datastore-specific attributes with a DIAttribute block.

```
<DIAttributes>
  <DIAttribute name="DBLiveLoad" value="no" />
  <DIAttribute name="application_type" value="Custom" />
  <DIAttribute name="cdc_enabled" value="no" />
  <DIAttribute name="datastore_repotype" value="local" />
  ...
  <DIAttribute name="ds_configurations" hasNestedXMLTree="true">
```

Specify one or more datastore configurations inside the DIAttribute block with a DSConfigurations block. Only one configuration can be set as default.

```
    <DSConfigurations>
      <DSConfiguration default="true" name="<configuration_name>">
        <case_sensitive>no</case_sensitive>
        <database_type>Microsoft_SQL_Server</database_type>
        <loader_xact_size>1000</loader_xact_size>
        <locale_codepage>default</locale_codepage>
        <locale_language>default</locale_language>
        <locale_territory>default</locale_territory>
        <mssql_windows_authentication>
          no
        </mssql_windows_authentication>
        <password>;907A8897CEF453232929BD93946</password>
        <server_codepage>default</server_codepage>
        <sql_server_database>
          DS32_Source
        </sql_server_database>
        <sql_server_dataserver>
          testMachine
        </sql_server_dataserver>
        <sql_server_version>
          Microsoft SQL Server 2000
        </sql_server_version>
        <user>ods</user>
      </DSConfiguration>
    </DSConfigurations>
```

Close the DIAttribute block.

```
  </DIAttribute>
</DIAttributes>
```

End the database datastore definition with the closing tag of the DIDatabaseDatastore element.

```
</DIDatabaseDatastore>
```

Available DIAttribute names

The available DIAttribute names correspond to object parameters and properties, but do not necessarily match the wording or location used in the Designer. The specific DIAttributes and XML elements available vary greatly depending on which type of database you are accessing. It's recommended that you create your datastore definitions using the Designer and then export them to XML.

For a complete description of each attribute, see the “Descriptions of objects” section in the *Designer Guide*.

7.9.3.7 Database table

> Tip
>
> It's strongly recommended that you use the Designer to create and export your objects, and then use your application to adapt them as required. Many object options and parameters interact in complex ways, and do not always match the way they appear in the Designer.

Creating the object definition

Open the database table definition with the DITable element.

```
<DITable name="<TableName>" owner="<Owner>"
  datastore="<DatastoreName>" database="<DatabaseName>"
  description="<Description>">
```

Apply table-specific properties with a DIProperties block. To define the table as a template table, set the value of the Loader_Is_Template_Table DIAttribute to `yes`.

```
<DIProperties>
  <DIAttribute name="Table_Type" value="TABLE" />
  <DIAttribute name="Estimated_Row_Count" value="50000" />
  <DIAttribute name="Loader_Is_Template_Table" value="no" />
  <DIAttribute name="db_alias_name" value="ODS" />
  ...
</DIProperties>
```

Specify column definitions with DIColumn elments. You can also define the content type for a column with the Content_Type attribute.

```
<DIColumn name="Cust_ID" datatype="VARCHAR" size="10"
  nullable="false" />
<DIColumn name="Cust_classf" datatype="VARCHAR" size="2"
  nullable="true" />
<DIColumn name="Address" datatype="VARCHAR" size="35"
  nullable="true" Content_Type="ADDRESS">
  <DIProperties>
    <DIAttribute name="Content_Type" value="ADDRESS" />
  </DIProperties>
</DIColumn>
```

Define the primary keys with a DIPrimaryKey block.

```
<DIPrimaryKey>
  <DIPrimaryKeyColumn name="Cust_ID" />
</DIPrimaryKey>
```

Define the unique table index with a DITableIndex element and specify the column name in a DIIndexColumn element.

```
<DITableIndex name="PK__ODS_CUSTOMER__7C8480A" unique="true">
  <DIIndexColumn name="Cust_ID" />
</DITableIndex>
```

End the database table definition with the closing tag of the DITable element.

```
</DITable>
```

Available DIAttribute names

The available DIAttribute names correspond to object parameters and properties, but do not necessarily match the wording or location used in the Designer. For a complete description of each attribute, see the “Descriptions of objects” section in the *Designer Guide*.

7.9.3.7.1 To use as a source

To use a database table as a source within a data flow, invoke the table with the DIDatabaseTableSource element. The DIDatabaseTableSource element must be placed within the DITransforms section of a data flow.

```
<DIDatabaseTableSource typeId="22" datastoreName="<DatastoreName>"
  ownerName="<OwnerName>" tableName="<TableName>">
```

Specify a name for the output schema with the DIOutputView element.

```
<DIOutputView name="<SchemaName>" />
```

Apply source-specific attributes with a DIAttribute block.

```
<DIAttributes>
  <DIAttribute name="array_fetch_size" value="1000" />
  <DIAttribute name="cache" value="yes" />
  <DIAttribute name="connection_port" value="no" />
  <DIAttribute name="enable_partitioning" value="no" />
  ...
</DIAttributes>
```

End the source definition, with the closing tag of the DIDatabaseTableSource element.

```
</DIDatabaseTableSource>
```

Available DIAttribute names

The available DIAttribute names correspond to object parameters and properties, but do not necessarily match the wording or location used in the Designer. For a complete description of each attribute, see the “Descriptions of objects” section in the *Designer Guide*.

DIAttribute name	Designer
array_fetch_size	*Source Table Editor* > *Performance* > *Array fetch size*
cache	*Source Table Editor* > *Performance* > *Cache*
connection_port	*Source Table Editor* > *Make port*
enable_partitioning	
name	*Source Table Editor* > *Datastore name*
package_size	
reader_is_DB2CDC_table	
reader_overflow_file	
reader_template_table	
reader_use_overflow_file	
table_weight	*Source Table Editor* > *Performance* > *Join rank*

7.9.3.7.2 To use as a target

To use a database table as a target within a data flow, invoke the table with the DIDatabaseTableTarget element. The DIDatabaseTableTarget element must be placed within the DITransforms section of a data flow.

```
<DIDatabaseTableTarget typeId="11" bulkLoader="false"
  datastoreName="<DatastoreName>" ownerName="<OwnerName>"
  tableName="<TableName>">
```

Specify a name for the input schema with the DIInputView element.

```
<DIInputView name="<SchemaName>" />
```

Apply target-specific attributes with a DIAttribute block.

```
<DIAttributes>
  <DIAttribute name="connection_port" value="no" />
        <DIAttribute name="loader_template_table" value="yes" />
  ...
  <DIAttribute name="ldr_configuration_enabled"
    value="yes" />
  <DIAttribute name="ldr_configurations"
    hasNestedXMLTree="true">
```

Specify the target configuration inside the DIAttribute block with a LDRConfigurations block.

```
    <LDRConfigurations>
      <LDRConfiguration database_type="Microsoft_SQL_Server"
```

```
        database_version="Microsoft SQL Server 2000">
        <auto_correct_using_merge>Yes</auto_correct_using_merge>
        <bulk_ldr_all_rows></bulk_ldr_all_rows>

        <bulk_ldr_rows_per_commit></bulk_ldr_rows_per_commit>
        <enable_partitioning>no</enable_partitioning>
        <ignore_column_case>yes</ignore_column_case>
        <ignore_columns_null>No</ignore_columns_null>
        <ignore_columns_value></ignore_columns_value>
        <loader_auto_correct>no</loader_auto_correct>
        <loader_bulk_load>0</loader_bulk_load>
        ...
      </LDRConfiguration>
    </LDRConfigurations>
```

Close the DIAttribute block.

```
  </DIAttribute>
</DIAttributes>
```

End the target definition, with the closing tag of the DIDatabaseTableTarget element.

```
</DIDatabaseTableTarget>
```

Available DIAttribute names

The available DIAttribute names correspond to object parameters and properties, but do not necessarily match the wording or location used in the Designer. The specific DIAttributes and XML elements available vary greatly depending on which type of database you are accessing. It's recommended that you create your database table targets using the Designer and then export them to XML.

For a complete description of each attribute, see the "Descriptions of objects" section in the *Designer Guide*.

DIAttribute name	Designer
connection_port	*Target Table Editor* › *Target* › *Make port*
name	*Target Table Editor* › *Target* › *Datastore name*
use_unicode_varchar	

7.9.3.8 Data Quality transforms

The options of Data Quality transforms have complex interactions and do not always match the way the transform configuration appears in the Designer. It's strongly recommended that you adapt exported versions of these transforms that have already been mostly configured how you want. By adapting existing objects, you can be more confident that the objects generated by your application will be free of problems, and function as you expect.

Because of the complexity of the Data Quality transforms, XSD files are provided for each transform. By default, the XSD files are installed to `LINK_DIR\Admin`.

> **Note**
>
> XML exported from the Designer may not validate correctly against the provided XSD files due to element ordering. However, any objects created by using the XSD files will operate correctly when imported to SAP Data Services.

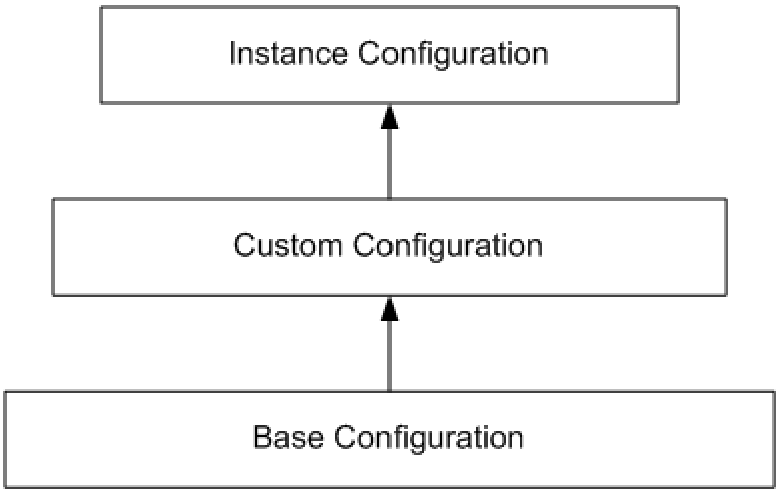
Related Information

Adapting objects [page 2314]

7.9.3.8.1 Hierarchy and inheritance

The ability to reuse transform configurations is a powerful feature of all Data Quality transforms available in SAP Data Services. To successfully use Data Quality transforms with the object creation XML toolkit, it's important to understand the rules of option inheritance and configuration reuse.

Data Quality transforms support three levels of configurations: base configuration, custom configuration, and instance configuration. Each level of configuration inherits the options and settings from the levels below it. However, settings defined explicitly at a higher level always take precedence over those inherited from a lower level.



In the Designer, the base configuration is simply represented in the form of the base transform. For example, the Global_Address_Cleanse transform. The base configuration carries the default settings for all options available for that transform. If you double-click any base transform, the configuration is opened in the Transform Configuration Editor. The Options tab lists all options set on the base configuration.

The custom configuration inherits the default settings from the base configuration, but also provides the ability to modify the values of any options at the custom level. In the Designer, the custom configuration level is represented by the available transform configurations. For example, for Global Address Cleanse, custom transform configurations such as Australia_AddressCleanse, Europe_AddressCleanse, and USA_AddressCleanse are available. For more information about transform configurations, see the “Data Flows, Transforms” section in the *Designer Guide*.

The instance configuration inherits default settings from the custom configuration, and provides the ability to further modify the values of any options. In the Designer, the instance configuration is represented by a transform instance within a data flow.

7.9.3.9 Query transform

🡆 Tip

It's strongly recommended that you use the Designer to create and export your objects, and then use your application to adapt them as required. Many object options and parameters interact in complex ways, and do not always match the way they appear in the Designer.

Creating the object definition

Open the query transform definition with the DIQuery element.

```
<DIQuery typeId="122">
```

Specify the name of the query transform and additional user interface options, such as the SQL where clause, in the DIUIOptions block.

```
<DIUIOptions>
  <DIAttribute name="ui_display_name" value="QryCDC" />
  <DIAttribute name="ui_where_text" value="<WhereClause>" />
</DIUIOptions>
```

Define the output schema with DIElement elements within a DISchema block. The input schema for each field is defined in the ui_mapping_text attribute, using the format **`<InputSchemaName>.<InputFieldName>`**.

```
<DISchema name="QryCDC">
  <DIElement name="CUST_ID" datatype="VARCHAR" size="10" key="true">
    <DIAttributes>
      <DIAttribute name="Description" value="" />
      <DIAttribute name="ui_mapping_text"
        value="ODS_CUSTOMER.CUST_ID" />
    </DIAttributes>
  </DIElement>

  <DIElement name="CUST_CLASSF" datatype="VARCHAR" size="2">
    <DIAttributes>
      <DIAttribute name="Description" value="" />
      <DIAttribute name="ui_mapping_text"
        value="ODS_CUSTOMER.CUST_CLASSF" />
    </DIAttributes>
  </DIElement>

  ...
</DISchema>
```

Define the expression for each output field with DIExpression elements within a DIProjection block. For exported XML, additional XML syntax for the output field may be present, but only the form used in the expr attribute is required.

```
<DISelect>
<DIProjection>
  <DIExpression isString="true" expr="ODS_CUSTOMER.CUST_ID">
    <COLUMN_REFERENCE qualifier1="ODS_CUSTOMER"
      column="CUST_ID" />
  </DIExpression>
  <DIExpression isString="true"
    expr="ODS_CUSTOMER.CUST_CLASSF" />
</DIProjection>
```

Specify the input schema in the DIFrom element.

```
<DIFrom>
  <DITableSpec name="ODS_CUSTOMER" />
</DIFrom>
```

Define the SQL where clause with a DIExpression element within a DIWhere block. For exported XML, additional XML syntax for the expression may be present, but only the form used in the expr attribute is required. The format is the same as it appears in the Designer.

```
<DIWhere>
  <DIExpression isString="true"
    expr="((ODS_CUSTOMER.CUST_TIMESTAMP &gt;=
      $GV_STARTTIME) AND$#xA; (ODS_CUSTOMER.CUST_TIMESTAMP
      &lt;= $GV_ENDTIME))">
    <!-- Additional XML syntax -->
  </DIExpression>
</DIWhere>
</DISelect>
```

Apply query-specific attributes with a DIAttribute block.

```
<DIAttributes>
  <DIAttribute name="distinct_run_as_separate_process"
    value="no" />
  <DIAttribute name="group_by_run_as_separate_process"
    value="no" />
  <DIAttribute name="join_run_as_separate_process"
    value="no" />
  <DIAttribute name="order_by_run_as_separate_process"
    value="no" />
  ...
</DIAttributes>
```

End the query transform definition with the closing tag of the DIQuery element.

```
</DIQuery>
```

Available DIAttribute names

The available DIAttribute names correspond to object parameters and properties, but do not necessarily match the wording or location used in the Designer. For a complete description of each attribute, see the “Descriptions of objects” section in the *Designer Guide*.

DIAttribute name	Designer
distinct_run_as_separate_process	*Query Editor ▸ Advanced ▸ Run DISTINCT as a separate process*

7.9.3.10 Parameters and variables

You can increase the flexibility and reusability of components generated by your application by using local and global variables when designing your jobs. For more information about including variables and parameters in the design of your jobs, see the “Variables and Parameters” section of the *Designer Guide*.

Global variables

Global variables can be accessed in XML within the DIScript element. For example, to assign a constant value to a global variable, you could use the DIAssignmentStep element:

```
<DIAssignmentStep typeId="12" variable="$GV_STARTTIME">
  <DIExpression isString="true"
    expression="'2001.01.01 00:00:000'" />
</DIAssignmentStep>
```

After the global variable is defined, you can use it elsewhere in script expressions used by your job. For example, you might insert the value of the variable into a table using a SQL query:

```
<DIFunctionCallStep typeId="23">
  <DIExpression isString="true"
    expr="sql('Target_DS', 'INSERT INTO TARGET.CDC_TIME
      VALUES ({$GV_STARTTIME})')" />
</DIFunctionCallStep>
```

For more information about using global variables in your jobs, see the “Variables and Parameters, Using global variables” section of the *Designer Guide*.

Substitution parameters

You can import one or more substitution parameter configurations to the repository with the Import_Repo_Object web service operation, as well as the Designer. In XML, substitution parameters are specified within the DISubVarStore and SVConfigurations elements.

```
<DISubVarStore typeId="103">
<SVConfigurations>
```

A default configuration can be specified with the DIAttribute element. This element is not required to import the substitution parameters.

```
<DIAttributes>
<DIAttribute name="SV_Config_Default"
  value="Configuration_1" />
</DIAttributes>
```

Specify a substitution parameter configuration with the SVConfiguration and SubVar elements. You can include more than one SVConfiguration block to specify additional substitution parameter configurations.

```
<SVConfiguration name="Configuration_1">
<SubVar name="ReportsAddressCleanse">1</SubVar>
<SubVar name="ReportsMatch">2</SubVar>
<SubVar name="USPSProviderLevel">3</SubVar>
<SubVar name="RefFilesAddressCleanse">4</SubVar>
...
</SVConfiguration>

</SVConfigurations>
</DISubVarStore>
```

After importing the substitution parameter configurations to the repository, they can be used normally in your data flows. For more information about using substitution parameters, see the “Variables and Parameters, Substitution parameters” section of the *Designer Guide*.

7.9.3.11 Basic example

This example assumes that you have a simple job named myTestJob that calls a data flow named myTestDataflow. The data flow contains a flat-file source (mySource), a Query transform (FormatFields), and a flat-file target (myTarget).

Additionally, this example assumes that all objects for the job have been exported to a single XML file.

Example

All object definitions are enclosed in the DataIntegratorExport element.

```
<?xml version="1.0" encoding="UTF-8" ?>
<DataIntegratorExport repositoryVersion="12.2.0.0000"
  productVersion="12.2.0.0">
```

The NameDate flat-file format definition is contained in the DIFlatFileDatastore element. Field names, types, and sizes are defined in the DISchema block.

```
<DIFlatFileDatastore name="NameDate" typeId="3">

<DISchema>
  <DIElement name="FirstName" datatype="VARCHAR" size="7">
  </DIElement>
  <DIElement name="LastName" datatype="VARCHAR" size="7">
  </DIElement>
  <DIElement name="DateOfBirth" datatype="VARCHAR" size="10">
  </DIElement>
</DISchema>
```

Various attributes, such as file name, directory, file type, column delimiter, and locale settings are specified in the DIAttributes block, and the flat-file format definition is closed.

```
<DIAttributes>
<DIAttribute name="abap_file_format" value="no" />
<DIAttribute name="blank_pad" value="leading" />
<DIAttribute name="cache" value="yes" />
<DIAttribute name="column_delimiter" value="," />
<DIAttribute name="column_width" value="1" />
<DIAttribute name="column_width1" value="7" />
<DIAttribute name="column_width2" value="7" />
<DIAttribute name="column_width3" value="10" />
<DIAttribute name="date_format" value="yyyy.mm.dd" />
<DIAttribute name="datetime_format"
  value="yyyy.mm.dd hh24:mi:ss" />
<DIAttribute name="file_format" value="ascii" />
<DIAttribute name="file_location" value="local" />
<DIAttribute name="file_name" value="NameDate.txt" />
<DIAttribute name="file_type" value="delimited_file" />
<DIAttribute name="locale_codepage" value="&lt;default&gt;" />
<DIAttribute name="locale_language" value="&lt;default&gt;" />
<DIAttribute name="locale_territory"
  value="&lt;default&gt;" />
<DIAttribute name="name" value="NameDate" />
<DIAttribute name="reader_capture_data_conversion_errors"
  value="no" />
<DIAttribute name="reader_capture_row_format_errors"
  value="yes" />
<DIAttribute name="reader_error_file_name" value="" />
<DIAttribute name="reader_error_file_root_dir" value="" />

```

```
</DIJob>
```

The myTestdata flow data flow definition is contained in the DIDataflow element.

```
<DIDataflow name="myTestDataflow" typeId="1">
```

Transforms are invoked within the DITransforms element. Because this data flow has three transforms, source, Query, and target, there are three corresponding sections in the DITransforms element.

```
<DITransforms>
```

The file-format source definition is contained in the DIFileSource element. The name of the output schema is specified with the DIOutputView element. By default, the schema is given the same name as the file format. However, you can change it to any unique name, provided you use the same name in later transforms.

```
<DIFileSource typeId="33" formatName="NameDate"
  filename="NameDate.txt">

<DIUIOptions>
<DIAttribute name="ui_display_name" value="mySource" />
</DIUIOptions>

<DIOutputView name="NameDate" />

<DIAttributes>
<DIAttribute name="adaptable" value="no" />
<DIAttribute name="cache" value="yes" />
<DIAttribute name="connection_port" value="no" />
<DIAttribute name="file_location" value="local" />
<DIAttribute name="name" value="NameDate" />
<DIAttribute name="reader_filename_col"
  value="DI_FILENAME" />
<DIAttribute name="reader_filename_col_size" value="100" />
<DIAttribute name="reader_filename_only" value="no" />
<DIAttribute name="reader_include_filename" value="no" />
<DIAttribute name="reader_maximum_warnings_to_log"
  value="-99" />
<DIAttribute name="root_dir"
  value="C:\Data Services\Tutorial Files" />
<DIAttribute name="table_weight" value="0" />
</DIAttributes>

</DIFileSource>
```

The FormatFields Query transform definition is contained in the DIQuery element. The output schema name is specified with the DISchema element.

```
<DIQuery typeId="122" >

<DIUIOptions>
<DIAttribute name="ui_display_name" value="FormatFields" />
</DIUIOptions>

<DISchema name="FormatFields">
```

Each output field is defined with DIElement and DIAttributes elements. The ui_mapping_text attribute for each output field is required by the Designer. For the Full Name output field, the expression shows the concatenation of two input fields (FirstName and LastName). The additional encoded text is used to maintain formatting within the Designer and is optional.

```
<DIElement name="FirstName" datatype="VARCHAR" size="7">
<DIAttributes>
<DIAttribute name="Description" value="" />
<DIAttribute name="ui_mapping_text"
  value="NameDate.FirstName" />
</DIAttributes>
</DIElement>

<DIElement name="LastName" datatype="VARCHAR" size="7">
<DIAttributes>
<DIAttribute name="Description" value="" />
<DIAttribute name="ui_mapping_text"
  value="NameDate.LastName" />
</DIAttributes>
</DIElement>

<DIElement name="DateOfBirth" datatype="VARCHAR" size="10">
<DIAttributes>
<DIAttribute name="Description" value="" />
<DIAttribute name="ui_mapping_text"
  value="NameDate.DateOfBirth" />
</DIAttributes>
</DIElement>

<DIElement name="Full Name" datatype="VARCHAR" size="20">
<DIAttributes>
<DIAttribute name="Description" value="" />
<DIAttribute name="ui_mapping_text"
  value="NameDate.FirstName ||
    NameDate.LastName&#xD;&#xA;&#xD;&#xA;" />
</DIAttributes>
</DIElement>

</DISchema>
```

The SQL select projection syntax is contained in the DISelect and DIProjection elements, and varies depending on how the Query transform is configured.

```
<DISelect>
<DIProjection>
```

Each output field is defined in a DIExpression element. The expr attribute contains the actual ATL expression as displayed in the Designer. Note that each field contains an additional XML representation of the expression. This additional representation is optional, and not required for correct operation.

```
<DIExpression isString="true" expr="NameDate.FirstName">
<COLUMN_REFERENCE qualifier1="NameDate" column="FirstName" />
</DIExpression>

<DIExpression isString="true" expr="NameDate.LastName">
<COLUMN_REFERENCE qualifier1="NameDate" column="LastName" />
</DIExpression>

<DIExpression isString="true" expr="NameDate.DateOfBirth">
<COLUMN_REFERENCE qualifier1="NameDate"
  column="DateOfBirth" />
</DIExpression>

<DIExpression isString="true" expr="(NameDate.FirstName ||
  NameDate.LastName)">
<CONCAT>
```

```
<COLUMN_REFERENCE qualifier1="NameDate" column="FirstName" />
<COLUMN_REFERENCE qualifier1="NameDate" column="LastName" />
</CONCAT>
</DIExpression>

</DIProjection>
```

The input schema for the Query is defined using the DIFrom element. Attributes for the Query are specified in a DIAttributes block.

```
<DIFrom>
<DITableSpec name="NameDate" />
</DIFrom>
</DISelect>

<DIAttributes>
<DIAttribute name="distinct_run_as_separate_process"
  value="no" />
<DIAttribute name="group_by_run_as_separate_process"
  value="no" />
<DIAttribute name="join_run_as_separate_process"
  value="no" />
<DIAttribute name="order_by_run_as_separate_process"
  value="no" />
<DIAttribute name="run_as_separate_process" value="no" />
</DIAttributes>

</DIQuery>
```

The file-format target is defined within the DIFileTarget element

```
<DIFileTarget typeId="3" formatName="NameDate"
  filename="NameDate_out.txt">

<DIUIOptions>
<DIAttribute name="ui_display_name" value="myTarget" />
</DIUIOptions>
```

The input schema for the target is specified using the DIInputView element, and attributes for the target are specified using a DIAttributes block.

```
<DIInputView name="FormatFields" />

<DIAttributes>
<DIAttribute name="connection_port" value="no" />
<DIAttribute name="file_location" value="local" />
<DIAttribute name="isstreamdebugfile" value="no" />
<DIAttribute name="loader_load_choice" value="replace" />
<DIAttribute name="name" value="NameDate" />
<DIAttribute name="root_dir" value="D:\temp" />
<DIAttribute name="validate_decimal_data" value="yes" />
</DIAttributes>

</DIFileTarget>

</DITransforms>
```

Attributes for the myTestdata flow data flow are specified in a DIAttributes block, and the file is finished by closing the DataIntegratorExport element.

```
<DIAttributes>
<DIAttribute name="Cache_type" value="pageable_cache" />
<DIAttribute name="Parallelism_degree" value="0" />
```

```
<DIAttribute name="allows_both_input_and_output"
  value="yes" />
<DIAttribute name="run_once" value="no" />
<DIAttribute name="use_dataflow_links" value="no" />
<DIAttribute name="use_datastore_links" value="yes" />
<DIAttribute name="validation_xform_exists" value="no" />
<DIAttribute name="validation_xform_stats" value="no" />
</DIAttributes>

</DIDataflow>

</DataIntegratorExport>
```

7.10 Job launcher execution commands

The job launcher, exported as part of a job's execution commands, includes a specific command line option for server groups. You can use this option to change the job servers in a server group.

For complete information about the job launcher, see the *Management Console Guide*.

The following table lists job launcher flags and their values.

Flag	Value
`-w`	The job launcher starts the job(s) and then waits before passing back the job status. If -w is not specified, the launcher exits immediately after starting a job.
`-t`	The time, in milliseconds, that the Job Server waits before checking a job's status. This is a companion argument for `-w`.
`-s`	Status or return code. 0 indicates successful completion, non-zero indicates an error condition. Combine `-w`, `-t`, and `-s` to execute the job, wait for completion, and return the status.
`-C`	Name of the engine command file (path to a file which contains the Command line arguments to be sent to the engine).
`-v`	Prints `AL_RWJobLauncher` version number.
`-S`	Lists the server group and Job Servers it contains using the following syntax: `"SvrGroup-Name;JobSvr1Name:JobSvr1Host:JobSvr1Port;JobSvr2Name:JobSvr2Host:JobSvr2Port";` For example: `"SG_DEV;JS1:HPSVR1:3500;JS2:WINSVR4:3505";`
`-R`	The location and name of the password file. Replaces the hard-coded repository connection values for `-S, -N, -U, -P`.

There are two arguments that do not use flags:

- `inet` address—The host name and port number of the Job Server. The string must be in quotes. For example:

  ```
  "inet:HPSVR1:3500"
  ```

  If you use a server group, inet addresses are automatically rewritten using the `-S` flag arguments. On execution, the first Job Server in the group checks with the others and the Job Server with the lightest load executes the job.
- `server log path`—The fully qualified path to the location of the log files. The server log path must be in quotes. The server log path argument does not appear on an exported batch job launch command file. It appears only when the software generates a file for an active job schedule and stores it in the following directory: **`<DS_COMMON_DIR>`**`/Log/`**`<JobServerName>`**`/`**`<RepositoryName>`**`/`**`<JobInstanceName>`**
  You cannot manually edit server log paths.

7.11 Legacy adapter information

7.11.1 Legacy adapter for external web services

> ⚠ Caution
>
> This section is provided for legacy reference only. For improved performance in new web service data flows, use the native web service datastore type.

You can add functionality to SAP Data Services to invoke web services in external applications from data flows. This functionality requires configuring the software's built-in Web Services Adapter. The Web Services Adapter provides support for locating and importing metadata for a web services server as well as invoking web service operations.

The Web Services Adapter works by sending a request and waiting until it receives a reply from a web services server.

For example, you might create a web services server as a front-end to a legacy application. You could call the web services server daily from a data flow to access inventory and update an inventory data mart.

The interaction between the Web Services Adapter and an external web service has these parts:

- Creating an adapter datastore that identifies the WSDL, which describes the web services server.
- Importing metadata to extract the information form the WSDL needed to access the web service server.
- Creating a data flow that uses the imported function call to call the web services server.

Related Information

To access a web service using the Designer [page 2258]

7.11.1.1 Legacy adapter installation

The Web Services Adapter is part of each Job Server installation. The installer automatically configures an adapter instance in the Administrator, which is the only adapter instance that SAP Data Services requires to configure a web services client. You do not need to configure adapter operations. The software automatically configures the Web Services Adapter with *Autostart* set to `FALSE` so that it does not consume resources when you do not use Web services. However, you can invoke adapters set with *Autostart* disabled, when needed. You do not need to edit the adapter instance that the software provides for the Web Services Adapter.

The installer allows you to configure a Job Server to manage adapters by presenting a list of Job Servers to you during installation. To view any adapter instance in the Administrator, select *Adapter Instance* **<Job Server>**.

The software creates the following values for an adapter instance.

Field name	Value automatically inserted
Adapter Instance Name	WebService
Access Sever host	(not required) Blank
Access Server port	(not required) Blank
Adapter Retry count	(default value) 0
Adapter Retry Interval	(default value) 3000
ClassPath	JAR files required in the classpath to start the Java process: **<LINK_DIR>**/lib/acta_adapter_sdk.jar **<LINK_DIR>**/lib/acta_broker_client.jar **<LINK_DIR>**/lib/acta_tool.jar **<LINK_DIR>**/ext/lib/xerces.jar **<LINK_DIR>**/lib/acta_webservice_adapter.jar **<LINK_DIR>**/ext/lib/qname.jar **<LINK_DIR>**/ext/lib/axis.jar **<LINK_DIR>**/ext/lib/commons-logging.jar **<LINK_DIR>**/ext/lib/commons-discovery.jar **<LINK_DIR>**/ext/lib/wsdl4j.jar **<LINK_DIR>**/ext/lib/saaj.jar **<LINK_DIR>**/ext/lib/jaxrpc.jar
AutoStart	TRUE
Trace Mode	FALSE (If set to TRUE, the adapter writes trace messages to the `WebService_trace.txt` file in the **<DS_COMMON_DIR>**/`adapters/log` directory)
Additional Java launcher options	(default values) -Xms64m -Xmx256m

Field name	Value automatically inserted
Adapter type name	(Read-only) Name of adapter used to create this instance
Adapter version	(Read-only) Version of adapter used to create this instance
Adapter class	(Read-only) Name that identifies the adapter entry point

7.11.1.2 Legacy adapter configuration

To configure access to a specific web service, use the Designer. In the Designer's Datastore Editor window, specify the datastore as an adapter datastore, select the Job Server that is managing the Web Services Adapter, and select the Web Services Adapter. Data Services provides access to web services as stream-oriented function calls, which it configures when you import metadata.

When you configure an adapter datastore, in addition to the normal adapter settings, specify the URL of the web services server for a data flow to access. It must be the same URL that accepts a web service connection and returns the WSDL.

The adapter connects to the web services server using the URL to locate the definitions of published services.

7.11.1.2.1 To access a web service

1. Create an adapter datastore:
   a) Use the Web Services Adapter instance that SAP Data Services automatically creates during installation.
   b) In the datastore editor under Adapter Options, configure the following parameters:
      - *URL of the Web Service* — Enter the URL of the web services server. This URL must accept a web service connection and return the WSDL. This information is required for data flow access.
      - *XML Recursion Level* — Enter the number of passes the software should run through the XSD to resolve names. The default is 0.
      - *Keystore Path* — If the web services server uses an SSL connection, specify the location of the keystore used to establish the connection. When unsure, contact your network administrator.
      - *User Name* — Enter your user name for HTTP basic authentication.
      - *Password* — Enter your password for HTTP basic authentication.

      > Note
      >
      > To obtain user name and password information, contact your web services provider.

   c) Click *OK*.
2. Import metadata:
   a) From the object library, double-click a Web Services Adapter datastore.

      The Designer calls the adapter. The adapter calls the web services server at the indicated WSDL URL and obtains a list of published services and ports.
   b) Expand the ports to see the published operations available for import.

The list reflects the name and description of operations currently published by the configured web service.

c) Right-click an operation and select *Import*.

The software imports web service operations as function calls and lists them under the Web Services Adapter datastore in the object library. Each function call includes a definition for both the input and output messages required for communication with a web service operation. The adapter extracts the details about the request and reply messages and generates XML Schema files that describe the messages.

3. From the Designer, add a web service function call to a job.

   As a web services client, the software calls a web services server twice:

   - During design time to import metadata for the functions and data types that a particular web service supports.
   - During run time to call the web service and invoke this functionality.

7.11.1.2.2 To add web service calls to a job

Once an adapter datastore is created and metadata is imported, use the following procedure to add a function call to an SAP Data Services job.

1. Open the Designer.
2. Create a Web Services Adapter datastore.
3. Import operation metadata from an external web service.
4. Add a query to your job.
5. Open the query editor, right-click the target schema and select *New Function call*.

   The Function Editor opens listing the operation metadata that you imported under its datastore name.
6. Select a datastore to view the metadata that you want to add to your job.
7. Select the metadata name and click *Next*.
8. Map the input schema to the output schema.

   > Note
   >
   > If you want to nest data in the target schema, use this first query to place the schema in your job and additional queries to perform the nesting. The Function Editor does not allow complex schema configuration.
9. Click *OK*.

   The imported schema appears in the query.
10. Configure the remainder of your job by supplying input to the function call and extracting the response information obtained from the web service.

7.11.1.3 Configuring SSL with the legacy adapter

With Secure Socket Layer (SSL), the web services adapter can use secure transport over TCP/IP networks.

The overall process is:

- Generate certificates and keystores for both the server and client.
- Configure the web server.
- Configure the SAP Data Services web services adapter.

7.11.1.3.1 To generate certificates and keystores

1. Generate the server keystore.
2. Export the certificate from the server keystore to a file and get it signed by an authorized Certificate Authority.
3. Generate the client keystore.
4. Export the certificate from the client keystore to a file and get it signed by an authorized Certificate Authority.
5. Import the client's certificate into the server's keystore.
6. Import the server's certificate into client's keystore.

7.11.1.3.2 To configure Tomcat and the legacy adapter

1. Uncomment the following entry from the `server-di.xml` file in the `TOMCAT_HOME/conf` directory.

```
<Connector port="8443"
maxThreads="150" minSpareThreads="25" maxSpareThreads="75"
enableLookups="false" disableUploadTimeout="true"
acceptCount="100" debug="1" scheme="https" secure="true"
clientAuth="false" sslProtocol="TLS" />
```

2. Inside the `Connector` tag, add/update the value of the `keystoreFile` and `keystorePass` parameters. The `keystoreFile` parameter should contain the *.keystore file path created when generating the keystore. The `keystorePass` parameter should contain the password used to create the keystore when generating it.
3. You might also need to modify the `wrapper.properties` file in the `LINK_DIR\ext\webserver\conf` directory. In the section `Defining the classpath`, ensure the following third-party libraries are in the path:

```
wrapper.class_path=$(ACTAHOME)\ext\lib\jnet.jar
wrapper.class_path=$(ACTAHOME)\ext\lib\jsse.jar
wrapper.class_path=$(ACTAHOME)\ext\lib\jcert.jar
```

4. After completing the configuration changes, restart the web server. If the web server starts successfully, then you should be able to access any web application supported by Tomcat via SSL.
5. In the Designer, configure the web services adapter by opening the adapter datastore, click *Advanced*, and enter the client keystore path.

7.11.1.4 Legacy adapter error messages

In addition to the error logs, the following list identifies web services client error messages and their descriptions:

- Web services client is unable to create a SOAP request to send to a server. Error = <adapter-generated exception message>
  The Web Services Adapter returns this error message if the XML message passed from SAP Data Services as a Web Services Adapter function call could not be packaged into a SOAP Envelope. Processing stops before a call to a web services server is made.

  To find extended error information, see the Web Services Adapter trace log file (▶ *Adapter Instances* ▶ **<JobServerName>** ▶). To use extended diagnostics, use debug tracing in the `webadmin.log` file.
- Web services client is unable to invoke a web services server. Error = <adapter-generated exception message>
  The client returns this error message if the Web Services Adapter cannot call the web services server. It indicates that the adapter has successfully packaged the XML message passed from the software into a SOAP Envelope. However, the call to the web services server is not going through. In most cases, this will be an error in locating the service, not a case of the service refusing a request. If a web service operation is refusing a request, it will return a fault message.

  To find extended error information, see the Web Services Adapter trace log file (▶ *Adapter Instances* ▶ **<JobServerName>** ▶). To use extended diagnostics, use debug tracing in the `webadmin.log` file.
- Web services client called a web services server. The server returned the following fault message: <server-generated error message>
  The client returns this error message if the web services server is called and returns a fault message indicating the call failed. The adapter has successfully packaged the XML message passed from the software into a SOAP Envelope, called the web services server, and the server received the call.

  To find extended error information, see the Web Services Adapter trace log file (▶ *Adapter Instances* ▶ **<JobServerName>** ▶) and perhaps the server itself if it maintains diagnostics. To use extended diagnostics, use debug tracing in the `webadmin.log` file.
- Web services client called a web services server and received a reply that cannot be interpreted. Error = < adapter-generated exception message >
  The client returns this error message if the SOAP Envelope returned from the web services server cannot be unpacked to extract the XML message to be returned to the job.

  To find extended error information, see the Web Services Adapter trace log file (▶ *Adapter Instances* ▶ **<JobServerName>** ▶). To use extended diagnostics, use debug tracing in the `webadmin.log` file.

8 Supplement for J.D. Edwards

8.1 Overview

The SAP Data Services J.D. Edwards (JDE) interface is a license-controlled feature. With this interface, you can use the Designer to:

- View modules and tables in a database instance under a specified J.D. Edwards environment
- Import metadata for tables into SAP Data Services
- Create batch data flows that use J.D. Edwards tables as sources

Related Information

System requirements [page 2353]
Datastores [page 2354]

8.2 System requirements

The J.D. Edwards interface allows you to connect SAP Data Services with two J.D. Edwards applications:

- World
- OneWorld

Both of these applications operate on an underlying database. Install the drivers you need to connect J.D. Edwards with SAP Data Services on the same computers on which you install the Designer and Job Server components.

8.2.1 World

The J.D. Edwards interface supports World version A7.3 and later. SAP Data Services only supports this application when World uses an underlying DB2 database on an AS/400 computer. Use either an ODBC datastore connection (using IBM's iSeries Access driver) or a Detail_DB2 datastore connection.

Related Information

Defining a J.D. Edwards World datastore [page 2354]

8.2.2 OneWorld

The J.D. Edwards interface supports OneWorld version B7.3 and compatible versions, including Xe. SAP Data Services supports this application if OneWorld uses one of three underlying databases:

- DB2 for AS/400 (use an ODBC datastore connection using IBM's iSeries Access)
- Microsoft SQL Server
- Oracle

J.D. Edwards OneWorld environment data sources include system-control data sources and business data sources. Your J.D. Edwards system-control data sources and your business data sources must reside on the same database instance. If a system control table is not located in the same database instance, you cannot create a datastore for that J.D. Edwards application.

Related Information

Defining a J.D. Edwards OneWorld datastore [page 2356]

8.3 Datastores

SAP Data Services uses datastore connections to link with other applications or databases. In a design environment, you use datastores to browse, search, or import metadata that represents external tables, files, messages, and other database objects. When running jobs, the software uses datastore information to move data between source and target databases and applications.

After defining a J.D. Edwards datastore in SAP Data Services, you can browse application modules, tables, table descriptions, and column descriptions.

You must define J.D. Edwards datastore connections with accurate J.D. Edwards information to ensure the accessibility of the tables.

8.3.1 Defining a J.D. Edwards World datastore

You can use two methods to access the J.D. Edwards World application:

- ODBC driver
- Mainframe interfaces

Both options access a DB2 for AS/400 database.

8.3.1.1 ODBC driver

You can access the J.D. Edwards World application using an ODBC driver called iSeries Access. Before creating a datastore using this ODBC driver, you must install and configure the driver on the same computers on which you installed the Designer and Job Server components. Use the ODBC Administration utility to install and configure the driver. In the driver's library list, be sure to list all the libraries needed in your particular J.D. Edwards environment.

8.3.1.2 Mainframe interfaces

You can access the J.D. Edwards World application using Mainframe interfaces. Refer to the pertinent documentation for installation and setup instructions.

8.3.1.2.1 To define a J.D. Edwards World datastore

1. In the object library of the Designer, go to the *Datastores* tab.
2. Right-click inside the object library window and select *New*.
3. In the Datastore Editor window, enter a name for this datastore (`DS_JDEWorld`, for example).
4. In the *Application type* list, select *JDE World*.
5. In the *Database Type* list, select *ODBC*.
6. Enter the connection information.
7. Click the *JDE World Properties* tab and enter the required information. SAP Data Services handles J.D. Edwards data in a logical grouping of libraries.

Option	Description
Environment	Enter the J.D. Edwards application environment name.
Local library	Enter the name of the library where SAP Data Services can find the J.D. Edwards system control table F0005.
Data dictionary library	Enter the name of the library where SAP Data Services can find the J.D. Edwards data dictionary table F9201.
Security library	Enter the name of the library where SAP Data Services can find J.D. Edwards security tables, such as F0094.

8. Click *OK*.

   The J.D. Edwards datastore appears in the object library.

Related Information

Reference Guide: Objects, Database datastores [page 868]

8.3.2 Defining a J.D. Edwards OneWorld datastore

A J.D. Edwards environment uses a logical construct called a data source to associate the J.D. Edwards application layer data with the database layer data (for example, Microsoft SQL Server). J.D. Edwards uses some data sources to associate system-control data and uses other data sources to associate business data.

The distributed nature of J.D. Edwards architecture allows an instance of J.D Edwards to have data sources on multiple database servers. For example, a finance data source can be on a Microsoft SQL Server while the system-control data source is on Oracle. Because a SAP Data Services datastore can only be associated with one database server, you must follow these rules when defining a J.D. Edwards OneWorld datastore connection in SAP Data Services:

- The data sources within a J.D. Edwards environment that you want to access must be in the same Microsoft SQL Server, DB2 for AS/400, or Oracle instance.
- You must specify required system control data sources, and in some cases, you must enter the owner ID of the data source. For Microsoft SQL Server, you must also enter the database name for each, and for DB2 for AS/400, you must enter the library for each.
- If using Microsoft SQL Server, you must configure a new datastore for each business data source on a unique database even if all databases are on the same Microsoft SQL Server. For example, if you want to extract Human Resource and Finance information from separate databases on the same Microsoft SQL Server instance, you must create two different datastores.

8.3.2.1 To define a J.D. Edwards OneWorld datastore

1. In the object library of the Designer, go to the *Datastores* tab.
2. Right-click inside the object library window and select *New*.
3. In the Datastore Editor window, enter a name for this datastore (`DS_JDEOneWorld`, for example).
4. In the *Application Type* list, select *JDE_One_World*.
5. In the *Database Type* list, select the database on which your J.D. Edwards application runs.

If you choose:	Do this:
Microsoft SQL Server	Enter the database-related information including the user name and password for the database. In the *Database server name* box, enter the name of the SQL Server instance. In the *Database name* box, enter the name of the database containing your business data, such as a finance database. If you have more than one database of business data create a separate J.D. Edwards datastore like the first except enter a different database name here.

If you choose:	Do this:
	Note With Microsoft SQL Server as your database, the Job Server must be installed on Windows NT or 2000.
Oracle	Enter the information required to connect to the Oracle database.

6. Click the *JDE OneWorld Properties* tab and enter the required information: the environment name and the databases to which the data sources point.

   Some J.D. Edwards data sources contain system-control information. SAP Data Services needs this system-control information to properly translate J.D. Edwards data. Like all data sources, these system-control data sources can be anywhere on the Microsoft SQL Server, DB2 for AS/400, or Oracle instance. Enter the database names for each data source.

Option	Description
Environment	Enter the J.D. Edwards application environment name.
System data source	Enter the name of the database where the tables F986101, F98611, and F00941 are located. This option is available for DB2 and Microsoft SQL Server databases.
System data source owner	Enter the owner ID for the system data source. This option is available for Microsoft SQL Server and Oracle databases.
Object librarian data source	Enter the name of the database where the tables F9860 and F9861 are located. This option is available for DB2 and Microsoft SQL Server databases.
Local data source	Enter the name of the database where the table F0005 is located. This option is available for DB2 and Microsoft SQL Server databases.
Data dictionary data source	Enter the name of the database where the table F9203 is located. This option is available for DB2 and Microsoft SQL Server databases.

7. Click *OK*.
   The J.D. Edwards OneWorld datastore appears in the object library.

8.3.3 Browsing and importing metadata

After creating a J.D. Edwards datastore, you can browse and import the metadata from the connected application.

8.3.3.1 To browse and import the metadata

1. View the modules in the J.D. Edwards application. You can:
   - ○ Right-click the datastore name and select *Open*
   - ○ Double-click the datastore name

   The workspace shows the list of application modules.
2. View the tables in a particular module. You can:
   - ○ Expand the module tree
   - ○ Double-click a module (folder)
3. To import table data, right-click a table name and select *Import*.

   > Note
   >
   > When you import a table into SAP Data Services via the J.D. Edwards interface, the software does not preserve the table hierarchy. All tables are listed at the same level.

You can also import tables using the Designer *Import by Name* and *Search* features.

8.3.4 Extracting data from J.D. Edwards systems

When extracting data from either J.D. Edwards application, SAP Data Services processes and converts data types appropriately. For example, the software recognizes null values for date columns. J.D. Edwards, on the other hand, does not support null values. Instead, J.D. Edwards stores dates as numeric values. When date data is not present, J.D. Edwards stores the number 0. Therefore, the software automatically translates a value of zero for a date to NULL. If you expect a column to have zeros in it, do not use the date type in the primary key.

SAP Data Services automatically translates most data types. In some cases, you must translate output explicitly.

Related Information

Data types [page 2358]

8.4 Reference information

8.4.1 Data types

SAP Data Services uses unique processing to translate some J.D. Edwards data types:

- Translating decimals

- Translating dates
- Translating time

8.4.1.1 Translating decimals

J.D. Edwards translates decimal values using an additional piece of information from the underlying database: the decimal separator shift integer. This value indicates the number of digits to move left from the end of the value number. For example, to represent a number like 1.23, J.D. Edwards stores the value as "123" with a decimal separator shift of "2" (starting at the end of the number, the decimal shifts two places to the left).

To process J.D. Edwards decimal values, the software extracts the numeric value stored in the underlying database and then applies the decimal separator shift to determine where the decimal belongs. The software applies the translation when a decimal column appears in a SQL statement against the database.

SAP Data Services interprets J.D. Edwards currency data types as decimals.

The software does not automatically translate decimal data types in three cases:

- SQL transform
- sql function
- pushdown_sql function

In these cases, translate decimals explicitly. To translate decimals explicitly, you must know the decimal shift value for your selected column. Use the shift number to determine the denominator for decimal translation. For example, if column `COL26` in table `JDETAB` is a JDE decimal column and it has a shift value of `2`, you would manually modify the SQL statement to say something like `SELECT COL26/100 FROM JDETAB`. The denominator in this statement has two zeros following the `1`. If the shift value was `3`, the statement would be `SELECT COL26/1000 FROM JDETAB`.

8.4.1.2 Translating dates

J.D. Edwards stores dates as numeric values. The J.D. Edwards date format is similar to Julian date format except the year starts with 1900.

SAP Data Services handles J.D. Edwards numeric values by reading the date information and translating with an internal formula based on the J.D. Edwards start year. For example, the software would handle the date February 18, 1999 as follows:

Year = (1999 - 1900) * 1000;

Day = 31 + 18; [31 is the # of days in January]

The resulting Day value is the number of days since 1/1/1999. The Julian date value is Year + Day = `99049`.

Like decimal translation, there are three cases when the software does not automatically translate dates:

- SQL transform
- sql function
- pushdown_sql function

In these cases, you must use the `JDE_Date` function.

Related Information

JDE_Date [page 2360]

8.4.1.3 Translating time

SAP Data Services does not automatically interpret J.D. Edwards time data types. If you need to translate a number to its time value, you can use the `JDE_Time` function.

Related Information

JDE_Time [page 2361]

8.4.2 Functions

When conversion is not automatic, you can use SAP Data Services functions to convert J.D. Edwards data to internal SAP Data Services data types:

- JDE_Date
- JDE_Time

You can access these functions from the query editor: go to the *Mapping* or the *Where* tabs, and click the *Functions* button.

> i Note
>
> You cannot use the lookup function with a J. D. Edwards datastore. Use the lookup_ext function instead.

8.4.2.1 JDE_Date

Given a Julian date stored in a J.D. Edwards database, `JDE_Date` returns the equivalent value as a SAP Data Services date data type.

Syntax

```
JDE_Date(<jde_julian_date>)
```

Return Value

date: The SAP Data Services date data type equivalent to the specified Julian date.

Where

`<jde_julian_date>` : The integer column in the input table that contains a J.D. Edwards Julian date.

Example

Function	Results
`JDE_Date (99049)`	`2/18/1999`

You can translate J.D. Edwards Julian dates using column mapping. When you input a J.D. Edwards Julian date number (for example, `99049`), an SAP Data Services date type results (for example, `2/18/1999`). Enter the function in the *Mapping* section of the Query transform editor.

Use this function when the software does not automatically translate dates.

Note

Because this function takes an integer as input, map the incoming column to an integer column before applying the function.

Related Information

Translating dates [page 2359]

8.4.2.2 JDE_Time

Given a number representing time in J.D. Edwards, `JDE_Time` returns an SAP Data Services character value that represents the equivalent military time in **`<HH24:MI:SS>`** format (where **`<HH>`** is hours, **`<MI>`** is minutes, and **`<SS>`** is seconds).

Syntax

```
JDE_Time(<time_integer>)
```

Return Value

Char(8): The time in **`<HH>`** `24`: **`<MI>`** : **`<SS>`** format.

Where

`<time_integer>` : An integer column in the input table that represents a J.D. Edwards time.

Example

Function	Results
`JDE_Time(92513)`	`09:25:13`

You can translate times from J.D. Edwards formatting into SAP Data Services formatting using column mapping. For instance, if you input a J.D. Edwards record update time of 92513, the resulting SAP Data Services time would be 9:25:13. Enter the function in the *Mapping* section of the Query transform editor.

9 Supplement for Oracle Applications

9.1 Introduction

The SAP Data Services Oracle Applications interface allows you to create Oracle Application datastores and import tables for use as sources in SAP Data Services jobs. With this interface, you can use the Designer to:

- View objects such as tables, functions, and procedures in a database instance under a specified Oracle Applications environment.
- Import metadata for Oracle Applications objects into SAP Data Services.
- Create data flows that use Oracle Applications objects (such as tables) as sources and targets.

9.2 System requirements

The Oracle Applications interface allows you to connect SAP Data Services with Oracle Applications for importing metadata.

These applications operate on an underlying Oracle database. Install the drivers you need to connect Oracle with SAP Data Services on the same computers on which you install the Designer and Job Server components.

The Oracle Applications interface supports version 11.5 and later versions.

The Oracle Applications interface can be installed using the SAP Data Services installer.

Because Data Services connects to Oracle through a database connection, the software can see, import, and use all Oracle Applications objects that the provided Oracle database user (such as APPS) can access without requiring application user login security information.

The Oracle Applications interface uses Oracle Application object library tables (which use the prefix `FND_%`) to get metadata information. For more information about Oracle Application metadata, see your Oracle Application Object Library/Workflow Technical Reference Manual.

9.3 Datastores

SAP Data Services uses datastore connections to link with other applications or databases. In a design environment, you use datastores to browse, search, or import metadata that represents external tables, files, messages, and other database objects. When running jobs, the software uses datastore information to move data between source and target databases and applications.

After you define an Oracle Applications datastore in SAP Data Services, you can browse application modules, tables, table descriptions, and column descriptions. While stored procedures and functions are also displayed, they are not grouped by application because they are not application-specific.

You must define Oracle Applications datastore connections with accurate Oracle Applications information to ensure the accessibility of the tables.

9.3.1 Defining an Oracle Applications datastore

With an Oracle Applications datastore connection, you can browse Oracle Applications metadata.

9.3.1.1 To define an Oracle Applications datastore

1. In the object library of the Designer, go to the *Datastores* tab.
2. Right-click inside the object library window and select *New*.
3. In the *Datastore Editor* window, enter a name for this datastore (`DS_OracleApps`, for example).
4. In the *Application type* list, select *Oracle_Applications*.
5. Enter the connection information.
6. Click *OK*.
   The Oracle Applications datastore appears in the object library.

9.3.1.2 Oracle datastore options

The following table describes the options specific to Oracle Applications.

Oracle Applications option	Possible values	Description
Process flexfield names	Yes, No	Determines whether SAP Data Services should use descriptive names for flexfield columns based on the flexfield information. If set to No, the software uses database column names for all columns including those that belong to flexfields.
Schema owner	Refer to the requirements for your application	Type the schema owner name for foundation tables (the name is usually **`apps`**).

9.3.2 Browsing and importing metadata

After creating an Oracle Applications datastore, you can browse and import the metadata from the connected application.

i Note

Although you cannot browse packages (there are too many), you can import them by name.

9.3.2.1 To browse and import the metadata

1. View the modules in the Oracle Application. You can:
    - Right-click the datastore name and select *Open*, or
    - Double-click the datastore name

   The workspace displays the list of application modules.
2. View the tables in a particular module. You can:
    - Expand the module tree, or
    - Double-click a module (folder)
3. To import table data, right-click a table name and select *Import*.

   > Note
   >
   > When you import a table into SAP Data Services via the Oracle Applications interface, the software does not preserve the table hierarchy. All tables are listed at the same level.

You can also import tables using the Designer's *Import by Name* feature.

9.3.3 Extracting data from Oracle Applications systems

When extracting data from Oracle Applications, SAP Data Services processes and converts data types appropriately.

9.4 Flexfields

SAP Data Services processes both descriptive flexfields and key flexfields from Oracle Applications if they are in use. Furthermore, Data Services can distinguish between context-specific and non-context-specific flexfields. The meaning of a context-specific flexfield is based on the value of another (context or structure) field.

Columns created from flexfields have column names based on the physical database name or end-user column name for that flexfield.

For consistency, when the software bases a column name on an end-user column name, it will translate the end-user column name from lowercase letters to uppercase, replacing all non-alphanumeric characters with an underscore.

If the physical name of a flexfield is descriptive (like `TAX_CODE_FLAG`), the software displays that physical name as the column name in a schema. However, if the physical name is generic (for example, `ATTRIBUTE1` or `SEGMENT1`) and associated with a descriptive end-user column name, the software truncates the end-user column name to 50 characters, appends it with an alphanumeric suffix, and uses it as the column name.

The software appends column names created from descriptive flexfield end-user column names with a `_D#` while column names created from key flexfields are appended with a `_K#` where `#` is a unique number. For example, if the physical name of a descriptive flexfield is `ATTRIBUTE1` and the end-user column name is `Status code`, the logical name might display as `STATUS_CODE_D6`.

When a descriptive flexfield's end-user column name is context-specific, representing multiple names, the first end-user column name (with suffix identifier) appears as the column name and a note appears in the key flexfield's column description, structured as follows:

```
<first end-user
             column name> (multi-flex column - multiple structures based on
          <content field COLUMN
             NAME> =
          <"content value>"
             - <field comment> )
```

When a key flexfield's end-user column name is structure-specific, representing multiple names, the first end-user column name (with suffix identifier) appears as the column name and a note appears in the key flexfield's column description, structured as follows:

`<first end-user column name>` (multi-flex column - multiple structures based on `ID_FLEX_CODE=` `"`**`<structure code value>`**`"ID_FLEX_NUM-` **`<column name>`** `=` **`<structure number>`** `-` **`<field comment>`**)

The following table shows how flexfield column names for both descriptive and key flexfields are based on physical name and end user column name:

Table 184: Descriptive Flexfields

From Oracle Applications		To SAP Data Services	
Physical name:	**End-user column name:**	**Column name:**	**Business name:**
STAT_CODE	N/A	STAT_CODE	STAT_CODE
ATTRIBUTE1	Status code	STATUS_CODE_D1	Status code
ATTRIBUTE1	-(None)	ATTRIBUTE1	-(None)

Table 185: Key Flexfields

From Oracle Applications		To SAP Data Services	
Physical name:	**End-user column name:**	**Column name:**	**Business name:**
STAT_CODE	N/A	STAT_CODE	STAT_CODE
SEGMENT1	Status code	STATUS_CODE_K1	Status code
SEGMENT1	-(None)	SEGMENT1	-(None)

i Note

Using flexfields with SQL function calls is not supported and causes an invalid column name error. Instead, use physical column names in functions that pass commands directly to the database such as SQL and PUSHDOWN_SQL.

To learn more about flexfields, see the *Oracle Applications Flexfields Guide*.

10 Supplement for PeopleSoft

10.1 Introduction

Welcome to the *SAP Data Services Supplement for PeopleSoft*. This guide contains information about how to use Data Services with PeopleSoft.

10.1.1 Using Data Services in a PeopleSoft environment

If you install the PeopleSoft interface, you can use PeopleSoft HRMS and ERP application data as a data source in SAP Data Services.

Through the PeopleSoft datastore you define, you can navigate through PeopleSoft metadata external to SAP Data Services (using standard PeopleSoft panels and menus) and import metadata for PeopleSoft source tables into the repository. The local object library then displays the datastore objects including PeopleSoft domains, hierarchies, and tables.

In addition, capabilities in the software that support PeopleSoft include the following:

- You can view valid domain values for a column from within the query transform.
  This allows you to filter on specific domain values for a column.
- The software can determine whether a given value for a column is valid within the domain of the column.
  The software flags those that are not valid.
- The software allows extraction of data based on effective dates without requiring you to write a secondary query. This functionality is particularly useful in implementing data warehouses containing HR data—it significantly reduces the complexity and increases the performance of extracting effective-dated data.
- The software allows extraction of the hierarchical data in PeopleSoft trees.

10.2 PeopleSoft Datastores

With the PeopleSoft interface, you can use a PeopleSoft system as an SAP Data Services source. To use a PeopleSoft data source, you must:

- Define a datastore that will serve as the logical link to your PeopleSoft system
- Import your PeopleSoft metadata into the datastore

Related Information

Designer Guide: Datastores [page 209]

10.2.1 Defining PeopleSoft datastore

You must define a PeopleSoft datastore in SAP Data Services when you are extracting data from or loading data to PeopleSoft.

1. Go to the *Datastores* tab of the object library.
2. Right-click inside the object library window and choose *New*.

   The *Create New Datastore* window appears.
3. Enter a name for the new datastore in the *Datastore name* box.

   You can give the datastore any name you want, and you can change the name later if necessary. The name can contain any alpha or numeric characters or underscores (_). It cannot contain spaces.
4. In the *Datastore type* box, choose *PeopleSoft*.
5. In the *Database type* box, choose the appropriate database.
6. Enter the appropriate information for the database type you selected.
7. Click *OK*.

   The software creates the datastore and it appears in the object library window.

Related Information

Reference Guide: Datastore [page 860]

10.2.2 Browsing PeopleSoft metadata

After you create the datastore, you can access the PeopleSoft metadata via the SAP Data Services datastore explorer, which displays information in a tree format.

The information displayed consists of metadata related directly to database data—no information about calculation fields, images, buttons, or other GUI-related items is included.

Browsing PeopleSoft data in the software is a lot like browsing in PeopleTools—icons in the display represent PeopleSoft menu groups, menus, menu bars, menu items, panels, and panel fields. Each panel field displays the caption, table column, and table name.

Icon	Metadata type	Description
🗔	Menu Group	The entire set of commands available in PeopleSoft applications for a specific database.
🗔	Menu	A set of commands for a specific application.
🗏	Menu Bar	The top level of the menu.

Icon	Metadata type	Description
▤	Menu Item	The commands that make up each menu bar.
▤	Panel	A vehicle for capturing and displaying data. Each panel can have multiple sub-panels, each represented by the same icon.
▭	Panel Fields	Represents a column on a table or in a specific view.

10.2.2.1 To browse PeopleSoft metadata

1. In the object library, go to the *Datastores* tab.
2. Right-click the PeopleSoft datastore name and select *Open*.

   The datastore explorer window opens.

10.2.3 Importing PeopleSoft metadata

To access PeopleSoft metadata from SAP Data Services, you must import the metadata into the object library.

You can import tables, PeopleSoft trees (called *hierarchies* in SAP Data Services), and domains.

You can import PeopleSoft metadata in one of three ways:

- By name
- By browsing
- By searching

10.2.3.1 To import PeopleSoft metadata by name

1. In the object library, go to the *Datastore* tab.
2. Right-click the datastore name and select *Import By Name*.
3. In the Import by Name dialog box, specify the *Type* of the item to import.

   To import a PeopleSoft tree, select Hierarchy.
4. In the *Name* box, enter the name of the item to import.

   The default is to import domain information automatically with any tables you import. You can choose not to import the associated domains by deselecting the *Import associated domains* option.
5. To import a hierarchy, enter the tree name in the *Name* box and enter the Category and Structure associated with the hierarchy.
6. Click *OK*.

   The information appears in the object library.

10.2.3.2 To import PeopleSoft metadata by searching

You can search for PeopleSoft items as you would any items to be imported into the software. That is, right-click the datastore name in the object library and choose *Search*.

Related Information

Designer Guide: Importing metadata through a database datastore [page 219]

10.2.3.3 To import PeopleSoft metadata by browsing

1. In the object library, go to the *Datastores* tab.
2. Right-click the datastore name and choose *Open*.

   The datastore explorer opens in the workspace and lists the available tables, domains, and hierarchies.
3. Right-click the names of the items you want to import and choose *Import*.

   To import a table, select a name at the panel field level.

   To import a hierarchy, select a name at the tree level.

10.2.4 Metadata for PeopleSoft domains

This section discusses metadata for PeopleSoft domains.

Related Information

What is a domain? [page 2372]
Using PeopleSoft domains in SAP Data Services [page 2372]

10.2.4.1 What is a domain?

A domain is a lookup table that pairs a coded value with a textual description of the value. Domain values are typically used to specify column data where the possible range of values is constrained within a particular set.

Using a domain value instead of the text description can save space when the number of records is large. However, when working with the table to create queries, you might prefer to see a text description as opposed to looking for the appropriate code for the source data.

10.2.4.2 Using PeopleSoft domains in SAP Data Services

Domain values in PeopleSoft are available to end users only through PeopleSoft panels.

SAP Data Services has built-in capabilities that make it much easier to deal with domain values in data movement applications.

You browse, search, and import domain metadata in the same way you browse, search, and import any PeopleSoft metadata.

PeopleSoft tables have columns that should be constrained to contain only values from a particular set (that is, a set within a domain). This set of possible domain values is in another table in the PeopleSoft database called XLATTABLE.

When importing table metadata from a PeopleSoft database, the software can automatically import associated domain data to make it easier to work with the values that appear in rows from the imported table. By default, the software imports associated domain data, but you can prevent this by deselecting the *Import associated domains* check box on the Import By Name window.

When importing domain values, the repository only stores the currently effective value. The currently effective value is determined using the date when the import takes place.

Imported domains appear nested under the datastore in the object library.

Related Information

Browsing PeopleSoft metadata [page 2369]
Importing PeopleSoft metadata [page 2370]
Using PeopleSoft domains in data flows [page 2375]

10.2.5 Metadata for PeopleSoft trees

You can perform the same kind of business model navigation and data browsing on PeopleSoft trees (called hierarchies in Data Services) that you can on other objects.

You browse, search, and import hierarchy metadata similarly to the way you browse, search, and import any PeopleSoft metadata.

Imported hierarchies appear nested under the datastore in the object library.

Related Information

Browsing PeopleSoft metadata [page 2369]
Importing PeopleSoft metadata [page 2370]
Extracting PeopleSoft tree data [page 2377]

10.3 Data Flows with PeopleSoft Data

Data flows extract, transform, and load data. This section describes information unique to data flows that extract, transform, and load PeopleSoft data.

Related Information

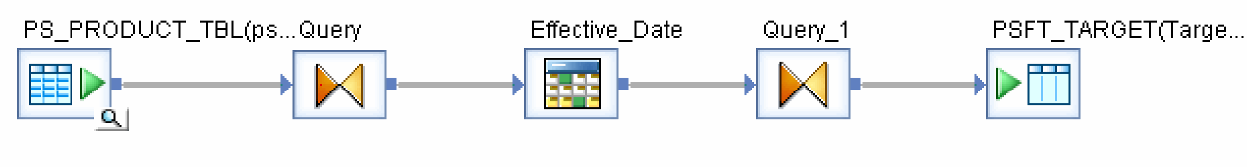
Designer Guide: Data Flows [page 281]

10.3.1 Using effective dates from PeopleSoft data

This section provides an example that shows how you can use effective dates when populating a dimension table in the product group. This example includes several operations:

- Extracts data from table `PS_PRODUCT_TBL`
- Selects a subset of columns for the target
- Filters the data based on status
- Creates effective date ranges using the Effective Date transform
- Retrieves only the rows effective on a particular date
- Loads the data into the target

One data flow completes these operations.



10.3.1.1 Selecting a subset of source columns

The first query selects a subset of the columns:

```
PS_PRODUCT_TBL.EFF_STATUS = 'A'
```

10.3.1.2 Filtering based on status

The first query includes a `WHERE` clause that limits the products selected to those with a status of `Active`. The status information comes from the domain values in the `EFF_STATUS` column in the input.

Related Information

Using PeopleSoft domains in data flows [page 2375]

10.3.1.2.1 To display the relevant domain values for the EFF_STATUS column

1. Click *Domains* in the `WHERE` tab of the query editor. The Picker window opens and shows a list of domains and descriptions.
2. Select the `EFF_STATUS` domain and click the *Show Values* button (second button at the top of the Picker window) to see the available domain values. The domain values appear to the right of the descriptions.
3. To put the domain value in the `WHERE` clause,
   a) Drag the `EFF_STATUS` column from the source schema into the `WHERE` clause.
   b) Enter an equal sign (=) after the column name.
   c) Place the cursor where the value needs to appear in the *WHERE* tab and click the description name *Active* in the Picker window.

10.3.1.3 Creating effective date ranges

This example retrieves only those product groups that are valid today. There are three steps involved:

1. Retrieve the effective-from date (`EFFDT` column) from the source.
2. Generate effective-to dates for the source rows using the Effective Date transform.
3. Filter out rows that are not effective on today's date.

Related Information

Reference Guide: Transforms [page 1067]

10.3.1.4 Retrieving records with current effective dates

The second query in the data flow contains a `WHERE` clause that selects:

- Those rows where the effective-from date from the source (`EFFDT`) is less than or equal to the system date AND
- Those rows where the effective-to date from the results of the Effective Date transform is greater than the system date

The query editor contains the `WHERE` clause.

```
Effective_Date.EFFDT <= sysdate( ) and
Effective_Date.EFFECTIVE_TO_COLUMN > sysdate ( )
```

10.3.1.5 Using PeopleSoft domains in data flows

SAP Data Services helps you:

- Build queries containing domain values
- Substitute domain descriptions for cryptic domain values
- Build queries where you need to know some domain values, for example while filtering
- Validate imported data that contains domain values

The properties for a given column enable you to explicitly associate a given column with a given domain.

You can assign any available domain to any column regardless of data type.

Related Information

Metadata for PeopleSoft domains [page 2371]

10.3.1.5.1 To assign a domain to a column

1. Right-click a table name in the object library and select *Open*.
2. To open the column properties, right-click a column name in the table metadata and select *Properties*.
3. The drop-down list in the *Associated domain* text box displays the available domains.

Any available domain can be assigned to any column regardless of data type.

10.3.1.6 Using the Picker window

To open the domain Picker window, click the *Domains* button in a query editor that has a table as a source.

The four buttons at the top of the Picker window control the content of the window and initiate actions.

	Click to toggle between displaying "all" and "relevant" domains. All domains (default) are listed in alphabetical order; relevant domains are shown in the order in which they are used in the table or tables you have selected.
	Click to display the domain values in the window. Click again to hide the domain values.
#	Click to toggle between pasting only the domain value (default) and both the value and a commented description in the `WHERE` clause when you select the value.
	Pastes all selected values in the `WHERE` clause. Descriptions are not included. To enable this button, use Ctrl-clicks to select more than one domain description.

10.3.1.6.1 To include a column and a related domain value in a WHERE clause

1. Drag the column from the source schema into the `WHERE` clause.
2. Enter an equal sign (=) after the column name.
3. Enter a value or paste the value from the Picker window.

   Click Domains to open the Picker window.

10.3.1.7 Validating domains

Capabilities built into SAP Data Services allow you to validate data that contains domain values:

- value IN domain clause (part of a `WHERE` clause)
  This clause enables you to ensure that all rows in a table have a valid value for a domain column.
  Syntax:
  value IN datastore_name.owner.domain_name
  This clause returns TRUE if the value is a member of the domain specified.
  If the clause is part of a job being executed, the software searches the domain values in the XLATTABLE.
- `get_domain_description` function
  This function returns the description for a domain name. The description is returned as a quoted string.
  Syntax:

```
get_domain_description
(<'datastore_name..domain_name',>
< table_name.domain_name>)
```

10.3.1.8 Restrictions using domains

Some restrictions involving domains include:

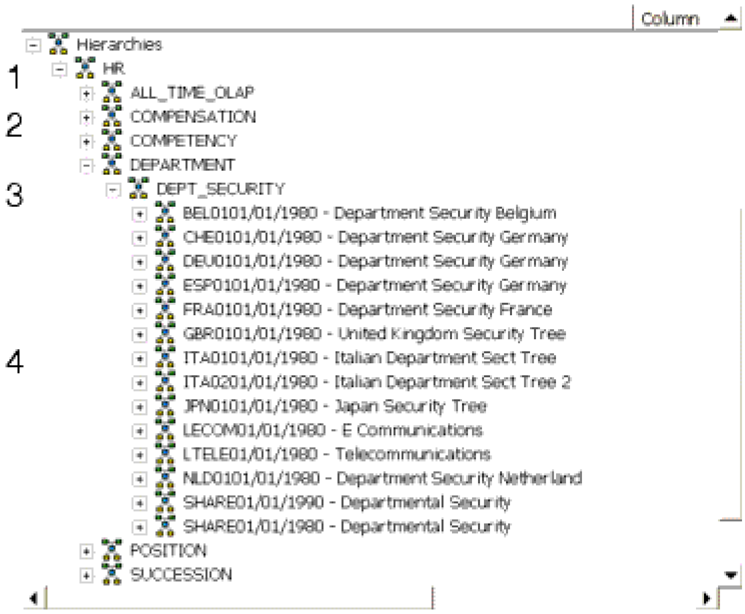
Prompt tables are not supported. (A prompt table is a user-defined table similar to the XLATTABLE in a database.)

Prior to validation at execution time, there is no type checking when a domain is associated with a column.

10.3.2 Extracting PeopleSoft tree data

In this example, SAP Data Services extracts data from a hierarchy (tree) and loads it into a table.

You can browse hierarchy information when you open a datastore. Expanding the hierarchy node in the workspace shows the tree levels. Consider the following example of an expanded hierarchy node in the workspace with *External Metadata* selected.

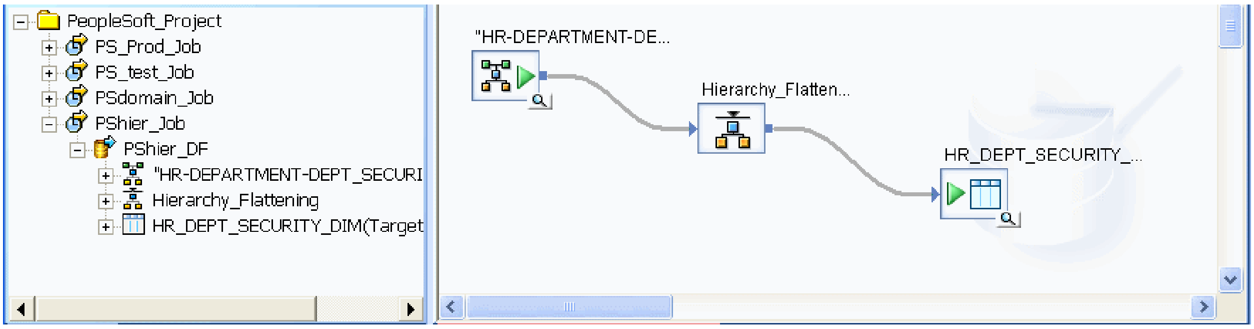


```
Hierarchies
  HR
    ALL_TIME_OLAP
    COMPENSATION
    COMPETENCY
    DEPARTMENT
      DEPT_SECURITY
        BEL0101/01/1980 - Department Security Belgium
        CHE0101/01/1980 - Department Security Germany
        DEU0101/01/1980 - Department Security Germany
        ESP0101/01/1980 - Department Security Germany
        FRA0101/01/1980 - Department Security France
        GBR0101/01/1980 - United Kingdom Security Tree
        ITA0101/01/1980 - Italian Department Sect Tree
        ITA0201/01/1980 - Italian Department Sect Tree 2
        JPN0101/01/1980 - Japan Security Tree
        LECOM01/01/1980 - E Communications
        LTELE01/01/1980 - Telecommunications
        NLD0101/01/1980 - Department Security Netherland
        SHARE01/01/1990 - Departmental Security
        SHARE01/01/1980 - Departmental Security
    POSITION
    SUCCESSION
```

1. Category
2. Structure
3. Tree
4. Set

You import hierarchical data at the tree level. To import the tree into SAP Data Services, select the tree DEPT_SECURITY, right-click, and choose *Import*. After you import the tree, it appears as a hierarchy in the object library.

The sample job PShier_Job consists of a single data flow that extracts the data from the source hierarchy object HR-DEPARTMENT-DEPT_SECURITY and loads it into a table.



Double-clicking the source hierarchy object opens the editor to show the options available for it.

In the hierarchy editor, you must specify:

- All set IDs, a specific set ID, or multiple set IDs.
  Select the *All set IDs* check box to obtain all the set IDs associated with this hierarchy. Each set ID identifies a subset of a tree that groups data that have similar values or rules. In this example, the tree contains a set of data for Belgium (BEL01), a set for France (FRA01), and so forth.
  Clear the *All set IDs* check box to open the Set ID box where you can:
  - Enter the name of the specific set ID for which you want to extract data.
  - Enter multiple set IDs, separated by commas. For example:

    ```
    BEL01, FRA01
    ```
- Date options
  - Current date
    Select Current date to extract data that is effective as of the date returned by the sysdate function.
  - All dates
    Select All dates to extract data with all effective dates for the set IDs that you specified.
  - Snapshot date
    Select Snapshot date to extract data that was effective on a specific date. Specify a date in the past or future in one of the following ways:
    - Date
      Select Date in the drop-down list to specify the date as a four-digit year, a period, a two digit month, a period, and a two-digit day (YYYY.MM.DD). You can select each part of the date and use the arrows to increment or decrement each value.
    - Variable
      Select Variable in the drop-down list to specify a varchar variable name that contains a valid date in the yyyy.mm.dd format.
      You can select one of the variable names in the drop-down list. Alternatively, you can type in the name of a new variable, but you must define it in the Variables and Parameters window (▶ *Tools* ▶ *Variables* ▶).
      If you do not enter a variable name, the Snapshot date defaults to the current date.

> Note
>
> You can use a local or global variable for the date. Because the variable can be a global variable, validating the data flow or work flow does not check for invalid data types for this variable. Be sure to validate the Job to check for invalid data types for this date variable.

Before you load the tree data into the table, you can flatten it with the Hierarchy_Flattening transform. On the transform editor:

- Choose to flatten the tree horizontally or vertically.
- Specify the *Parent column* and *Child column* to identify the columns in the source data that contain the parent identifier and child identifier in each parent-child relationship.
- Select *View* > *Refresh* or press F5 to refresh the target schema after you identify the source columns.

Hierarchy [page 2382]

10.4 Reference Information

This section contains reference information specific to the PeopleSoft interface for SAP Data Services.

Specifically, this section describes SAP Data Services objects specific to PeopleSoft and SAP Data Services objects with supplemental information for the PeopleSoft interface.

This section contains information about the following objects:

Object	Class	Description
Datastore	Single-use	Specifies the connection information Data Services needs to access a database or other data source. Cannot be dropped.
Domain	Reusable	A lookup table that pairs a coded value with a textual description of the value. Domain values are typically used to specify column data where the possible range of values is constrained within a particular set.
Hierarchy	Reusable	Browse, search, and import hierarchy metadata.
Query	Single-use	Retrieves a data set that satisfies conditions that you specify.

10.4.1 Datastore

Class

Reusable

Access

In the object library, click the *Datastores* tab.

Description

A datastore provides a connection to a data source such as a database. Through the datastore connection, SAP Data Services is able to import descriptions of the data source such as its metadata. When you specify tables as sources or targets in a data flow, the software uses the datastore to determine how to read data from or load data to those tables. In addition, some transforms and functions require a datastore name to qualify the tables they access.

If you delete a datastore from the object library, you must remove references to the datastore from the following locations:

- Source or target tables using this datastore in your diagrams
- The `lookup` and `key_generation` functions and Key_Generation, History_Preserving, Table_Comparison, and SQL transform references

Datastores have the following properties:

Attribute	Description
Name	The name of the object. This name appears on the object in the object library and in the calls to the object.
Description	Text that you enter to describe and document the datastore.

After you create a datastore, you can import metadata about the objects, such as tables and functions, in that datastore.

PeopleSoft datastores

Set the following options to define a PeopleSoft datastore:

Option	Description
Name	Specify the datastore name. The software uses this name to reference the datastore from other object definitions.
Datastore type	Choose PeopleSoft to display the options for PeopleSoft datastores. You cannot edit this option after creating the datastore.
Database type	Select either *Microsoft_SQL_Server* or *Oracle* to indicate the database type used as the database layer of your PeopleSoft application server. The remaining options in the datastore definition are specific to the database type.

Related Information

Designer Guide: Datastores [page 219]
Reference Guide: Database datastores [page 868]

10.4.2 Domain

Class

Reusable

Access

- To view the list of imported domains and domain values from the object library, click the *Datastores* tab.
- Use domain values from inside query transforms with inputs from tables associated with domains. Click *Domains* on the *Where* tab to open a window that helps you pick domain values.

Description

A domain is a lookup table that pairs a coded value with a text description of the value. You will typically use domain values to specify column data where the possible range of values is constrained to a particular set.

Domains have two built-in attributes.

Attribute	Description
Name	The name of the object. This name appears on the object in the object library and in the calls to the object.
Description	The description of the domain imported from the application or database.

View domain values, descriptions of the values, and the effective dates for each value by opening the domain from the object library.

10.4.3 Hierarchy

Class

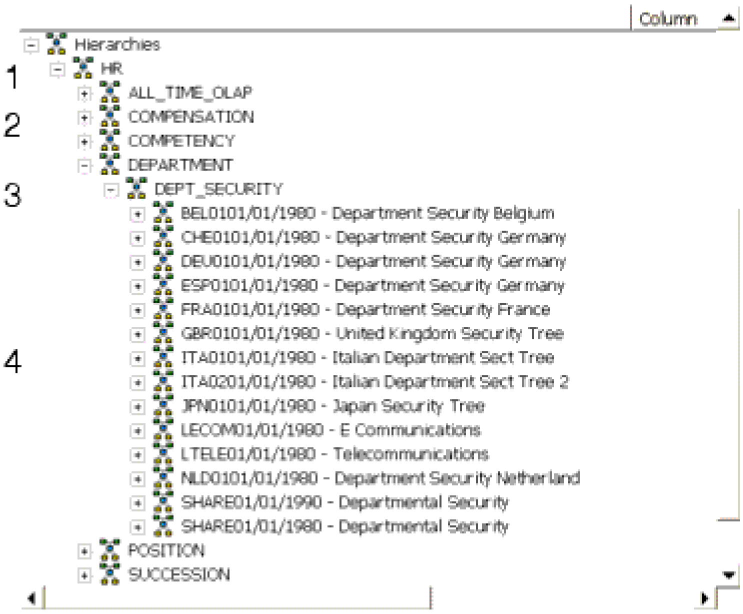
Reusable

Access

In the object library, click the *Datastores* tab and expand a datastore listing (click the plus sign next to the datastore name).

Description

A hierarchy is a PeopleSoft tree.



```
Hierarchies
  HR
    ALL_TIME_OLAP
    COMPENSATION
    COMPETENCY
    DEPARTMENT
      DEPT_SECURITY
        BEL0101/01/1980 - Department Security Belgium
        CHE0101/01/1980 - Department Security Germany
        DEU0101/01/1980 - Department Security Germany
        ESP0101/01/1980 - Department Security Germany
        FRA0101/01/1980 - Department Security France
        GBR0101/01/1980 - United Kingdom Security Tree
        ITA0101/01/1980 - Italian Department Sect Tree
        ITA0201/01/1980 - Italian Department Sect Tree 2
        JPN0101/01/1980 - Japan Security Tree
        LECOM01/01/1980 - E Communications
        LTELE01/01/1980 - Telecommunications
        NLD0101/01/1980 - Department Security Netherland
        SHARE01/01/1990 - Departmental Security
        SHARE01/01/1980 - Departmental Security
    POSITION
    SUCCESSION
```

A hierarchy contains the following levels:

1. Category: A category represents a major business organization. The example datastore explorer displays the category *HR*.
2. Tree structure: A tree structure represents a department or group within a category. The example datastore explorer displays three tree structures: *COMPENSATION*, *COMPETENCY*, and *DEPARTMENT*.
3. Tree: A tree represents a specific type of data within a tree structure. The example datastore explorer shows the *DEPT_SECURITY* tre expanded. You import hierarchical data at the tree level.
4. Set: A set is a subset of the tree that contains data that have similar values or rules. Each set is identified by a set ID. The above datastore explorer shows set IDs *BEL01*, *DEU01*, and so forth, and each set contains data specific to an organization.

To extract hierarchical information, select a hierarchy type or tree, import its metadata into your repository, then drag the hierarchy icon from the object library into a data flow.

From the datastore explorer, you can choose the hierarchy to import.

You can also import a tree by specifying the tree by name. Select the datastore in the object library, right-click, and choose *Import By Name*.

Choose *Hierarchy* from the *Type* drop-down menu.

Imported tree

After you import the tree, it appears as a hierarchy object in the object library nested under the datastore name.

The hierarchy object has the following properties:

Property	Description
Name	The name of the hierarchy object. The name is constructed as follows: `category-structure-tree(datastore)` The name (except the datastore name) is case sensitive.
Description	The description of the tree as included in the PeopleSoft table.

The hierarchy object has the following attributes, the values of which are included in the metadata imported for the hierarchy.

Attribute	Description
Category	Tree_Node_Description
Structure	Tree_Node_Record_Primary_Key1 -Tree_Node_Record_Primary_Key9
Set_ID	
Snapshot_Date	
Tree_Name	Tree_Leaf_Field_Name
Tree_with_Leaf?	Tree_Leaf_Description
Tree_Node_Record_Name	Tree_Leaf_Record_Primary_Key1 - Tree_Leaf_Record_Primary_Key9
Tree_Node_Field_Name	

Selecting the hierarchy in the object library and choosing *Open* displays the object properties and the source schema that results from the hierarchy extraction.

Source column name	Description
NodeID	The parent value in the relationship described by this row.
Description	The parent description.
ChildID	The child value in the relationship described by this row.
ChildDesc	The child description.
MaxDepth	The maximum number of nodes between the root node and the lowest node in the hierarchy.
TreeLevel	The level in the hierarchy that this row describes.
Category	The category in which this hierarchy is included.
Structure	The tree structure in which this hierarchy is included.
SETID	The identification of the subset of the tree. Each set groups together data that have similar values or rules.
SnapshotDate	The date when the hierarchy data was extracted.
EFFDT	The date when the data in a set became or will become effective.

Hierarchy instance

You can drag a hierarchy from the object library into a data flow definition.

The hierarchy editor displays the datastore information for the hierarchy and provides options for the instance of the hierarchy object:

Option	Description
All set IDs or *Set ID*	*Set ID* selects one or more trees out of the structure imported into SAP Data Services. Use commas to separate multiple set IDs. The set ID identifies a subset of the tree that groups together data that have similar values or rules. It appears as part of the name of the level below the level of hierarchy structure imported into the software. *All set IDs* selects all versions of a tree.
Current date or *All dates* or *Snapshot date*	*Current date* selects only the data that has an effective date that is equal to the date returned by the sysdate function. *All dates* selects data with all effective dates. *Snapshot date* filters the extracted values by the effective date you specify in one of the following ways: ● *Date* allows you to specify the date as a four-digit year, a period, a two digit month, a period, and a two-digit day (YYYY.MM.DD). You can select each part of the date and use the arrows to increment or decrement the digits. ● *Variable* allows you to specify a varchar variable name that contains a valid date in the yyyy.mm.dd format You can select one of the variable names in the drop-down list. Alternatively, can type in the name of a new variable, but you must define it in the Variables and Parameters window (▶ *Tools* ▶ *Variables* ◀). If you do not enter a variable name, the Snapshot date defaults to the current date. ℹ Note You can use a local or global variable for the date. Because the variable can be a global variable, validating the data flow or work flow does not check for invalid data types for this variable. Be sure to validate the Job to check for invalid data types for this date variable.

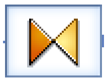
Related Information

Importing PeopleSoft metadata [page 2370]

Extracting PeopleSoft tree data [page 2377]

Importing PeopleSoft metadata [page 2370]

10.4.4 Query



Class

Single-use

Access

With a data flow diagram in the workspace, click the query icon in the tool palette, then click in the workspace.

Description

A Query transform, like a SQL SELECT statement, retrieves a data set that satisfies the conditions you specify. With a Query transform, you can:

- Map columns from input to output schema
- Add new columns, nested schemas, and functions to the output schema
- Choose the data to extract
- Perform operations on the data
- Join data from multiple sources

Editor

From tab: Use the *From* tab to specify joins and set join conditions.

Where tab: Use the *Where* tab to restrict the result set.

With the PeopleSoft interface, you can use the *Domains* button. Domains constrain retrieved data sets. Click the *Domains* button to open the Picker window, which helps you build an expression using a domain.

Related Information

Metadata for PeopleSoft domains [page 2371]

11 Supplement for Salesforce.com

11.1 Introduction

This user guide tells you how to use the SAP Data Services Adapter for Salesforce.com interface to integrate Salesforce.com with Data Services.

The Data Services Adapter for Salesforce.com interface allows you to create a datastore that connects to the Salesforce.com web service and retrieves data using Data Services data flows.

11.1.1 Audience and assumptions

This user guide assumes the following:

- You understand how to use the most current version of SAP Data Services to design and run batch and real-time data flows and administer Data Services processes. (Administer adapters from the Administrator.)
- You have a working knowledge of Salesforce.com..
- You know what an adapter is and the role it plays in business systems integration.
- You are familiar with how to use SQL query statements.
- You understand Changed Data Capture concepts.
- You are familiar with object-oriented modeling and can work with an object-oriented XML configuration file.
- Because you will integrate Data Services, the Data Services Adapter for Salesforce.com, and Salesforce.com, familiarity with systems administration and systems integration issues is recommended.

11.2 Overview and installation

11.2.1 Installing the Adapter for Salesforce.com

The SAP Data Services Adapter for Salesforce.com is automatically installed when you install Data Services version 12.0.0 or later. The adapter is associated with several files including:

- Adapter jar files
- Adapter configuration templates
- Salesforce.com Software System extensions
- *Supplement for Salesforce.com* (this document)

11.2.1.1 Requirements

The Job Server you associate with adapters must be configured to manage adapters. For general Job Server installation and configuration information, see the *SAP Data Services Installation Guide*.

Note

For information about Salesforce.com, visit the Salesforce.com Web page.

Related Information

Deployment overview [page 2390]

11.2.2 Adapter overview

The SAP Data Services Adapter for Salesforce.com allows you to access Salesforce.com data from within the native Data Services extraction, transformation and loading (ETL) environment. The adapter interface allows you to quickly and easily take advantage of Salesforce.com by:

- Supporting a fully automated process for Salesforce.com configuration
- Allowing you to browse Salesforce.com schema metadata in the same manner as all sources and targets from within the Designer interface

11.2.2.1 To use the Adapter for Salesforce.com from SAP Data Services

1. Install SAP Data Services version 12.0.0 or later (for more information, see the *Installation Guides*). Installing the software automatically installs the Salesforce.com adapter.
2. Configure the Job Server local to your installation of the software for adapter management. See the *Installation Guides* and the *Administrator Guide* for Job Server configuration details.
3. Configure the Data Services Adapter for Salesforce.com interface.

   Configure one or more adapter instances. You can configure and use multiple instances simultaneously.
4. Through the Designer, use the adapter inside data flows. You can:
   - Create the adapter's datastore
   - Import the adapter's metadata
   - Use imported metadata as sources in your data flows
   - Run jobs and verify results

11.3 Deploying the Adapter

This section explains the actions required to deploy the SAP Data Services Adapter for Salesforce.com interface. Tasks are sequenced in logical order of performance. However, you may need to modify the sequence based on your environment.

11.3.1 Deployment overview

All Data Services adapters communicate with Data Services through a designated Adapter Manager Job Server. An adapter must be installed on the same computer as this Job Server before you can integrate the adapter with the software using the Administrator and Designer. After the adapter is installed:

1. Use the Server Manager utility to configure adapter connections with the Adapter Manager Job Server. For details, see the "Server management" section in the *Data Services Administrator Guide* as well as the "Adapters" section in the *Data Services Management Console Guide*.
2. From the Administrator:
   - Configure an adapter instance.
   - Start and stop the adapter instance.
3. From the Designer:
   - Create the datastore in the object library. The datastore and adapter make it possible for you to import metadata from Salesforce.com into the software.
   - Browse and import metadata through the datastore. Use metadata accessed through the adapter to create batch and/or real-time jobs. For details, see the "Adapter datastores" section of the *Data Services Designer Guide*.
   - Design flows that move Salesforce.com data through the applications you design using the software.
   - Run applications to finalize the integration process (includes troubleshooting and parameter adjustments).

11.3.2 Configure the adapter

Integrate SAP Data Services with Salesforce.com by combining an instance of the Adapter for Salesforce.com with a data flow created in the Designer. To use an adapter instance, you must first configure it as described in this section. You can configure one or more adapter instances.

11.3.2.1 Configure an adapter instance

Use the Administrator to add an Adapter for Salesforce.com to the SAP Data Services system and to edit existing adapter configurations. Until you add the adapter in the Administrator, you cannot run jobs using information from that adapter.

Note

Before you add an adapter in the Administrator, you must first establish Administrator connection to your adapter-enabled repository. For general information on connecting repositories to the Administrator, refer to the "Administrator Management" section of the *Management Console Guide*.

11.3.2.1.1 To add an adapter instance in the Administrator

1. Select a Job Server name under the *Adapter Instances* node in the navigation tree. Or, select *Adapter Instances* > *Job Server*.
2. Select the Configuration tab.
3. On the Adapter Instance Configuration page, click *Add* to see a list of adapters managed by that Job Server.
4. Select the Adapter for Salesforce.com from the list, then click *Apply*.
5. Complete the Adapter Instance start-up configuration form.

Option	Description
Adapter Instance Name	(Required) Enter a unique name to identify this instance of the adapter.
Access Server Host	Leave blank (or you can provide the correct Access Server Host information). Note If you enter incorrect information in this text box, configuration will fail with an error message.
Access Server Port	Leave blank (or you can provide the correct Access Server Port information). Note If you enter incorrect information in this text box, configuration will fail with an error message.
Character Set	Converts text characters to and from bytes.
Adapter Retry Count	Applies if the adapter instance fails or crashes. Enter 0 for no retries and a negative number for indefinite retries.
Adapter Retry Interval	Wait in milliseconds between adapter retry attempts.
Classpath	Indicates the -classpath Java parameter value when the adapter starts.
Autostart	When set to True, the adapter interface automatically starts when the Administrator starts.
Trace mode	Set this flag to control the number of trace messages the adapter writes. There are two settings: True Adapter interface writes additional information messages to help debug problems. False Adapter interface writes minimal information messages. The adapter writes trace message to the adapter_instance_name_trace.txt file in the LINK_DIR\adapters\logs directory.

Option	Description
Additional Java Launcher Options	Enables when launching the Java process that hosts the adapter. ℹ Note If you are connecting to the adapter from behind a proxy server, append the following to the Additional Java Launcher options: `-Dhttp.proxyHost=<proxy_server_name> -Dhttp.proxyPort=<proxy_server_port>`
Adapter type name	(Read-only) The name of the adapter used to create this instance.
Adapter version	(Read-only) The version of the adapter used to create this instance.
Adapter Class	(Read-only) A name that identifies the adapter class. The name depends on the type of adapter.

6. Click *Apply* and the Administrator adds your adapter instance to the list of those available to the SAP Data Services system.
7. Start the adapter, verify that it functions.

Related Information

Start and stop the adapter instance [page 2392]

11.3.2.2 Start and stop the adapter instance

Click the *Status* tab to view the status of all adapter instances you configured. From this tab, you can Start adapter instances and Shutdown or Abort instances that are running.

From the *Status* tab, you can also navigate to view Adapter Instance configuration details, Log Files, and Dependent Objects for each configured adapter instance.

11.3.3 Create the datastore

To associate the SAP Data Services Adapter for Salesforce.com with data flows, you must create an adapter datastore in the Designer. For general information on creating an adapter datastore, refer to the Datastores section of the *Designer Guide*.

11.3.3.1 To create an Adapter for Salesforce.com datastore

1. In the Datastores tab of the Designer Object Library, right-click and select *New*.

   The *Datastore Editor* window appears.
2. Type a unique, descriptive name in the *Datastore name* box.
3. Select *Adapter* from the *Datastore type* list.
4. Select the *Job server* associated with the adapter for Salesforce.com.
5. For *Adapter instance name*, choose the instance name you configured in the Administrator.
6. Click the *Advanced* button to access Adapter Options. Configure the following options:
   a) *Username* and *Password* (for Salesforce.com access)
   b) *Web service end point* (*https://www.salesforce.com/services/Soap/u/6.0*)
   c) *Batch size* (200 is default)
   d) *Metadata resilience?* Select *yes* if you want the adapter to perform in any of the following ways without throwing an error message (*no* is default)

When reading from normal or CDC sources	When reading from normal or CDC sources	When loading data to Salesforce.com
If a table no longer exists, the adapter sends no record of that table to SAP Data Services	If a table no longer exists, the adapter sends no record of that table to SAP Data Services.	If a table no longer exists, the adapter sends no data for that table to Salesforce.com.
If a field use in a data flow no longer exists, the adapter returns a NULL value for that field to Data Services	If a field used in a dataflow no longer exists, the adapter retains a NULL value for that field to Data Services.	If a column no longer exists, the adapter sends no value for that column to Salesforce.com.
If a field used in a WHERE clause no longer exists, all conditions that use that field automatically evaluate to FALSE, possibly reducing the conditions. For example, if the WHERE clause is 'WHERE ColumnA = A and (ColumnB = B or ColumnC = C)' and ColumnC no longer exists, the clause will be processed as follows: 'WHERE ColumnA = A and (ColumnB = B or ColumnC = C)' 'WHERE ColumnA = A and (ColumnB = B or FALSE)' 'WHERE ColumnA = A and ColumnB'		

The software can push the date and datetime fields down to Salesforce.com if you use the software's default formats ("yyyy-mm-dd hh:mi:ss" for datetime and "yyyy-mm-dd" for date) in your WHERE clause.

> Note
>
> Salesforce.com does not support the "like" operator on an ID type field. the software maps this type to varchar. The software's optimizer is unable to recognize a Salesforce.com ID field and cannot push down SQL statements containing the "like" operator in the ID field.

e) *Enable CDC* Select *yes* to configure as a CDC datastore (*no* is default).

> Note
>
> To avoid data processing problems, it is recommended that after you create the datastore you do not modify the Enable CDC value. Instead, create a new datastore and configure with the other Enable CDC value.

f) Set *Default Based64Binary field length* to establish the default length for a Salesforce.com Base64Binary field.

7. Click *OK* to save values and finish creating the datastore.

   If you did not provide the correct user name and password, or if you entered an invalid parameter, you will see an error message stating that the "Adapter connection failed."

11.3.4 Working with Salesforce.com metadata

The Salesforce.com adapter supports only tables (not function calls, documents, and so on).

11.3.4.1 Browse and import metadata

For general information on how to browse and import metadata using a SAP Data Services datastore, see the Datastores section of the *Designer Guide*.

11.3.4.1.1 To browse and import adapter metadata

1. Double-click your adapter datastore icon, or double-click the *Tables* icon underneath the adapter datastore icon. Alternatively, you can right-click the datastore icon and select *Open*.

   The Adapter Metadata Browser window opens with a list of table objects (and their descriptions) from Salesforce.com that are available for viewing.
2. Click to open nodes and browse the available metadata.

   Two or three folders appear under each table node. These folders include: Referenced by, References, and Columns.

   - The Referenced by and References folders show relationships between the expanded table and itself as well as other tables. (For example, if a Contact belongs to an Account, it will have an AccountId column pointing to its parent account. So, Account is "referenced by" Contact and Contact "references" Account.)

- The Columns folder lists the table columns and their descriptions.

3. Right-click any node to find out if that metadata can be imported into SAP Data Services. If *Import* appears as a right-click menu option, select it to import the metadata object.

Option	Imports
Table node	That table
Referenced By node	All tables directly under that node
References node	All tables directly under that node

4. You can also import metadata by name.
   a) Go to the Datastores tab of the object library.
   b) Right-click the adapter datastore and choose *Import By Name*.
   c) In the *Import By Name* window, enter the full, exact table name in the *Value* column.

11.3.4.2 The DI_PICKLIST_VALUES table

The Salesforce.com adapter includes a SAP Data Services proprietary table you can import like any other Salesforce.com table. This table contains all Salesforce.com picklists (a set of enumerated values from which to select). To use the DI_PICKLIST_VALUES table as a source in data flows, import the DI_PICKLIST_VALUES just like you would any other table, then drag-and-drop it as a source in your data flow. Connect to a Query transform and drill down to add a WHERE clause and filter the values you require. Columns defined for this table include:

OBJECT_NAME, FIELD_NAME, VALUE, IS_DEFAULT_VALUE, IS_ACTIVE, and LABEL.

i Note

If you have translated pickup values in Salesforce.com, the LABEL column returns values for the language specified in your personal information settings. If pickup values are not translated, the VALUE and LABEL columns return the same values.

11.3.4.3 Open and delete imported metadata

You can open imported metadata to view input and output schemas. To open an imported table, double-click its icon. To find the icon go to the adapter datastore in the object library and open *Tables*.

From the Designer, you can also delete imported metadata by right-clicking an imported object and selecting *Delete* from the menu.

After you import metadata, it is available for use in Data Services data flows.

11.3.4.4 Metadata mapping

Salesforce.com data types map to SAP Data Services data types as follows:

Salesforce Datatype	Description	SAP Data Services Datatype
xsd:base64Binary	Base 64-encoded binary data	varchar
xsd:boolean	Boolean (True/False) values	varchar ('true' or 'false')
xsd:date	Date values	date
xsd:datetime	Date/time values (time-stamps)	datetime
xsd:double	Double values	decimal
xsd:int	Integer values	int
xsd:string	Character strings	varchar

The date/time values that the Salesforce.com adapter retrieves from Salesforce.com are all in ISO 8601 format, reflect GMT time, and include a time zone field. To adjust for any time zone differences, the Salesforce.com adapter automatically performs a translation based on the associated local and server clocks. When the Salesforce.com adapter communicates datetime information to SAP Data Services, the software receives those values in local time and the time zone field is not considered.

> **Note**
>
> If your local and server clocks are not synchronized, translation speed is unaffected. However, if your local clock is not set to the correct time, the software may send incorrect times to Salesforce.com and changes that you expected to be returned may not be returned until a later synchronization.

Examples:

- If we are in Pacific Standard Time (PST) and the adapter receives '2005-08-10T23:00:00Z' (where 'Z' means GMT time) from Salesforce.com, the value sent to the software will be '2005.08.10 15:00:00'.
- You want to retrieve information that has changed since yesterday at 6:00 PM local time. You write a condition stating: SFDC_TIMESTAMP >='2005.08.10 18:00:00' and the software sends this condition "as is" to the adapter. Because Salesforce.com will not understand this timestamp (it lacks a time zone indicator), the Salesforce.com adapter automatically converts the time specified in the software to a format that Salesforce.com understands, formatting the value to '2005-08-11T01:00:00Z'.

11.3.4.5 CDC datastore tables and generated columns

The CDC table nodes differ from normal tables. If you expand a CDC table node, you will only see a Columns folder that contains the same columns as the original table with three generated columns. The generated columns are used for CDC data retrieval. Generated columns include:

- DI_SEQUENCE_NUMBER: The sequence number (int).
- DI_OPERATION_TYPE: The operation type (varchar).
- SFDC_TIMESTAMP: The Salesforce.com timestamp (datetime).

11.3.5 Design flows

After importing metadata as datastore objects in the Designer, you can use that metadata when designing data flows.

(For general application design and administration information, see the *SAP Data Services Designer Guide* and the *SAP Data Services Administrator Guide*.)

11.3.5.1 Changed data and Salesforce.com

One simple usage of the Salesforce.com tables is to read changed data. The following example explains one way you can schedule SAP Data Services to query Salesforce.com for changed data after loading Salesforce.com tables into your local repository.

11.3.5.1.1 Reading changed data from Salesforce.com

1. Import CDC table metadata into your local repository.
2. Build a data flow by selecting a CDC table as a source object and connecting that source to a Query transform.
3. Drill into the source object and select the following tabs to set CDC-related options:

   CDC Options. CDC table options include:

Option Name	Description
CDC subscription name	(Required) A name that Data Services uses to keep track of your location in a continuously growing Salesforce.com CDC table. Salesforce.com CDC uses the subscription name to mark the last row read so that the next job starts reading the CDC table from that position. You can use multiple subscription names to identify different users who read from the same imported Salesforce.com CDC table. Salesforce.com CDC uses the subscription name to save the position of each user. Type a new name to create a new subscription. A subscription name must be unique within a datastore, owner, and table name. For example, you can use the same subscription name without conflict with different tables that have the same name in the same datastore if they have different owner names. The software requires that you enter a value for this option.
Enable check-point	Enables the software to restrict CDC reads using check-points. After a check-point is in place, the next time the CDC job runs, it reads only the rows inserted into the CDC table since the last check-point. By default, check-points are not enabled.

Option Name	Description
Get before-image for each update row	Some databases allow two images to be associated with an UPDATE row: a before-image and an after-image. If your source can log before-images and you want to read them during change-data capture jobs, enable this option. By default, the software retrieves only after-images.

a) Specify a value for the *CDC subscription name*.

b) If you select *Enable check-point*, the software remembers the timestamp of last load and automatically applies that timestamp as the start time for the next load. By using the *Enable check-point option*, you do not need to define a WHERE clause in the Query transform.

c) Do not select *Get before-image for each update row* (for use only if your source can log before-images and you want to read them during change-data capture jobs) as Salesforce.com provides no before-images.

Adapter source options include:

Option Name	Description
Column delimiter	Specify a one-character delimiter for data columns by entering the forward-slash (/) followed by a three-digit ASCII code to indicate an invisible character.
Row delimiter	Specify a one-character delimiter for data rows by entering the forward-slash (/) followed by a three-digit ASCII code to indicate an invisible character.
Escape character	Must be one character.
CDC table source default start date	This option works with the CDC *Enable check-point* option. Salesforce.com requires the software to supply a start date and end date as part of a changed data request.
Fetch deleted records	Set this value to *Yes* to also fetch the deleted records from the table. The default value is *No*.

4. Add a Map_CDC_Operation transform after the Query transform.
5. Drill into the Map_CDC_Operation transform and configure the CDC columns in the transform editor.
   - Note that the software automatically pre-populates the *Sequencing column* and the *Row operation columns* fields with DI_SEQUENCE_NUMBER and DI_OPERATION_TYPE, respectively.
     The software fills DI_SEQUENCE_NUMBER using sequential numbers starting at 0 every time the CDC operation starts. Returned rows are always sorted by this column.
     The DI_OPERATION_TYPE indicates the type of operation performed on the object: INSERT, UPDATE or DELETE (I, U or D). The adapter does not return before-image records (B).
   - The SFDC_TIMESTAMP value will always indicate the time at which the operation was performed, (when the object was inserted, deleted, or last updated).
   - The other column values may or may not be set by the software, depending on the operation type. For a DELETE operation, only the ID will be set. For UPDATE and INSERT, the columns are set to represent the state of the object after the operation.
6. Connect the Map_CDC_Operation transform to your target table (where the INSERT, UPDATE and DELETE commands will be executed).

The following table shows the CDC operation mapping of data from Salesforce.com to the software:

Salesforce.com data since last CDC operation	Records returned to Data Services
INSERT	INSERT

Salesforce.com data since last CDC operation	Records returned to Data Services
UPDATE	UPDATE
DELETE	DELETE
INSERT & UPDATE	INSERT & UPDATE
INSERT & DELETE	DELETE
UPDATE & DELETE	DELETE
INSERT & UPDATE & DELETE	DELETE

If an object was inserted and updated after the reference time, two CDC records are returned to the software, one for each operation. However, both records will contain the same information, reflecting the state of the object after the UPDATE. So, in this type of situation, there is no way of knowing the object state after the INSERT operation.

Related Information

Designer Guide: Techniques for Capturing Changed Data, Using mainframe check-points [page 758]
Designer Guide: Techniques for Capturing Changed Data, Using before images from mainframe sources [page 759]

11.3.5.1.2 Using check-points

If you can replicate an object, Salesforce.com allows applications to retrieve the changed data for that object. Salesforce.com saves changed data for a limited amount of time (for details, see your Salesforce.com technical documentation). Salesforce.com monitors neither the retrieving application nor the data retrieved.

When you enable check-points, a CDC job in Data Services uses the subscription name to read the most recent set of appended rows and to mark the end of the read (using the SF_Timestamp of the last record). If you disable check-points, the CDC job always reads all the rows in the CDC data source which increases processing time.

To use check-points, on the Source Table Editor enter the CDC Subscription name and select the *Enable check-point* option. If you enable check-points and run a CDC job in recovery mode, the recovered job begins to review the CDC data source at the last check-point.

Note

To avoid data corruption problems, do not reuse data flows that use CDC datastores because each time a source table extracts data it uses the same subscription name. This means that identical jobs, depending upon when they run, can get different results and leave check-points in different locations in the file.

11.3.5.1.3 Using the CDC table source default start date

The CDC table source default start date is dependent on several factors. This date can be a value you specify, a check-point value, or a date related to the Salesforce.com retention period.

When you do not specify a value for the start date:

- SAP Data Services uses the beginning of the Salesforce.com retention period as the start date if a check-point is not available (during initial execution).
- The software uses the check-point as the start date if a check-point is available and occurs within the Salesforce.com retention period. If the check-point occurs before the retention period, the software uses the beginning of retention period as the start date.
- However, if a table is created within the Salesforce.com retention period and a check-point is not available, the execution returns an error message. Drill into the source object and enter a value for the CDC table source default start date. The value must be a date that occurs after the date the table was created to work around this problem.

When you specify a start date value, if your date occurs:

- Within the Salesforce.com retention period and no check-point is available, then the software uses your specified value.
- Within the Salesforce.com retention period and after the check-point, the software uses your specified value.
- Within the Salesforce.com retention period and before the check-point, the software uses the check-point value as the start date.
- Outside of the Salesforce.com retention period, the Salesforce.com Adapter ignores the value.

11.3.5.1.4 Limitations

The Table Comparison and SQL transforms and the lookup and lookup_ext functions cannot be used with a source table imported with a CDC datastore because of the existence of the SAP Data Services generated columns. You cannot compare or search these columns.

11.3.6 Run applications

After you design your application(s), you must run them to finalize SAP Data Services-Salesforce.com integration. These are the basic startup tasks:

- In the Administrator, start each application to be used in the integration.
  Real-time: Start services and applications that use this service.
  Batch: Start/schedule the job.
- In the Administrator, monitor progress for each job. You can monitor pending requests, processed requests, failed requests, and status.

> Note
>
> The Administrator does not automatically refresh views. To refresh views, go to the View menu and select Refresh.

- In the Administrator, monitor progress for each (real-time) service.
- On the Salesforce.com Server, monitor messaging progress for the configured queues.

If problems occur:

- For error message descriptions and suggested troubleshooting actions, see the Understanding error messages section.
- To understand the source of a problem, use error and log tracing.
- To enable debug tracing for the adapter instance, use the Administrator.

Related Information

Understanding error messages [page 2401]

11.3.7 Understanding error messages

During the course of designing and deploying your jobs, you may encounter error messages. Find error messages and their descriptions (including suggested actions) listed in the following table:

Error Message	Description
Login operation has failed. SForce.com message is {0}	Invalid user name/password or user account is blocked for another reason, which is explained by the Salesforce.com message. ACTION: Confirm password or contact Salesforce.com for more information.
Unknown object type. SForce.com message is {0}	The table used in the query is no longer available or visible to the user. ACTION: Browse Salesforce.com metadata and look for the table.
Invalid field. SForce.com message is {0}	One or more fields used in the query are no longer available. ACTION: Browse Salesforce.com metadata to determine if there is a difference between the imported table and the actual metadata. If necessary, rebuild your data flow.
Unsupported SQL statement: {0}	Your data flow is not supported by Salesforce.com. ACTION: Rebuild according to the restrictions described in this document.
Malformed query: {0}. SForce.com message is {1}	The submitted query is unsupported by Salesforce.com. Most likely you have encountered a bug translating between data flows and Salesforce.com queries. ACTION: Contact product support.
Invalid session parameter: name = {0}, value = {1}	The URL or batchSize session parameter is invalid. Either the URL is malformed or batchSize is not a positive integer.

Error Message	Description
	ACTION: Check the integrity of the URL and confirm that the batchSize is a positive integer.
Invalid CDC query: {0}	The data flow built over a CDC table is invalid. ACTION: Check for (and fix) any missing WHERE clause condition for SFDC_TIMESTAMP.
There was a service connection error when talking to SForce.com: {0}	The adapter could not connect to Salesforce.com. ACTION: Confirm that the web service end point is correct and accessible through your network.
There was a communication error when talking to SForce.com: {0}	A protocol error occurred. ACTION: Contact product support.
There was an unexpected error. SForce.com message is {0}	An unknown, unexpected error occurred. ACTION: Contact product support.

12 Supplement for SAP

12.1 Introduction

This guide contains information about how to use Data Services with SAP applications and SAP NetWeaver Business Warehouse. It is organized to complement the information in the *Data Services Designer Guide*, and the reference section complements the information in the *Data Services Reference Guide*.

12.1.1 Terms

The following table describes SAP terminology for this release.

Term	Abbreviation	Description
SAP Applications	Not applicable	Applications are the main building blocks of the SAP solution portfolios for industries. They provide the software foundation with which organizations address their business issues. SAP delivers the following types of applications: • General-purpose applications: These include applications provided within SAP Business Suite software such as the SAP Customer Relationship Management application and the SAP ERP application. • Industry-specific applications: These applications perform targeted, industry-specific business functions. Examples are the SAP Apparel and Footwear application for the consumer products industry and the SAP Reinsurance Management application for the insurance industry. SAP R/3 software is available today as SAP ERP. Therefore, SAP R/3 software functionality falls under the category of SAP Applications.
SAP Master Data Services	Not applicable	A solution powered by SAP HANA that provides enterprises with instant access to a complete view of their entire customer’s information and

Term	Abbreviation	Description
		relationships—data that is seamlessly consolidated and enriched from heterogeneous sources across the enterprise.
SAP NetWeaver technology platform	Not applicable	Helps organizations perform a wide variety of IT processes such as user productivity enablement, information management, and business process management. Includes several components and tools
SAP NetWeaver Application Server component	SAP NetWeaver AS	Supports platform-independent Web services, business applications, and standards-based development. This software enables you to leverage existing technology assets for Web-services-oriented solutions. It is a component of the SAP NetWeaver technology platform. Formerly referred to as the SAP Web Application Server or Basis.
SAP NetWeaver Business Warehouse component	SAP NetWeaver Business Warehouse	Enables you to integrate data from across the enterprise and transform it into practical, timely business information to drive sound decision-making. It is a component of the SAP NetWeaver technology platform.

12.1.2 SAP interfaces

Data Services includes the following SAP interfaces:

- SAP Applications ODP [Operational Data Provisioning] sources
- SAP Applications ABAP
- SAP Applications BAPI (Business Application Programming Interface)
- SAP Applications IDoc
- SAP Master Data Services
- SAP NetWeaver Business Warehouse (BW)
- SAP NetWeaver BW Open Hub Destination service

The following table lists SAP interfaces, their intended functionality, and the types of data flows you can use with each.

Feature	How is this feature designed to be used?	Which data flow should be used?
SAP applications ODP sources i Note Refer to the *What's New Guide* for ODP sources	Use an SAP Applications datastore to import metadata from SAP ODP sources to create batch jobs that extract data from SAP application sources.	data flow or ABAP data flow
SAP Applications ABAP	An alternative to SAP ODP sources. Use an SAP Applications datastore to import metadata (tables, files, hierarchies, and functions) to create batch jobs to extract data from SAP application sources.	ABAP data flow
SAP Applications BAPI	Use an SAP Applications datastore to import BAPI function metadata to be included in batch or real-time jobs. BAPI functions can be used to update SAP application and SAP NetWeaver BW sources.	data flow
SAP Applications IDoc	Use an SAP Applications datastore to import IDoc metadata which can be used to create the following for batch and real-time jobs: For batch jobs • IDoc file sources • IDoc message sources • IDoc message targets For real-time jobs • IDoc file sources • IDoc message sources • IDoc file targets • IDoc message targets	data flow
SAP Master Data Services	Use an SAP Master Data Services datastore to import SAP Master Data Services metadata to create batch jobs that can be run from Data Services to read from SAP Master Data Services sources or update SAP Master Data Services targets.	data flow
SAP NetWeaver BW	Use an SAP BW Target datastore to import BW metadata to create batch jobs that can be run from SAP NetWeaver BW or Data Services to update SAP BW targets.	data flow (batch jobs only)
SAP NetWeaver BW Open Hub Destination service	Use an SAP BW Source datastore to import Open Hub Destination tables that are sources from which Data Services can read data.	data flow

12.1.3 Version checking

Data Services provides version information for SAP application ABAP programs and functions. With this feature, Data Services can:

- Embed version information in ABAP programs (programs that are both provided by Data Services for an SAP application environment and generated by Data Services from ABAP data flows)
- Generate warnings to update ABAP programs that were uploaded during a previous Data Services installation
- Compare an ABAP program with its ABAP data flow and produce a warning if it finds a version mismatch
- Compare functions on an SAP application server (uploaded during a previous Data Services installation) with those required by the current Data Services installation and produce a warning if it finds a version mismatch

To avoid version mismatches, it is recommended that when you upgrade Data Services, use it with the transport files supplied in the same product package and regenerate ABAP programs from ABAP data flows if you pre-loaded them to an SAP application server.

12.1.3.1 Generated ABAP programs

If you select *Execute Preloaded* for the *ABAP execution option mode* in your SAP Applications datastore, when Data Services executes a job that contains an ABAP data flow, it runs the previously generated and uploaded ABAP program. If this program was generated by an old version of Data Services, the job might not be taking advantage of the performance improvements in the latest version.

You can set Data Services to trigger version warning messages when a job executes. If you find a version mismatch, upgrade the generated ABAP program on the SAP server to match the Data Services version.

12.1.3.2 To upgrade a generated ABAP program stored on an SAP application server

1. Open a project containing the ABAP data flow that you want to update.
2. In the project area, select the ABAP data flow.
3. Select *Validation* > *Generate ABAP code* .
4. Modify your ABAP program on the SAP application server using this new code.

> i Note
>
> If you select the *Generate and Execute* mode for an SAP Applications datastore configuration, Data Services generates an ABAP program each time a job runs. Data Services does not need to check an ABAP program's version if the program is generated each time a job runs.

12.1.3.3 Data Services ABAP programs

When you connect to an SAP application environment, Data Services makes use of and tracks version information for built-in ABAP programs. If you encounter a warning, upgrade the Data Services ABAP programs to match the current Data Services version.

12.1.3.4 Data Services functions

If you want to connect to an SAP application environment, Data Services provides functions for you to load onto an SAP application server. Data Services tracks version information for these functions and can trigger warning messages if it finds that functions from a previous Data Services installation exist on the server. If you encounter a warning, upgrade the Data Services functions on the SAP application server to match the current Data Services version.

12.1.3.5 Warning messages

You can enable and disable version checking.

12.1.3.6 To enable or disable version checking for ABAP programs and functions

1. From the Designer, select *Tools* > *Options* > *Job Server* > *General* .

   This dialog allows you to modify the configuration of the default Job Server.
2. Set the following keys in the al_engine section as needed.

   These keys control different SAP application warning messages:

Key	Messages
ABAP_PRELOAD_VERSION_MISMATCH	151201, 151203
ABAP_PRELOAD_KEY_MISMATCH	151202, 151204
ABAP_SUPPLIED_VERSION_MISMATCH	151205
SAP_FUNCTION_MISMATCH	151206

   The default for ABAP_PRELOAD_VERSION_MISMATCH and ABAP_PRELOAD_KEY_MISMATCH is FALSE, and the default value for ABAP_SUPPLIED_VERSION_MISMATCH and SAP_FUNCTION_MISMATCH is TRUE.

As described in the following sample scenarios, if you enable warnings for the ABAP and function version checking feature, Data Services provides an appropriate response:

Scenario	Response
After installing a new release of Data Services and enabling the version warning messages feature, you try to use Data Services against function metadata imported by an older Data Services version.	Data Services generates a warning message: 151206 3 3 4 "Warning: a mismatch was detected for SAP function <%s (%s)> : installed version <%s>. The expected version is <%s>. Please upload the correct function."
You just upgraded to a new version of Data Services but chose not to upgrade the SAP application server and you do not want to encounter warning messages.	You do nothing. However, it is recommended that you avoid this scenario by regenerating and uploading ABAP files when you upgrade Data Services.
You generate ABAP and upload it to your SAP server. After enabling all version warning messages and running it in execute_preloaded mode for a while, you change an ABAP data flow.	Data Services generates a warning message.
You generated an ABAP program and uploaded it to your SAP server. After enabling all version warning messages and running it in Execute Preloaded mode for a while, you upgrade Data Services.	Data Services generates a warning message because of the potential benefits you will gain by re-generating ABAP.

12.1.3.7 /BODS/GET_VERSION function

This function is included in each transport file for SAP applications.

/BODS/GET_VERSION retrieves the list of Data Services provided functions and their versions from the SAP application server.

I / P_FUNC / RFCFUNC-FUNCNAME

E / O_DI_VER / RFCFUNC-FUNCNAME

T / ENTRIES / TAB512

12.2 Installing Functions on the SAP Server

SAP Data Services provides functions that support the use of the ABAP, BAPI, and IDoc interfaces on SAP servers. You will need some or all of these functions in the normal operation of the software in an SAP environment. These functions perform such operations as dynamically loading and executing ABAP programs from Data Services, efficiently running preloaded ABAP programs, allowing for seamless metadata browsing and importing from SAP servers, and reporting the status of running jobs. Some of these functions read data from SAP NetWeaver BW sources.

You must upload the provided functions to your SAP server in a production environment. It is recommended that you always upload the functions to your SAP server whether you are in a development, test, or production environment. The functions provide seamless integration between Data Services and SAP servers.

The default installation places two function module files for SAP servers in the `...\Data Services\Admin\R3_Functions\transport` directory. You then upload these files to SAP servers using the SAP Correction and Transport System (CTS) or manually. Using CTS allows for version control as the functions evolve across releases.

The installation provides two versions of transport files (depending on the server version you are using) to install the functions on the SAP server. To obtain the names of the latest transport files for installing or upgrading these SAP server functions, see the readme.txt file in the `...\Data Services\admin\R3_Functions\transport` directory.

12.2.1 Installing the functions using CTS

If you are installing SAP Data Services for the first time or upgrading to a new release, you must add the provided functions to the SAP server. The recommended method is to use the SAP Change and Transport System (CTS). This procedure assumes you are familiar with CTS and have the authorization to perform the transport.

To install provided functions using the CTS system:

1. Copy the provided transport files to the appropriate directories on your SAP server.

   > **Note**
   >
   > In these steps, **`<900XXX.XXX>`** is a variable. To substitute the correct file name for the current release, see the readme.txt file in the `...\Data Services\admin\R3_Functions\transport` directory.

   a) Copy **`<R900XXX.XXX>`** to the `/usr/sap/trans/data` directory.
   b) Copy **`<K900XXX.XXX>`** to the `/usr/sap/trans/cofiles` directory.
2. Log on to the SAP server and run the transaction `/nSE37` to determine if function group /BODS/BODS already exists. The CTS system will install the Data Services functions into a single function group /BODS/BODS that it automatically creates on the SAP server if it does not already exist.

   If function group /BODS/BODS exists and contains previously installed Data Services functions, add an unconditional mode 2 option (parameter U2) to the `tp import` command described in step 4 below (`tp import <xxx>K900<xxx> <SID> U2`).
3. From a command window, run the following transport command:

   ```
   tp addtobuffer <xxx>K900<xxx> <SID>
   ```

   (where SID is the SAP system ID)

   You receive the response:

   ```
   This is tp version <SAP TP and SAP versions> for
               <database type> database. Addtobuffer successful for
               <xxx>K900<xxx> tp finished with a return code: 0 meaning:
               Everything OK
   ```
4. Run the next transport command:

   ```
   tp import <xxx>K900<xxx> <SID>
   ```

   (where SID is the SAP System ID)

   You receive a response that indicates the SAP TP and SAP versions, database type, SAP server name, and the TP return code, which indicates whether or not the TP command successfully uploaded the functions.

5. Run `/nSE37` again to verify that the functions uploaded.

When importing the functions, you might see an error such as the following:

```
1 of 1 requests do not match the component version of the target system
```

To prevent this error, in STMS enable the *Ignore Invalid Component Version* option.

12.2.2 Function modules

The names of the SAP Data Services functions have the prefix /BODS/ added to the corresponding SAP function names. The appropriate Data Services function modules for your SAP version are installed when you upload them to your SAP server.

12.2.2.1 Packaging of /BODS/ RFC_ABAP_INSTALL_AND_RUN

For SAP servers, SAP Data Services provides a function called /BODS/RFC_ABAP_INSTALL_AND_RUN in its transport file. This function is used in the generate_and_execute mode (set in an SAP datastore) to generate ABAP code on Data Services and execute it on an SAP server. This function allows dynamic program generation and is particularly useful in a development environment. However, it also provides a level of write access to an SAP server that might not be acceptable to your security environment. If this is a concern, remove this function from your SAP server.

12.2.2.2 Sample function module

The following example illustrates the function module /BODS/SYNTAX_CHECK:

Example

```
FUNCTION /BODS/SYNTAX_CHECK.
*"--------------------------------------------
*"*"Local interface:
*"    EXPORTING

    *"         VALUE(ERRORMESSAGE) LIKE SY-MSGV1
*"    TABLES
  *"         PROGRAM STRUCTURE PROGTAB OPTIONAL
*"--------------------------------------------
DATA: MESS(72), LIN(72), WRD(72).
   SYNTAX-CHECK FOR PROGRAM MESSAGE MESS LINE LIN WORD WRD.
  IF MESS <> SPACE.
  ERRORMESSAGE = MESS.
  EXIT.
   ENDIF.
ENDFUNCTION.
```

12.2.2.3 Function parameters

The following table describes information about functions, their interfaces, and function source code. This table describes the parameters with the following format:

```
Parameter type / Parameter name / Reference field
```

The parameter types are:

- I: Import parameter
- E: Export parameter
- T: Table parameter

Function name	Description

/BODS/ABAP_RUN	Executes generated or preloaded ABAP programs.
	`I / PROGRAMNAME / SY-REPID`
	`E / ERRORMESSAGE /  SY-MSGV1`
	`T / SELTAB /  RSPARAMS`
	`LOG /  LISTZEILE`
	Exception: PROGRAM_DOES_NOT_EXIST

/BODS/AUTH_IMPORT	Imports SAP application authorization profiles used by /BODS/ABAP_RUN.
	`I / AUTHPROF /  USR10-PROFN`
	`T / AUTHOBJ /  LISTZEILE`
	Exception: SECURITY_PROFILE_DOESNOT_EXIST

/BODS/BW_QUERY	Gets metadata information from an SAP BW system.
	`I / P_CODE / DD01D-DATATYPE`
	`I / P_IAREA / DD01D-DDTEXT`
	`I / P_ICUBE / DD01D-DDTEXT`
	`I / P_ODSO / DD01D-DDTEXT`
	`T/ ENTRIES / TAB512`

/BODS/COLUMN_SEARCH	/BODS/COLUMN_SEARCH is currently not used and is reserved for future implementation.
	`I / P_TNAME / DD03VT-DDTEXT`
	`I / P_CNAME / DD03VT-DDTEXT`
	`I / P_CDESC / DD03VT-DDTEXT`
	`I / P_LANG / DD03VT-DDLANGUAGE`
	`I / P_MAXROWS / SY-TABIX`
	`T / P_RETURN / LISTZEILE`

/BODS/DATA_PROFILE	Profiles an SAP table.
	` I / P_CODE / DD02L-TABNAME`
	` I / P_TABLE / DD02L-TABNAME`
	`I / P_FIELD / DD03L-FIELDNAME`
	`T / WRITES / LISTZEILE`

Function name	Description

/BODS/EXTRACTOR_IMPORT	Allows import of an ERP extractor metadata into the Data Services repository.
	`I / P_LANG / DD02T-DDLANGUAGE DEFAULT SY-LANGU`
	`I / P_NAME / ROOSOURCE-OLTPSOURCE`
	`E / P_ERRORMESSAGE / SY-MSGV1`
	`T / P_RESULT / LISTZEILE`
	`T / P_VIEW_DEF / LISTZEILE`
	Exceptions:
	● EXTRACTOR_IS_NOT_SUPPORTED
	● NO_AUTHORITY
	● GET_METADATA_FAIL
	● EXTRACTOR_DOES_NOT_EXIST

/BODS/EXTRACTOR_NAVIGATE	Allows various ways of listing available ERP extractors in an SAP system.
	`I / P_LANG / DD02T-DDLANGUAGE DEFAULT SY-LANGU`
	`I / P_APPLNM / ROOSOURCE-APPLNM`
	`I / P_TYPE / ROOSOURCE-TYPE`
	`I / P_ALLEXT / CHAR_01`
	`T / P_RETURN / LISTZEILE`

/BODS/EXTRACTOR_SEARCH	Allows searches for ERP extractors.
	`I / P_LANG / DD02T-DDLANGUAGE DEFAULT SY-LANGU`
	`I / P_NAME / ROOSOURCE-OLTPSOURCE`
	`I / P_MAX_ROWS / I`
	`I / P_FLAG / I`
	`T / P_RETURN / LISTZEILE`

/BODS/FILE_ROWCOUNT	Puts/gets the row count information for each transported file in the data flow into/from the /BODS/BODS table.
	`I / NAME / /BODS/BODS-NAME`
	`I / ROWCOUNT / /BODS/BODS-TOTAL_ROW`
	`I / SET / SONV-FLAG`
	`E / TOTAL_ROW / /BODS/BODS-TOTAL_ROW`

/BODS/FUNCTION_GET	Gets the function interface.
	`I / FUNCNAME / TFDIR-FUNCNAME`
	`T / PRMTAB / CATFU`

/BODS/GET_VERSION	Retrieves the list of Data Services provided functions and their versions from the SAP application server. This function is included in each transport file.
	`I / P_FUNC / RFCFUNC-FUNCNAME`
	`E / O_DI_VER / RFCFUNC-FUNCNAME`
	`T / ENTRIES / TAB512`

Function name	Description

/BODS/IDOC_IMPORT	Imports IDocs from SAP applications.
	`I / IDOCTYP / EDISYN-DOCTYP`
	`I / LANG /  EDISEGT-LANGUA`
	`T / SEGMENTS / LISTZEILE`
	Exception: IDOC_TYPE_DOESNOT_EXIST

/BODS/IDOC_SEARCH	Searches existing IDocs in SAP applications.
	`I / P_NAME / EDIDOT-DOCTYP`
	`I / P_DESC /  EDIDOT-DESCRP`
	`I / P_LANG / EDIDOT-LANGUA`
	`I / P_MAXROWS / SY-TABIX`
	`I / P_FLAG / SY-TABIX`
	`T / P_RETURN / LISTZEILE`

/BODS/JOB_LOG	Provides error handling and retrieves the SAP application job log when a job is cancelled. This function is required for the execute_preloaded access method you can define for an SAP Applications datastore.
	`I / JOBCOUNT / TBTCO-JOBCOUNT`
	`I / JOBNAME / TBTCO-JOBNAME`
	`I / HOST / TBTCO-BTCSYSREAX`
	`T / LOG / BTCTLE`
	Exceptions:
	• JOB_NOT_FOUND
	• JOB_LOG_NOT_FOUND
	• JOB_NUMBER_NOT_VALID
	• LOGNAME_WRONG_FORMAT
	• LOGNAME_MISSINGLOG_HANDLE_ERROR
	• LOG_IS_EMPTY
	• LOG_NOT_FOUND
	• TEMSE_CONVERSION_NOT_POSSIBLE
	• TEMSE_ERROR
	• TEMSE_FUNCTION_ERROR

/BODS/JOB_RUN	Submits ABAP jobs for background execution.
	`I / PROGRAMNAME / SY-REPID`
	`I / JOBGROUP /  TBTCO-JOBGROUP`
	`I / JOBNAME / TBTCO-JOBNAME`
	`I / HOST / TBTCO-BTCSYSREAX`
	`I / JOBCLASS / TBTCO-JOBCLASS`
	`E / JOBCOUNT /  TBTCO-JOBCOUNT`
	`E / JOB_RELEASED / BTCH0000-CHAR1`
	`T / SELTAB /  RSPARAMS`
	Exceptions:
	• ABAP_PROGRAM_SYNTAX_ERROR

Function name	Description
	• CANT_CREATE_JOB • INVALID_JOB_DATA • JOBNAME_MISSING • CANT_START_IMMEDIATE • INVALID_STARTDATE • JOB_CLOSE_FAILED • JOB_NOSTEPS • JOB_NOTEX • LOCK_FAILED • ABAP_PROGRAM_DOES_NOT_EXIST

/BODS/ JOB_STATUS	Queries ABAP job status after a job is successfully submitted.
	`I / JOBNAME / TBTCO-JOBNAME`
	`I / JOBCOUNT / TBTCO-JOBCOUNT`
	`I / HOST / TBTCO-BTCSYSREAX`
	`E / STATUS / TBTCO-STATUS`
	Exception: JOB_NOT_FOUND

/BODS/ MODEL_NAVIGATE	Allows you to navigate through the SAP data model, helping to identify tables.
	`I / P_OID / DM41S-DMOID`
	`I / P_LANG / DD02T-DDLANGUAGE`
	`T / P_RETURN / LISTZEILE`

/BODS/ READ_TEXT	Allows extraction of text from SAP applications. This function is an RFC-enabled version of the SAP application function module, READ_TEXT.
	`I / CLIENT / SY-MANDT`
	`I / ID / THEAD-TDID`
	`I / LANGUAGE / THEAD-TDSPRAS`
	`I / NAME / THEAD-TDNAME`
	`I / OBJECT / THEAD-TDOBJECT`
	`I / ARCHIVE_HANDLE / SY-TABIX`
	`E / HEADER / THEAD`
	`T / LINES / TLINE`
	Exceptions:
	• ID: Text ID invalid
	• LANGUAGE: Invalid language
	• NAME: Invalid text name
	• NOT_FOUND: Text not found
	• OBJECT: Invalid text object
	• REFERENCE_CHECK: Reference chain interrupted
	• WRONG_ACCESS_TO_ARCHIVE: Archive handle invalid

Function name	Description

/BODS/RFC_ABAP_INSTALL_AND_RUN	Allows Data Services to dynamically generate and run programs on an SAP server.
	`I / MODE / SY-MSGTY`
	`I / PROGRAMNAME / SY-REPID`
	`E / ERRORMESSAGE / SY-MSGV1`
	`T / PROGRAM / PROGTAB`
	`T / WRITES / LISTZEILE`

/BODS/RFC_READ_EXTRACTOR	Allows extraction of data from an ERP extractor.
	`I / P_NAME / ROOSOURCE-OLTPSOURCE`
	`I / P_DELIMITER / SONV-FLAG`
	`I / P_ROWCOUNT / SOID-ACCNT`
	`I / P_IS_VIEWDATA / CHAR_01`
	`I / P_WHERE /  /BODS/CH2K-WA`
	`I / P_SIZE / RSIDOCSIZE`
	`E / P_OUT_TABLE / DD02L-TABNAME`
	`T / P_FIELDS / RFC_DB_FLD`
	`T / P_TBLOUT128 / /BODS/CH128`
	`T / P_TBLOUT512 / /BODS/CH512`
	`T / P_TBLOUT2048 / /BODS/CH2K`
	`T / P_TBLOUT8192 / /BODS/CH8192`
	`T / P_TBLOUT30000 / /BODS/CH30K`
	Exceptions:
	• DATA_BUFFER_EXCEEDED
	• EXTRACTOR_INIT_FAIL
	• EXTRACTOR_GETNEXT_FAIL
	• NO_AUTHORITY
	• GET_METADATA_FAIL
	• SYNTAX_ERROR
	• FIELD_NOT_VALID

/BODS/RFC_READ_TABLE	Allows extraction of SAP application table data.
	`I / QUERY_TABLE / DD02L-TABNAME`
	`I / DELIMITER / SONV-FLAG DEFAULT SPACE`
	`I / NO_DATA / SONV-FLAG DEFAULT SPACE`
	`I / ROWSKIPS / SOID-ACCNT DEFAULT 0`
	`I / ROWCOUNT / SOID-ACCNT DEFAULT 0`
	`T / OPTIONS / RFC_DB_OPT`
	`T / FIELDS / RFC_DB_FLD`
	`T / DATA / /BODS/CH2K`
	Exceptions:
	• TABLE_NOT_AVAILABLE
	• TABLE_WITHOUT_DATA
	• OPTION_NOT_VALID
	• FIELD_NOT_VALID
	• NOT_AUTHORIZED
	• DATA_BUFFER_EXCEEDED

Function name	Description

/BODS/RFC_READ_TABLE2	Allows extraction of SAP application table data (enhanced version of /BODS/RFC_READ_TABLE).
	`I / QUERY_TABLE / DD02L-TABNAME`
	`I / DELIMITER / SONV-FLAG`
	`I / NO_DATA / SONV-FLAG`
	`I / ROWSKIPS / SOID-ACCNT`
	`I / ROWCOUNT / SOID-ACCNT`
	`E / P_OUT_TABLE / DD02L-TABNAME`
	`T / OPTION S/ RFC_DB_OPT`
	`T / FIELDS / RFC_DB_FLD`
	`T / TBLOUT128 / /BODS/TAB128`
	`T / TBLOUT512 / /BODS/TAB512`
	`T / TBLOUT2048 / /BODS/TAB2048`
	`T / TBLOUT8192 / /BODS/TAB8192`
	`T / TBLOUT30000 / /BODS/TAB30K`
	Exceptions:
	• TABLE_NOT_AVAILABLE
	• TABLE_WITHOUT_DATA
	• OPTION_NOT_VALID
	• FIELD_NOT_VALID
	• NOT_AUTHORIZED
	• DATA_BUFFER_EXCEEDED

/BODS/RFC_READ_TABLE_FILE	Allows extraction of SAP application table data (writes the data to the specified file).
	`I / QUERY_TABLE / DD02L-TABNAME`
	`I / DELIMITER / SONV-STATUS`
	`I / NO_DATA / SONV-FLAG`
	`I / OUT_DIR / / BODS/CH2K`
	`I / DATA_FILE / /BODS/CH2K`
	`I / EMPTY_FILE / SONV-FLAG`
	`T / OPTIONS / RFC_DB_OPT`
	`T / FIELDS / RFC_DB_FLD`
	Exceptions:
	• TABLE_NOT_AVAILABLE
	• TABLE_WITHOUT_DATA
	• FIELD_NOT_VALID
	• NOT_AUTHORIZED
	• DATA_BUFFER_EXCEEDED

/BODS/SYNTAX_CHECK	Performs a syntax check for generated or preloaded ABAP. This function is required for the execute_preloaded access method you configure in an SAP Applications datastore.
	`E / ERRORMESSAGE / SY-MSGV1`
	`T / PROGRAM /  PROGTAB`

/BODS/TABLE_IMPORT	Imports SAP application table definitions into the Data Services repository.
	`I / TABNAME / DD03L-TABNAME`
	`I / LANG / DD02T-DDLANGUAGE`

Function name	Description

	`E / DESCRIPTION / DD02T-DDTEXT`
	`E / TABCLASS / DD02L-TABCLASS`
	`T / COLUMNS / LISTZEILE`
	`T / INDEXES / LISTZEILE`
	`T / FKEYS / LISTZEILE`
	Exceptions: NO_TABLECLASS_FOR_TABLE

/BODS/TABLE_SEARCH	Allows searches for SAP application tables.
	`I / P_NAME / DD02-DDTEXT`
	`I / P_DESC / DD02VV-DDTEXT`
	`I / P_LANG / DD02V-DDLANGUAGE`
	`I / P_MAXROWS / SY-TABIX`
	`I / P_FLAG / SY-TABIX`
	`T / P_RETURN / LISTZEILE`

/BODS/TEXTS	Allows extraction of texts for program areas (currently not used).
	`I /P_CODE/PROGTAB-LINE`
	`T /ENTRIES/TAB512`

/BODS/TREE_IMPORT	Allows you to import ERP hierarchy metadata into the Data Services repository.
	`I / P_LANG / DD04T-DDLANGUAGE`
	`I / P_TREEAREA / DD02D-DDTEXT`
	`I / P_TREEGROUP / DD04L-ROLLNAME`
	`I / P_TREETABLE / DD02D-TABNAME`
	`E / DESCRIPTION / DD04T-DDTEXT`
	`E / CONTROLLING_AREA / DD02D-DDTEXT`
	`E / CHART_OF_ACCT / DD02D-DDTEXT`
	`E / TABLE_NAME / DD02D-TABNAME`
	`E / FIELD_NAME / DD03D-FIELDNAME`
	`E / DOMAIN_NAME / DD03L-DOMNAME`
	`E / CHECK_TABLE / DD03L-CHECKTABLE`
	`E / CONT_AREA_LIST / TAB512-WA`
	`T / COLUMNS / LISTZEILE`

/BODS/TREE_NAVIGATE	Allows GUI-based navigation of an SAP application environment.
	`I / P_LANG / DD04T-DDLANGUAGE`
	`I / P_TREEAREA / DD02D-DDTEXT`
	`I / P_TREEGROUP / DD04L-ROLLNAME`
	`I / P_TREETABLE / DD02D-TABNAME`

/BODS/TREE_PROF	Reads an ERP hierarchy for profiling.
	`I / P_GROUP / DD04L-ROLLNAME`
	`I / P_TABLE / DD02D-TABNAME`
	`T / WRITES / LISTZEILE`

/BODS/TREE_SEARCH	Allows GUI-based search and selection in an SAP application environment.
	`I / TREENAME / DD08T-MESTEXT`
	`I / TREEDESC / DD04T-DDTEXT`
	`I / LANG / SY-LANGU`
	`I / MAX_ROWS / SY-TABIX`

Function name	Description

	`I / FLAG / SY-TABIX`
	`T / P_RETURN / LISTZEILE`

/BODS/TREE_NAVIGATE40	Provides a GUI-based method to import tables and fields for SAP R/3 version 4.x and later environments.
	`I / P_LANG / DD04T-DDLANGUAGE`
	`I / P_TREEAREA / DD02D-DDTEXT`
	`I / P_TREEGROUP / DD04L-ROLLNAME`
	`I / P_TREETABLE / DD02D-TABNAME`
	`T / P_RETURN / LISTZEILE`

/BODS/TREE_IMPORT40	Provides a GUI-based method to import tables and fields for SAP R/3 version 4.x and later environments.
	`I / P_LANG / DD04T-DDLANGUAGE`
	`I / P_TREEAREA / DD02D-DDTEXT`
	`I / P_TREEGROUP / DD04L-ROLLNAME`
	`I / P_TREETABLE / DD02D-TABNAME`
	`E / DESCRIPTION / DD04T-DDTEXT`
	`E / CONTROLLING_AREA / DD02D-DDTEXT`
	`E / CHART_OF_ACCT / DD02D-DDTEXT`
	`E / TABLE_NAME / DD02D-TABNAME`
	`E / FIELD_NAME / DD03D-FIELDNAME`
	`E / DOMAIN_NAME / DD03L-DOMNAME`
	`E / CHECK_TABLE / DD03L-CHECKTABLE`
	`E / CONT_AREA_LIST / TAB512-WA`
	`T / COLUMNS / LISTZEILE`

/BODS/TREE_SEARCH40	Allows GUI-based search and selection in an SAP R/3 version 4.x environment.
	`I / TREENAME / DD08T-MESTEXT`
	`I / TREEDESC / DD04T-DDTEXT`
	`I / LANG / SY-LANGU`
	`I / MAX_ROWS / SY-TABIX`
	`I / FLAG / SY-TABIX`
	`T / P_RETURN / LISTZEILE`

/BODS/UPLOAD	Uploads a Data Services-generated ABAP program to the SAP server.
	`I / P_PNAME / SY-REPID`
	`I / P_TITLE / RS38M-REPTI`
	`I / P_DEVC / TDEVC-DEVCLASS`
	`I / P_APPL / TRDIR-APPL`
	`I / P_RSTAT / TRDIR-RSTAT`
	`I / P_REQNUM / E070-TRKORR`
	`I / P_TSKNUM / E070-TRKORR`
	`T / PROGRAM / PROGTAB`
	`T / ENTRIES / TAB512`

/BODS/RFC_STREAM_READ_TABLE	Allows data streaming via RFC protocol.
	`I / QUERY_TABLE / TABNAME`
	`I / CALLBACK_FM / FUNCNAME`
	`I / DELIMITER / SONV-FLAG`
	`I / BATCH_SIZE / INT4`
	`I / NUMB_OF_LINES / INT4`

Function name	Description

	`T / PROJECTIONS / RFC_DB_OPT`
	`T / SELECTIONS / RFC_DB_OPT`

12.2.3 SAP applications security levels

You can choose from three security levels based on your system requirements. Typically, application development environments have four application phases: development, consolidation, test, and production. ABAP programs are generated in the development phase, consolidated from multiple developers, transported to the test phase for testing, and finally transported to the production phase. The Data Services security mechanisms were designed using the SAP application paradigm. The following table displays the various authorization levels and application phases.

User	Authorization level	Application phase
DEVUSER	High	Design or Design and Consolidation
TESTUSER	Middle	Test or Consolidation and Test
PRODUSER	Low	Production

A typical application passes through four phases:

1. In the design phase, a high-security profile user designs the data and work flows, and generates ABAP programs. The ABAP programs are dynamically communicated to SAP and executed.
   After execution, ABAP programs are automatically deleted.
   To do this, the developer must have authorization that could be designated DEVUSER.
2. In the consolidation phase, developers upload generated ABAP programs into their SAP system with predefined program names and preregistered correction numbers. A user in that phase can run these programs with a lower security profile, TESTUSER, for example.
   Consolidation can also occur in the design phase.
   Here TESTUSER can create ABAP programs, install SAP functions, and schedule jobs.
3. In the test phase, the Data Services repository must be exported to a new repository, and the generated ABAP programs must be transported to the SAP test system. This is usually performed by TESTUSER.
4. The production phase begins when no additional program modifications are required.
   The user involved in the move to the production phase has the lowest security profile. The user in this phase could be called PRODUCER.

SAP authorization can be managed in two ways:

1. Profile generation method
   Every user is assigned to activity groups. Each activity group contains information about allowed activities (such as transaction and menu path). Only users with an activity authorization can perform that activity.
2. Profiles assigned to users method
   Every profile contains authorizations. The user administrator creates new authorizations, assigns them to profiles, and assigns profiles to users.

Data Services provides various authorization choices to meet your organization's needs:

- Some organizations use DEVUSER during all the application phases.
- Others do not want to assign DEVUSER authorization, which requires a high security profile, to any individual. In Data Services you can use the TESTUSER authorization to:
  - Generate ABAP on the development system
  - Upload it to SAP, then execute
- PRODUSER typically has the lowest authorization. This user can usually only execute ABAP programs to which TESTUSER has been granted authorization.

Data Services provides the checking mechanisms necessary to prevent unauthorized users from executing Data Services-generated programs in your SAP system. If you specify a security profile in SAP datastores (see *Defining SAP Applications datastores* [page 2438]), Data Services verifies authorization before executing the program.

If you do not specify a security profile, the Data Services programs do not perform a security check prior to execution.

12.2.4 SAP user authorizations

This section describes how to define a profile using the profile generation method and the specific user authorization level method. It also lists recommended SAP applications security profiles and authorizations for using Data Services.

12.2.4.1 Creating an SAP applications profile using profile generation

1. Create a user (for example for SAP DEV, TEST, or PRD systems).
2. Open the SAP Profile Generator (transaction PFCG).
3. Create an Activity group or Role.
4. Enter a description for the role.
5. Go to the *Authorizations* tab and click *Change authorization data*.
6. On the *Change Role: Authorizations* screen, click the *Manually*, toolbar icon.
7. The *Manual Selection of Authorizations* window opens.
8. Enter the required authorizations for this role.
9. Click *OK*
10. Return to the *Change Role: Authorizations* screen.
11. Manually configure components by entering the values documented in the section *Authorizations for Data Services* [page 2423].
12. To complete the security profile, click the *Back* icon (or press F3), select the *User* tab, enter your SAP user ID for Data Services, and click the *Save* icon.

12.2.4.2 Defining a Data Services-specific authorization level

1. Determine which SAP profile you need.

   Required profiles depend on how you use Data Services. See *SAP application profiles* [page 2421].
2. In SAP, create the required authorizations for your profiles.

   The required authorizations for your profiles are listed in *SAP application profiles* [page 2421]. Settings for each authorization are listed in *Authorizations for Data Services* [page 2423].
3. Create an SAP profile.

   For example, you might create a profile specific to developing applications in Data Services: DS_DEV.
4. Assign the SAP authorizations to the SAP profile.
5. Assign the profile to an SAP user for Data Services.

12.2.4.3 SAP application profiles

How you use Data Services determines the profiles you need to define:

- Development and test profile
- Production profile

For information about the SAP BW loading profile, see *SAP NetWeaver BW loading profile* [page 2512].

12.2.4.3.1 Development and test profile

To support development and test, create an SAP profile such as DS_DEV, that defines authorizations for DEVUSER or TESTUSER. This profile requires the following authorizations.

- S_BTCH_JOB
- S_DEVELOP
- S_RFC
- S_TABU_DIS
- S_TCODE

Related Information

Authorizations for Data Services [page 2423]

12.2.4.3.2 Production profile

To support production, create an SAP profile such as DS_PROD that defines authorizations for PRODUSER. This profile requires the following authorizations:

- S_BTCH_JOB
- S_RFC
- S_TABU_DIS
- S_TCODE

Related Information

Authorizations for Data Services [page 2423]

12.2.4.4 Development versus production functions

User permissions differ between development and production environments. A user with S_DEVELOP authorization can execute any function. If that authorization isn't present, the ABAP code checks the authorization object ZSDS.

Note that you can create custom authorization checks for any function by modifying the sample ABAP code in the shipped file sample_badi_impl.txt (admin\R3_Functions\ManualInstall).

12.2.4.4.1 Development-only functions

The following functions should be used only in development environments, not on production systems:

/BODS/AUTH_IMPORT

/BODS/EXTRACTOR_IMPORT

/BODS/FUNCTION_GET

/BODS/IDOC_IMPORT

/BODS/RFC_ABAP_INSTALL_AND_RUN

/BODS/TABLE_IMPORT

/BODS/TREE_IMPORT

/BODS/TREE_IMPORT40

/BODS/UPLOAD

12.2.4.4.2 Production functions

If the system is not a development system, then the user can only execute the following limited set of functions.

/BODS/BW_QUERY

/BODS/EXTRACTOR_NAVIGATE

/BODS/EXTRACTOR_SEARCH

/BODS/FILE_ROWCOUNT

/BODS/GET_VERSION

/BODS/IDOC_SEARCH

/BODS/JOB_LOG

/BODS/JOB_STATUS

/BODS/MODEL_NAVIGATE

/BODS/READ_TEXT

/BODS/SYNTAX_CHECK

/BODS/TABLE_SEARCH

/BODS/TEXTS

/BODS/TREE_NAVIGATE

/BODS/TREE_NAVIGATE40

/BODS/TREE_SEARCH

/BODS/TREE_SEARCH40

/BODS/COLUMN_SEARCH

/BODS/ABAP_RUN

/BODS/JOB_RUN

/BODS/RFC_READ_EXTRACTOR

/BODS/RFC_READ_TABLE

/BODS/RFC_READ_TABLE2

/BODS/RFC_READ_TABLE_FILE

/BODS/TREE_PROF

/BODS/DATA_PROFILE

/BODS/RFC_STREAM_READ_TABLE

12.2.4.5 Authorizations for Data Services

This section describes the authorizations that support Data Services operations.

For improved security, avoid using wildcards, generic, or blank values for authorization fields, especially in a production environment. Enter more specific values that are appropriate to your business applications.

12.2.4.5.1 Open Hub

The necessary authorizations to use the Open Hub interface in Data Services are contained in the S_BI-WHM_RFC profile.

In addition, Data Services needs the following authorization to work with the Open Hub interface:

S_RFC_ADM

Purpose: This object includes authorization checks for accessing individual administration functions in transaction SM59

Use: DEV, PROD

Class: Cross-application Authorization Objects

Text (Description): Administration for RFC Destination

Field	Values
Activity	03
RFCTYPE	T
RFCDEST	List of RFC destinations the user is allowed to access
ICF_VALUE	Authorizations for destination in transaction SM59

12.2.4.5.2 G_800S_GSE

Purpose: This authorization allows Data Services to access ERP hierarchies.

Use: DEV, PROD

Text (Description): Special Purpose Ledger Sets: Set

Class: Financial Accounting

Field	Values
Authorization group	Not used
Activity	03

12.2.4.5.3 S_BTCH_ADM

Purpose: This authorization checks background processing privileges.

Use: DEV, PROD

Text (Description): Background Processing: background Administrator

Class: Basis

Field	Values
Background administrator ID	Y

12.2.4.5.4 S_BTCH_JOB

Purpose: This authorization checks batch job release privileges.

Use: DEV, PROD

Text (Description): Batch processing

Class: Basis

Field	Values
Job operation	RELE
Summary of jobs for a group	Not used

12.2.4.5.5 S_CTS_ADMI

Purpose: This authorization allows Data Services to perform CTS operations.

Use: DEV

Text (Description): Administration Functions in Change and Transport System

Class: Basis: Administration

Field	Values
Administration Tasks for Change and Transport System	PROJ

12.2.4.5.6 S_DEVELOP

Data Services uses the S_DEVELOP authorization in several ways.

Purpose: This implementation allows Data Services to perform a column search.

Use: DEV, PROD

Text (Description): ABAP Workbench

Class: Basis - Development Environment

Field	Values
Package	List of packages for tables that a user is allowed to access
Object type	TABL
Object name	List of tables that a user is allowed to access
Authorization group ABAP/4 program	Not used
Activity	03

Purpose: This authorization allows Data Services to run generated programs on the SAP server.

Use: DEV

Text (Description): ABAP Workbench

Class: Basis - Development Environment

Field	Values
Package	$TMP
Object type	PROG
Object name	List of temporary program names that are allowed to be generated
Authorization group ABAP/4 program	Not used
Activity	01 and 02

Purpose: This implementation allows Data Services to import a table or to search for a table.

Use: DEV, PROD (table search)

Text (Description): ABAP Workbench

Class: Basis - Development Environment

Field	Values
Package	List of packages for tables that a user is allowed to access
Object type	VIEW, TABL and TTYP
Object name	List of tables and views that a user is allowed to access
Authorization group ABAP/4 program	Not used
Activity	03

12.2.4.5.7 S_IDOCDEFT

Purpose: This authorization allows Data Services to work with IDocs.

Use: DEV, PROD

Text (Description): WFEDI: S_IDOCDEFT - Access to IDoc Development

Class: Basis - Central Functions

Field	Values
Activity	03
Extension	Not used
Basic type	Not used
Transaction Code	WE30

12.2.4.5.8 S_RFC

Purpose: This authorization allows users to execute remote functions on an SAP server.

Use: DEV, PROD

Text (Description): Authorization check for RFC access

Class: Cross-application authorization object

Field	Values
Activity	16
Name of RFC to be protected	BAPI, CADR, RFC1, SCAT, SDIF, SLST, SUNI, SUTL, SDTX, SYST, /BODS/BODS, RSAB, SDIFRUNTIME, and any other required function group
Type of RFC object to be protected	FUGR

12.2.4.5.9 S_RFC_ADM

Purpose: This authorization is required for RFC streaming

Use: DEV, PROD

Text (Description): Administration for RFC Destination

Class: Cross-application

Field	Values
Activity	03
Type of Entry in RFCDES	Not used
Logical Destination (Specified in Function Call)	RFC destination
Internet Communication Framework Values	Not used

12.2.4.5.10 S_RO_OSOA

Purpose: This authorization checks DataSource access prvileges.

Use: DEV, PROD

Text (Description): SAP DataSource Authorizations

Class: BW Service API

Field	Values
Activity	03
DataSource (OSOA/OSOD)	DataSource for data extraction
Application Component of a DataSource (OSOA/OSOD)	Not used
Subobject for DataSource	DATA

12.2.4.5.11 S_RS_ADMWB

Purpose: Use this authorization for BW loading.

Use: DEV, PROD

Text (Description): Administrator Workbench - Objects

Class: Business Warehouse

Field	Value
Administrator Workbench object	WORKBENCH, SOURCESYS, APPLCOMP, INFOAREA, INFOOBJECT, INFOPACKAG, ODSOBJECT
Activity	03

Related Information

SAP NetWeaver BW as a target [page 2512]

12.2.4.5.12 S_RS_ICUBE

Purpose: This authorization allows Data Services to access an InfoCube.

Use: DEV, PROD

Class: Business Information Warehouse

Text (Description): Data Warehousing Workbench - InfoCube

Field	Values
InfoArea	List of InfoAreas that a user is allowed to access
InfoCube	List of InfoCubes that a user is allowed to access
InfoCube Subobject	DEFINITION
Activity	03

12.2.4.5.13 S_RS_ODSO

Purpose: This authorization allows Data Services to access a DataStore Object.

Use: DEV, PROD

Text (Description): Data Warehousing Workbench - DataStore Object

Class: Business Information Warehouse

Field	Values
InfoArea	List of InfoAreas that a user is allowed to access
DataStore Object	List of DataStore Objects that a user is allowed to access
Subobject for ODS Object	DEFINITION
Activity	03

12.2.4.5.14 S_SCRP_TXT

Purpose: This authorization allows Data Services to read SAP texts.

Use: DEV, PROD

Text (Description): SAPscript: Standard text

Class: SBOP Data Services Authorization Object

Field	Values
Language Key	List of language keys that a user is allowed to access
Text ID	List of text IDs that a user is allowed to access
Name	List of text names that a user is allowed to access
Activity	SHOW

12.2.4.5.15 S_TABU_DIS

Purpose: This authorization allows Data Services to access table data in an SAP system.

Use: DEV, PROD

Text (Description): Table Maintenance (via standard tools such as SM30)

Class: Basis

Field	Value
Activity	03
Authorization group	Table groups that a user is allowed to access

12.2.4.5.16 S_TCODE

Data Services uses the S_TCODE authorization in several ways.

Purpose: This authorization grants the user access to specific transactions.

Text (Description): Authorization check for transaction start

Class: Cross-application authorization object

Field	Value
Transaction Code	SE37, SE38, SU53

Purpose: This authorization allows Data Services to execute functions in the Data Warehousing Workbench.

Use: DEV, PROD

Text (Description): Transaction Code Check at Transaction Start

Class: Cross-application Authorization Objects

Field	Values
Transaction Code	RSA1

In addition, you should have access to the contents of the following tables:

RSDAREA

RSDAREAT

RSDCUBE

RSDCUBET

RSDODSO

RSDODSOT

12.2.4.5.17 S_TRANSPRT

Purpose: This authorization allows Data Services to access the Transport Organizer.

Use: DEV

Text (Description): Transport Organizer

Class: Basis - Development Environment

Field	Values
Request Type (Change and Transport System)	DTRA
Activity	01

12.2.4.5.18 S_USER_GRP

Purpose: This authorization allows Data Services to establish a connection to the SAP server.

Use: DEV, PROD

Text (Description): User Master Maintenance: User Groups

Class: Basis: Administration

Field	Values
User group in user master maintenance	User group for Data Services user

12.2.4.5.19 S_USER_PRO

Purpose: This authorization allows Data Services to import an authorization profile.

Use: DEV

Text (Description): User Master Maintenance: Authorization Profile

Class: Basis: Administration

Field	Values
Auth. profile in user master maintenance	Authorization Profile to be imported
Activity	03

12.2.4.5.20 ZDSAUTH

Purpose: This authorization gives a user an access to Data Services functions.

Use: DEV, PROD

Text (Description): SBOP Data Services - general authorization

Class: SBOP Data Services Authorization Object

Field	Values
ACTVT: Activity	16 (Execute)

12.2.4.5.21 ZDSDEV

Purpose: This is the general authorization object (Data Services-specific version of S_DEVELOP).

Use: DEV, PROD

Text (Description): SBOP Data Services Authorization Object for development

Class: SBOP Data Services Authorization Object

Field	Values
Package	List of packages for tables that a user is allowed to access
Object type	VIEW, TABL, and TTYP
Object name	DD objects that a user is allowed to access
Authorization group ABAP/4 program	Not used
Activity	03

12.2.4.5.22 ZPGMCHK

Purpose: This authorization determines which programs may execute in a production environment.

Use: PROD

Text (Description): SBOP Data Services Authorization Object for program names

Class: SBOP Data Services Authorization Object

Field	Values
ACTVT: Activity	16 (Execute)
PROGRAM: ABAP program name	Program names that are allowed to be executed in a production environment

12.2.4.5.23 ZSDS

Purpose: This authorization lets you to define whether the SAP system should be treated as a development or production system from the perspective of Data Services.

Use: DEV, PROD

Text (Description): Data Services Authorization Object for functions

Class: SBOP Data Services Authorization Object

Field	Values
ACTVT	Not used
ZSYSTYPE	D: Development system Any other value: Production system

12.2.4.5.24 Browsing metadata for an SAP BW source datastore

In addition, if you need to be able to browse metadata for an SAP BW source datastore, you should have access to the contents of the following tables:

RSDAREA

RSDAREAT

RSDCUBE

RSDCUBET

RSDODSO

RSDODSOT

12.3 Enabling security between SAP and Data Services

12.3.1 Authentication using Secure Network Communications (SNC)

Enabling SNC provides a secure connection between SAP systems and Data Services.

This procedure describes how to configure Authentication using SNC between Data Services clients for secure communications from SAP systems.

For more information about SNC security, on the SAP Service Marketplace see the *SNC User's Guide* at *https://service.sap.com/~form/sapnet?_SHORTKEY=00200797470000074724*.

1. In Data Services, verify installation of a 64-bit SNC library.
2. Complete the procedure "Configuring the Use of the SAP Cryptographic Library for SNC" including creating a trusted certificate. This document is available on the SAP Service Marketplace Web site at *https://service.sap.com/~form/sapnet?_SHORTKEY=00200797470000074724*.
3. Add or open the datastore editor to configure and click *Advanced* to display the *Authentication* options. For *Authentication*, select *SNC*. Complete the remaining SNC options as applicable.

Related Information

Datastore [page 2531]
Secure Network Communications (SNC) in BW [page 2436]

12.3.2 Security between SAP BW and the Data Services RFC server

Data Services provides two separate options for enabling security between SAP BW and the Data Services RFC server.

- Access Control List (ACL): ACL security authorizes user access permissions to Data Services repositories through the SAP BusinessObjects Central Management Server.
- Secure Network Communications (SNC): SNC provides a secure connection between SAP BW and the Data Services RFC server.

Sample usage scenarios:

- In a private network where the SAP user's identity must be verified to access a Data Services repository, implementing the ACL option is sufficient.
- In a public network but with trusted SAP users, implemeting the SNC option is sufficient.
- In a public network where the SAP user's identity must be verified to access a Data Services repository, implement both the ACL and SNC options.

For more information about SAP security, on the SAP Service Marketplace Web site see *https://service.sap.com/security*.

12.3.2.1 Access Control List (ACL)

Enabling ACL security authorizes and authenticates users for access to Data Services repositories from SAP BW using the SAP BusinessObjects Central Management Server (CMS). The interface for the CMS is the Central Management Console (CMC). For help using the CMC, after logging in click the question mark icon.

This procedure also includes configuration steps in the SAP BW system and in the Data Services Administrator.

1. In the CMC, authenticate the SAP BW system as follows:

a) Select the *Authentication* management area from the drop-down list.

b) Double-click the *SAP* object to open it.

c) On the *Entitlement Systems* tab, select the system to authenticate and click *Update*.

d) On the *Role Import* tab, add the SAP role(s) to import (that correspond to the Data Services repositories you want to secure) and click *Update*.

e) On the *User Update* tab under *Update Roles and Aliases*, click *Update Now* to import the users associated with the imported SAP roles.

> **Note**
>
> You can also select *Schedule* to schedule regular updates to the user list.

f) Close the dialog box.

To ensure the SAP roles and users have been imported, select the CMC *Users and Groups* management area. Select the *User List* and *Group List* (or *Group Hierarchy*) nodes to view the imported users and roles. *Roles* are referred to as *groups* in the CMC.

2. In the CMC, set group and user rights for access to Data Services repositories as follows:

a) Select the *Data Services* management area from the drop-down list.

b) Open (double-click) the repository to configure.

c) Select *User Security*.

d) Click *Add Principals*.

e) Select the user or group to configure and click *Add and Assign Security*.

f) On the *Access Levels* tab, assign the desired access level(s) and click *Apply.*

g) To add or remove rights for principals, click the *Advanced* tab > *Add/Remove Rights*. You can grant only the following general global rights for Data Services:

Delete objects: Delete objects only

Edit objects: Edit, delete, or view objects

View objects: View objects only

h) To grant a principal the right to execute batch jobs in Data Services, select the *Applications* managemant area and open the *Data Services Application* object. Repeat steps 2c through 2g, except on the *Add/ Remove Rights* dialog box, you can grant the specific right *Execute batch job*.

3. In the SAP BW system, configure the profile parameters login/create_sso2_ticket=2 and login/ accept_sso2_ticket=2. You can use transaction rz11. See the *Maintain profile parameters* > *Profile parameter maintenance* interface.

For more information, refer to the procedure "Changing Profile Parameters for SSO" on the SAP Help Portal at *http://help.sap.com/saphelp_nw70/helpdata/en/45/590250736a6628e10000000a1553f6/frameset.htm*.

4. In the SAP BW system, configure RFC destination authentication as follows:

a) Use transaction sm59 to access RFC Destinations.

b) Expand *TCP/IP connections*.

c) Open the RFC destination to configure.

d) On the *Logon and Security* tab, select *Send Assertion Ticket*.

The assertion ticket contains user authentication information.

e) Save the configuration.

5. In the Data Services Administrator, enable ACL security as follows:

a) Configure the RFC server if you haven't already.

Navigate to *SAP Connections* > *RFC Server Interface* > *RFC Server Interface Configuration* > *Add*. For more information, see the Data Services *Management Console Guide*.

b) On the RFC Server Configuration page, expand the *Server security* node and select the *Enable ACL check* box.

Related Information

Secure Network Communications (SNC) in BW [page 2436]

12.3.2.2 Secure Network Communications (SNC) in BW

Enabling SNC provides a secure connection between SAP BW and the Data Services RFC server.

This procedure describes how to configure SNC between SAP BW and the Data Services RFC server for jobs that are launched from SAP BW.

1. In Data Services, verify installation of a 64-bit SNC library.
2. Complete the procedure "Configuring the Use of the SAP Cryptographic Library for SNC" including creating a trusted certificate. This document is available on the SAP Service Marketplace Web site at *https://websmp207.sap-ag.de/~form/sapnet?_SHORTKEY=00200797470000074724*.
3. Taking the results from the procedure in step 2, navigate to the Data Services Administrator *RFC Server Configuration* page to enable SNC security (*SAP Connections* > *RFC Server Interface* > *RFC Server Interface Configuration* and select the server name):
   a) Expand the *Server security* node.
   b) Select *Enable SNC*.
   c) Enter the *Server SNC name*.
   d) Enter the *SNC library path*.
   e) Select the desired *SNC quality of protection* from the drop-down list.

Related Information

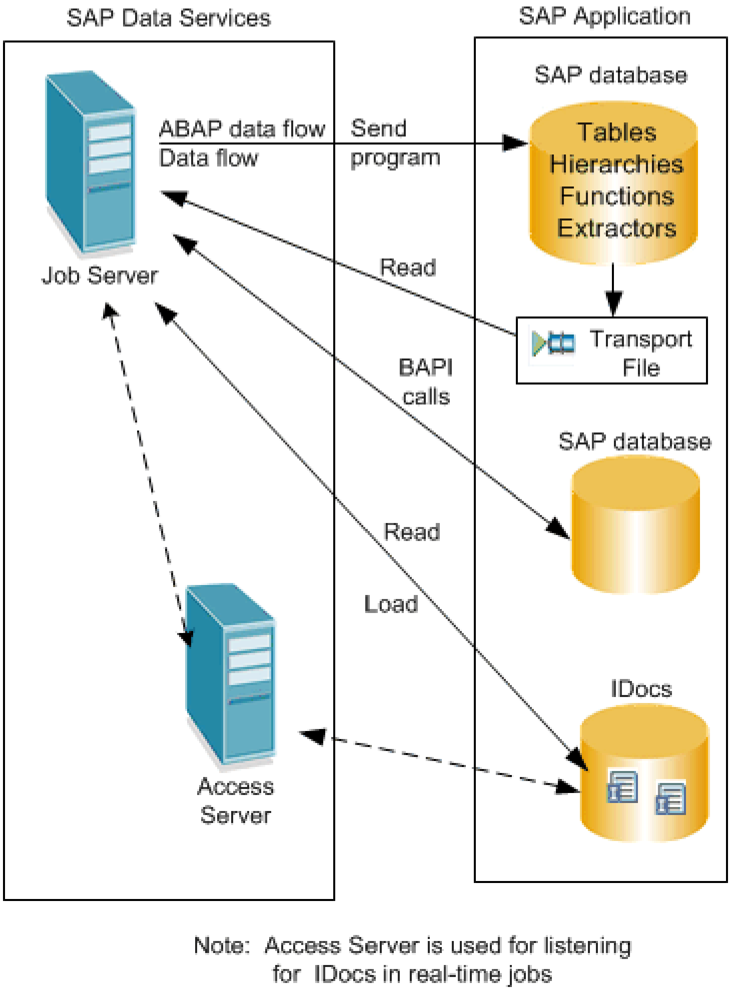
Access Control List (ACL) [page 2434]
Authentication using Secure Network Communications (SNC) [page 2433]

12.4 Connecting to SAP Applications

Data Services provides several methods for moving data into and out of SAP applications:

Application	Description
Streaming data from SAP using RFC	Reads data from SAP applications using regular data flows and supports tables and ODP sources.
ABAP programming language	Reads data from SAP applications using ABAP data flows and supports tables, hierarchies, ODP sources, and functions with scalar arguments.
RFC/BAPI	Loads data to SAP applications and allows direct access to application tables outside of the data flows through RFC function calls. Because a function is handled as a nested column within a query, it can return SAP tables, structures, or scalar parameters, which can be loaded into any target. Data Services can process any RFC-enabled function call including all available parameters plus user-supplied functions. These functions are often used to write certain information into an SAP system or read data that has to be calculated by the function.
IDoc interface	Reads from and loads data to SAP applications. Data Services can send, receive, and create SAP IDocs including extended and custom IDocs and supports reduced input sets, parallel processing, real-time, and batch processing.

The following diagram shows a high-level overview of the components involved with reading data from and loading data to SAP applications.



You can search an SAP application server for tables, IDocs, functions, hierarchies, and ODP sources. You import metadata using an SAP Applications datastore connection.

Once you have imported metadata, Data Services provides:

Objects	Description
ABAP data flows	Move table and hierarchy data between SAP applications and Data Services using ABAP.
Data flows in batch jobs	Can contain ABAP data flows (as sources), tables, hierarchies, and ODP objects (as sources), or IDocs (as sources or targets), and SAP RFC-enabled functions.
Data flows in real-time jobs	Can contain SAP tables, IDocs as sources and targets, and RFC-enabled functions.

12.4.1 SAP Applications datastores

This section discusses the steps required to use an SAP application as a Data Services data source:

- Defining SAP Applications datastores
- Browsing, searching, and importing metadata from SAP applications

12.4.1.1 Defining SAP Applications datastores

An SAP application datastore includes the following information:

- Connection information including the application server name, the language used by the SAP client application, the client and system numbers, and optionally reference to an sapnwrfc.ini file.
  You supply these values based on your installation of the SAP application.
- Data transfer method used to exchange information between Data Services and the SAP application.
  Select the method and supply the appropriate information based on decisions you make about running Data Services jobs.
- Security information, specifically the SAP security profile to be used by all connections instigated from this datastore between Data Services and the SAP application. You supply a security profile based on your installation of the SAP application.

Related Information

Data transfer methods [page 2479]
SAP applications security levels [page 2419]

12.4.1.1.1 To define an SAP Applications datastore

1. In the object library, select the *Datastores* tab.
2. Right-click inside the object library window and choose *New*.

   The datastore editor opens.
3. Enter a unique name for the datastore in the *Datastore name* box.

   The name can contain alphanumeric characters and underscores. It cannot contain spaces.
4. For *Datastore type*, select *SAP Applications*.
5. Enter the *Application server* name.
   Refer to your SAP documentation for the appropriate syntax.
6. Enter the *User name* and *Password* information.
7. You can either save the datastore or add more information to it:
   - To save the datastore and close the Datastore Editor, click *OK*.
   - To add more parameters, click *Advanced*.
     To enter values for each configuration option, click the cell next to each configuration name. For details, see the *SAP Data Services Reference Guide*.

Related Information

Datastore [page 2531]

12.4.1.1.2 Using the sapnwrfc.ini file

To change or add parameters without modifying the datastore settings, you can specify them in an `sapnwrfc.ini` file.

Place your sapnwrfc.ini file in the same directory as the RFC client/server program (for Data Services, commonly `%LINK_DIR\bin`). Or you can specify the DS_NWRFC_INI environment variable in the operating system. For example, you could can place the sapnwrfc.ini file in `C:\Temp` and specify `DS_NWRFC_INI=C:\Temp`.

You can specify an `sapnwrfc.ini` file for two different applications in Data Services:

- To use an sapnwrfc.ini file to override datastore settings, edit the SAP datastore in the Designer. From the object library, open the editor for the SAP datastore to configure and click *Advanced*. Under the *SAP* option category, for *Use sapnwrfc.ini*, select *Yes* and enter the appropriate *Destination name*.
- To use an sapnwrfc.ini file for real-time IDocs, configure the RFC client in the Administrator. Expand the *Real-Time* node, and for the Access Server to configure, click *Client Interfaces*. Open an instance of the RFC client, and select the check box to *Use sapnwrfc.ini* and enter a destination name.

> i Note
>
> Data Services ignores the parameters USER, PASSWD, and CLIENT in sapnwrfc.ini because storing these security-related parameters could introduce a security risk.

For more information about how to use the `sapnwrfc.ini` file, refer to the SAP documentation at *http://help.sap.com/saphelp_nwpi711/helpdata/en/48/ce50e418d3424be10000000a421937/frameset.htm*.

12.4.1.1.3 SAP security profiles

You can associate a security profile with a datastore so that data flows that access SAP application sources defined by the datastore include appropriate authorization checking.

SAP security profiles are useful for:

- Creating profiles of users that can access particular ABAP programs
- Moving ABAP programs from development to test and production

Specify a security profile in the Advanced options in the datastore editor. By default, Data Services does not use any SAP security profile.

Specify any security profile defined in SAP (a predefined profile or a profile you defined). Authorization checks are embedded in generated ABAP code.

Related Information

SAP user authorizations [page 2420]

12.4.1.2 Browsing, searching, and importing metadata from SAP applications

The processes for browsing, searching, and importing metadata from SAP applications are similar to the processes you would use for any source system.

There are several types of SAP objects for which you can import metadata into the Data Services object library. You can import metadata for each one by name. You can import metadata for hierarchies, IDocs, and tables by searching. You can also browse SAP applications to find hierarchies and tables.

SAP item	Methods for importing metadata
Functions	Name
Hierarchies	Name, search, browse
IDocs	Name, search
Tables	Name, search, browse
ODP sources	Name, search, browse

12.4.1.2.1 Importing metadata by name

1. In the object library, select the *Datastores* tab.
2. Right-click the SAP Applications datastore you want to use, and select *Import by Name*.
   The *Import by Name* window opens.
3. In the *Type* box, select the SAP item to import.
4. In the *Name* box, enter the name SAP uses for the item you want to import. For example, enter **`SISC001`** for an IDoc.

   > i Note
   >
   > Hierarchies require entering a controlling area and set table.

5. Click *OK*.

12.4.1.2.2 Importing table and hierarchy metadata by browsing

Tables and hierarchies can be imported by browsing the data available through the SAP datastore.

For more information about importing SAP application hierarchies, see *Extracting data from SAP application hierarchies* [page 2456].

To import table and hierarchy metadata by browsing:

1. In the object library, click the *Datastores* tab.
2. Right-click the datastore you want to use, and choose *Open*.
   The items already imported from the datastore appear in the workspace.
3. Click *External Data*.

   Click the plus sign next to a folder icon to navigate the structure of tables or hierarchies. Tables appear with a table icon.

   Hierarchies are also nested according to their use in SAP.
4. Select the items for which you want to import metadata.

   For example, to import a table, you must select a table rather than a folder that contains tables. To import a hierarchy, select the hierarchy group that contains the hierarchy.
5. Right-click and choose *Import*.
6. In the object library, expand the datastore to display the list of imported objects.

12.4.1.2.3 Importing IDoc metadata using the Search option

To use IDocs, you must first import the metadata from SAP into your repository. IDocs can be imported by name or by using the Search option.

1. In the object library, click the *Datastores* tab.
2. Right-click an SAP Applications datastore and select *Search*.
   The *Search* window opens.
3. Verify the datastore or repository in which to search displays in the *Look in* box, select *External data*, and for *Object type* select *IDocs*.
4. Enter search text in either the *Name* or *Description* box:
   - In the *Name* box enter the name or part of the name of the IDoc you want to find.
   - In the *Description* box, enter a full or partial description instead of the name.
5. Click *Search*.
   A list of objects appears in the window.
6. Right-click the name of the IDoc you want to import, and choose *Import*.

   The IDoc appears in the object library under its datastore and under the IDoc category.

   Data Services imports the schema for the IDoc type, maintaining hierarchical relationships among the data fields. Double-click the IDoc type in the object library to display the IDoc schema.

12.4.1.2.3.1 Adding an IDoc to a job

1. Select an imported IDoc from the object library.
2. Drag the IDoc into a data flow.
3. Select an appropriate option from the pop-up menu: *Make IDoc file source*, *Make IDoc file target*, *Mark IDoc message source*, or *Make IDoc message target*.

12.4.2 Reading from SAP ODP sources

This section describes how to browse, import, and read from SAP ODP sources.

Data Services can read from ODP sources in the following ways:

Method	Description
ODP data sources	Refers to ODP sources that use the Operational Data Provider data replication API (ODP data replication API). In Data Services, you can browse the hierarchy of applications. Data Services supports all types supported by the ODP data replication API in addition to changed-data capture (CDC) functionality (referred to as “delta” in SAP applications).
Native	Refers to extractors that do not use the ODP data replication API. Data Services supports the TRAN and ATTR types only, and changed-data capture is not available.

Related Information

ODP source [page 2557]

12.4.2.1 Browsing ODP sources

Use an SAP Applications datastore to connect to the ODP source. Then in the object library on the *Datastores* tab, right-click the datastore and click *Open* (or double-click the datastore) to view the datastore explorer.

With *External Metadata* selected, expand the ODP node to display the available ODP sources organized in following subfolders:

Folder	Description
All	Displays an alphabetical list of all ODP sources
By Application	Displays the ODP sources hierarchically by application and type

Related Information

To define an SAP Applications datastore [page 2439]

12.4.2.2 Importing ODP source metadata

You can import ODP source by name, by browsing, or by searching.

To import by browsing, in the datastore explorer with *External Metadata* selected, right-click an ODP source and click *Import*.

In the dialog box, enter a unique combination for *Name of consumer* and *Name of project* to identify the subscription for this ODP source.

- *Name of consumer*: Use a system name such as “Data Services”.
- *Name of project*: For a given consumer (such as “Data Services”), you have the option of creating several independent subscriptions. For example, you might want to access the same DataSource in full or changed-data capture (delta) mode with different selection criteria. Therefore, enter a unique project name here to identify this subscription.

For example, for the *Name of consumer* “Data Services” and *Name of project* “Extraction for Data Warehouse 1”, you might create initial (full) and CDC data flows for a customer dimension table. Both data flows would use this same instance (subscription) of the ODP source. But for a second project that loads another data warehouse, you could import the ODP source a second time using the same consumer name but a different project name such as “Extraction for Data Warehouse 2” to make the two subscriptions independent.

For the *Extraction mode* options, if the ODP source is not delta-enabled in the SAP system, the only option is to import the ODP source in *Query* mode. These ODP sources do not support changed-data capture. In Query mode, the ODP source returns all data and pushes down WHERE clauses.

If the ODP source is delta-enabled, *Changed-data capture (CDC)* is the default extraction mode. Here you can optionally configure changed-data capture (delta) parameters as described in the next section.

To import multiple ODP sources, Ctrl-click the ODP source, right-click, and click *Import*. You can choose between *Changed-data capture* or *Query* mode for this set of ODP sources. In this case, configuration details for changed-data capture (CDC) are not available, but you can configure them for each ODP source after importing.

After importing the ODP source, you can also view properties such as the ODP source type by right-clicking the object in the object library and clicking *Properties*. To view column properties, open the ODP source, right-click a column name, and select *Properties*.

Related Information

Browsing, searching, and importing metadata from SAP applications [page 2440]

12.4.2.3 Capturing changed data

Data Services supports changed-data capture (CDC) for ODP sources enabled with the Operational Data Provider (ODP) data replication API. You can configure different CDC options in several places:

- When importing or reimporting the ODP source metadata from the datastore explorer
- On the ODP source object properties *Extraction process* tab
- After importing the object into a data flow, in the object's source properties

12.4.2.3.1 Importing for CDC

When you import an ODP data source, the *Importing (ODP source name) ODP source* dialog box displays. Define the subscription by entering a *Name of consumer* and a *Name of project*.

To optionally configure CDC for the ODP source during import:

1. Verify that the Extraction mode *Changed-data capture (CDC)* is selected.
   The table for defining CDC filters is enabled.
2. For each filter, select a *Field name* using the drop-down box in the first cell.
3. The comparison operators include:
   - Equals
   - Contains pattern
   - Between
4. Enter value(s) in the *From* and (optionally) *To* fields.
   Values are constant literals and cannot be variables or expressions.
5. Repeat the *Field name*, *Sign*, *Comparison*, and *From/To* selections for each filter.
6. Click *Import*.

The object imports with a name of the format `<ExtractorName_NameofProject>`.

When reimporting an ODP source (right-click the object name and select *Reimport*), you can also change the CDC filters at that time (however at that time the name fields cannot be changed).

Related Information

Importing ODP source metadata [page 2443]

12.4.2.3.2 Editing CDC filters

After importing the ODP source, you can also edit the CDC filters in the object properties.

1. In the object library, right-click the ODP source name and select *Properties*.
2. Select the *Consumer details* tab.
   The *Name of consumer* and *Name of project* fields cannot be changed.
3. Edit the *Field name*, *Sign*, *Comparison*, *From*, and *To* values for each filter.
4. Click *OK*.

If you change the filter properties for an ODP source, “reset” the job by running it with the source option *Initial load* selected. Then you can run the job with CDC filters applied (with *Initial load* cleared).

12.4.2.3.3 CDC columns

The import operation adds the following columns to the original table:

Column name	Description	Source
DI_SEQUENCE_NUMBER	Contains an integer for sequencing.	Data Services
DI_OPERATION_TYPE	Contains the row operation type: I (insert), D (delete), X (unknown)	Data Services
ODQ_CHANGEMODE	For CDC, identifies the row type. Works in conjunction with ODQ_ENTITYCNTR to determine how to handle the row. C (create), U (update), D (delete)	SAP
ODQ_ENTITYCNTR	For CDC, an integer that works in conjunction with ODQ_CHANGEMODE to determine how to the handle row.	SAP

The following table describes the relationships between ODQ_CHANGEMODE and ODQ_ENTITYCNTR.

CHANGEMODE	ENTITYCNTR	Description
C	+1	The record is new and inserted.
U	+1	The record is inserted.

CHANGE-MODE	ENTI-TYCNTR	Description
		If there is a record with same key already available, the record is updated. In this case, there should be a corresponding U- (short notation for U and -1) record. The record contains the new information.
U	-1	The record is deleted and replaced with the corresponding record with same key and U + (short notation for U and +1) if available. The record contains the previous (old/ outdated) information.
U	0	The record is updated, but the key figures must be added to the already available key figures. So the record returns the difference between the old record and the new record, not the new record itself.
D	-1	The record is deleted. It contains the same key as an already existing record, but the key figures are inverted. So the record might be "deleted" by adding the key figures to the already available values. They should sum up to 0.
D	0	The record is deleted. It contains the actual data in both key and key figures.

12.4.3 Reading from SAP tables

You can use a regular data flow to process large volumes of data from SAP tables.

To improve the performance while reading large volumes of data, the source table editor includes the following options:

- The *Enable partitioning* option allows the software to read R/3 table data using the number of partitions in the table as the maximum number of parallel instances. The *Partition type* option in the *Partition* tab on the *Properties* window for a table must be set to Range or List in order to use the *Enable partitioning* option.
- The *Array fetch size* option allows the data to be sent in chunks, which avoids large caches on the source side.
- The *Execute in background (batch)* option lets you run the SAP table reader in batch mode (using a background work process) for time-consuming transactions.

Related Information

Batch execution mode [page 2488]
Open Hub Table source [page 2565]

12.4.4 ABAP data flow processing

In Data Services, ABAP data flows extract SAP data from tables and follow this general execution process:

- In a development environment, Data Services generates the ABAP code, or in production, the program is uploaded to the SAP server
- Data Services connects to the SAP application server through remote function call (RFC).
- The SAP application server executes the ABAP code.
- The ABAP program results are generated and communicated back to Data Services, which then loads the target data cache.

> **Note**
>
> Some operations such as uploading generated ABAP programs or using the Direct Download data transfer method require interoperability with the SAP GUI. If you experience connection problems with these operations, implement the appropriate Support Package as described in *SAP Note 1258742*, “Starting SAPGUI using external RFC libraries”.

12.4.4.1 ABAP interface objects and options

The following Designer objects and options pertain to SAP.

12.4.4.1.1 Data flow objects

The Data Flows tab of the object library includes both the *Data Flows* and *ABAP Data Flows*.

You can place ABAP data flows into batch jobs as a source. ABAP data flows generate ABAP code. In most cases, you use a data transport object as the target of an ABAP data flow. A data transport specifies a staging file for data extracted from SAP applications.

ABAP data flows and data transport objects also appear in the tool palette.

Related Information

SAP-specific objects [page 2552]

12.4.4.1.2 Data flow commands

With a data flow in the workspace, the following commands appear in the *Validation* menu:

- *Validate* > *Validate ABAP*
  Validates the ABAP code Data Services produces for the data flow
- *Generate ABAP*
  Displays the ABAP generated for the current data flow

12.4.4.1.3 SAP environment options

In the Designer, the following options are available under *Tools* > *Options* > *SAP* > *Environment*.

Option	Description
Maximum number of rows buffered before transfer to Data Services	The maximum number of rows held in the SAP buffer prior to writing to the data transport file. The default value is 5000 rows. This option lets you manage the amount of memory used by generated ABAP programs by selecting the number of rows to write in a given batch. You set this value once and it applies to all SAP application connections initiated by Data Services.
Prefix for ABAP program names	You can define this parameter to separate Data Services-generated ABAP program names from other ABAP program names. Because ABAP program names must begin with a Y or a Z, this option provides a default that begins with ZW. The maximum for this option is two characters.
Convert SAP null to null	Converts NULL values from SAP sources in data flows to database-specific NULL.
Disable background SAP job status in Data Services log	Disables trace log entries when Data Services queries the status of jobs submitted in background (using the datastore option *Execute in background (batch)*).

Related Information

Working with null values from SAP applications [page 2581]

12.4.4.1.4 Data transfer requirements

When you configure SAP Applications datastores in Data Services, you specify the data transfer method. This method defines how data that is extracted by the ABAP running on the SAP application server becomes available to the Data Services server (the computer on which the Data Services Job Server runs). The options are:

Option	Description
RFC	Use to stream data from the source SAP system directly to the Data Services data flow process using RFC.
Direct download	The SAP server transfers the data directly to the *Local directory* using the SAP-provided function GUI_DOWNLOAD or WS_DOWNLOAD.
Shared directory	Default method. The SAP server loads the transport file into the *Working directory on SAP server*. The file is read using the *Application path to the shared directory* from the Job Server computer.

Option	Description
FTP	The SAP server loads the *Working directory on SAP server* with the transport file. Then the Job Server calls an FTP program and connects to the SAP server to download the file to the *Local directory*.
Custom Transfer	SAP server loads the *Working directory on SAP server* with the transport file. The file is read by a third-party file transfer (custom transfer) program and loaded to the *Custom transfer local directory*.

Related Information

Data transfer methods [page 2479]

12.4.4.1.5 SAP applications permissions

Data Services uses different execution methods to execute generated ABAP in design, development, test, and production environments. Each method has different security requirements.

Related Information

SAP applications security levels [page 2419]

12.4.4.1.6 Security profile

ABAP programs generated by Data Services can verify the permissions of the user executing the program. If a security profile is provided, the generated ABAP verifies that the user executing the program has the permissions specified by that profile. This security profile should be transported to the production system prior to running Data Services against it.

12.4.4.2 Data flows

SAP applications commonly consist of three key components:

Component	Description
SAPGUI client	A front-end application that provides a logical view of the entire SAP system

Component	Description
Application layer	An application server that interprets ABAP, SAP's proprietary fourth-generation language, and generates and executes SQL statements against the database
Database layer	A database manager that manages the SAP data in its tables

Interacting directly with the SAP application database layer can be problematic because:

- It is complex.
- The data contained in pool and cluster tables can be accessed only through ABAP, not through SQL.

The Data Services SAP ABAP interface allows you to extract SAP application data, through the application layer, using ABAP. This interface also provides the ABAP data flow and its associated Data Services Designer options. This means that:

- You do not need to understand many of the complexities of the SAP database layer.
- You can use Data Services to access not only transparent tables, but also pool and cluster tables.
- You can call corresponding SAP functions to ensure the results match what SAP would display.

To use an ABAP data flow, create a batch job, create a data flow inside the job, then create an ABAP data flow inside the first data flow. This type of batch job uses the following general execution process:

- Data Services generates the ABAP code.
- Data Services connects to the SAP application server via remote function call (RFC).
- The ABAP code executes on the SAP application server.
- The ABAP program results are generated and communicated back to Data Services, which then loads the target data cache.

Related Information

Designer Guide: Naming data flows [page 281]

12.4.4.2.1 What is an ABAP data flow?

An ABAP data flow extracts and transforms data from SAP application tables, files, and hierarchies. The ABAP data flow produces a data set that you can use as input to other transforms, save to a file that resides on an SAP application server, or save to an SAP table. When Data Services executes ABAP data flows, it translates the extraction requirements into ABAP programs and passes them to SAP to execute.

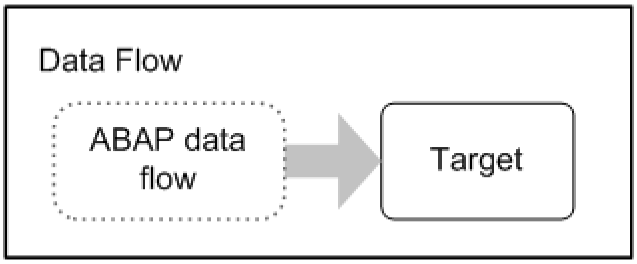
When you plan to use the SAP extracted data outside the ABAP data flow, the ABAP data flow can place the extracted data set in a file. A Data Services data transport passes the data in the file to the parent data flow. A data transport indicates how data is communicated between the SAP application server and Data Services.

When the target inside the ABAP data flow is the final destination for the data, you do not need a data transport. The ABAP data flow stores the data in a file saved on the SAP application server. In this case, the ABAP data flow must be the only object in a data flow.

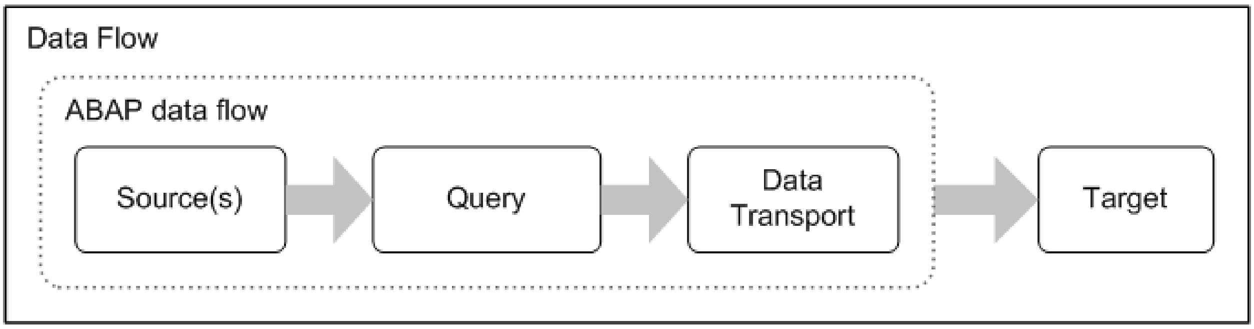
You can also use a data flow to extract data from an SAP table. When you use a data flow, Data Services extracts data from SAP using an RFC (remote function call). However, when you use an ABAP data flow, Data Services extracts data using ABAP and performance is generally better.

Because SAP performs all operations in an ABAP data flow, you want the operations in an ABAP data flow to make best use of SAP system capabilities. Therefore, the preferred method of use involves ABAP.

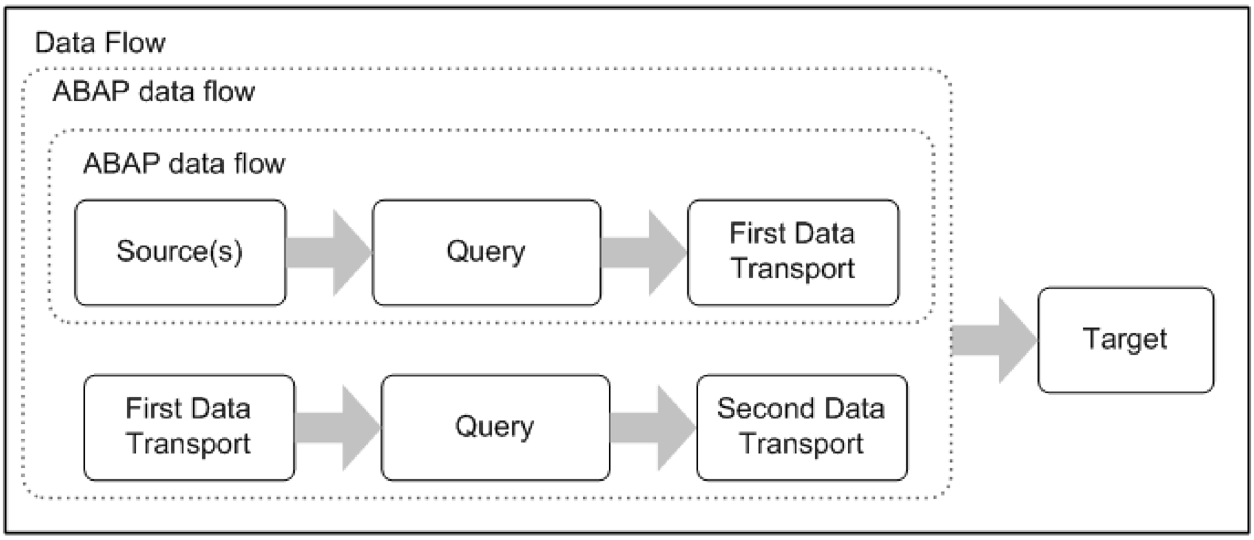
Consider the simple case of extracting data from an SAP application table and loading it into a non-SAP target. The parent data flow contains two objects: an ABAP data flow and a target.



The ABAP data flow defines the specific source tables from which you want to extract data and contains a data transport for the resulting data set.



In some cases, the transformations you need to perform in the SAP application are too complex to include in just one ABAP data flow. For example, the transformation might require multiple passes over the data. Data Services allows you to nest an ABAP data flow inside another ABAP data flow so that you can simplify each data flow. You can keep the output from the inner data flow in a file on the ABAP server and use the file in the outer data flow.



Note

Although ABAP data flows are used in data flows, data flows cannot be placed in ABAP data flows. As shown above, only other ABAP data flows can be placed inside ABAP data flows. Also, ABAP data flows cannot be used as embedded data flows.

12.4.4.2.2 Defining ABAP data flows

This section describes the four procedures to complete when defining an ABAP data flow:

- Creating R/3 data flows.
- Specifying sources
- Defining a query
- Specifying a target

12.4.4.2.2.1 Adding an ABAP data flow

This procedure describes how to first add and configure the data flow that will contain the ABAP data flow.

1. In the workspace, add a new data flow and open it.
2. On the tool palette, click the icon for an ABAP data flow.
3. Click a location in the workspace.
   The *Properties* window appears, prompting for the ABAP data flow options.
4. In the *Datastore* list, select the SAP datastore to use for the extraction.
5. In the *Generated ABAP file name* box, enter the file name for the ABAP program that this data flow generates. Data Services writes this file in the generated ABAP directory specified for the datastore.
6. Enter other options in the window.

- *ABAP program name*
  Specifies the name Data Services uses for the ABAP program name that runs in the SAP application. It must begin with Y or Z.
- *Job name*
  Specifies the name used for the job that runs in the SAP application. It defaults to the name of the data flow.
- *ABAP row limit*
  Can be used for the test phase of development to reduce the number of data rows sent to the transport file. The default value of zero indicates that all data rows will be output to the transport file. When this value is set to a number greater than zero, only the specified number of rows go to the transport file.

  If you enter a number here, you can then enable/disable this feature from the *Tools* > *Options* control panel. The Designer and Job Server must be on the same computer. ABAP row limit is enabled/disabled globally for all SAP jobs associated with this Job Server. Remember to disable this feature before moving the jobs into a production environment.

  To enable or disable the option, select *Tools* > *Options* > *Job Server* > *General*. Enter data (case sensitive) as follows:

Field	Entry
Section:	AL_Engine
Key:	ABAP_ROW_LIMIT
Value:	TRUE

  Then click *OK*.
- *Join rank*
  If the calling data flow uses output from this ABAP data flow (in the form of a data transport) in a join, join rank indicates the rank of the source relative to other sources in the data flow. The software joins sources with higher join ranks before joining sources with lower join ranks.
  Join rank specified in the Query transform editor FROM tab overrides any join rank specified in a source. Best practice is to specify a join rank only in the Query transform editor.
  Join rank must be a non-negative integer. Default value is 0.
- *Parallel process threads*
  Specifies the number of threads that read or load data. This option allows you to parallel process reading and loading.
- *RFC data transfer package size*
  With the *Data transfer method* of *RFC* selected at the datastore level, you can adjust the number of rows to process per data package to maximize streaming performance. Defaults to 5000 rows.
- *Cache*
  If the calling data flow uses output of the ABAP data flow as the inner source for a join, you can cache the output to improve the performance of the join. Use caching only if you are sure the data is small enough to fit in the memory allotted to the cache.
  Default setting is No.
  The option is ignored if the ABAP data flow is nested inside another ABAP data flow.

7. Click *OK*.

   An ABAP data flow appears in the workspace and the project area.
8. With the ABAP data flow name highlighted, type a new name.
9. Click the ABAP data flow name.

   Data Services opens the workspace where you next add and define the components of the ABAP data flow.

12.4.4.2.2.2 Specifying sources

You can add SAP application tables or hierarchies to an ABAP data flow as sources. This example adds a table.

Do not use non-SAP or IDoc sources here; add those sources to the parent data flow and use a query (including BAPI functions as needed) to join those sources with the data set produced by the ABAP data flow.

To specify data sources:

1. From an SAP Applications datastore, click an SAP table and drag it into the workspace of an open ABAP data flow.
2. Click the name of the source table in the workspace to open the source table editor.
   In the source table editor, you can set three options:
   - *Join rank*
     Indicates the rank of the source relative to other tables joined in the data flow. The software joins sources with higher join ranks before joining sources with lower join ranks.
     Join rank specified in the Query transform editor FROM tab overrides any join rank specified in a source. Best practice is to specify the join rank only in the Query transform editor.
     Must be a non-negative integer. Default value is 0.
   - *Cache*
     Indicates whether Data Services should read the required data from the table and load it into memory. Best practice is to specify the cache in the Query transform editor. When sources are joined using the Query transform, the cache setting in the Query transform takes precedence over the setting in the source. In the Query editor, cache is set to Automatic by default. The automatic setting carries forward the setting from the source table.
     There are three options in sources:

Cache option	Description
Yes	The table is always cached unless it is the outer-most table in a join.
No	The table is never cached. Package size operation is bypassed.
Automatic	Data Services determines whether or not to cache the table based on table size and number of filtered records.

     The default option is No.
   - *Package size*
     The package size option limits the number of rows brought into memory when building internal tables. By limiting the number of rows, less memory is used to construct internal tables.
     You should use this option only for cached tables whose size could lead to excessive memory consumption.

Related Information

Extracting hierarchy set data [page 2457]
Optimizing inner joins [page 2467]
Manually setting join order [page 2471]

Tables used in a join [page 2473]

Source [page 2541]

12.4.4.2.2.3 Defining a query

Define a query to produce the desired data set. With a query, you can manipulate SAP application sources as follows:

- Join the data sets from more than one source
- Select the rows to extract from the source
- Define the schema of the extracted data set
- Perform calculations on column values

A single query can have several inner joins or several left outer joins, but may not contain mixed inner joins and left outer joins.

Best practice when joining multiple sources is to set join rank and cache for all sources in the Query editor.

When sources are joined using the Query transform, the cache setting in the Query transform takes precedence over the setting in the source. In the Query editor, cache is set to Automatic by default. The automatic setting carries forward the setting from the source table. The following table shows the relationship between cache settings in the source, Query editor, and whether the software will load the data in the source table into cache.

Cache Setting in Source	Cache Setting in Query Editor	Effective Cache Setting in ABAP data flow
Yes	Automatic	Yes
No	Automatic	No
Automatic (Data Services determines whether or not to cache the table based on table size and number of filtered records)	Automatic	Automatic (based on table size and number of filtered records)
Yes	Yes	Yes
No	Yes	Yes
Automatic	Yes	Yes
Yes	No	No
No	No	No
Automatic	No	No

Note

If any one input schema has a cache specified in the Query editor, the software considers only Query editor cache settings and ignores all source editor cache settings.

Data Services supports using the results of an ABAP data flow inside another ABAP data flow. If you are using the data in another ABAP data flow, make sure to:

- Keep the data on the SAP application server rather than on the Data Services server.
- Use *FTP* or *Shared directory* as the data transfer method.

You specify the location of the output file and data transfer method in the SAP datastore associated with the ABAP data flow.

To define a query:

1. Add a query to the ABAP data flow.
2. Draw the data flow connections.
3. Use the query editor to specify the desired data set.

Related Information

Reference Guide: Transforms, Platform Transforms, Query [page 1441]

12.4.4.2.2.4 Specifying a target

Specify a target for the resulting data set. Potential targets include a data transport, which makes the data set available to the calling data flow, or a file on the SAP application server.

To define a data transport:

1. Add a data transport to the ABAP data flow and rename it.
2. Connect the components of the ABAP data flow and map the query.
3. Click the name of the data transport.
   The data transport editor appears in the workspace.
4. In the data transport editor, enter the *File name* of the transport file.
   The file is placed in the *Working directory on SAP server* specified in the datastore definition.
5. If necessary, you can specify that the output file will be appended to an existing file with the same name (presumably created in a previous run of this same job). The default behavior is to replace any existing file.
6. Click the back arrow to return to the ABAP data flow.

   Upon execution, the ABAP data flow populates the file designated in the *File name* box.

12.4.4.2.3 Extracting data from SAP application hierarchies

The Data Services hierarchy object can extract set hierarchy information from the following set types:

Set type	Description
Basic sets	Sets containing values from one dimension. For example, in a basic set such as Assets that uses the dimension Accounts, all values in Assets are account numbers or ranges of account numbers.

Set type	Description
Single-dimension sets	Combinations of basic sets and/or other single-dimension sets that contain values from the same dimension. For example, the basic set Assets can be combined with the basic set Liabilities because they both use the same dimension Accounts.

In particular, Cost Center and Cost Element hierarchies in the Controlling module of SAP ERP are supported set hierarchies.

The following sections describe how hierarchies are defined in SAP applications and how Data Services translates the hierarchical relationships into horizontal or vertical representations:

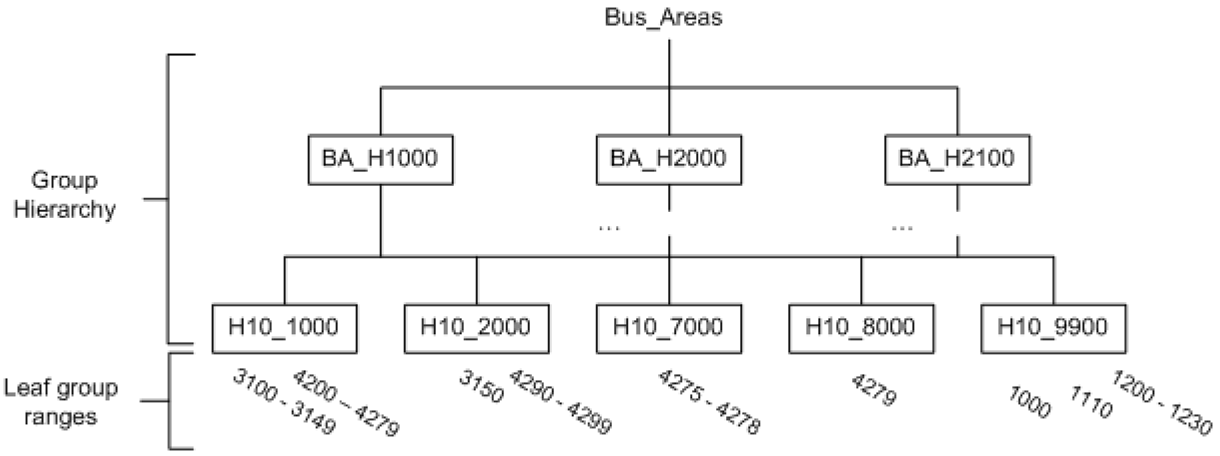
Related Information

SAP application hierarchy sets [page 2457]
Extracting hierarchy set data [page 2457]
Example data flow with an SAP source [page 2459]

12.4.4.2.3.1 SAP application hierarchy sets

Hierarchy set information from SAP applications includes hierarchy nodes and ranges of values associated with the leaf nodes. The possible values are defined by the domain upon which the hierarchy is based. The values themselves are stored in the set table associated with the hierarchy.

The set data represented in this hierarchy is as follows:



12.4.4.2.3.2 Extracting hierarchy set data

Data Services provides a hierarchy object that extracts group nodes and leaf group ranges from supported SAP set hierarchies. When Data Services extracts the hierarchy using a hierarchy object, the result includes a row for each parent-child relationship in the hierarchy and associated leaf group ranges.

A hierarchy object produces the following output when extracting the Business area hierarchy from Controlling area 1000 shown previously.

	Parent_ID	Child_ID	VALUE_FROM	VALUE_TO
NULL parent to root node		0HBUS_AREAS		
Root node to first child	0HBUS_AREAS	0HBA_H1000		
First child (now parent) to its first child	0HBA_H1000	0HH10_1000	0000003100	0000003149
	0HBA_H1000	0HH10_1000	0000004200	0000004279
First child (now parent to its second child	0HBA_H1000	0HH10_2000	0000003150	0000003150
	0HBA_H1000	0HH10_2000	0000004290	0000004299
First child (now parent) to its third child	0HBA_H1000	0HH10_7000	0000004275	0000004278
First child (now parent) to its fourth child	0HBA_H1000	0HH10_8000	0000004279	0000004279
First child (now parent) to its fifth child	0HBA_H1000	0HH10_9900	0000001000	0000001000
	0HBA_H1000	0HH10_9900	0000001110	0000001110
	0HBA_H1000	0HH10_9900	0000001200	0000001230
Root node to second child	0HBUS_AREAS	0HBA_H2000		
Second child (now parent) to its first child	0HBA_H2000	0HH20_3000	2-4200	2-4200
	0HBA_H2000	0HH20_3000	2-4210	2-4210
Root node to third child	0HBUS_AREAS	0HBA_H2100		
Third child (now parent) to its first child	0HBA_H2100	0HH21_9000	21-3100	21-3100
			...	

When you view the SAP hierarchy types in Data Services, you do not see the data associated with the hierarchy; instead, you see all of the hierarchy types grouped in two ways:

- Together in a single section (all hierarchy types organized across controlling areas by extraction logic)
- By controlling area

The names of the hierarchy types are made up of the SAP application set table name and the hierarchy group name. The hierarchies are named after the root node.

To extract data using a hierarchy, import the hierarchy metadata as part of an SAP application datastore definition.

To import a hierarchy type from an SAP application to your repository:

1. In the object library, select the *Datastore* tab and open the datastore corresponding to the SAP instance from which you want to import the hierarchy type.
2. In the workspace select *External Data*.
3. Expand the Hierarchy node.

4. Select the hierarchy type to import.

   The available hierarchies are listed according to the controlling areas with which they are associated. You can also browse through all hierarchies regardless of controlling area in the section labeled “All Controlling Areas”.
5. Right-click and choose *Import*.

The internal view of the datastore shows the hierarchy type.

12.4.4.2.3.2.1 The imported hierarchy

After a hierarchy type is imported into a datastore, it appears in the object library.

12.4.4.2.3.2.2 A hierarchy instance in an ABAP data flow

Use a hierarchy object as you would a table from the object library: select the hierarchy, then drag it into the definition of the ABAP data flow open in the workspace.

The instance of the hierarchy object in the data flow has options you can set to specify:

- A single controlling area or all controlling areas from which the hierarchy data is extracted.
  If you imported the hierarchy type from a controlling area in the browser, or if you specified a controlling area when importing the hierarchy by name, a single controlling area is already specified in the hierarchy definition. If you imported the hierarchy type from the All Hierarchies browser section or did not specify a controlling area, you can specify the controlling area for each instance of the hierarchy.
  Choose a single controlling area from the list for best performance.
- A single hierarchy or all hierarchies in the hierarchy type.
  Choose a single hierarchy for best performance. Enter the hierarchy name as it is shown in the external browser of the datastore.

12.4.4.2.3.3 Example data flow with an SAP source

This section describes one technique for extracting and transforming the hierarchy so you can easily report on any level of the hierarchy.

The job in this example consists of three data flows:

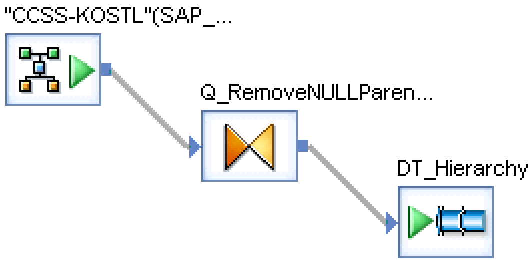
Data flow	Description
Hierarchy_Extraction	An ABAP data flow that extracts the Business Areas hierarchy for Controlling Area 1000.
Hierarchy_Leaf_Values	An ABAP data flow that associates the leaf data with the child nodes of the hierarchy.

Data flow	Description
DF_Hierarchy_Flattening	A data flow that horizontally flattens the hierarchy.

12.4.4.2.3.3.1 Hierarchy_Extraction data flow

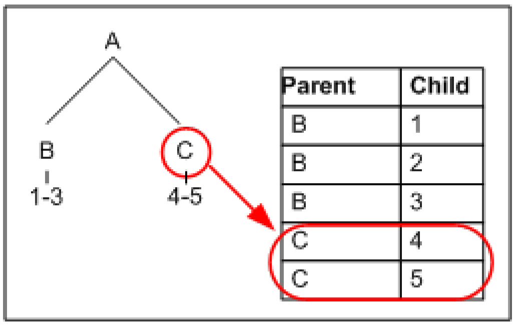
The Hierarchy_Extraction data flow is an ABAP data flow that extracts the hierarchy from SAP. It performs these operations:

1. Extracts the hierarchy type from SAP.
2. Filters NULL parent rows from the output.
3. Maps the parent, child, leaf and root flags, and controlling area columns to the output.



12.4.4.2.3.3.2 Hierarchy_Leaf_Values data flow

The Hierarchy_Leaf_Values data flow is an ABAP data flow that extracts values from the set table that correspond to the leaf nodes in the hierarchy. It produces a new set of parent/child pairs where the new parents are the leaf nodes from the hierarchy and the new children are the values associated with the leaf nodes. The result of this data flow is essentially another level to the hierarchy.

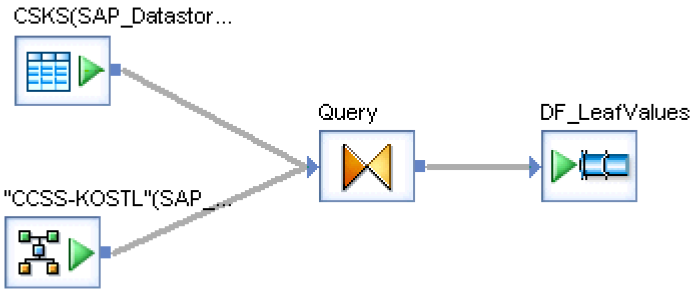


Parent	Child
B	1
B	2
B	3
C	4
C	5

Specifically, the data flow does the following:

1. Joins the hierarchy with the set table to produce a row for each leaf group value, filtering for valid cost centers and Controlling Area 1000.

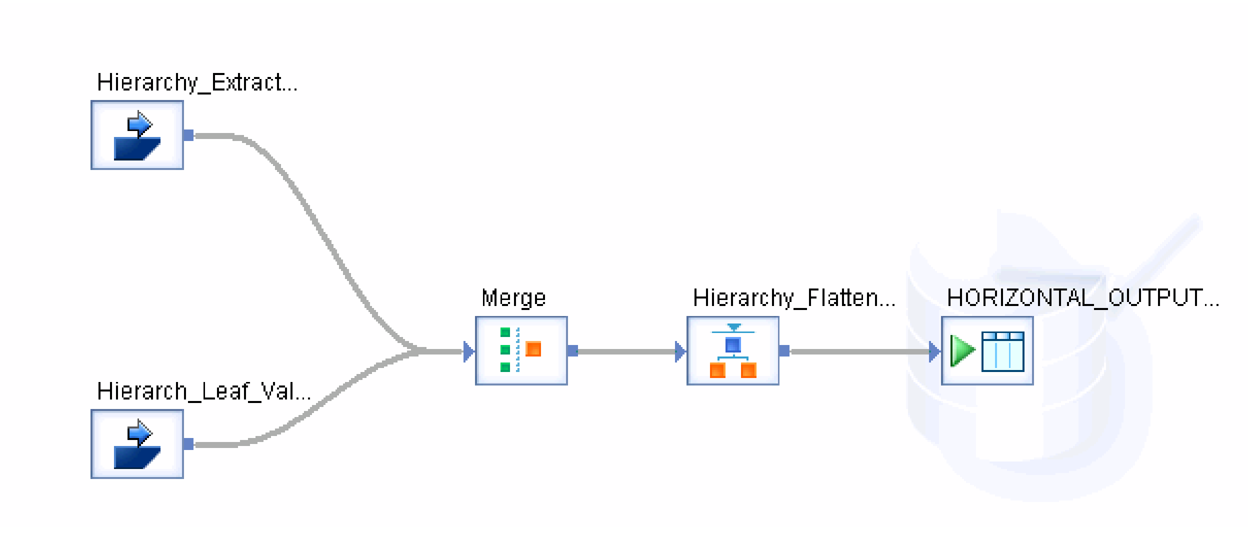
2. Maps the child_id and child_desc from the hierarchy to the parent_id and parent_desc in the output. Maps the cost center id (KOKRS) from the set table to the child_id in the output.
3. Looks up a text description of the cost center id and maps the result to the child_desc.



12.4.4.2.3.3.3 DF_Hierarchy_Flattening data flow

The DF_Hierarchy_Flattening data flow merges the leaf group values with the hierarchy and horizontally flattens the hierarchy as follows:

1. Merges the output from the two ABAP data flows.
2. Horizontally flattens the data using the Hierarchy_Flattening transform.
3. Loads the data into a target.



The output contains a row for each node in the hierarchy including each leaf group value. The table below shows a section of the output including the BA_H2000 cost center group:

Current leaf		Level 0	Level 1	Level 2	Level 3
0HBUS_AREAS	0	0HBUS_AREAS	0HBA_H2000		

Current leaf		Level 0	Level 1	Level 2	Level 3
0HBA_H2000	1	0HBUS_AREAS	0HBA_H2000		
0HH20_3000	2	0HBUS_AREAS	0HBA_H2000	0HH20_3000	
2-4200	3	0HBUS_AREAS	0HBA_H2000	0HH20_3000	2-4200
2-4210	3	0HBUS_AREAS	0HBA_H2000	0HH20_3000	2-4210
21-3100	3	0HBUS_AREAS	0HBA_H2000	0HH20_3000	21-3100
21-3110	3	0HBUS_AREAS	0HBA_H2000	0HH20_3000	21-3110
21-4200	3	0HBUS_AREAS	0HBA_H2000	0HH20_3000	21-4200
21-4210	3	0HBUS_AREAS	0HBA_H2000	0HH20_3000	21-4210
21-4280	3	0HBUS_AREAS	0HBA_H2000	0HH20_3000	21-4280
0HH20_4000	2	0HBUS_AREAS	0HBA_H2000	0HH20_4000	
2-3100	3	0HBUS_AREAS	0HBA_H2000	0HH20_4000	2-3100
2-3110	3	0HBUS_AREAS	0HBA_H2000	0HH20_4000	2-3110
2-3200	3	0HBUS_AREAS	0HBA_H2000	0HH20_4000	2-3200
2-4100	3	0HBUS_AREAS	0HBA_H2000	0HH20_4000	2-4100
2-4120	3	0HBUS_AREAS	0HBA_H2000	0HH20_4000	2-4120
2-4130	3	0HBUS_AREAS	0HBA_H2000	0HH20_4000	2-4130
2-4200	3	0HBUS_AREAS	0HBA_H2000	0HH20_4000	2-4200
2-4210	3	0HBUS_AREAS	0HBA_H2000	0HH20_4000	2-4210
21-3100	3	0HBUS_AREAS	0HBA_H2000	0HH20_4000	21-3100
21-3110	3	0HBUS_AREAS	0HBA_H2000	0HH20_4000	21-3110
21-4200	3	0HBUS_AREAS	0HBA_H2000	0HH20_4000	21-4200
21-4210	3	0HBUS_AREAS	0HBA_H2000	0HH20_4000	21-4210
21-4280	3	0HBUS_AREAS	0HBA_H2000	0HH20_4000	21-4280
0HH20_9900	2	0HBUS_AREAS	0HBA_H2000	0HH20_9900	
2-1110	3	0HBUS_AREAS	0HBA_H2000	0HH20_9900	2-1110
2-1200	3	0HBUS_AREAS	0HBA_H2000	0HH20_9900	2-1200

12.4.4.2.4 Creating custom ABAP transforms

You can create ABAP programs and incorporate them into an ABAP data flow as custom ABAP transforms. This section gives you information about creating and using custom transforms based on ABAP programs.

12.4.4.2.4.1 ABAP program requirements

You can map a custom-written ABAP FORM logic block to a Data Services custom ABAP transform. The ABAP logic block needs to perform the following functions:

- Extract data out of the SAP application using custom logic that is not currently supported by Data Services ABAP generation logic—for example, import statements and submit statements.

  > Note
  >
  > A subset of call function statements is supported: Functions returning scalar values are supported; ones returning tables are not.

- Load the resulting data into an output schema defined for the custom ABAP transform. You can also define and pass parameters to a custom ABAP transform. To include executing the ABAP logic block as part of your Data Services data movement, define a custom ABAP transform via the transforms tab. Then add it to an existing ABAP data flow.

12.4.4.2.4.1.1 Modifying custom ABAP for Data Services

Use an SAP FORM to modify a custom ABAP program. The custom ABAP must be enclosed in a FORM block to work with Data Services. In the structure shown below, notice the beginning of the FORM section after the comments. Use a FORM to pass the parameters to the output.

```
Comments
Start "FORM" block
Customer's custom ABAP
Start "OTAB1" block
End "OTAB1" block
End "FORM" block
```

12.4.4.2.4.1.2 Custom ABAP program tips

FORMNAME should be entered as it is shown at the beginning of the custom ABAP program. It will be replaced when the final ABAP program is generated.

$CONT_AREA and $ROOTNODE are parameters. Their data types are referenced in the ABAP. These optional parameters can be passed to the transform if defined in the Variables and parameters interface of the Designer and initialized.

After the FORM block, add a OTAB1 logic block immediately after the custom ABAP and before the ENDFORM line. The custom ABAP extracts the results from the SAP application server. The OTAB1 logic block takes these results and moves them into an internal table called OTAB1. You should not declare the OTAB1 in the FORM because it will be replaced in the final generated ABAP. The internal table OTAB1 is replaced by ITAB1 and made accessible to Data Services. Use the OTAB1 logic block as a guide, but it must be modified to follow the logic of your custom ABAP.

12.4.4.2.4.2 Using ABAP logic blocks in transforms

If you have ABAP logic blocks you want to use in your Data Services data movement, you can make them available as transforms.

12.4.4.2.4.2.1 To import an ABAP logic block

1. Open the object library to the *Transforms* tab.
2. Right-click the *Platform* node and choose *New ABAP Transform*.

   A new ABAP transform appears in the object library.
3. Right-click the transform and choose *Properties*.
4. Change the name of the transform so users can find it in the object library.
5. Click *OK*.
6. Right-click the transform and choose *Open* to define the custom ABAP transform.
7. For *ABAP language file name*, enter the full path name of the file containing the ABAP logic block.

   You can also click the button next to the box to navigate to the file.
8. For *Join rank*, you can enter a weight to indicate the rank of this data set in a join. You can also set this value when the transform is used in an ABAP data flow.

12.4.4.2.4.2.2 To define the output schema created by the transform

1. In the output schema, right-click and choose *New Output Column*.

   A Column Properties window opens.
2. Enter the *Name* of the column.
3. Select the *Data type* of the column.
4. Enter the *Content type* of the column.
5. Enter a *Description* of the column.
6. Click *OK*.
7. Repeat for each column in the schema produced by the ABAP logic block.

12.4.4.2.4.2.3 To define the input and output parameters for the transform

1. From the *Tools* menu, choose the *Variables* option to open the Variables and Parameters window.

   The transform is the current context in the window.

2. Right-click in the window and choose *Insert*.
3. Right-click the new parameter and choose *Properties*.
4. Change the name of the parameter.

   Choose a *Name* that identifies this parameter so users can map appropriate data to it.
5. Set the *Data type* of the parameter.
6. Set the *Parameter type*.
7. Repeat to define additional parameters.

12.4.4.2.4.2.4 To use the transform in an ABAP data flow

1. Open an ABAP data flow in the workspace.
2. Drag the transform from the object library into the workspace.

   The transform appears in the ABAP data flow as a source.
3. Construct the rest of the ABAP data flow using the data schema produced by the transform.

12.4.4.2.4.2.5 To pass values to the transform

1. With the ABAP data flow open in the workspace, click ▶ *Tools* ▶ *Variables* ◀.

   The *Variables and Parameters* window opens with the ABAP data flow as its context.
2. Click the *Calls* tab.
3. To set a value for one or more parameter(s), double-click each parameter and specify an expression or value in the *Value* field.

12.4.4.2.4.3 Troubleshooting ABAP programs

Custom ABAP functions can cause a FUNCTION_CONFLICT runtime error executing generated ABAP if a parameter data type specified in the custom ABAP is not the same as expected by the SAP application.

For example, you write a custom ABAP program that writes a varchar(10) value to an SAP system variable, but SAP expects a char(30) value for the same variable. When you execute a job that contains a call to the custom ABAP program, the job fails at run time and adds a function conflict error to the error log for the execution.

12.4.4.2.5 Optimizing ABAP

Data Services generates ABAP code to extract data from SAP applications. Data Services optimizes the generated code to make the best use of SAP application resources. When optimized, the generated ABAP program executes as fast as possible with minimal impact on SAP applications. By producing the best possible ABAP program, Data Services minimizes execution time and maximizes total throughput.

Data Services makes use of the features offered by different version of the SAP platform. Therefore, the ABAP code Data Services generates depends on the version you are running.

12.4.4.2.5.1 Optimizations using SAP application open SQL features

Data Services optimizes ABAP using the open SQL features used by different versions of SAP applications. The open SQL features include:

- Inner joins
- Outer joins
- Aggregate functions
- Group by clause
- Order by clause
- Distinct statement

12.4.4.2.5.1.1 SQL features available in SAP applications

All supported versions of SAP applications support these open SQL features:

- Aggregate functions (`AVG, MAX, MIN, SUM, COUNT*`)
- Group by clause
- Order by clause
- Distinct statement
- Inner joins
- Outer joins

When possible, Data Services generates ABAP code that pushes these operations to the SAP database. To push the operation to the database, several conditions must be met:

- Query can be completed by a single ABAP `SELECT` statement
- Select list does not contain `count()` aggregate.
- No expression is inside an `aggregate` function.
- Parameter column of the aggregate function is a Data Services numeric data type.

> Note
>
> Data Services numeric data types include integer, real, and double. The SAP NUMERIC data type is mapped to Data Services type VARCHAR, which is not a numeric data type.

When any of these conditions is not met, Data Services generates ABAP code that completes the operation within ABAP.

12.4.4.2.5.1.2 Optimizing inner joins

SAP applications can retrieve related data from multiple tables with a single SELECT statement using the JOIN command. You no longer need to use nested SELECT loops. Because a single SELECT statement requires fewer database accesses, performance improves.

When you create ABAP data flows that join transparent tables and that use at least one simple join predicate in the ON clause, Data Services creates a single SELECT statement using the JOIN command and pushes the operation to the SAP application database layer. For inner joins, simple join predicates are AND, =, <>, <, >, <=, and >=. These predicates must evaluate simple columns. Any complex join predicates are evaluated inside the select loop.

Data Services uses the table's join rank to determine which tables to join into a single SELECT statement and the order to join the tables. Specifically, tables that have the same join rank are joined together with a single SELECT statement that is pushed to SAP. Tables with higher join ranks are joined before tables with lower join ranks. Tables or groups of tables with different join ranks are joined with nested SELECT loops. These joins are not pushed to SAP.

When a table has the default join rank (zero), Data Services determines the best join rank for that table. Data Services decides based on which fields the table shares with other tables, using the fields that link the tables in the WHERE clause. Other tables in the join keep their assigned join rank.

When joining tables with a single SELECT statement, SAP determines which is the inner table and which is the outer table of the join. When joining tables with nested SELECT loops, Data Services uses the table or joined tables with the higher join rank as the outer table and the table or joined tables with the lower join rank as the inner table.

For example, suppose you want to join five transparent tables, A through E, with three different join ranks.

Table	Join Rank
A	10
B	10
C	5
D	3
E	3

Data Services creates a single SELECT statement joining A and B and pushes the operation to SAP (these tables have the same join rank and the highest value).

Next, Data Services creates a single select statement joining D and E and pushes the operation to SAP (these tables have the same join rank but a lower value). In both cases, SAP determines which table is the inner table and which table is the outer table.

Finally, Data Services creates a nested SELECT loop that joins the joined tables A and B with table C and joins the result with the joined tables D and E. The joined tables A and B are used as the outer table in the first join, and the joined tables A, B, and C are used as the outer table in the second join (the table with the higher rank is used as the outer table).

Now, suppose you specified four different ranks.

Table	Join Rank
A	10

Table	Join Rank
B	4
C	5
D	3
E	3

In this case, Data Services creates a single SELECT statement joining D and E, and pushes the operation to SAP. Next, Data Services creates a nested SELECT loop that joins table A with table C, joins the result with table B, and joins that result with the joined tables D and E. Table A is the outer table in the first join, the joined tables A and C are the outer tables in the second join, and the joined tables A, C, and B are the outer tables in the third join.

Finally, suppose you specified five different ranks for the five tables.

Table	Join Rank
A	10
B	4
C	5
D	3
E	8

In this case, none of the joins are done with a single SELECT statement that is pushed to SAP. Instead, Data Services creates a nested SELECT loop. The loop joins A with E, the result with C, that result with B, and that result with D.

When Data Services determines which table is the outer table and which table is the inner table of a join, it uses information about the table size and estimates the effect any filters will have on the number of rows retrieved. Data Services uses the smaller data set as the outer table in a join.

Data Services determines the table size based on the *Estimated row count* attribute for the table. You can enter a value for any table.

For joins containing nested relations, Data Services uses the statistics of the embedding table when determining the best join order. For joins containing clustered fields, Data Services uses the statistics of the transparent table when determining the best join order.

Reference Guide: Table [page 956]

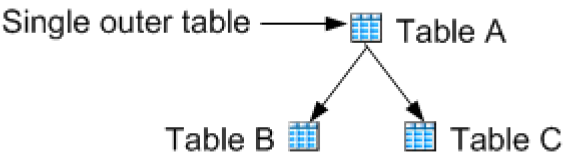
12.4.4.2.5.1.3 Optimizing outer joins

SAP applications can perform an outer join between two tables using the LEFT OUTER JOIN command. Using this ABAP command avoids awkward code that leads to unnecessary database table scans and poor performance.

SAP can only use the LEFT OUTER JOIN command when joining transparent tables with at least one simple expression in the ON clause. For left outer joins, simple expressions specify fields using AND commands with an equals condition. If the join also specifies a complex expression, Data Services will evaluate that expression inside the SELECT loop. Furthermore, SAP applications only support left outer joins when one table is used as the outer table in the join. In other words, within SAP you cannot have an outer join between two tables and use the result in another outer join.

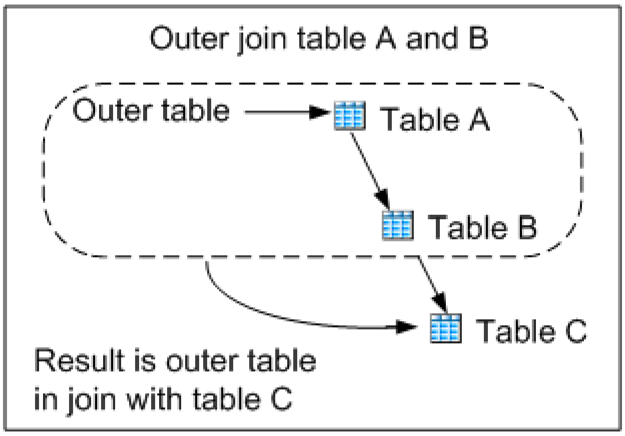
When you create ABAP data flows with an outer join that joins transparent tables and uses simple expressions in the ON clause, Data Services attempts to use the LEFT OUTER JOIN command and push the operation to the SAP application database layer.

When the outer join only uses one table as the outer table in the join, Data Services can create a single SELECT statement using the LEFT OUTER JOIN command and push the operation to the SAP application database layer.



You can use the join rank to control the order in which tables are joined.

When the outer join uses more than one table as the outer table in the join (such as the result of a previous outer join), then Data Services cannot create a single SELECT statement. Instead, Data Services chooses one outer join to complete using the LEFT OUTER JOIN command and then uses a nested SELECT loop to complete the join. Data Services randomly chooses which tables to join using the LEFT OUTER JOIN command.



12.4.4.2.5.2 Optimizations using nested SELECT statements

When working with SAP R/3 version 4.0 or later, you might need to use a nested SELECT statement because of restrictions on using the JOIN command and WHERE clause. When joining tables using a nested select statement, Data Services creates ABAP code that joins the tables in the order it anticipates is most efficient. You can override the decision with manual settings.

When joining data in a nested SELECT statement, Data Services extracts data in loops—the first table is read in an outer loop and subsequent tables are read in an inner loop. The number of loops depends on the number of tables joined. For best performance, you want the table that limits the most records read in the outer loop. By defining the smaller data set first, you will limit database operations when searching for matching records in the inner table. Data Services uses rules to ensure that this happens. You can override these rules and manually specify the join order.

During a join, only two tables are read at one time. However, outer joins that are split into multiple query transforms can reduce extraction performance. Therefore, join performance is better if outer joins that include more than two tables are specified in a single query transform.

Related Information

Designer Guide: Query transform overview [page 310]

12.4.4.2.5.2.1 Automatically determining join order

Data Services automatically identifies the most appropriate table to read first in the join (that is, the table to use as the outer table). Data Services applies several rules:

1. Use the smaller source.
   Data Services estimates the table size using the Estimated_Row_Count attribute for the table. You can change this value to better reflect the actual size of the data set.
2. Use the table with fewer key fields specified in an ON clause.
   When joining tables, the ON clause specifies key fields that must match. Some tables, such as a detail table that is joined with a header table, have additional key fields that are not used in the match. Typically, the table with additional key fields is larger; the table with fewer key fields defines a smaller data set.
   Data Services detects the number of keys, and uses the table with fewer key fields in the outer SELECT loop and the table with the extra keys in the inner SELECT loop.

   > ℹ Note
   >
   > It is important to use all the SAP-specified keys when joining two related tables. If they are not included in the join, the underlying database used by the SAP application may scan the entire table rather than use the primary index.

3. Use the table with a constraint in the WHERE clause.
   When the WHERE clause in the joining Query transform includes a constraint, Data Services assumes that the selection based on a literal constraint will result in fewer selected records and that this table should be in the outer SELECT loop (which may not be the desired result).

For joins containing nested relations, Data Services uses the statistics of the embedding table when determining the best join order. For joins containing clustered fields, Data Services uses the statistics of the transparent table when determining the best join order.

Related Information

Reference Guide: Table [page 956]

12.4.4.2.5.2.2 Manually setting join order

In some cases, you may not want Data Services to automatically determine the join order. For a particular join, the ON conditions or keys may lead to less-than-optimal performance when Data Services applies its rules to determine join order. In these cases, you can specify the join order manually.

To specify the join order manually, set the join rank to a positive non-zero integer for each table in the join. Set the join rank using the Query editor. The table with the largest join rank becomes the outer table in the join. The other tables are included based on the order of their join ranks.

If the join ranks of all source tables remain at the default value (0) and are also not specified in the Query editor, Data Services automatically assigns the join rank.

Even though the join ranks specify tables in the proper order, the underlying SAP application access methods might still prevent optimal performance. In this case, consider alternatives to the multiple table join, including using a two-way join with a table lookup using caching or small tables.

Related Information

Specifying sources [page 2454]
Automatically determining join order [page 2470]

12.4.4.2.5.2.3 Determining the best join order

Use the information available for the data sets involved in a join to determine the best join order. This section shows two types of common joins and the techniques for determining the appropriate join orders.

12.4.4.2.5.2.3.1 Header and detail tables

For “header” and “detail” table joins, you usually want the header table to be the outer table and the detail table to be the inner table.

Because there are typically many line items for each header, the header table defines the smaller data set. Therefore, you want to use the header table as the outer table in the join and the line item table as the inner table in the join. The join operation reads all of the rows of the detail table into memory. Then for each row of the header table, the join matches multiple rows from the detail table. Producing the output requires reading through each table one time, with comparisons made for each row in the smaller table.

The alternative would be to read the header table first, then for each row of the detail table, read through the header table to find the matching details. Producing the output in this alternative requires reading through each table one time, with comparisons made for each row in the larger table. The cost of the join operation is higher in this case.

For example, when extracting rows from a purchase order line item table, you would join them with the corresponding row from the purchase order header table.

This join would produce a row for each controlling area and document number identified in the header table. You might limit the results by setting bounds on when the document was created, using document creation dates from the header table.

12.4.4.2.5.2.3.2 Identifier and description tables

When joining tables to extract text "“descriptions”" for “identifiers”, you often find that the description table is much larger than the identifier table. In that case, you want to use the identifier table as the outer table and the description table as the inner table.

The join operation reads all of the rows of the description table into memory. Then for each row of the identifier table, the join matches a row from the description table. Producing the output requires reading through each table one time, with comparisons made for each row in the smaller table.

For example, when extracting business areas and descriptions, you might join areas from the business area table (the identifier) with text descriptions from the business areas description table (the description).

Because the description table is larger than the identifier table, you want the join to use the identifier table, TGSB, as the outer table and the description table, TGSBT, as the inner table. This join would produce a row for each business area identifier in the TGSB table. You might limit the results by language values from the TGSBT table.

12.4.4.2.5.2.4 Checking join order in ABAP

Before actually running a job, you can check the order in which tables will be joined by examining the ABAP that Data Services generates for the ABAP data flow. In the ABAP, look for the appropriate SELECT loop description. The outer table is described before the inner table.

For example, for a join between two tables MARA with join rank 2 and MAKT with join rank 1, the ABAP contains two separate SELECT statements for the outer table (MARA) and the inner table (MAKT). The generated *ABAP Language* window might appear as follows:

```
select
  MATNR
  MTART
  MBRSH
  MATKL
into corresponding fields of MARA from MARA.
ALTMP2 = MARA-MATNR.
ALTMP3 = MARA-MTART.
ALTMP4 = MARA-MBRSH.
ALTMP5 = MARA-MATKL.
select
  MATNR
  SPRAS
  MAKTX
into corresponding fields of MAKT from MAKT where
((SPRAS = 'E')
AND MATNR = MARA-MATNR))
ALTMP1 = MAKT-MAKTX.
  MOVE ALTMP1 TO ITAB3-MAKTX.
```

where :

- The first SELECT statement is for the outer join, followed by the column list from the outer table
- The second SELECT statement is for the inner join, followed by the column list from the inner table
- The join expression in the WHERE clause displays at the end

12.4.4.2.5.2.4.1 To generate and view ABAP

1. Open the ABAP data flow in the workspace.
2. Choose ▶ *Debug* ▶ *Generate ABAP* ◀.

   The ABAP Language window opens in the workspace.

   If there are errors in the ABAP data flow, the Output window opens with a list of any errors or warnings. There cannot be any errors in the data flow for ABAP to be generated.
3. Locate the correct SELECT statements.

   Use the Find button or browse through the code by scrolling.

The first table in the set is the outermost table.

12.4.4.2.5.3 Optimizations for table caching

SAP applications can cache a table (that is, load it into memory). You can cache tables in two cases:

- Tables used in a join
- Tables used in a lookup function

12.4.4.2.5.3.1 Tables used in a join

Caching tables used as inner tables in joins improves performance as fewer database accesses are required. You can manually set or override table caching.

> ℹ Note
>
> Best practice when joining multiple sources is to set join rank and cache for all sources in the Query editor.

When sources are joined using the Query transform, the cache setting in the Query transform takes precedence over the setting in the source. The default option in the Query editor is Automatic and in a table source is No. The automatic setting in the Query editor carries forward the setting from the source table. The following table shows the relationship between cache settings in the source, Query editor, and whether the software will load the data in the source table into cache.

Cache Setting in Source	Cache Setting in Query Editor	Effective Cache Setting in ABAP data flow
Yes	Automatic	Yes
No	Automatic	No
Automatic (Data Services determines whether or not to cache the table based on table size and number of filtered records)	Automatic	Automatic (based on table size and number of filtered records)
Yes	Yes	Yes
No	Yes	Yes
Automatic	Yes	Yes
Yes	No	No
No	No	No
Automatic	No	No

Note

If any one input schema has a cache specified in the Query editor, the Data Services Optimizer considers only Query editor cache settings and ignores all source editor cache settings.

The default option in the Query editor is Automatic and in a table source is No.

If you enable the cache on all tables in a join, inner and outer tables are read into internal tables prior to a join. This construct replaces SELECT LOOP processing. You should then use the Package Size option on the outer loop of the join to limit the size of the internal tables brought into memory.

The rows extracted from cached tables must fit into the production SAP system memory. When you select the *Automatic* option in the table source, Data Services estimates the table size and number of filtered records and projects the number of rows that must be extracted. When Data Services projects that 2,500 or fewer rows will be extracted and the table is used as the inner loop of a join, Data Services caches the table. To estimate the table size, Data Services uses the *Estimated row count* attribute for the table. You can enter a value for any table.

When cached tables do not fit into memory, Data Services throws an overflow or memory contention error when executing the ABAP program. Errors can occur when tables you select for caching (tables with the cache option set to *Yes*) do not fit into memory or when tables Data Services selects for caching (tables with the cache option set to *Automatic*) do not fit into memory.

If you experience either type of error, you have two options:

- Change the cache option to *No* for one or more tables, and re-run the program until you can execute it without an error.
- Use the Package size option to limit the number of rows read into memory.

Related Information

Specifying sources [page 2454]
Reference Guide: Table [page 956]

12.4.4.2.5.3.2 Tables used in a lookup function

Caching the values that a lookup function needs from a translation table reduces the number of times the system must be queried and improves system performance.

When creating a lookup function, you can specify whether or not to cache the translation table. When you specify that a translation table is cached, Data Services is able to improve performance. There are three options:

Option	Description
NO_CACHE	Data Services caches no values.
PRE_LOAD_CACHE	Data Services applies filters and caches all the matching lookup columns in the translation table. Select this option if the table can fit into memory.
DEMAND_LOAD_CACHE	: Data Services searches the ABAP data flow for other lookup functions that use the same translation table and have the same cache setting. When Data Services finds two or more lookups, it combines those lookups and caches the results into an internal table. The SAP application reads the internal table to find the results of individual lookups. Select this option when you use the table in multiple lookups and the compare conditions are highly selective, resulting in a small subset of data.

Because a lookup may retrieve many records, you must be careful that the caching requirement does not exceed available memory. If you get an error message indicating a lack of memory, you should remove caching from one or more tables.

Related Information

lookup [page 2572]

12.4.4.2.5.4 Making table size information available to jobs

When optimizing execution algorithms, Data Services makes decisions based on the size of tables being imported.

You can:

- Make table size information known to jobs for automatic tuning
- Use cost coefficients to further tune job performance

12.4.4.2.5.5 Optimizations for testing ABAP data flows

You can control the number of rows returned from an ABAP program when you run its job in test mode.

When you drop an ABAP data flow into the workspace, the Properties window for that data flow appears. On the *Options* tab, use *ABAP Row Limit* to limit the number of rows that the data flow reads. Then, select the *Test Mode* option from the *Execution Properties* window when you execute this job. This feature allows you to quickly run jobs in a development environment using SAP application data.

Related Information

Adding an ABAP data flow [page 2452]

12.4.4.3 Executing batch jobs that contain ABAP data flows

This section contains specific information about executing batch jobs that contain ABAP data flows.

> Note
>
> This section assumes you are an experienced SAP user and have already followed similar procedures. Your system may be configured differently than the examples, so you should treat the steps in the procedures as high-level information—you may need to fill in additional details or you may need to do the steps in a somewhat different order.

Related Information

Designer Guide: Executing Jobs [page 421]

12.4.4.3.1 Data Services functions supporting ABAP data flows

Using ABAP data flows, Data Services extracts data from SAP applications by directly accessing the SAP application server with Data Services-generated ABAP.

Data Services can execute the ABAP by the following methods:

- *Generate and Execute*
  This method calls the Data Services function /BODS/RFC_ABAP_INSTALL_AND_RUN. If this Data Services function was not uploaded to the SAP server, then the SAP function RFC_ABAP_INSTALL_AND_RUN is called.

  > i Note
  >
  > This method requires that users who submit the job have S_DEVELOP authorization. Most SAP production systems do not provide this combination of authorizations to one user. Additionally, the RFC_ABAP_INSTALL_AND_RUN function is not well suited to execute in parallel. When multiple users access the system at the same time, some jobs could fail due to ABAP program name conflicts.

- *Execute Preloaded*
  This method uses Data Services-provided functions to overcome the security and stability issues inherent in the Generate and Execute method.

Related Information

ABAP execution options [page 2479]

12.4.4.3.2 Validating, generating, and installing ABAP code

Data Services enables you to check generated ABAP syntax errors before you run a job. The errors Data Services detects include mismatches between strings and numerals in parameter passing.

To request ABAP validation, you must have the Data Services function module /BODS/SYNTAX_CHECK installed on your SAP system.

Related Information

Installing Functions on the SAP Server [page 2408]

12.4.4.3.2.1 To validate ABAP code created by Data Services

1. From the Designer, select an SAP data flow object (data flow, table, or transport) in the project area or open an object in the workspace.
2. Select *Debug* > *Validate* > *Validate ABAP* .

   Data Services checks for ABAP errors and opens a window to indicate what the errors are, or that there are no errors.

12.4.4.3.2.2 To generate and install ABAP independent of execution

To install generated ABAP code, you must first meet the following prerequisites:

- You must have necessary privileges in the SAP system to create a new program using transaction SE38.
- If the upload is performed while the SAP Applications datastore is in generate_and_execute mode, you must ensure that SAP client software (SAPGUI) is installed on the machine where the Data Services Designer is running.

> ⚠ Caution
>
> If a program already exists in the SAP system with the same name as an ABAP program you upload with this procedure, the uploaded program overwrites (without confirmation or warning) the previously existing program. You must ensure that name conflicts do not exist.

1. In the local object library, right-click an ABAP data flow object.

   > i Note
   >
   > You can select more than one ABAP data flow object (even from different datastores) and proceed with these steps. However, you won't see the program of any of the data flows, as you do when you work with one data flow at a time.

2. From the context-sensitive menu, select *Generate ABAP Code*.
   The ABAP Programs Generation Dialog appears.
3. In the *Generate ABAP programs in directory* field, specify the path of the ABAP programs.
4. To enable automatic installation of the ABAP programs, select the *Upload generated programs* box.
5. Click *OK*.
   Data Services generates and installs the ABAP programs. Because the SAP system must process the ABAP programs, the installation time could be somewhat lengthy.

12.4.4.3.2.3 To change the Generated ABAP directory

1. In the object library, select an SAP Applications datastore.
2. Right-click and select *Edit*.
3. Click *Advanced*.
4. Enter the new directory path in the *Generated ABAP directory* box.
5. Click *OK*.

12.4.4.3.3 ABAP job execution scenarios

Much of the SAP Applications datastore definition determines how the ABAP data flow portion of a Data Services batch job executes and returns data.

12.4.4.3.3.1 ABAP execution options

For executing ABAP, Data Services provides the following options:

Option	Description
Generate and Execute	ABAP is sent to the SAP application server via the Data Services function /BODS/RFC_ABAP_INSTALL_AND_RUN. If this Data Services function does not exist, then the SAP-supplied RFC_ABAP_INSTALL_AND_RUN is used. This option is designed to be used during the development stage of a project. When a job is executed using an SAP Applications datastore set to the generate_and_execute mode, Data Services generates a random ABAP program name. Use the Designer's ▶ *Tools* ▶ *Options* ▶ *SAP* ▶ *Environment* ◀ option called *Prefix to ABAP program name* to assign a prefix to the random name generated by Data Services. Generated files are stored in the directory you defined for the datastore.
Execute Preloaded	Communication between Data Services and SAP is handled by the Data Services RFC function modules, which must have been pre-installed on SAP. This option is generally used only in the test and production stages of an application project. When you select *Execute Preloaded*, Data Services doesn't generate ABAP to run the job. It simply calls an ABAP program name on the SAP application server. This program was created when you ran the job in Generate and Execute mode. Load the previously generated ABAP program into SAP, rename it as desired, and from the *Options* tab of the data flow *Properties* window, enter its name in the *ABAP program name* box.

12.4.4.3.3.2 Data transfer methods

ABAP data flows in Data Services allow you to automatically create ABAP programs. After an ABAP program runs, it creates a flat file (transport file) on the SAP application host. This file is later transferred from the SAP application host to a directory local to the job server executing the Data Services job.

To use a data transfer method for this outbound SAP file, select an option when configuring a datastore for your SAP application host. Data transfer options specified in an SAP Applications datastore editor determine the method by which the results (from batch jobs that contain ABAP data flows) are returned to Data Services. The options are:

Option	Description
RFC	Use to stream data from the source SAP system directly to the Data Services data flow process using RFC.
Direct download	SAP application server transfers the data directly to the *Client Download directory*.
Shared directory	SAP application server loads the *Working Directory on SAP server* with the transport file. The file is read using the *Data Services Path to the shared directory*.

Option	Description
FTP	SAP application server loads the *Working Directory on SAP server* with the transport file. The file is read using the *FTP relative path to the SAP working directory* and written to the *Client download directory*.
Custom Transfer	SAP application server loads the *Working Directory on SAP server* with the transport file. The file is read by a third-party file transfer program and loaded to the *Local directory*.

12.4.4.3.3.2.1 Custom Transfer method

Using the custom transfer method, you specify a third-party file transfer program which Data Services uses to transport data between the remote SAP application server and a local directory on a Data Services Job Server machine. The transfer from SAP applications to Data Services is enabled using a data transport object (used in ABAP data flows).

When you select the *Custom Transfer* option, provide:

- A transfer program (to be invoked during job execution)
- (optional) Additional arguments used by the transfer program such as security, compression, or Data Services system variables.

Like other datastore settings, custom transfer program settings can be overridden if they are changed in a particular ABAP data flow. You can also edit the *Custom Transfer* option when exporting an SAP Applications datastore.

Datastore profiles support the *Custom Transfer* option.

Related Information

Designer Guide: File transfers [page 269]

Designer Guide: Creating and managing multiple datastore configurations [page 239]

12.4.4.3.3.2.1.1 Data Services system variables to transfer a file from SAP applications

System variables can be used to provide the connection data you enter into Data Services to the custom transfer program. The following system variables can be used in the *Custom Transfer Arguments* box:

Data entered in this field:	Is substituted for this variable if it is defined in the Arguments box
SAP application server	$AW_SAP_HOST

Data entered in this field:	Is substituted for this variable if it is defined in the Arguments box
Working directory on SAP server	$AW_SAP_WORK_DIR
Custom transfer user name	$AW_USER
Custom transfer password	$AW_PASSWORD
Local directory (Local denotes the job server computer)	$AW_LOCAL_DIR
File name This field is on the data transport object and is part of an ABAP data flow.	$AW_FILE_NAME

12.4.4.3.3.2.1.2 Shared directory requirements

To use the Shared Directory data transfer method, set up a shared directory between the SAP application server and your Data Services Job Server computer:

- If the SAP application server is on UNIX, use NFS or a similar disk sharing process. Use these steps to verify that the Job Server can access files generated by SAP:
  a) Log in to the SAP application server computer.
  b) Sign onto the NFS system.
  c) Navigate to the directory you specified in the datastore as the "Working directory on SAP server."
  d) Enter the command `touch bodi`.

     Note that you can use any term instead of bodi. The touch command creates a file with zero length in the current directory.
  e) Log into the Data Services Job Server computer.
  f) Navigate to the directory you specified in the datastore as the "Data Services path to the shared directory."
  g) Look for the file `bodi`.
  h) Use the command `file bodi` to verify that the Job Server can read the file.
- If the SAP application server is on Windows, use Windows directory sharing to provide mutual access to the staging area. Include paths to:
  - The shared device on the application server
  - The shared device on the Data Services Job Server

> **Note**
>
> Because both the Data Services and the SAP application server can run on either Windows or UNIX platforms, mapping between computers can be interrupted if one of the computers is rebooted.

Observe the following recommendations:

- If you are running SAP and the Data Services on UNIX, make sure that your network will automatically mount the volumes you want to use when any computer is re-booted.
- If you are running the SAP application server on Windows and the Data Services Job Server on UNIX and you re-boot the UNIX computer, you may need to re-map Data Services to the SAP application server. If your jobs return error messages such as the following, disconnect then remap the NFS connection in SAP.

  ```
  The SAP Job Canceled Host...
            File xxx cannot be opened...
  ```

Related Information

ABAP job execution scenarios [page 2478]

12.4.4.3.3.2.2 Direct download transport method

With *Direct download*, the data produced by the SAP application after running the ABAP program is returned by the Job Server computer via a ws_download function call. The data is stored in the *Client download directory*.

You should avoid using this method except when you need a quick way to return a small amount of data; it might not be reliable and does not scale well.

12.4.4.3.3.2.3 FTP transport method

The FTP method is most useful in heterogeneous environments (Windows and UNIX). It scales well and provides a good level of security, making it a recommended method of data transport.

12.4.4.3.3.2.4 Shared directory transport method

With shared directory transport method, both Data Services and SAP applications have direct access to the directory where data is stored. This method works best in a homogeneous environment (both systems are on Windows). The security risk inherent in a shared directory may pose a problem for some organizations. If this is the case, FTP is probably a better choice.

12.4.4.3.4 Sample execution sequence for an ABAP job

This section describes how a batch job that contains an ABAP data flow (also called an ABAP job) executes.

The following execution sequence is for a hypothetical job with the following characteristics:

- The batch job contains a data flow that, in turn, calls an ABAP data flow.
- The ABAP data flow extracts data from a subset of the columns in an SAP table.
- The calling data flow passes the output from the ABAP data flow into a query transform and loads a target table or file.
- The datastore options selected are *generate_and_execute* and *shared_directory*.

The scenario is valid for jobs initiated in Data Services as well as jobs initiated in SAP.

Oracle is assumed for this example, but the process is similar for other environments.

12.4.4.3.4.1 The execution steps

1. Data Services retrieves the job specification from the repository.
2. Data Services validates the job specification.
3. Data Services performs any required optimizations.
4. Data Services compiles the job specification.
   As part of this step, Data Services generates an ABAP program corresponding to the ABAP data flow specification and writes it to the path specified in the SAP Applications datastore options.
   All the parameters are replaced with data before ABAP is submitted to SAP to execute.
5. Data Services invokes `RFC_ABAP_INSTALL_AND_RUN` with the ABAP program as a parameter.
6. Depending on whether the ABAP job is running in the background or foreground, one of the following happens:
   - If the *Execute in background (batch)* option is set to *No*, then the ABAP program runs as a foreground job in dialog user mode in SAP. The `RFC_ABAP_INSTALL_AND_RUN` return code is checked for status. (`RFC_OK` return status implies successful completion of the ABAP program.)
   - If the *Execute in background (batch)* option is set to *Yes*, then the ABAP program runs in the background in SAP. A special Data Services-internal ABAP program runs in SAP and polls for status from the job status table TBTCO based on the job name that was assigned. The status column TBTCO-STATUS provides status information.
7. The ABAP portion of Data Services SAP-related jobs cannot run in parallel, so Data Services serializes the requested processes.

   > Note
   >
   > ABAP jobs can run in parallel when you specify execute_preloaded and the job executes with Data Services RFC.

8. Data Services schedules the job by calling SAP functions JOB_OPEN and JOB_CLOSE.
9. The job is scheduled as a class C job.
10. Data Services queries the job status every 15 seconds.
11. When the job finishes, the ABAP is deleted, but the job is still listed with a status of "finished."
12. When the ABAP program completes successfully, it writes output to the file name specified in the data transport in the path specified as *Working directory on SAP server* in the datastore definition.
13. The ABAP data flow is done and returns to the calling data flow.
14. Data Services reads the output file generated from ABAP data flow execution and processes it.
    Processing may include performing joins with other ABAP data flows or tables from other source databases or source files. It may also include any column transformations and/or transforms applied to the entire SAP

output data set. Once all transformations are done, Data Services is ready to place the resulting data set in an output file or target table.

15. If the output is to a target table, these are the options available for loading the table:
    - If Oracle is the target database, then bulk loading is the typical choice.
      If bulk loading is turned on, Data Services generates the control file (.CTL) and the input (to the SQL*Loader) data file (generated_filename.dat) in the `C:/Data Services/Log/BulkLoader/` directory or the bulk loader directory specified in the Oracle datastore. It then invokes SQL*Loader on the client side (the system running Data Services) to load the data according to the control file specification.
    - If bulk loading is not used, Data Services builds and sends batch INSERT SQL statements to the Oracle server to execute and load the rows. A batch size option specifies the commit size.

12.4.4.3.5 Scheduling jobs from SAP

The following is an overview of the execution process for jobs initiated in SAP.

1. When it is time to run a job, SAP sends an extract request to Data Services through the RFC server.
2. Data Services generates ABAP and submits it to SAP.
3. The Data Services batch file initiates execution. The job runs on the job server specified when the job was exported.
4. The ABAP is executed on the SAP application server.
5. The SAP application server generates the specified results.
6. Data Services is notified of the results.

12.4.4.3.5.1 Creating the program that will execute the schedule

You need to create the ABAP program that will initiate communications with the Data Services RFC server to execute the job schedule.

We recommend that you use the model ABAP code provided for you at `Data Services\Admin\R3_Functions\schedule\yschedul.abap` (the procedures in this section assume you do so). You can also create your own program.

12.4.4.3.5.2 To create an ABAP program in SAP applications

1. Run transaction *SE38*.
2. Select *yschedul* in the *Program* drop-down box.
3. Click the *Create* button.
   The *Program Attributes* screen appears.
4. From the *Program Attributes* screen:
   - In the *Title* box, add a title.
   - In the *Type* box, enter *1* (online).
5. Click *Save*.
6. Click the *Source code* button.
7. In the *Create object catalog entry* screen, enter the development class for this job.
   This can be any development class you have created for this purpose. We recommend using zact.
8. Click *Save*.
   An ID number has been assigned to this job (the correction and transport number).
9. Click *Save*.
   The ABAP/4 Editor: *Edit Program* screen appears.
10. Choose *Upload* from the ▶ *Utilities* ▶ *Upload/Download* ▶ menu.
11. From the Upload dialog, navigate to yschedul.abap.
    The default location is `C:\Data Services\Admin\R3_Functions\Schedule`.
12. Click *OK*.
    This returns you to the ABAP/4 Editor: Edit Program screen.
13. Click *Save*.
14. Click the back arrow to get back to the ABAP/4 Editor: Initial Screen.
15. From the ABAP/4 Editor: Initial Screen, click *Execute*.
16. Add the fully qualified path to the batch file containing the job you want to run and the RFC destination name.
17. Click *Save*.
18. Enter a variant name and (optionally) a description.
    A variant name is a collection of parameters that determine how a job is run. Use any name that is meaningful to you.
19. Click or press *Enter*.
    The SE38 procedure is complete.

12.4.4.3.5.3 To create a job schedule in SAP applications

1. Run transaction *SM36*.
   View the Define Background Job screen.
2. From the Define Background Job screen:
   a) Add a job name.
   b) Add the target host (the SAP application server).
3. Click the *Steps* button.

The Create Step 1 screen appears.

4. In the Create Step 1 screen, click the *ABAP/4* button.
   Items in the ABAP program section are now available.
5. Add the program *Name* (yschedul).
6. Add the appropriate variant information.
7. Click *Save*.
8. Return to the *Define Background Job* screen.
9. Click the *Start date* button.
10. Add the date and time for the job to run.
11. Complete additional information as needed and click *Save* to complete the job schedule.

The job runs at the time you scheduled it.

If Data Services is active when the job begins to run, the execution window (with the trace button active) appears.

12.4.4.3.5.4 To register the Data Services RFC server in SAP applications

1. Run transaction *SM59*.
2. If you have not yet created the TCP/IP connection between Data Services and SAP applications, do so from the TCP/IP connection choice on this screen.
3. When the TCP/IP connection has been created and is active, click the *Create* button on the Display and Maintain RFC Destinations screen.
4. In the RFC destination box, add an RFC destination name.

   This can be any name you choose.
5. Under ▶ *Technical Settings* ▸ *Connection type* ◀, choose *T* (for TCP/IP).
6. (Optional) Under *Description*, add descriptive text.
7. Click or press *Enter*.

   The RFC Destination screen appears.
8. In the *Registration — Program ID* text box, fill in the name of the Program ID.

   This is the job name you specified for RFC Program name in the RFC Server Interface connection (see Starting the RFC server [page 2486]).
9. Click the *Test connection* button to check if the connection is successful.

   If the connection is not successful, you receive an error message. You need to debug the problem before proceeding.

12.4.4.3.5.5 Starting the RFC server

The Data Services RFC (remote function call) server is the execution link for Data Services jobs initiated by SAP applications or SAP NetWeaver BW.

To start the RFC server, in the Administrator from the *RFC Server Interface Status* page, select the desired RFC server and click *Start*. For details, see the *Data Services Administrators Guide*.

You can verify the RFC server is running in several ways:

- In the Administrator, select *SAP Connections* > *RFC Server Interface* > *RFC Server Interface Status* tab.
- View the SAP application processes.
- View the Windows or UNIX processes (depending on where the RFC server has been installed in your environment)
  If the Data Services RFC server is running, it appears among the running processes listed, for example RfcSvr.

Related Information

Management Console Guide: Starting or stopping an RFC server interface connection [page 1936]

12.4.4.3.6 Monitoring ABAP jobs in SAP applications

You can monitor an ABAP job generated by Data Services just as you would any ABAP job using the SM37 batch monitoring window.

The Data Services job name appears in the list of jobs in the SM37 window.

12.4.4.3.7 Execution modes of ABAP data flows

There are two execution modes for ABAP data flows:

- Dialog execution mode
- Batch execution mode

i Note

You cannot use the dialog and batch capabilities at the same time.

Related Information

Dialog execution mode [page 2488]

Batch execution mode [page 2488]

12.4.4.3.7.1 Overview of preparation steps

For jobs where the schedule is set and the job is initiated by SAP, do the following.

1. In Data Services, export the job to a batch file (*.bat file for Windows environments, and *.sh file for UNIX environments).
2. In SAP from transaction SE38, create the ABAP program that will execute the job schedule.
3. From transaction SM36, create the job schedule.
4. From transaction SM59, create the RFC destination by registering the Data Services RFC server with SAP.
5. In Data Services, ensure that the Job Server is running (or will be running when the job begins to execute).
6. Add an RFC Server Interface.
7. Start the RFC server or ensure that it is running (or will be running when the job begins to execute).

In SAP from transaction SM37, you can monitor the job as it runs. You can also monitor the job in Data Services. The Designer does not need to be running. If it is running, the execution window opens when the job begins to run.

Related Information

Management Console Guide: Administrator, Batch Jobs, Using a third-party scheduler (To export a job for scheduling) [page 1900]

Designer Guide: Executing Jobs, Ensuring that the Job Server is running [page 423]

Monitoring ABAP jobs in SAP applications [page 2487]

12.4.4.3.7.2 Dialog execution mode

In dialog execution mode, Data Services connects to SAP, submits and executes an ABAP program as a foreground job in SAP, then disconnects from SAP after the program execution finishes.

Dialog is the default execution mode.

An ABAP program executed in dialog mode is subject to the dialog execution time constraint (typically set to be 5 minutes) defined in the SAP system profile. If the execution time of a program executing in dialog mode exceeds the specified time-out period, SAP aborts execution of the program, producing an ABAP data flow runtime error and an exception error in Data Services.

The execution time constraint is set using the vdisp/max_wprun_time parameter in the profile corresponding to the system executing the job.

12.4.4.3.7.3 Batch execution mode

In batch execution mode, Data Services connects to SAP, submits the ABAP program as a background job in SAP, then disconnects from SAP after the program is submitted. Data Services schedules and executes the submitted program as a background job.

An ABAP program executed in batch mode is not subject to the dialog execution time constraint mentioned in that mode. However, there is a slight performance overhead due to background scheduling in SAP and execution status checking by Data Services.

> Note
>
> If you kill a Data Services job containing an ABAP data flow defined to run in batch mode, the batch program still executes. You must use SAP facilities to terminate the batch program.

When more than one ABAP data flow is running concurrently in batch mode, the batch job submissions are serialized. However, after the batch jobs are submitted, they run in parallel in the SAP application server if the server has more than one batch processor available.

To run the ABAP generated by the ABAP data flow in batch execution mode, click *Advanced* on the Edit Datastore window and set the *Execute in Background (batch)* option to *Yes*. Make sure that the Data Services SAP functions are uploaded to the SAP system running the job.

> Note
>
> The SAP application server name is not case sensitive, but the *Target host* name must be entered as it is actually registered in the SAP system.

Related Information

Installing Functions on the SAP Server [page 2408]

12.4.4.3.8 Debugging and testing ABAP jobs

Generating and executing ABAP programs from Data Services can result in the following kinds of errors:

Task	Type of error	Result
Design	Validation errors	Execution stops. Information is available interactively (in a pop-up error window).
ABAP generation	Generation errors	Execution stops. Information is available interactively (in a pop-up error window).
ABAP validation	ABAP syntax errors	Execution stops. For errors detected by Data Services, detailed information is provided in the error log. For errors detected by SAP, the message in the error log is RFC_CLOSED. In this case, you need to run the ABAP program manually in SAP to identify the problem more precisely.

Task	Type of error	Result
ABAP execution (dialog mode)	ABAP execution errors	Execution stops. Information is available interactively (in a pop-up error window).
ABAP execution (batch mode)	Job execution errors (job was cancelled)	Execution stops. The job log from SAP is available in the Data Services error log.
ABAP execution	Function exceptions	Causes an exception. Information is available in the Data Services error log if the Data Services function modules have been installed on SAP.

Related Information

Installing Functions on the SAP Server [page 2408]

12.4.4.3.9 Generating ABAP code

You can generate ABAP code to be executed manually on SAP.

12.4.4.3.9.1 To generate ABAP code

1. Open the ABAP data flow.
2. Choose ▶ *Validation* ▶ *Generate ABAP code* ◀.

   When the generation is complete, Data Services opens the text file containing the ABAP program.

   This file name and location were specified when you defined the ABAP data flow.

12.4.5 Working with functions

You can use SAP remote function calls (RFCs) in queries created in Data Services data flows. In addition, Data Services provides the SAP application BAPI interface to support the use of remote function calls designed for business transactions (BAPIs). Use the SAP application datastore to import BAPI function metadata.

SAP functions that are not RFC-enabled can be used in ABAP data flows with the following restrictions:

- The function can have only scalar, multiple input parameters. The function cannot use table parameters.
- For the output you can select only one scalar parameter.

Data Services cannot use normal functions in data flows because an SAP application normal function is not an RFC function.

However, you can write a wrapper for a normal function, which can change the function to be RFC enabled. In this case, a normal function would be supported in data flows including table parameters.

Related Information

SAP application RFC and BAPI function calls [page 2568]

12.4.5.1 Calling BAPI functions

A real-time job can apply data to SAP applications using a real-time job remote function call (RFC). The RFCs that are included in SAP application releases, called Business Application Programming Interface (BAPI) function calls (such as BAPI_SALESORDER_CREATEFROMDAT1) can be particularly useful.

The metadata for the function—displayed through the function wizard in a query—describes the input and output parameters of the function, including the columns and tables included in the transaction applied to SAP.

Related Information

Browsing, searching, and importing metadata from SAP applications [page 2440]
Calling RFC functions [page 2491]

12.4.5.2 Calling RFC functions

A real-time job can use RFC-enabled functions to retrieve information from and apply information to SAP applications. With nested tables, you can include tables as input or output parameters to the function. Functions allow you to:

- Return a specific response based on specific input you provide to the function
- Apply data to or retrieve data from more than one SAP table at a time

RFC functions can require input values for some parameters; SAP supplies default values for other inputs, and some can be left unspecified. You must determine the requirements of the function to prepare the appropriate inputs.

> Note
>
> To avoid returning errors from RFC calls, make sure input is formatted as required by SAP. For example, all character data must be in uppercase; some values require padding to fill out the length of the data type.

To make up the input, you can specify the top-level table, top-level columns, and any tables nested one-level down relative to the tables listed in the FROM clause of the context calling the function. If the RFC includes a structure as an input parameter, you must specify the individual columns that make up the structure.

A data flow may contain several steps that call a function, retrieve results, then shape the results into the columns and tables required for a response.

12.4.5.2.1 To call a function that includes tables as input or output parameters

1. Create a table that includes the columns required as input to the function as the input data set to a query.
2. In the output schema of the query, right-click and choose *New Function Call*.
3. In the *Select function* wizard, under *Function categories* select the datastore corresponding to the SAP application server where you want to apply the function.
4. Select the RFC function to call and click *Next*.
5. Enter the input parameters for the function and click *Next*.

   If there are more parameters than fit on a page in the function wizard, click the down arrow to display the next page of input parameters.
6. Select which parameters to return by selecting a column or table to include on the left and moving it to the list on the right. Click *Finish*.
   In the Query, the function appears as a nested table in the output. Your output parameters are listed as columns or tables under the function.
7. The function is automatically marked to unnest in the output of the query, so the nesting level indicated by the function name is not included in the input to the next step in the data flow.

12.4.6 IDoc interface connectivity

Your SAP system should be configured to send and receive IDocs from Data Services. Refer to the SAP application documentation for more information. Set the communication type to Unicode if the SAP system supports it.

IDoc message sources (SAP outbound IDocs) must be configured in the Data Services Designer and in the RFC client branch of the Data Services Administrator. However, you do not need to configure RFC clients for IDoc message targets (SAP inbound IDocs). The partner number, partner type, message type, and IDoc type settings you save in the Designer's IDoc target editors are the ones needed to send messages to SAP application via transactional remote function calls (tRFCs).

The remainder of this section describes Data Services functions and SAP security levels and user authorizations. These sections all apply to the ABAP, RFC, and IDoc interfaces.

Source [page 2541]

Importing IDoc metadata using the Search option [page 2441]

12.4.6.1 Batch and real-time processing overview

An SAP IDoc is an intermediate document that can be used to send and receive business documents between SAP application servers and other servers.

SAP applications offer numerous IDocs that describe different business documents. The data in an IDoc supports a particular transaction. An IDoc can contain data from multiple tables and can contain hierarchical data.

Data Services processes outbound and inbound IDocs from and to the SAP application server. SAP outbound IDocs are called IDoc sources in Data Services. SAP inbound IDocs are called IDoc targets.

The method of processing IDocs depends on the type of job in which you define the IDoc and whether the IDoc is handled as a message or a file.

In Data Services, an IDoc can be used as a source or target object in a batch or real-time job. An Idoc can be processed as a message or as a file, however the only limitation is that batch jobs cannot process IDoc messages as sources.

For example, Data Services real-time processes IDoc source messages (outbound IDocs from the SAP application server) as follows:

- The SAP system administrator includes the Access Server as a TCP, remote function call (RFC) destination.
- The SAP application server (client) publishes an IDoc after processing a transaction. For example, when an operator enters a sales order.
- The Access Server receives the published IDoc and dispatches it to an available service provider for processing.
- If no service providers are available for this IDoc type, the Access Server queues the request and dispatches it when a service provider becomes available.
- When available, a service provider processes the IDoc. The IDoc data can trigger queries to the SAP application server or cached data as required to enrich the IDoc data. The real-time job flattens and loads the required information into a data cache and/or an IDoc message target as specified in its data flow design.
- The service provider returns a response to the Access Server indicating the successful IDoc processing.
- The Access Server receives the response and sends an acknowledgment to the SAP application server so the IDoc can be marked as processed.

Target [page 2548]

12.4.6.2 IDocs and batch jobs

12.4.6.2.1 IDoc sources in batch jobs

In batch job data flows, IDoc file sources can hold one file or many individual files (to be processed at a later time).

IDoc file sources are processed as follows:

- The IDoc file is opened and the IDoc record type is examined to see which type it is.

  > Note
  >
  > IDoc file sources are validated against the IDoc Type, the IDoc Type related hierarchy, and the SAP Release.

- Related IDoc metadata is read.
- The IDoc list (one or many IDocs) is built based on the information in the *IDoc File* box.
  If an error occurs, a message like the following one displays:

  ```
  Cannot build IDoc from IDoc file: <%s>. Please see the error
                  log.
  ```

  The process terminates, and the next file is processed (if multiple IDoc files are defined).
- Each IDoc is read one by one from the IDoc list and passed to the query. A trace message is recorded in the job's trace log such as:

  ```
  Process IDoc number: <no. in the file: filename>.
  ```

Related Information

Source [page 2541]

12.4.6.2.1.1 Multiple file read

You can configure Data Services to read multiple files by listing the names of these IDoc files in the *IDoc file* box of the source editor in the Designer.

Examples:

- If you specify the IDoc file as `D:\temp\IDOC_R3*.txt`, Data Services processes data from all files in the `D:\temp` directory with names beginning with `IDOC_R3` and the extension `.txt`.
- If you specify the IDoc file `D:\temp\IDOC_R3?.txt`, Data Services processes data from all files in the `D:\temp` directory with names beginning with `IDOC_R3`, with any character before the extension, and the extension .txt.
- If you specify the IDoc file `D:\temp\IDOC_01.txt`, `D:\temp\DOC_02.txt`, `D:\temp\IDOC_03.txt`, Data Services processes data from these three IDoc files.

12.4.6.2.1.2 Variable file names

You can use variable file names in the *IDoc File/s* box. Define a global or local variable for an initialization script of a job. For example:

```
$filepath = 'D:\temp\IDOC_R3*.txt'
```

Then enter **`$filepath`** in the *IDoc File/s* box. In this way you can avoid opening each IDoc object to configure the location of source files.

12.4.6.2.2 IDoc targets in batch jobs

In batch job data flows, one or more sources can be transformed into an IDoc message target.

The sources may become active on a scheduled basis. As soon as all sources are present, the transform (a query, for example) processes the data into the IDoc format configured in the query's output schema and the IDoc message(s) are sent to SAP via a tRFC connection.

A data flow that contains an IDoc file target can be used to store IDocs. When you configure an IDoc file target, Data Services allows you to capture data for more than one IDoc. Each time a root segment passes into a file target (for example, *IDoc File* C:\temp\idoc), a new file is created and named using an eight-character suffix starting with `00000000.txt`. For example, an *IDoc File* set to `C:\temp\idoc` can store `idoc00000000.txt` to `idoc99999999.txt`.

Related Information

Target [page 2548]

12.4.6.2.3 Adding an IDoc to a batch job

When you drag an IDoc into a data flow, Data Services displays a popup menu, with valid options: *Make IDoc file source*, *Make IDoc file target*, *Make IDoc message target*.

To add an IDoc to a batch job:

1. Select an IDoc from the object library.
2. Drag it into an open data flow.
3. Select the appropriate option.

12.4.6.3 IDocs and real-time jobs

12.4.6.3.1 IDoc sources in real-time jobs

For real-time data extraction from and loading to SAP applications, Data Services uses SAP Application Link Enabling (ALE) technology and Intermediate Documents (IDocs) to capture and process transactions

Each real-time job can contain only one message source. For extracting data from SAP applications, using Data Services, that message source must be an IDoc.

A real-time job can contain other sources. Data from these supplementary sources is extracted on-demand when the real-time job is processing data from the message source.

The message source object represents the schema of the expected messages. Messages received are compared to the schema. If a data flow receives a message that does not match the schema, the data flow throws an error at run time.

You must import the schema for each SAP IDoc message type your real-time system will process.

Related Information

Defining SAP Applications datastores [page 2438]

12.4.6.3.1.1 Creating real-time jobs using IDoc sources

To create and run a real-time job that uses an IDoc message source, perform the following steps.

First see *IDoc interface connectivity* [page 2492] for information about configuring SAP to send IDocs to Data Services.

In the Designer:

1. Create an SAP Applications datastore.
2. Import IDoc metadata into the Data Services repository.
3. Create a real-time job using one or more data flows.
4. Drag an IDoc Type into the first data flow and select *Make IDoc message source*.

   > **Note**
   >
   > You cannot configure XML message sources or targets in a real-time job that has an IDoc message source.

5. Add a query and a target to the data flow.
6. Connect the objects.
7. Map the schema using the Query editor.
8. Validate and execute the real-time job by running it in test mode. Results are saved to a file you specify.
9. When the job runs as desired, open the Data Services Administrator to set up the job in a test/production environment.

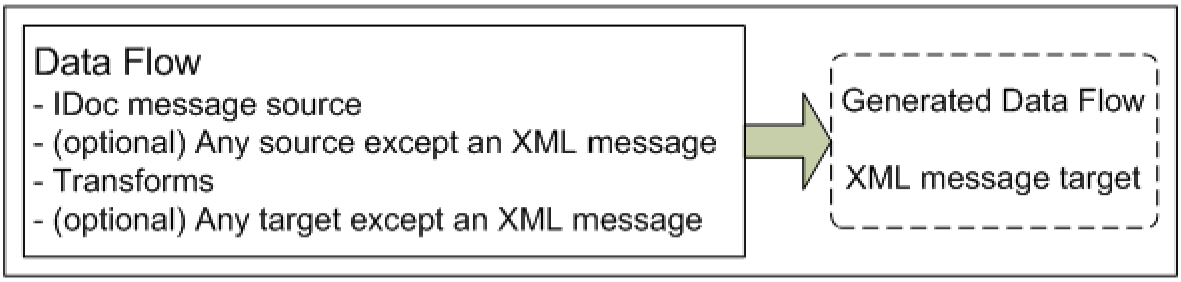
In the Administrator:

1. If you have not already done so, add a connection to the repository that contains the real-time job and add a connection to the Access Server that will manage the real-time service.
2. Add a service and service providers for the real-time job.
3. Configure an Access Server to communicate with SAP to process IDocs in real-time jobs as follows. Under the *Real-Time* node for the Access Server to configure, click *Client Interfaces*. From the *Client Interface Configuration* tab, add an RFC connection, then add supported IDocs from the *List of Supported IDocs* tab. On the *Add IDoc* page, specify the *IDoc type* (used in the job) and the *Service name* (that you just created for the real-time job).
4. From the *Real-Time Services Status* page, start the service for the real-time job.
5. From the *Client Interface Status* page, start the client.
6. From the *Real-Time Services Status* page, monitor the service and view Job Server error and trace logs to verify the service is successfully processing IDocs from SAP.

12.4.6.3.1.2 Request/acknowledge data flow model

The request/acknowledge data flow model supports the use of an IDoc as a message source in the first data flow inside a real-time processing loop. Data Services automatically generates a final data flow in any real-time processing loop that contains an IDoc message source. This final data flow contains an XML message target.

The XML message target sends an acknowledgement back to the Access Server indicating that the IDoc message source was received from the SAP application. The Access Server returns the acknowledgement to the SAP application.



Data Flow
- IDoc message source
- (optional) Any source except an XML message
- Transforms
- (optional) Any target except an XML message
Generated Data Flow
XML message target

Figure 8: Request/Acknowledge model with a single data flow

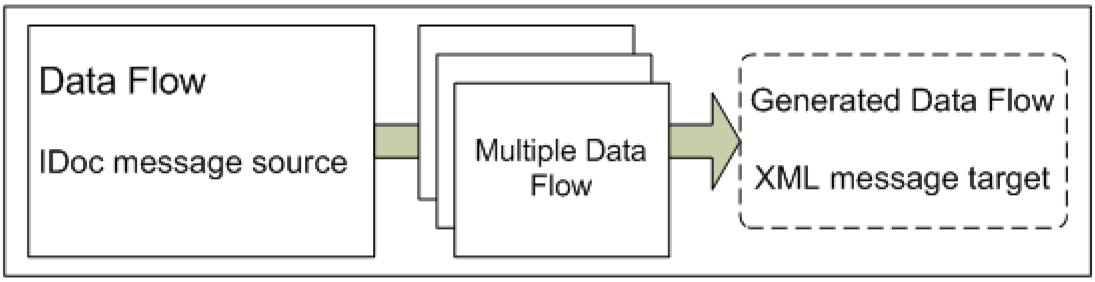


Figure 9: Request/Acknowledge model with multiple data flows

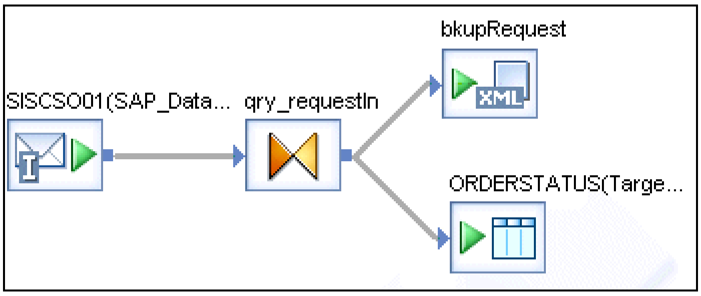
When using the request/acknowledge model, after the first data flow you can configure additional data flows, work flows, scripts, conditionals, and so on. The only limitation is that because an IDoc message source is used, XML message sources and targets cannot be configured in the job. Outside the real-time processing loop you can add initialization and/or clean-up objects as desired.

12.4.6.3.1.2.1 First data flow in a request/acknowledge model

In a request/acknowledge data flow model, the first data flow in a real-time processing loop contains an IDoc message source. To move a data set to succeeding data flows (optional), you can use a memory table as shown in the example below.



12.4.6.3.1.3 Adding an IDoc source to a data flow

Use the following procedure to add an IDoc source to a data flow.

1. Open the data flow in the workspace.
2. In the object library, select the *Datastores* tab.
3. Expand the datastore that defines the connection to the SAP application server.
4. Inside the datastore, expand the IDocs node.
5. Drag the IDoc that the data flow will process into the workspace and choose to use it as a file or message source by selecting *Make IDoc file source* or *Make IDoc message source* from the pop-up menu.

> Note
>
> If your data flow is the first one inside a real-time processing loop, it can have one and only one message source. If another message source already exists in the data flow definition, Data Services will not allow you to place another one in the workspace.

6. Drop a Query and a target (optional if your data flow is part of a real-time job) and connect the objects.
7. Define source editor options by clicking the name of the IDoc to open the source editor.

   If the IDoc source contains nested data, the schema displays nested tables to represent the relationships among the data.

   IDocs contain many nested tables and potentially hundreds of columns across the levels. It is possible that you only need to load data from a fraction of the columns from the IDoc. To make working with the IDoc contents easier, consider deleting columns and nested tables that you do not need.
8. Define the output schema.

   First double-click the Query object to open it.

   You can drag and drop or copy and paste columns from the input schema to the output schema. The icons indicate when a column is mapped. The following table shows sample input and output schemas:

Input schema	Description	Output schema	Description
E1CVBAK-VBELN	Sales document number	E1CVBAK-VBELN	Sales document number
E1CVBAK-AUART	Sales document type	E1CVBAK-E1CVBP0-PARVW	Partner function
E1CVBAK-E1CVBAP-POSNR	Sales document item number		
E1CVBAK-E1CVBP0-PARVW	Partner function		

Considerations:

- All IDoc fields have type char.
- To use two columns with the same name, you must change the name of the first column before adding the second column.

9. (Optional) Join IDoc data with an SAP table using a Query transform.

   Extract data from the SAP application table using an RFC function call. This is efficient for a small amount of data.

IDoc file [page 2562]

IDoc message [page 2564]

12.4.6.3.2 IDoc targets in real-time jobs

Most actions that users perform through a Web-enabled application require some response from the system in the form of data. The response can be as simple as an acknowledgment that a message was received. It can also be a specific set of data extracted from an SAP system or data cache. If you have configured a real-time job using an IDoc message source, you do not need to configure a target to send an acknowledgement because Data Services generates an acknowledgement (an XML message) automatically.

IDocs can also be configured as message or file targets in real-time jobs. IDoc message targets move data to SAP applications. IDoc file targets can be used to collect data for testing, data flow validation, and backup.

For example, you might want to create two identical data flows. The first has an IDoc message target and the second has an IDoc file target. The second data flow could be used to store IDocs in a file temporarily. It could be used in a job that your system administrator starts only when it is known that the target server will be down. Later, you can use a job to update the database with the data captured in the IDoc file target.

IDoc target messages can be sent from Data Services on a regular schedule or in real-time because you can choose to use IDoc message targets in either batch or a real-time jobs.

While there can only be one IDoc message source in a real-time job, any number of IDoc targets can be included in a data flow. In addition, if your source is not an SAP application server, a data flow can have an XML message as a source and an IDoc message or file as a target.

Any number of IDoc message targets can be added to a data flow. A data flow can also contain other targets such as a table or file.

Data flows in real-time and batch jobs that contain an IDoc message target send IDocs to SAP applications in the same way. The only difference is when the data is sent. Data can be sent to SAP applications on demand, or if you use an IDoc message target in a batch job, data is sent when the job is scheduled to run.

When a job is executed, output statistics from the IDoc target object are written to the real-time job's monitor log. The number of IDocs written is recorded. The number of IDocs increments for every root-level row of data passed to SAP because IDocs contain only a single root segment.

12.4.6.3.2.1 Data and format considerations

IDoc targets can insert and update data in SAP applications. For example, to create an IDoc target in Data Services, you import metadata from an existing IDoc, then reuse this metadata to create an IDoc target object in Data Services.

12.4.6.3.2.1.1 Data

The following examples list data consistency issues you should consider when planning to use IDoc targets.

Example 1

If your IDoc contains information to update a sales order, then the target IDoc (sales order) must:

- Be defined with a valid IDoc Type (name).
  In SAP, a name for an IDoc is called an IDoc type. IDoc types are subsets of message types. An example of a message type is ORDERSP, while an example of an IDoc type is ORDERS04.
- Match the SAP order number.
- Match SAP segment field formatting.
- Contain all mandatory IDoc segments for its message type.
  SAP segments are sections of IDocs. They are equivalent to tables and nested tables in Data Services. Segment fields are equivalent to columns. Each SAP message type has required segments and segment fields without which the IDoc will not be posted to SAP.
  The *Query Transform Definition* window in Data Services displays SAP segments (as tables) and SAP segment fields (as columns with data types). However, the *Query Transform Definition* window does not indicate which segments are required, nor does Data Services enforce SAP's segment repetition rules. An attribute of a segment is that it has a minimum and maximum number of times that it can occur in a single IDoc.

View SAP front-end applications to ensure you have the required order numbers and segments and your IDoc will not violate segment repetition rules. This information is also available in Data Services in the object's class attributes metadata.

Example 2

If your IDoc is a new sales order, then the sales order must:

- Be defined with valid a IDoc type, partner number, partner type, and message type names.
  Partner numbers and types are used to distribute IDoc data in SAP applications. If they do not exist or you do not specify the correct values, your IDoc will not post to SAP successfully. Use SAP front-end applications to configure SAP to receive an inbound IDoc (IDoc target) from Data Services.
  SAP applications define message types for different IDoc tasks. The message type you choose must be appropriate for the processing goal of the IDoc. Message types provide part of the required description of what is being passed to SAP. Again, reference the list of message types using SAP front-end applications.
- Match SAP segment field formatting.
- Contain all mandatory IDoc segments for its message type.

12.4.6.3.2.1.2 Data types and formats

Data Services supports several data types. IDoc Targets support only varchar.

- If an IDoc Target has columns configured in the varchar data type, no conversion occurs when it is sent to an SAP application.
- If an IDoc Target column uses another data type, the data type is converted to varchar and a default ABAP format.

The following table lists Data Services data types and their default formats:

Data Services data type	Is converted to ABAP...
date	date (YYYYMMDD)
datetime	date (YYYYMMDD)
decimal	float
double	float
int	int
interval	float
long	int
real	float
time	time (HHMISS)
varchar	no conversion

These default formats are defined by Data Services to help with the data movement to SAP applications. However, if the IDocs or the ABAP modules for IDoc processing in SAP are customized, you are responsible for modifying the default formats as needed to match the requirements.

- An IDoc can be customized in SAP
  Importing the metadata for your IDoc target can limit the risk of having a failed posting to SAP due to inconsistent formats.

- Input and posting modules can be customized
  IDocs are generated and read by ABAP modules. IDocs are processed in SAP applications first by an input module and then by a posting module. ABAP program modules control how data is interpreted. The configuration of these modules can be customized.
  For example, a posting module might be coded to receive a date formatted such as MMDDYYYY or DDMMYYYY instead of the standard ABAP date type format YYYYMMDD.

You must modify the metadata in Data Services or the format of the IDoc data generated in SAP to account for customized formats.

12.4.6.3.2.2 Adding an IDoc target to a data flow

When you drag an IDoc into a data flow, Data Services presents a pop-up menu of options for the type of data flow you are using.

To add an IDoc target to a data flow:

1. Select an IDoc from the object library.
2. Drag it into an open real-time or batch data flow.
3. Select *Make IDoc file target* or *Make IDoc message target*.
4. Add one or more source objects and a Query.

   You must copy imported IDoc file and message targets from the IDoc message target definition window into the target schema of a Query before using them in Data Services data flows.
5. Connect the source object(s) to the Query and the Query to the IDoc target object.
6. Click the name of the IDoc target.
7. Complete the IDoc target editor boxes. See *Target* [page 2548] for more information.
8. Click *OK*.

12.4.7 File formats

This section discusses SAP application file formats and how they relate to Data Services.

Related Information

Designer Guide: File Formats [page 254]

12.4.7.1 The Transport_Format

The Transport_Format is a Data Services predefined file format object for reading flat files from SAP applications. It is automatically used to define data transport objects added to SAP application data flows.

The Transport_Format appears in the *Format* tab of the object library under *Flat Files*.

You can modify it for your own use. You cannot delete it.

12.4.7.1.1 To edit the Transport_Format

1. From the object library, right-click Transport_Format and select *Edit*.

   The file format editor opens.
2. Notice that the *Type* is set to *SAP transport*, the *Name* is set to *Transport_Format*, and the *Delimiters*, which indicates where one column ends and another begins, uses the ASCII characters /127 as the column marker.

   The default delimiter for the Data Transport object is /127.

12.4.7.2 Defining an SAP applications file format

When you want to read from or write to a file in an SAP data flow and do not want to use the predefined Transport_Format, you can create your own SAP application file format.

1. Open the object library.
2. Click the *Formats* tab.
3. Right-click *Flat Files* and choose *New*.

   The file format editor opens.
4. Set the *Type* to *SAP transport*.
5. For the *Name*, use the automatically generated name, or enter a name to identify the format inside Data Services.

   The name can include alphanumeric characters and underscores (_). It cannot contain blank spaces.
6. (Optional) To use an existing file as a template for a file format, point to a file using the *Data File(s)* attribute.
   a) Under *Location*, select *Local* to indicate that you want to use a file on the computer where the Data Services Designer is running, or select *Job Server* to choose a file residing on the same computer as the default Job Server you associated with the repository.
   b) When you select *Job Server*, the browse options are disabled, so you must type the absolute path to the File name(s), or you can use a substitution parameter.

      An absolute path on UNIX might look like this:

      ```
      /user/data/abc.txt
      ```

      A path on Windows might look like this:

      ```
      C:\DATA\abc.txt
      ```

   > Note
   >
   > The Data File(s) attribute is a design-time tool that allows you to view data and create metadata schema using a data file located on the local or the Job Server computer. When the file format you create is dragged into a data flow as a source or target, you might need to change the File name and Root Directory

attributes to reflect the data files used in your job. Your data file(s) must be located relative to the Job Server computer on which your job will be executed.

When you specify the file, the editor populates the Column Attributes work area for editing and places sample data from the file in the Data View work area. As you edit column attributes, the Data View work area changes to reflect those modifications.

	Field Name	Data Type	Field Size	Precision	Scale	Format
	Sales_Office	VarChar	15			
	Region	VarChar	15			
	Date_Open	VarChar	25			
	Country	VarChar	45			
	Name	VarChar	25			
	Phone	VarChar	25			
▶						

	Sales_Office	Region	Date_Open	Country	Name	Phone
1	SalesOffice	Region	DateOpen	Country		
2	0001	NW	01011986	USA		
3	0002	NE	06011987	USA		
4	0031	SW	05011987	Finland		

Click any cell to edit it. Use mouse or keyboard navigation (tab, arrow keys) to move through the fields and view lists from which you can choose data. Right-click to view a pop-up menu to insert or delete new rows.

7. (Optional) Modify the file format delimiter.
   a) Under *Delimiters* click the *Column* box.
   b) Click the down arrow to view menu options.
   c) Click to choose a delimiter type (*Comma*, *Semicolon*, *Space*, or *Tab*). Alternately, enter an ASCII character. Valid ASCII characters range from /0 to /254.
   d) If defining a file format for a source, verify that the column delimiter matches the file from which you are reading. If defining a file format for a target, you can keep the default value.

   Note

   The data in the file cannot contain the character(s) used as delimiters.

8. (Optional) To examine the ATL file associated with this file format, click *Show ATL* to view a read-only version of the ATL file.

   To search for specific words or phrases within the file, click *Find* and enter a key word or phrase, then click *Find Next* to find occurrences of the word or phrase. Click *Cancel* when you are finished finding words or phrases. Click *Cancel* again to return to the file format editor.
9. After you edit your column attributes, click *Save & Close*.
10. If you are using an existing file as a model, verify that the fields are delimited and have the data type you expect.

File format [page 2538]
Designer Guide: File format [page 254]

12.4.8 Real-time jobs

Data Services supports real-time data transformation including receiving messages from ERP systems (such as SAP ERP) or XML-based, analytic applications. “Real-time” means that Data Services reacts to messages as they are sent, performing predefined operations and responding appropriately.

You define the operations performed to process messages and create responses by building real-time jobs using the Data Services Designer and then by converting those jobs to on-demand services using the Data Services Administrator.

This section discusses real-time jobs in the SAP applications environment.

Related Information

Designer Guide: Real-time jobs [page 372]

12.4.8.1 SAP application table sources in real-time jobs

You can use SAP tables as sources in real-time jobs after you import metadata for the table into your repository. When you drag an SAP table to a data flow definition, it becomes a source.

When the data flow performs a query against the SAP table, it executes an SAP function call to extract the data through the SAP application server.

If you include an SAP table in a join with a real-time message source, Data Services includes the data set from the real-time message source as the outer loop of the join. If more than one supplementary source is included in the join, you can control which table is included in the next outermost loop of the join using the join ranks for the tables.

12.4.8.1.1 To use an SAP application table in a data flow

1. Import the metadata for the table using a datastore.

   The table appears in the table category under the datastore in the object library.
2. Drag the table into the data flow.
3. Connect a query to the output of the table.

Because SAP application tables are designed to extract a limited amount of data, the first step after the source would most likely be a query with a WHERE clause that limits the data extracted.

4. In the WHERE clause of the query, add an expression to reduce the amount of data extracted from SAP by this source.

   The join expression in the ON clause of the query includes specific data from the message that the data flow is processing. For example, if the data flow is using the ERP table VBUK to supply delivery status values to respond to an e-commerce application, the join expression would restrict the values from VBUK to the specific sales order referred to in the incoming message. In this case, the join expression restricts the values to sales order number and line item numbers matching the input.

12.4.8.2 Caching source data

All tables or files used as sources allow you to set a cache option. The option indicates that the data extracted is stored in memory until the data flow processing is complete.

In real-time jobs, you should not cache sources unless the data being cached is small and is unlikely to be updated in the life of the real-time process.

In batch jobs, caching can improve the performance of data flow processing by reducing the number of times a set of data is read from the database or file source. In real-time jobs, however, the improvement in performance provided by caching is minimized by the likelihood that the job reads only a small amount of data from the source for any given message. In addition, because the job reloads cached data only when the Access Server shuts it down and restarts it, cached data may become stale in memory.

12.4.8.3 Data cache targets and transactional loading

In addition to IDocs, you can use tables and files as targets in real-time jobs. Target tables in data flows also support transactional loading, in which the data resulting from the processing of a single message can be loaded into multiple tables as a single transaction. No part of the transaction is applied if any part fails.

You can specify the order that tables are included in the transaction through an option in each target table editor.

Loading targets as a single transaction only applies to targets in a single datastore. If the real-time job loads tables in more than one datastore, targets in each datastore are loaded independently.

In addition, the options to bulk load a table or to include pre-load or post-load commands are not available for tables used as targets in transactional loading.

12.5 Connecting to SAP NetWeaver Business Warehouse

To use an SAP data source as a Data Services source, you must define a Data Services datastore to serve as the logical link to SAP, then import your metadata into the Data Services datastore.

Related Information

Designer Guide: Datastores [page 209]

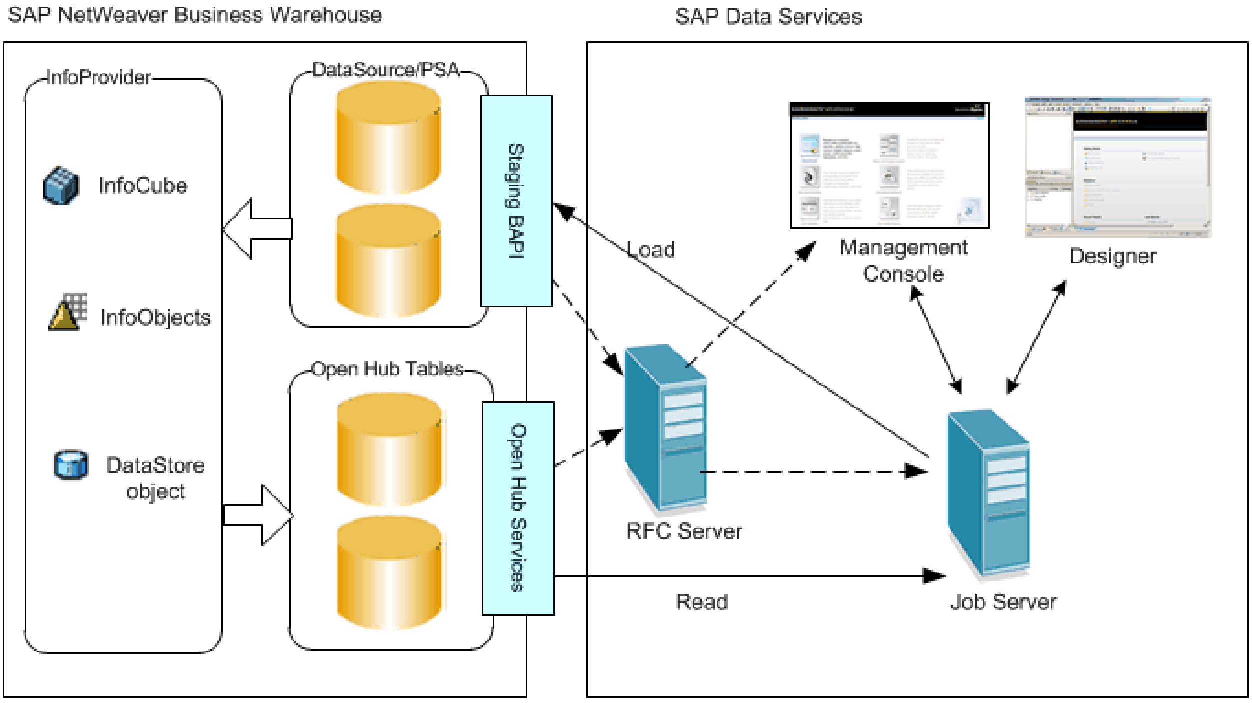
12.5.1 Using Data Services in SAP NetWeaver Business Warehouse environments

SAP Data Services provides the following capabilities in an SAP NetWeaver Business Warehouse (BW) environment:

- Read data from an InfoProvider (such as an InfoCube, DataStore object, and InfoObject) in one of the following ways:
    - SAP Open Hub Destination service which executes an SAP NetWeaver BW process chain that reads the data from the InfoProvider and loads an Open Hub Destination table that Data Services reads as a source table.
    - Auto-generated ABAP program or RFC functions that read data from the underlying tables of the InfoCube, DataStore object, or InfoObject.

  The preferred method is to use the SAP Open Hub Destination service to read from a BW InfoProvider.
- Load data into an SAP NetWeaver BW InfoSource by using a Data Services batch job which you can start in one of the following ways:
    - Execute a Data Services batch job that calls a BW InfoPackage automatically to load a BW InfoProvider.
    - Use an InfoPackage in SAP NetWeaver BW to schedule and execute the Data Services load job which has been exported to SAP NetWeaver BW.

The following diagram shows a high-level overview of the components involved with reading data from and loading data to an SAP NetWeaver BW system.



This diagram shows that:

1. Data Services can load data into a DataSource in the Persistent Storage Area (PSA) using the Staging Business Application Programming Interface (BAPI), with support from the RFC Server.
2. Data Services can read data from a BW system by using the Open Hub Service with support from the RFC Server.

For more information about Data Services and BW, see the following topics::

- *Netweaver 7.3: Transferring Data with SAP Data Services*
- *Netweaver 7.4: Transferring Data with SAP Data Services*

Loading into SAP NetWeaver BW [page 2524]

12.5.2 SAP NetWeaver BW datastores

SAP NetWeaver Business Warehouse (SAP NetWeaver BW) is a business warehouse application that runs on an SAP application server.

You can extract data from the SAP source, transform it as specified in a Data Services batch job, and load it into various targets including a predefined SAP BW InfoSource.

Data Services provides two datastore types for SAP BW: one for sources and one for targets. For other datastore types, you create a datastore, import objects such as tables, then create sources and targets using those objects. For SAP BW, you create separate source and target datastores because they expose different objects.

12.5.2.1 SAP NetWeaver BW as a source

SAP NetWeaver BW can be used as a source in Data Services by using a SAP BW Source datastore. You can import the same objects as in SAP Applications datastores except hierarchies. In addition, you can browse and import InfoAreas, InfoCubes, ODS objects, and Open Hub tables.

To use SAP NetWeaver BW data as a source:

- Define an SAP BW Source datastore that will serve as the logical link to your BW system.
- Import the SAP BW metadata into Data Services using the SAP BW Source datastore.

12.5.2.1.1 Defining an SAP BW Source datastore

To define an SAP BW Source datastore:

1. In the Designer's object library, select the *Datastores* tab.
2. Right-click in a blank area of the object library window and select *New*.
   The *Create New Datastore* window opens.
3. Enter a name for the datastore in the *Datastore name* box.

   The name can contain any alphabetic or numeric characters or underscores (_). It cannot contain spaces.
4. For the *Datastore type* box, select *SAP BW Source*.
5. In the *Application server* box, type the host name.

   The host name can be either the host name or an SAP routing string plus the host name. An example of valid syntax for an SAP routing string is:

```
/H/<IP_Address_of_local_SAP_router>/H/<IP_Address_of_target_SAP_router>/H/
<IP_Address_of_target_application_server>
```

6. Type the *User name* and *Password*.
7. Click *Advanced* to enter properties for the SAP application server on which BW is running.

   The recommended method to extract data from a BW system is through the Open Hub Destination service. However, it is still possible to use an ABAP program or RFC functions to extract data from the underlying tables of the InfoAreas, InfoCubes, and DataStore objects.

   a) The following Advanced options are always required regardless of which method you use to extract data from a BW system. Ensure that the default values for these Advanced options are what you want:

      ○ *Language*
      ○ *Code page*
      ○ *Client number*
      ○ *System number*

   b) If you want to use an ABAP program or RFC functions, you must also specify *Data transfer method* and the associated options for each transfer method (for details, see the link in Related Topics below).

8. Click *OK* to add the SAP BW Source datastore.

   The object library displays the newly created SAP BW Source datastore.

You can now browse and import the Open Hub tables or the BW InfoProvider tables that will serve as your SAP BW source.

Related Information

Datastore [page 2531]

12.5.2.1.2 Using the sapnwrfc.ini file

To change or add parameters without modifying the datastore settings, you can specify them in an `sapnwrfc.ini` file.

Place your sapnwrfc.ini file in the same directory as the RFC client/server program (for Data Services, commonly `%LINK_DIR\bin`). Or you can specify the DS_NWRFC_INI environment variable in the operating system. For example, you could can place the sapnwrfc.ini file in `C:\Temp` and specify `DS_NWRFC_INI=C:\Temp`.

You can specify an `sapnwrfc.ini` file for two different applications in Data Services:

- To use an sapnwrfc.ini file to override datastore settings, edit the SAP datastore in the Designer. From the object library, open the editor for the SAP datastore to configure and click *Advanced*. Under the *SAP* option category, for *Use sapnwrfc.ini*, select *Yes* and enter the appropriate *Destination name*.
- To use an sapnwrfc.ini file for real-time IDocs, configure the RFC client in the Administrator. Expand the *Real-Time* node, and for the Access Server to configure, click *Client Interfaces*. Open an instance of the RFC client, and select the check box to *Use sapnwrfc.ini* and enter a destination name.

> i Note
>
> Data Services ignores the parameters USER, PASSWD, and CLIENT in sapnwrfc.ini because storing these security-related parameters could introduce a security risk.

For more information about how to use the `sapnwrfc.ini` file, refer to the SAP documentation at *http://help.sap.com/saphelp_nwpi711/helpdata/en/48/ce50e418d3424be10000000a421937/frameset.htm*.

12.5.2.1.3 Browsing and importing metadata for an SAP BW source

You can import metadata from the object library in several ways:

- By name when you know the name of the object you want to import
- By browsing when you do not know the name of the objects

- By searching when you know the partial name of the object and you have a large number of objects

12.5.2.1.3.1 To import SAP NetWeaver BW source metadata by name

1. In the object library, select the name of your SAP NetWeaver BW Source datastore.
2. Right-click and choose *Import By Name*.
3. In the *Import by Name* window, select the type of metadata that you want to import from the Type drop-down list.
    - If you select *Open Hub Table*, type the name of the table in the *Name* field.
    - If you select InfoArea, InfoCube or ODS object, the *Name* field offers a list of available objects. Select the name of the object you want to import.
4. Click *OK*.

    The specified source appears in the object library.

12.5.2.1.3.2 To import SAP NetWeaver BW source metadata by browsing

1. In the object library, right-click the name of the BW datastore.
2. Select *Open*.
    The Repository Metadata opens in the workspace.
3. Select *External Metadata* to view the BW objects that you can import.

    The BW external metadata browser opens with the Open Hub Tables node expanded by default. You can scroll down to an InfoArea, InfoCube, or DataStore object, expand the object, and browse its lower level content to identify the objects that provide data to it.
4. Select the structures to import.

    For Open Hub Tables, you can select:
    - A parent category (imports all Open Hub Tables)
    - A single Open Hub Table
    - A subset of Open Hub Tables by using the CTRL or CTRL + SHIFT keys

    For InfoAreas, InfoCubes, or DSOs, you can select:
    - A parent category (imports the parent and all its children)
    - A single category
    - A subset of objects by using the CTRL or CTRL + SHIFT keys
5. Right-click and choose *Import*.
    The imported structures appear in the object library. You can also open the datastore to see the contents of the datastore in the workspace by using the Repository Metadata option.

12.5.2.1.3.3 To import SAP NetWeaver BW source metadata by searching

1. In the object library, select the name of your SAP NetWeaver BW Source datastore.
2. Right-click and choose *Search*.
3. Use the Search dialog to find and import metadata.

12.5.2.2 SAP NetWeaver BW as a target

Data Services can use SAP NetWeaver BW as a target by using an SAP BW Target datastore.

You can execute the job directly from the Data Services Designer or from SAP NetWeaver BW using BAPI functions through the Data Services RFC Server.

12.5.2.2.1 SAP NetWeaver BW loading profile

If you are using Data Services to load data into SAP NetWeaver BW during production, create an SAP application profile, such as BODS_BW_PROD, that defines additional authorizations for PRODUSER. This profile requires the following authorizations:

- S_RS_ADMWB
- S_RFC

Related Information

S_RS_ADMWB [page 2428]
S_RFC [page 2427]

12.5.2.2.2 To use an SAP NetWeaver BW InfoSource as a Data Services target

1. Define a Data Services SAP BW Target datastore that will serve as the logical link to your SAP system.
2. Import your SAP NetWeaver BW InfoSource metadata into the Data Services SAP BW datastore.

Related Information

Defining an SAP BW Target datastore [page 2513]

Browsing and importing metadata for an SAP BW target [page 2514]

12.5.2.2.3 Defining an SAP BW Target datastore

To define an SAP BW Target datastore:

1. In the Designer's object library, select the *Datastores* tab.
2. Right-click in a blank area of the object library window and select *New*.

   The *Datastore Editor* window opens.
3. Enter a name for the datastore in the *Datastore name* box.

   The name can contain alphanumeric characters or underscores (_). It cannot contain spaces.
4. For the *Datastore type* box, select *SAP BW Target*.
5. In the *Application server* box, type the SAP host name.
6. Type the *User name* and *Password*.
7. Click *Advanced* to verify the following required properties for the SAP application server on which BW is running:
   - *Language*
   - *Code page*
   - *Client number*
   - *System number*
   - *Routing string*

   Include routing string information if your application server is a remote system accessed through a gateway. No SAP application routing permissions are required, but you must use the specified syntax in the *Routing string* field to ensure connection. An example of valid syntax for an SAP routing string is:

   ```
   /H/<IP_Address_of_local_SAP_router>/H/<IP_Address_of_target_SAP_router>/H/
   <IP_Address_of_target_application_server>
   ```
8. Click *OK* to add the datastore.
   SAP BW Target datastores display in the object library.

You can now browse and import the metadata for the Master and Transaction Transfer Structures that will serve as your SAP BW target.

For more information, see “Internationalization” in the SAP Library.

Related Information

Datastore [page 2531]
SAP Library - Internationalization

12.5.2.2.4 Using the sapnwrfc.ini file

To change or add parameters without modifying the datastore settings, you can specify them in an `sapnwrfc.ini` file.

Place your sapnwrfc.ini file in the same directory as the RFC client/server program (for Data Services, commonly `%LINK_DIR\bin`). Or you can specify the DS_NWRFC_INI environment variable in the operating system. For example, you could can place the sapnwrfc.ini file in `C:\Temp` and specify `DS_NWRFC_INI=C:\Temp`.

You can specify an `sapnwrfc.ini` file for two different applications in Data Services:

- To use an sapnwrfc.ini file to override datastore settings, edit the SAP datastore in the Designer. From the object library, open the editor for the SAP datastore to configure and click *Advanced*. Under the *SAP* option category, for *Use sapnwrfc.ini*, select *Yes* and enter the appropriate *Destination name*.
- To use an sapnwrfc.ini file for real-time IDocs, configure the RFC client in the Administrator. Expand the *Real-Time* node, and for the Access Server to configure, click *Client Interfaces*. Open an instance of the RFC client, and select the check box to *Use sapnwrfc.ini* and enter a destination name.

> Note
>
> Data Services ignores the parameters USER, PASSWD, and CLIENT in sapnwrfc.ini because storing these security-related parameters could introduce a security risk.

For more information about how to use the `sapnwrfc.ini` file, refer to the SAP documentation at *http://help.sap.com/saphelp_nwpi711/helpdata/en/48/ce50e418d3424be10000000a421937/frameset.htm*.

12.5.2.2.5 Browsing and importing metadata for an SAP BW target

To access InfoSource metadata in Data Services, import its metadata into the object library.

You can import InfoSource metadata in one of two ways:

- By name
- By browsing

12.5.2.2.5.1 To import InfoSource metadata by name

1. In the object library, select the name of the SAP BW Target datastore.
2. Right-click, and choose *Import By Name*.
3. In the Import by Name window, specify the Source System and InfoSource names.

   Also, specify whether the InfoSource type is Master or Transaction. If the InfoSource type is Master, specify whether the subtype is Text, Attributes, or Hierarchy.
4. Click *OK*.

   The imported objects appear in the object library under the target datastore node.

12.5.2.2.5.2 To import InfoSource metadata by browsing

1. In the object library, right-click an SAP BW datastore.
2. Choose *Open*.

   The metadata browser opens in the workspace.

   From this viewer you can browse both Master and Transaction InfoSources. Both are sorted in alphabetical order.

   Master Transfer Structures contain dimension data, and Transaction Transfer Structures contain fact data.

   A single InfoSource can be loaded from multiple Source Systems. If you expand an InfoSource you can see all the Source Systems that provide data to it.
3. Select the structures to import.
4. Right-click and choose *Import*.

   The imported structures appear in the object library.

12.5.3 Reading from SAP NetWeaver BW

SAP NetWeaver Business Warehouse provides an Open Hub Service through which SAP Data Services can read data from an InfoProvider. The Open Hub Service extracts data from an InfoProvider and loads it into an Open Hub Destination object that Data Services reads. Data Services uses the Destination Type Third Party Tool.

The following is an overview of the tasks that you must do to read from an Open Hub Destination table:

- In the SAP Data Warehousing Workbench, define an RFC destination and set up the Open Hub Destination object.
- In the Data Services Management Console, set up the RFC server in the Administrator.
- In the Data Services Designer, do the following:
  - Define an SAP BW Source datastore to connect to the BW System that has the Open Hub Destination table.
  - Import the Open Hub Destination table.
  - Create an Data Services job to start the BW process chain that loads data from the InfoProviders into an Open Hub Destination table, receive notification when the data is available, read the data, and delete the data from the Open Hub Destination table after successfully reading the data.

Related Information

Setting up the Open Hub Destination object [page 2516]
Setting up the RFC server to read an Open Hub table [page 2516]
Defining an SAP BW Source datastore [page 2509]
Importing Open Hub tables [page 2517]
Creating a job to read an Open Hub table [page 2518]
Running the job to read an Open Hub table [page 2518]

12.5.3.1 Setting up the RFC server to read an Open Hub table

The Remote Function Call (RFC) Server is required when a job reads from an Open Hub Destination table in SAP NetWeaver Business Warehouse (BW). When you execute the SAP Data Services job, Data Services first launches the BW process chain to load the Open Hub Table. The RFC Server notifies Data Services when the load has completed. The Data Services job can then read data from the Open Hub Table, transform it, and load the data to a target.

To set up the RFC Server to read Open Hub Destination tables, you must do the following tasks:

- In the SAP Data Warehousing Workbench, define an RFC Destination:
  - Specify a name in *RFC Destination*.
  - Ensure that *Connection Type* has the value **`TCP/IP Connection`**.
  - On the *Technical Settings* tab, in the *Registered Server Program* area, specify a name for your RFC Server in *Program ID*.
    The value in *Program ID* is the value that you specify in option *RFC Program ID* when you configure the RFC Server in Data Services.
- In the Management Console of Data Services, go to the Administrator and do the following to configure the RFC Server:
  - Select ▶ *Management* ▶ *Repositories* ◢ on the navigation tree, and add the repository where you imported the Open Hub table.
  - Select ▶ *SAP Connections* ▶ *RFC Server Interface* ◢ on the navigation tree, and configure the RFC Server associated with the Open Hub table.
    In the option *RFC Program ID*, specify the value of option *Program ID* when you defined the RFC Server in the Data Warehousing Workbench. The value of attribute *3RDPARTYSYSTEM* for the Open Hub table is also the value of *Program ID*.
  - Start the RFC Server.

> i Note
>
> You cannot have multiple RFC server instances that refer to the same Program ID running in the Data Services environment.

Related Information

Management Console Guide: Administrator, Adding an RFC server interface [page 1935]

12.5.3.2 Setting up the Open Hub Destination object

Use the SAP Data Warehousing Workbench to define an RFC destination and set up an Open Hub Destination object.

1. Define an RFC Destination that points to Data Services RFC Server registered Program ID.

- ○ Specify a name in *RFC Destination*.
- ○ Ensure that *Connection Type* has the value **`TCP/IP Connection`**.
- ○ On the *Technical Settings* tab, in the *Registered Server Program* area, specify a name for your RFC Server in *Program ID*.
  The value in *Program ID* is the value that you specify in the option *RFC Program ID* when you configure the RFC Server in the Data Services Administrator on the Management Console.

2. Create an Open Hub Destination and specify the following options:
   - ○ For *Destination Type*, select *Third Party Tool* in the drop-down list.
   - ○ For *RFC Destination*, specify the name that you defined in step 1.
3. Create a Data Transfer Process (DTP) to extract data from an InfoProvider and load it to the Open Hub Destination table.
4. Create a process chain to execute the DTP.

   i Note

   Each process chain can only contain one DTP of the Open Hub Destination.

12.5.3.3 Importing Open Hub tables

The Open Hub Destination tables must already be defined in SAP NetWeaver BW before you can import their metadata into SAP Data Services. When you browse the list of Open Hub tables in the SAP BW Source datastore in Data Services, only the Open Hub objects with destination type Third Party Notification are visible.

i Note

Although import by browsing might be the simpler way to import Open Hub tables, the following procedure describes how to import by searching to provide an example if you have a BW system with a large number of objects and browsing might be more difficult.

1. In the object library, select the name of your SAP NetWeaver BW Source datastore.
2. Right-click and choose *Search*.
3. In the *Search* window, do the following actions to find and import metadata.
   a) Ensure that the value for *Select location* is *External Data*.
   b) In the *Object Type* drop-down list, select *Open Hub Tables*.
   c) Choose the *Select criteria* you want and type in the string you want to find.
   d) Click *Search*.
   e) From the search result list, select the table names that you want, right-click, and choose *Import*.

The *Local Object Library* shows the imported objects under the Open Hub Tables node under the datastore name.

Related Information

12.5.3.4 Creating a job to read an Open Hub table

This topic describes the usage scenario of one user reading from one Open Hub table.

> Note
>
> When you import Open Hub Tables, you can use them in regular data flows. If you import InfoAreas, InfoCubes, or DataStore objects, Data Services imports the underlying ABAP tables which you use in ABAP data flows so that you can push down the ABAP functions. If you use the ABAP tables in regular data flows, you cannot push down the ABAP functions.

1. In the SAP Data Services Designer, create a job, a work flow, and data flow within the job.
2. Select an Open Hub table from the local object library and drag it into the open data flow.
   The Open Hub table becomes a source object in the data flow.
3. Double-click the Open Hub source object in the data flow to open the editor and specify the following options.
   a) For *Open Hub Table*, leave the default value (name of the current Open Hub table).
   b) Select *Execute process chain before reading* to start the SAP NetWeaver BW process chain that loads the Open Hub table from which the Data Services Open Hub source object reads the data.
   c) For *Process chain name*, ensure that the default value (first process chain name listed in the attributes for the current Open Hub table) is the correct process chain.

   For details about the options on the Open Hub Table editor, see the Related Topic below.
4. Add the transforms you want to perform on the extracted data and add your target to the data flow.
5. If you want to take specific actions for any errors that might occur while accessing and reading the Open Hub table, add a try/catch block and select the exception group SAP BW execution errors (1009).
6. Save the job and data flow.

Before you execute the job, you must set up the RFC server.

Related Information

Setting up the RFC server to read an Open Hub table [page 2516]
Open Hub Table source [page 2565]
Designer Guide: Work Flows, Defining a try/catch block [page 338]

12.5.3.5 Running the job to read an Open Hub table

The SAP Data Services job initiates the process chain to load the Open Hub Destination table in SAP NetWeaver BW.

The following must be running for job execution to complete successfully:

- The SAP NetWeaver BW application server where the Open Hub Destination tables reside
- The SAP Data Services RFC Server
- The SAP Data Services Job Server

1. From the Designer of the SAP Data Services, open the project that contains your Open Hub job.
2. Right-click the job name and select *Execute*.
   The *Trace log* window opens and you can see the job progress messages. A message appears when the process chain completes.

   If an error occurs, the Error log displays the status of the process chain execution. For information about the status codes for the process chain execution, see the Related Topic below.

Related Information

sap_openhub_processchain_execute [page 1654]

12.5.3.6 Reading multiple Open Hub tables

This section describes examples of when you might want to read from multiple Open Hub tables.

12.5.3.6.1 Creating a data flow for multiple users to read one InfoProvider

In this scenario, two users want to extract data from the same InfoProvider (InfoCube or DataStore object) in SAP NetWeaver BW to transform and load to a target in SAP Data Services. For example, one user might want to obtain information about materials in Europe and a second user might want the same materials information in North America. Both users can use the same Data Services data flow and specify their specific Open Hub table and process chain with substitution parameters.

1. In the BW Administrative Workbench, define two different Open Hub Destinations that have the same schema. For each Open Hub Destination, define a Data Transfer Process (DTP) that extracts the data with a filter for each geographic area.
   For example, you might define `OpenHubEurope` and `OpenHubNA`.
2. In the Designer of Data Services, in your Open Hub datastore in the *Local Object Library*, import the Open Hub Destination tables.
3. Define substitution parameters for the Open Hub table name and process chain name. To add and define a substitution parameter:

   a) In the Designer of Data Services, select *Tools* > *Substitution Parameter Configurations*.
   b) In the *Substitution Parameter Editor*, scroll to the bottom of the parameter list and double-click the blank cell to enable editing.

   c) Type the name of your substitution parameter, prefaced with **`$$`**.
   For example, you can enter **`$$OpenHubTable`**.
4. You can define default values in a substitution parameter configuration and associate these defaults with a system configuration.
   For example, you might have an existing system configuration for Europe and one for North America.
   a) Create a substitution parameter configuration for each system configuration: **`Sub_Parm_Config_Europe`** and **`Sub_Parm_Config_NA`**.

      For details about creating a substitution parameter configuration and associating it with a system configuration, see the Related Topic below.
   b) To define default values, double-click in the blank cell next to the substitution parameter name in the column that identifies each substitution parameter configuration and type the constant value.
      For example, you might type **`OpenHubEurope`** as the default value for the substitution parameter *$$OpenHubTable* in the column for *Sub_Parm_Config_Europe*. Similarly, you might type **`OpenHubNA`** in the column for *Sub_Parm_Config_NA*.
5. Create a Data Services data flow.
6. Select an Open Hub table from the *Local Object Library* and drag it into the open data flow.
   The Open Hub table becomes a source object in the data flow.
7. Double-click the Open Hub source object in the data flow to open the editor and specify the following options.
   a) For *Open Hub Table*, click the arrow to display the drop-down list, and select the substitution parameter that you defined for the name of the Open Hub Table in step 2.
   b) Select *Execute process chain before reading* to start the SAP NetWeaver BW process chain that loads the Open Hub table from which the Data Services Open Hub source object reads the data.
   c) For *Process chain name*, click the arrow to display the drop-down list, and select the substitution parameter that you defined for the process chain name in step 2.

   For details about the options on the Open Hub Table editor, see the Related Topic below.
8. Add the transforms you want to perform on the extracted data and add your target to the data flow.
9. If you want to take specific actions for any errors that might occur while accessing and reading the Open Hub table, add a try/catch block and select the exception group SAP BW execution errors (1009). For details about how to define a try/catch block, see the Related Topic below.
10. Save the data flow.
11. Before you execute the job, ensure that the RFC server has been set up on the Management Console Administrator:
    - Configure the repository where you imported the Open Hub table.
    - Define the RFC Server associated with the Open Hub table.
    - Start the RFC Server.
12. When you execute the job, select the system configuration associated with your substitution parameter configuration.
    - In the Management Console Administrator, you can select the system configuration on the following pages:
      - Execute batch job.
      - Schedule batch job.
      - Export execution command.

      To override the default value of a substitution parameter, use the *Add Overridden Parameter* option on these pages.

- In the Data Services Designer, you can select the system configuration on the *Execution Options* tab of the *Execution Properties* window. To override the default value of a substitution parameter, use the *Pick a Substitution Parameter* option on the *Substitution Parameter* tab.

Designer Guide: Work Flows, Defining a try/catch block [page 338]

Setting up the RFC server to read an Open Hub table [page 2516]

12.5.3.6.2 Creating a data flow to join multiple Open Hub tables

In this scenario, one user reads two Open Hub tables to join the data from them. The Data Services job will consist of a work flow that contains the following:

- A script that contains an SAP function to launch the process chains that extract data from the InfoProvider objects and load it to tables in the Open Hub Destination.
- A data flow to read the Open Hub tables.
- A script to send the Open Hub read status to the BW system.

1. In the BW Administrative Workbench, define Process Chains, each with one Data Transfer Process that extracts the data from the InfoProvider and loads to the Open Hub Destination table.
2. In the Data Services Designer, import the Open Hub Destination tables that you want to join.
3. In the Data Services Designer, create a job, create a work flow, and add a script to the work flow.
4. Open the script and add the following:
   a) For each Open Hub table, add the function sap_openhub_processchain_execute to start the Process chain.
   The following sample function specifies the open hub table **`Materials`** and the process chain **`Materials_PC`**.

   ```
   sap_openhub_processchain_execute('open_hub_datastore','Materials',
   'Materials_PC',<$pclogid>,<$returntxt>)
   ```

   For details about this function, see the Related Topic.
   b) If you want to take specific actions for any errors that might occur while reading the Open Hub table, check the return value of the function sap_openhub_processchain_execute.
   For example, the following script commands check the return value, generate an exception, and print the error if the function is not successful.

   ```
   $status = sap_openhub_processchain_execute('open_hub_datastore',
   'Materials','Materials_PC',<$lpcogid>,
   <$returntxt>);
   If ($status != 'S') raise_exception ('Materials_PC process chain execution
   failed ' || $returntxt);
   ```

   c) If you want to take further actions for any errors that might occur while reading the Open Hub table, add a try/catch block around the data flow and select the exception group SAP BW execution errors (1009).

5. Create a data flow and, from the Local Object Library, drag in each Open Hub table that you want to join.
6. For this scenario, you do not need to open the Open Hub Table editor because you can leave the defaults for the following Open Hub source options:
   a) For *Open Hub Table*, leave the default value (the name of the current Open Hub table).
   b) *Execute process chain before reading* is unselected by default. Keep this default because the first script starts the SAP NetWeaver BW process chain that loads the Open Hub table from which the Data Services Open Hub source object reads the data.
   c) *Process chain name* will be disabled because *Execute process chain before reading* is not selected.

   For details about the options on the Open Hub Table editor, see the Related Topic below.
7. Add the Query transform to join the Open Hub tables, add any other transforms you want to perform on the extracted data, and add your target to the data flow.
8. Add a second script after the data flow in the work flow.
9. Open the second script and for each Open Hub table, add the function sap_openhub_set_read_status to the RFC Server to send the status of the Open Hub table read to the BW system.
   For example, the following function specifies the open hub destination **`Materials`**.

   ```
   sap_openhub_set_read_status('open_hub_datastore','Materials',
   <'X'>,<$returntxt>)
   ```

   The function sap_openhub_set_read_status deletes the data from the BW Open Hub Destination.
10. Save the job and data flow.
11. Before you execute the job, make sure you do the following:
    - Configure the repository where you imported the Open Hub table
    - Define the RFC Server associated with the Open Hub table
    - Start the RFC Server

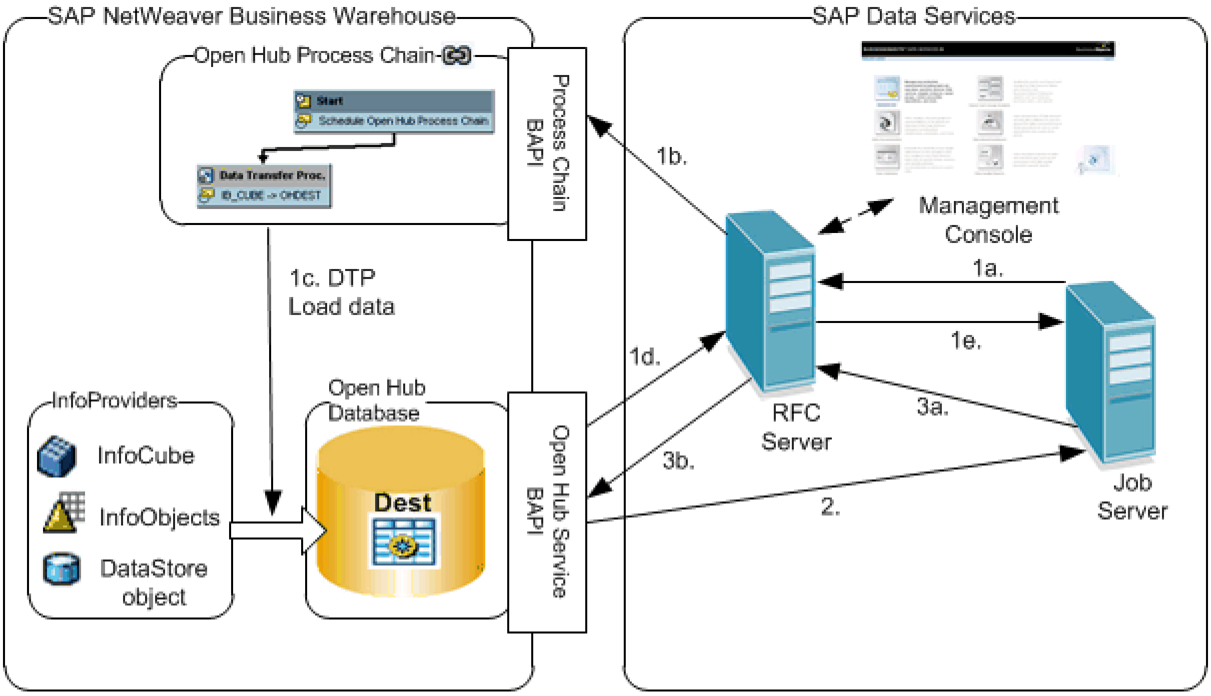
12.5.3.6.3 Data Services Open Hub Reader run-time architecture

The following diagram shows a high-level overview of the components involved when using the SAP Open Hub Destination service to read data from an SAP NetWeaver BW system.



This diagram shows:

1. The Data Services job executes function sap_openhub_processchain_execute which starts the following process:

   a.

   a. Sends a web service request to the Open Hub RFC Server to start the process chain.
   b. The RFC Server starts the Process Chain in BW system.
   c. The Process Chain contains a Data Transfer Process (DTP) that extracts data from the InfoProvider and loads the Open Hub Destination table.
   d. When the DTP completes, the Open Hub Service notifies the RFC Server.
   e. The RFC Server notifies the Job Server that the Open Hub table is loaded and returns the read request ID of the Open Hub Destination.
2. The Data Services data flow reads the data from the Open Hub table using read request ID.
3. The Data Services job contains a second script that executes the function `sap_openhub_set_read_status` which starts the following process:
   a. Sends a web service request to the Open Hub RFC Server to set the read status.
   b. RFC Server sets the read status in the Open Hub BW system which deletes the data from the Open Hub Destination table.

12.5.3.7 Open Hub table restrictions

The following restrictions exist when using Open Hub tables:

- Only one job at a time can read an Open Hub Destination table.
- A process chain of an Open Hub Destination can contain only one of its Data Transfer Processes (DTPs).
- Each process chain cannot contain DTPs for more than one Open Hub Destinations.

12.5.4 Loading into SAP NetWeaver BW

This section describes the following tasks:

- Preparing the job
- Setting up SAP NetWeaver BW InfoCubes and InfoSources
- Designating Data Services as a source system
- Job execution

You can execute Data Services jobs to load to SAP NetWeaver BW from the Designer or you can schedule them from SAP or Data Services.

> i Note
>
> This section assumes you are an experienced SAP NetWeaver BW user and have already followed similar procedures. Your system might be configured differently than in the examples, so treat the steps in the procedures as high-level information. You might need to provide additional details or do the steps in a somewhat different order.

12.5.4.1 Preparing the job

This topic provides an overview of how to prepare to load data into SAP NetWeaver BW.

First, in SAP NetWeaver BW define the appropriate SAP security profiles and authorizations.

In the Data Services Designer:

1. Add datastores for:
   - The system where your source data resides.
   - The system where your SAP NetWeaver BW InfoSource (Transfer Structure) resides (using an SAP BW Target datastore).
2. Import the source and target metadata.
3. Construct and validate the job that will extract data from the source to the SAP NetWeaver BW InfoSource.

In the Data Services Administrator:

1. Add the repository that includes the job.
2. Start the RFC server. In the Administrator, add an RFC Server Interface and start it from the status page.

Related Information

SAP NetWeaver BW as a target [page 2512]
Management Console Guide: Administrator, Starting or stopping an RFC server interface connection [page 1936]
Starting the RFC server [page 2486]
Executing the job [page 2527]

12.5.4.2 Setting up SAP NetWeaver BW InfoCubes and InfoSources

Use the SAP Data Warehousing Workbench to set up SAP BW.

To set up the environment:

1. Create and activate the InfoCube or InfoCubes where the extracted data will ultimately be placed.

   Your InfoCubes should be defined to hold data extracted using Data Services.
2. Create and activate the InfoSource where Data Services will place the extracted data:
   a) Go to the InfoSource window (*InfoSources* tab).
   b) Right-click InfoSources at the top of the hierarchy and select *Create Application Component*.
   c) Complete the window that appears with appropriate information. So for *Application comp*, you might enter: MYAPPCOMP. For *Long description*, you might enter: My application component.
   d) Click *Enter*.

      The application component is created and appears in the hierarchy list.
   e) Right-click the name of your new application component in the component list and select *Create InfoSource*.

      The Create InfoSource: Select Type window appears.
   f) Select the type of InfoSource you are creating (*Transaction data* or *Master data*) and click *Enter*.

      When you select Transaction data, the Create InfoSource (Transaction data) window appears.
   g) Enter the appropriate information and click *Enter*.

      The new InfoSource appears in the hierarchy under the application component name.

12.5.4.3 Designating Data Services as a source system

If the source system does not exist, right-click and choose *Create source system*, then create the new source system as explained in the following steps:

1. From the SAP Data Warehousing Workbench window, right-click *Source systems* at the top of the hierarchy, and choose *Create source system*.
   The *Select Source System Type* window appears.
2. Select the last check box on the window and click *Enter*.
   The *Create Source System* window appears.
3. Enter information about your system, then click *Enter*.
   The *RFC Destination* window appears.
4. Click *Registered Server Program*.
5. Enter the program ID.
6. Click the *Save* icon to complete registration.
7. Exit this menu and return to the Data Warehousing Workbench InfoSource window.
8. If the Source System already exists, right-click the InfoSource and select *Assign Source System*.
   The *Transaction data - InfoSource: Assign source system* window appears.
9. Enter the information required and click *Enter*.

10. Click the button to the right of the InfoSource name to view the Maintain Communication Structure window.
11. Add or change information as required.
12. Activate the Transfer Structure for this Source System:
    a) Right-click the InfoSource name and select *Update InfoSource Metadata*.
    b) Enter or change information as required, then click *Save*.

> Note
>
> If you will be performing both full and delta updates, check Delta update.

13. Map the transfer structure fields to the communication structure fields.

> Note
>
> You must successfully complete all previous steps to begin this step.

    a) Right-click the name of the external source system and select *Maintain Transfer Rules*.
    b) Map the fields and add transformation information as required.
    c) Click *Activate*.

12.5.4.4 Job execution

You can execute the job from the Designer or from SAP NetWeaver BW.

You can schedule the job to execute from SAP NetWeaver BW, which initiates the request that causes Data Services to extract data from the specified sources and make it available to SAP.

The batch job execution process consists of the following steps:

- If you are using the SAP NetWeaver BW scheduler, it executes code that sends the load request to the Data Services RFC server.
  The load request contains the following information:
  - The name of the batch file you exported from Data Services
  - The request ID, request date, request time, and full/delta update flag
- If you are using the SAP NetWeaver BW scheduler, the Data Services RFC server calls the Job Server which then invokes Data Services to extract and load the SAP NetWeaver BW InfoSource.
- Request information is passed to Data Services which executes the job and loads data to SAP NetWeaver BW with the request ID to identify into which transfer structure it is loading.
- Data Services extracts the data.
- Before loading to SAP NetWeaver BW (through the staging BAPI interface), Data Services first checks whether the InfoSource metadata changed since the last data import.
  If the metadata changed, Data Services produces an error message indicating that you must re-import the Transfer Structure metadata into the Data Services repository before proceeding to import the target data into the Transfer Structure.

12.5.4.4.1 Executing the job

You can execute the job from the Designer or from SAP NetWeaver BW.

To execute the job from the Designer, right-click the job name in the project area and click *Execute*.

To execute the job from SAP NetWeaver BW, first configure the connection in BW as follows.

1. Create a new InfoPackage.
2. On the *3rd Party Selections* tab, refresh the view to test the connection to the Data Services RFC server interface.
   If the connection is successful, the *3rd Party Selections* tab displays four returned parameters.
3. Enter the *Repository* and *Jobname*.

   The JobServer and Advanced parameters are for advanced use; leave them blank.
4. Refresh the display again.
   The tab now displays any global variables that have been configured for the job so you can provide values for them.

If you have Data Services Designer or the Administrator open when the job runs, the trace log appears automatically and remains open and active while the job is processing just as it does for a job whose execution is initiated from Data Services.

12.5.4.4.2 Monitoring the job

You can monitor the jobs and view logs in both Data Services and SAP NetWeaver BW. If you launch the job from BW and the Data Services Designer is running, the log opens automatically as it does when you launch jobs from Data Services.

To view the execution logs in Data Services, in the Administrator, under *SAP Connections*, click *RFC Server Interface* and click the name of the interface to view its most recent log. You can also view the previous two logs.

To view the execution logs in SAP NetWeaver BW, access the InfoPackage. In the *Extraction* monitor, click the *Non-SAP System Extraction Log* icon. The log will indicate whether the job completed successfully or if there were execution errors.

12.6 Connecting to SAP Master Data Services

SAP Data Services lets you create a datastore to the SAP Master Data Services application and import tables for use as sources in Data Services jobs. SAP Master Data Services is powered by the SAP HANA platform.

With the SAP Master Data Services interface, you can use the Designer to:

- Browse and import SAP Master Data Services tables.
- Use SAP Master Data Services tables as sources and targets.

12.6.1 SAP Master Data Services datastores

SAP Data Services uses datastore connections to link with other applications or databases.

- In a design environment, use a datastore to browse or import metadata that represents external tables and other database objects.
- In a production environment, Data Services uses datastore information to move data between source and target databases and applications.

After defining an SAP Master Data Services datastore in Data Services, you can browse tables that you want to import. You can also import tables by name.

Related Information

Defining an SAP Master Data Services datastore [page 2528]
Browsing and importing metadata [page 2529]

12.6.1.1 Defining an SAP Master Data Services datastore

With an SAP Master Data Services datastore connection, you can browse SAP Master Data Services application metadata.

12.6.1.1.1 To define an SAP Master Data Services datastore

1. In the object library of the Designer, go to the *Datastores* tab
2. Right-click inside the object library window and select *New*.
3. In the *Datastore Editor* window, enter a name for this datastore.
   The name can contain alphanumeric characters and underscores. It cannot contain spaces.
4. In the *Datastore type* list, select *SAP Master Data Services*.
5. Enter the connection information.
6. Click *OK*.
   The SAP Master Data Services datastore appears in the object library.

12.6.1.2 Browsing and importing metadata

After you create an SAP Master Data Services datastore, you can browse and import the metadata from the connected application.

12.6.1.2.1 To browse and import metadata

1. Right-click the SAP Master Data Services datastore name and select *Open*, or double-click the datastore name.

   The workspace displays the Tables folder.
2. To view all of the tables, expand the Tables folder.
3. To import table data, right-click one or more tables and select *Import*.

You can also import SAP Master Data Services metadata by right-clicking a Master Data Services datastore in the object library and selecting *Import by name*.

Once tables are imported, you can view column names, data types, and business names for use in creating jobs.

12.6.1.2.2 Table type

SAP Master Data Services applications use the following table types:

- *read:* Can be used as sources.
- *read_write:* Can be used as sources and targets.
- *write_only:* Can be used as targets.

12.7 Loading Spatial Data into SAP HANA

Data Services supports spatial data (for example, point, line, polygon, collection, or a heterogeneous collection) for the following databases:

- Oracle—reading
- SAP HANA—reading and loading

When you import a table with spatial data columns into Data Services, the spatial type columns are imported as character-based large objects (clob). The column has an attribute, Native Type, which has the value of the actual data type in the database; for example, SDO_GEOMETRY for Oracle or ST_GEOMETRY for SAP HANA.

Limitations

- Because spatial columns are imported into Data Services as clob, creating template tables with spatial types is not supported.
- Spatial data cannot be manipulated inside a data flow because the spatial utility functions are not supported.

12.7.1 To load spatial data from Oracle to SAP HANA

1. Import a source table from Oracle to Data Services.
2. Create a target table in SAP HANA with the appropriate spatial columns.
3. Import the SAP HANA target table into Data Services.
4. Create a data flow with an Oracle source as reader, include any necessary transformations, and then add the SAP HANA target table as a loader. Make sure not to change the data type of spatial columns inside the transformations.
5. Build a job that includes the data flow and run it to load the data into target table.

For more information about SAP HANA spatial data support, see the SAP HANA documentation.

12.8 Reference Information

This section contains SAP-specific reference information about SAP objects, functions, and data types.

For more information on all objects, see the *SAP Data Services Reference Guide*.

12.8.1 Objects

12.8.1.1 Common Data Services objects

The following table lists names and descriptions of SAP Data Services objects that are associated with SAP Applications and SAP NetWeaver Business Warehouse.

Object	Class	Description
Datastore	Single-use	Describes the connection information needed for Data Services to access a database, an SAP Applications system, or an SAP NetWeaver BW system. Cannot be dropped.
File format	Reusable	Indicates how data is arranged in a source or target file.
Job	Reusable	A job is a set of objects that you can execute together.
Source	Single-use	An object from which Data Services reads data in a data flow or an ABAP data flow.
Table	Reusable	Indicates an external DBMS table for which metadata has been imported into Data Services, or the target table into which data is or has been placed.

Object	Class	Description
		A table is associated with its datastore; it does not exist independently of a datastore connection. A table retrieves or stores data based on the schema of the table definition from which it was created.
Target	Single-use	An object in which Data Services loads extracted and transformed data in a data flow.

Related Information

Reference Guide: Objects [page 832]

12.8.1.1.1 Datastore

Class

Reusable

Access

In the object library, click the *Datastores* tab.

Description

A datastore provides a connection to a database. Data Services uses the connection defined by the datastore to import descriptions of the database and its tables (metadata). When you specify tables, hierarchies, or other objects as sources or targets in a data flow, Data Services uses the datastore to determine how to read data from or load data to those tables.

In addition, some transforms and functions require a datastore name to qualify the tables they access.

Data Services provides the following datastore types to connect to SAP systems:

- SAP Applications to read data from or load data to an SAP Applications system
- SAP BW Source to read data from an SAP NetWeaver BW system. The options for SAP BW Source datastores are the same as for SAP Applications.
- SAP BW Target to load data to an SAP NetWeaver BW system. The options for SAP BW Target datastores are common to all SAP datastores.

Note that if you delete a datastore from the object library, you must remove references to the datastore from the following locations:

- Source or target tables using this datastore in your data flows.
- The lookup and key_generation functions and Key_Generation, History_Preserving, Table_Comparison, and SQL transform references.
- ABAP data flows for SAP Applications connections.

SAP datastores have the following common options:

SAP option	Possible values	Description
Main window		
Datastore name	Alphanumeric characters and underscores	The name of the object. This name appears on the object in the object library and in the calls to the object.
Datastore type	SAP Applications SAP BW Source SAP BW Target	Select the type of datastore to which you are connecting.
Application server	Computer name, fully qualified domain name, or IP address	Name of the remote SAP application computer (host) to which the software connects.
User name	Alphanumeric characters and underscores	Enter the name of the account through which the software accesses the SAP application server.
Password	Alphanumeric characters and underscores, or blank	Enter the user's password. Note If you have problems connecting to a system that uses SAP_BASIS version 6.40 and earlier, the system might be expecting an uppercase password. To prevent this issue, install the appropriate kernel patch as described in *SAP Note 792850*, "Preparing ABAP systems to deal with incompatible passwords."
Locale		
Language	SAP-supported ISO two-letter language codes or <default>	Select the login language from the possible values in the drop-down list. The <default> option sets the language to what is set in the SAP system user profile.
Code page		Specify the character encoding of character data in the source in the following situations: • For ABAP data flow processing in SAP R/3 4.x systems • For processing IDoc files

SAP option	Possible values	Description
		Also see *Reference Guide: Locales and Multi-byte Functionality*.
SAP		
Client number	000-999	The three-digit client number. Defaults to 800.
System number	00-99	The two-digit system number. Defaults to 00.
Routing string	Refer to the requirements of the application	Enter the SAP routing string used to connect to SAP systems through SAPRouters.
Use sapnwrfc.ini	Yes, No	Select to use an sapnwrfc.ini file, which overrides the datastore settings. Place the sapnwrfc.ini file in the current directory of the process being executed (%LINK_DIR/bin). Defaults to *No*.
Destination name	Refer to the requirements of the application	If using an sapnwrfc.ini file, enter the destination name to reference.
Load balance		
Load balance	Yes , No	Select *Yes* to enable load balancing.
MS host	Computer name, fully qualified domain name, or IP address	Specify the message server host name. Overrides the setting in sapnwrfc.ini.
MS service	Refer to the requirements of the application	Specify this parameter only if the message server does not listen on the standard service sapms<SysID> or if this service is not defined in the services file and you need to specify the network port directly. Overrides the setting in sapnwrfc.ini.
Server group	**`<User input>`**, PUBLIC, SPACE	Optionally specify the group name of the application servers. Default: PUBLIC. Overrides the setting in sapnwrfc.ini.
System ID	Refer to the requirements of the application	Name of the SAP system. Overrides the setting in sapnwrfc.ini.
Authentication		
Authentication	Password, SNC	*Password*: The default. Deploys the user name and password entered in the datastore main window. *SNC*: Select to enable secure network communications (SNC) security and complete the remaining options in this section.
SNC library	Full file path and name of SNC security library	Enter the full path and name of the third-party security library to use for SNC communication (authentication, encryption, and signatures).Overrides the setting in sapnwrfc.ini. Alternatively you can configure the environment variable SNC_LIB.

SAP option	Possible values	Description
SNC name of Data Services	Refer to the requirements of the application	Enter the SNC name that the SAP system uses to identify Data Services. Overrides the setting in sapnwrfc.ini.
SNC name of SAP system	Refer to the requirements of the application	Enter the SNC name of the SAP system for this connection. Overrides the setting in sapnwrfc.ini.
SNC quality of protection	Max available Authentication Integrity Privacy	*Max available*: Maximum quality of protection that is supported by the target SAP system. This value is configured in the SAP Application Server profile parameter snc/data_protection/max. It could be configured to be Authentication, Integrity, or Privacy. *Authentication*: With this protection level, the system verifies the identity of the communication partner, which in this context is Data Services. This is the minimum protection level offered by SNC. No actual data protection is provided. *Integrity*: With this protection, the system detects any changes or manipulation of the data that might have occurred between the two end points of a communication. *Privacy*: With this protection, the system encrypts the messages being transferred to make eavesdropping ineffective. Privacy protection also includes integrity protection of the data. This is the maximum level of protection provided by SNC. Overrides the setting in sapnwrfc.ini.

SAP Applications

The following table lists the options specific to the SAP Applications datastore. The options change depending on which *Data transfer method* you select.

SAP Applications option	Possible values	Description
SAP		
ABAP execution option	Generate and Execute Execute Preloaded	Select the job execution strategy. Your choice affects the required authorizations. *Generate and Execute:* The ABAP created by the job resides on the same computer as the Job Server and is submitted to SAP using the SAP RFC_ABAP_INSTALL_AND_RUN function or /BODS/RFC_ABAP_INSTALL_AND_RUN function. Select this option if the job changes between scheduled executions.

SAP Applications option	Possible values	Description
		Execute Preloaded: ABAP resides on the SAP application server and is submitted using Data Services RFC function modules. Select this option if the job does not change between scheduled executions.
Execute in background (batch)	Yes, No	Specify whether the generated ABAP programs created by SAP application data flows defined with this datastore will execute in batch mode on the SAP server. Batch mode operation is slower than the normal console mode; however, choose batch mode if the application is too long to run during the console mode time frame. Defaults to No.
Target host	Computer name, fully qualified domain name, or IP address	If you chose to execute ABAP programs in the background, specify the target computer (host).
Job class	A, B, C	If you chose to execute ABAP programs in the background, specify the job class.
Data transfer method	Direct download RFC Shared directory FTP Custom transfer	Define how to retrieve data from the SAP application server to the Data Services server: *Direct download:* Use the SAP WS_DOWNLOAD function to stage the data to the *Local directory*. The Job Server reads from the file, then deletes it. Direct download is not recommended for production use because it cannot handle large amounts of data. *RFC*: Use to stream data from the source SAP system directly to the Data Services data flow process using RFC. For secure data transfer, configure *SNC* authentication with the required SNC quality of protection (in the datastore *Authentication* options). *Shared directory:* Both SAP Data Services and SAP have direct access to the directory where data is stored. This method works best when both systems are on Windows and security is not an issue. Use NFS (shares one network drive or directory). *FTP:* Use FTP. *Custom transfer:* Use a third-party program. When you select a data transfer method, the appropriate options for that method appear below the option.
ABAP RFC destination	SAPDS or **`<Destination name>`**	For the *RFC* data transfer method, enter a TCP/IP RFC destination. You can keep the default name of SAPDS and create a destination of the same name in the source

SAP Applications option	Possible values	Description
		SAP system, or you can enter a destination name for an existing destination.
Working directory on SAP server	Directory path or click *Browse*	A directory on the SAP application server where the software can write intermediate files. All the files used by the data flow should be placed in this directory. This directory also stores the transport file used by the FTP, shared-directory, and custom-transfer data transfer methods. By default, the value in this field uses the value that was typed into the *Application server* field. For example, if the value **`sap01`** was typed into the Application server field, the value of *Working directory on SAP server* becomes \\sap01\\.
Custom transfer	These options are visible if you selected the *Custom transfer* data transfer method.	
Custom transfer local directory	Directory path or click *Browse*	The client-side directory to which data from the SAP server downloads.
Custom transfer program executable	Refer to the requirements of the application	The name of the third-party file transfer program you want to use to transfer files from the SAP working directory to the local directory.
Custom transfer user name	Refer to the requirements of the application	(optional) Login ID for the SAP application server to which the custom transfer program connects.
Custom transfer password	Refer to the requirements of the application	(optional) Password for the SAP application server to which the custom transfer program connects. Passwords entered into this option are encrypted.
Custom transfer arguments	Refer to the requirements of the application	(optional) Specify arguments for your custom transfer program. Arguments can add security or compression mechanisms to your program or include Data Services system variables.
Application path to the shared directory	Directory path or click *Browse*	If you selected the *Shared directory* data transfer method, indicate the path from the Data Services server to the SAP application server's working directory. By default, the value in this field uses the value that was typed into the *Application server* field. For example, if the value **`sap01`** was typed into the Application server field, the value of *Working directory on SAP server* becomes \\sap01\\.
Local directory	Directory path or click *Browse*	If you selected the *Direct download* or *FTP* data transfer method, select a client-side directory to which data from the SAP server downloads.

SAP Applications option	Possible values	Description
Generated ABAP directory	Directory path or click *Browse*	Indicate the directory into which the software writes generated ABAP files. It can be the same directory as the local/direct download directory. The path is relative to the Job Server.
Security profile	Refer to the requirements of the application	Specify the security profile you want to use in the generated ABAP program. The user of the SAP datastore must have the required profile.
Routing string	Refer to the requirements of the application	Enter the SAP routing string used to connect to SAP systems through SAProuters.
Number of connection retries	Positive integer	The number of times Data Services tries to establish a connection with the SAP application server. Defaults to 1.
Interval between retries (sec)	Positive integer	The time delay in seconds between connection retries. Defaults to 10.
Upload attributes		
Status	P - SAP Standard Production Program K - Customer Production Program S - System Program T - Test Program	Indicates whether the program is a test program, a system program, or a production program. Default is *T - Test program*. The parameter can have only the value code or the value code and description, separated by a space.
Application	Refer to the drop-down list for available options	Indicates the application area to which the program belongs (Basis, General Ledger, Sales, and so on). The default value is *S - Basis*. The parameter can have only the value code or the value code and description, separated by a space.
Development class (Package)	Refer to the requirements of the application	Indicates the name under which related objects in the ABAP Workbench are grouped together in a package. Default is $TMP. The program is created as a local (non-transportable) object.
Request ID	Refer to the requirements of the application	Indicates the Change and Transport System (CTS) request ID. The default value is blank. This option is populated by Data Services if a non-local program object is created in SAP.
Task ID	Refer to the requirements of the application	Indicates the CTS task ID. The default value is blank. This option is populated by Data Services if a non-local program object is created in SAP.
FTP	These options are visible if you selected the *FTP* data transfer method.	

SAP Applications option	Possible values	Description
FTP relative path to the SAP working directory	Directory path or click *Browse*	Indicate the path from the FTP root directory to the SAP server's working directory. When you select FTP, this directory is required.
FTP host name	Computer (host) name, fully qualified domain name, or IP address	Must be defined to use FTP.
FTP user name	Alphanumeric characters and underscores	Must be defined to use FTP.
FTP password	Alphanumeric characters and underscores, or blank	Enter the FTP password.

SAP Master Data Services

The following table lists the options specific to the SAP Master Data Services datastore. For more information about all other options, see the SAP HANA database datastore section of the *SAP Data Services Reference Guide.*

SAP Applications option	Possible values	Description
SAP Master Data Services		
Schema owner	Refer to the SAP Master Data Services documentation	Enter the schema owner name for foundation tables (the name is usually apps).

12.8.1.1.2 File format

Class

Reusable

Access

In the object library, click the *Formats* tab.

Description

A file format describes the structure of an ASCII file. A file format can be specific to a single file, or it can be a generic description used for many data files. Construct file formats from the properties found in the file format editor.

The built-in file format for SAP is the Transport_Format which is under the *Flat Files* node. The following options are for the SAP transport type only.

Property	Possible values	Description
General		
Type	SAP transport	The format of the data in the text file. Available properties change based on the selected file format type.
Name	Any alphanumeric character and underscores (_)	A descriptive name for the file format. This name appears in the object library.
Data File(s)		
Location	Local, Job Server	(Optional) The computer on which the data file(s) are stored.
File name(s)	File name, file name including full path name, or blank	In new and edit modes, specify an existing file on which you base the file format description. Data from this file appears in the Column Attributes area. In these modes, you can leave this property blank. In source and target modes, specify the location of the actual file for this source or target. In these modes, you cannot leave this property blank. For added flexibility, you can enter: ● A variable that is set to a particular file with full path name. ● A list of files, separated by commas, or a file name containing a wild card. In this case, Data Services reads all these files as a single source.
Delimiters		
Column	Tab, Semicolon, Comma, Space	Specify the character that indicates the end of one column and the beginning of the next. Alternatively, enter an ASCII character. Valid ASCII characters range from /0 to /254.

Related Information

Reference Guide: Objects, File format [page 920]

12.8.1.1.3 Job

Class

Reusable

Access

- In the object library, click the *Jobs* tab.
- Right-click a job in the project area.

Description

A job is a set of objects that you can execute together. For Data Services to execute the steps of any object, the object must be part of a job. A single job must include all the steps you want executed.

The following are the additional references to SAP applications.

- Data Services retrieves results from the following types of steps:
  - ABAP data flows
  - ABAP data files
- Jobs have properties that determine what information Data Services collects and logs when running the job. Use Trace properties to select the information that Data Services monitors and writes to the trace log file during a job. You can turn several SAP application-related traces on and off.

Trace	Description
ABAP Query	Writes a message when an ABAP program is submitted and when the ABAP program completes. Also writes the ABAP job status every 15 seconds.
IDoc file reader	Writes a message when an IDoc file reader starts and when it finishes. This trace also reports: ○ The name of the file that the reader opens ○ The file status (succeeded or failed) ○ Total number of IDocs processed from the file

Trace	Description
RFC Function	Writes messages when Data Services calls an RFC function or BAPI. Specifically, this trace writes messages when: ○ An RFC function or BAPI starts ○ Processing for an individual record starts ○ Processing for an individual record finishes ○ New connections to SAP applications are established during real-time jobs ○ An RFC function or BAPI finishes
SAP Table Reader	Writes messages when Data Services reads from an SAP application table source. Specifically, this trace writes messages when: ○ Data Services establishes a connection with SAP ○ Data Services begins reading from the SAP application table ○ The RFC call to retrieve table content starts ○ The RFC call to retrieve table content finishes ○ Data Services finishes reading from the SAP application table

Related Information

Reference Guide: Objects, Log [page 935]

12.8.1.1.4 Source

Class

Single-use

Access

- To insert an SAP application table as a source, open the object library, go to the *Datastores* tab, select the table, drag it into a batch or ABAP data flow in the workspace, and select *Make Source*.
- To insert a file as a source, open the object library, go to the *Formats* tab, select a flat file format for the file, drag it into the workspace, and select *Make Source*. Use the file format editor to specify the file name.
- To insert an Open Hub table as a source in a data flow, select the table from the local object library *Datastores* tab and drag it into the work space.
- To insert an SAP ODP source as a source in a data flow or an ABAP data flow, select it from the local object library *Datastores* tab, drag it into the work space, and modify the import options as necessary.

- To insert an ABAP data flow as a source, open the object library, go to the *Data flows* tab, select the ABAP data flow, drag it into a batch or ABAP data flow in the workspace.
- To insert an XML message or file as a source, open the object library, go to the *Formats* tab, select the DTD or XML Schema format for the XML file, drag it into the workspace, and select *Make XML message source* or *Make XML file source*. Use the source editor to specify the test file name for the message or the source file name for the file.
- To view options of tables or files, click the name of the table or file in the workspace or in the project area. This opens the table or file editor.
- To view options of ABAP data flows, right click the data flow in the workspace or project area, select *Properties*, and go to the *Options* tab.
- To insert an IDoc message or file as a source, open the object library, click the *Datastores* tab, click an SAP Applications datastore, click the IDoc category, select an IDoc, drag it into a data flow, and select *Make IDoc message source* or *Make IDoc file source*. Use the source editor to specify object attributes.

> i Note
>
> A real-time job source can be one and only one XML or IDoc message. If another message source is already in the data flow definition, Data Services will not allow you to place the IDoc in the workspace.

Description

A source is an object from which Data Services reads data.

In a batch job, a source can be a table, an SAP application table, a previously defined template table, a file, an XML file, an IDoc file, ABAP data flow, or an SAP ODP source.

In a real-time job, a source can be a table, an SAP application table, a previously defined template table, a file, an IDoc file, an XML file, an IDoc message, or an XML message. Each real-time job must have exactly one real-time data source—either an IDoc message or an XML message.

In an ABAP data flow, a source can be another ABAP data flow, an SAP application table, a file located on the SAP application server, or an SAP ODP source. Files must be in a file format that SAP can read. Data Services provides a predefined flat file format called Transport_Format that SAP can read.

You can select an SAP application table as a source in any data flow. However, when you use an SAP application table as a data flow source, Data Services extracts data using the Data Services-provided RFC (remote function call) /BODS/RFC_STREAM_READ_TABLE. If this function is not loaded to the SAP application server, Data Services extracts data using the SAP-supplied function, RFC_READ_TABLE. This function call limits extracted data to 512 bytes per row.

When you use an SAP application table as a source in an ABAP data flow, Data Services extracts data using ABAP. For large amounts of data (larger than a few rows), performance is generally better when you extract data from SAP using an ABAP data flow.

With SAP ODP sources, Data Services automatically detects whether the extractor uses the ODP data replication API, which provides optimal performance and changed-data capture (delta) capability. In a regular data flow Data Services uses RFC to call the ODP data replication API. In an ABAP data flow, Data Services generates the ABAP that calls the ODP data replication API.

IDocs are used as message sources in real-time jobs and as file sources in batch or real-time jobs. Data flows in real-time jobs that use IDocs as message sources can be processed one at a time or in parallel. IDoc message sources are generated directly from SAP.

You can configure an IDoc file source in a data flow of a batch job to read files in groups and use variable file names.

> Note
>
> IDocs cannot be used as source or target objects in ABAP data flows.

A table source has options in addition to the datastore information:

Option	Description
Join rank	Indicates the rank of the table relative to other tables joined in a data flow. The software joins tables with higher join ranks before it joins tables with lower join ranks. Join rank specified in the Query transform editor FROM tab overrides any join rank specified in a source. Best practice is to specify the join rank only in the Query transform editor. Must be a non-negative integer. Default value is 0.
Cache	Indicates whether Data Services should read the required data from the table and load it into memory. Because an inner table of a join must be read for each row of an outer table, you may want to cache a table when it is used as an inner table in a join and when the data retrieved will fit into available memory. Best practice is to specify the cache only in the Query transform editor. Cache specified in the Query transform editor FROM tab overrides any cache specified in a source. The default option in the Query editor is Automatic. The automatic setting in the Query editor carries forward the setting from the source table. Note If any one input schema has a cache specified in the Query editor, the Data Services Optimizer considers only Query editor cache settings and ignores all source editor cache settings. For non-SAP application tables, there are two options: • *Yes*: The table is always cached unless it is the outer-most table in a join. • *No*: The table is never cached. For SAP application tables in an ABAP data flow, there are three options: • *Yes*: The table is always cached unless it is the outer-most table in a join. • *No*: The table is never cached. • *Automatic*: Data Services determines whether to cache the table. The default option is *No*. When two SAP application tables are involved in an inner join and you cache both tables, Data Services improves performance by generating ABAP using the array operations SELECT FOR ALL ENTRIES and IN_MEMORY MERGE JOIN. These operations are exclusive to inner joins, specifically two-way inner joins. Data Services sorts then merges the inner and outer tables to optimize join performance.

Option	Description
	To enable these operations, set the cache option for both tables to *Yes*. The result is that both inner and outer tables are read into internal tables prior to the join. Use *Package size* on the outer loop of the join to limit the size of internal tables.
Package size	Indicates the maximum number of rows loaded into memory. Limiting rows reduces memory consumption. Package Size is an extension of the SELECT_INTO_TABLE operation, which uses one SELECT statement to retrieve blocks of rows to create an internal table. Use this option when caching a table that might consume excessive memory. Data Services does not limit rows when you enter 0, a negative number, or when you set *Cache* to *No*.
Array fetch size	Indicates the number of rows to load into the ABAP memory table before Data Services fetches the rows. Avoids exceeding memory capacity on the source side. Default is 1000.
Execute in background (batch)	If the SAP table reader is taking more time to execute than what is in the SAP system dialog work process setting rdisp/max_wprun_time (SAP RZ11 transaction), select this option to avoid exceeding the time limit. Ensure an *RFC destination* has been specified in the datastore editor for this source. If there is no RFC destination defined, create an RFC destination object (SAP transaction sm59) and enter the name in the datastore definition.

Note

Data Services automatically uses the SELECT_INTO_TABLE operation when you cache a database table and the content of the cache populates an internal table, or when you cache one or more LOOKUP functions against one or more tables and the contents of the LOOKUP cache populates an internal table.

A file source also has the *Join Rank* and *Cache* options in addition to the file format information. Data Services interprets *Join Rank* and *Cache* the same in a file as a table.

An XML message source has these options in addition to read-only XML Schema or DTD format information:

Option	Description
XML test file	The location relative to the Job Server of an XML-formatted file to use as the message source when you execute the job in test mode.
Enable validation	A check box to turn on the comparison of the incoming message to the stored XML Schema or DTD format. When this option is selected, the real-time job throws an exception if the incoming message is not valid. When you are developing a real-time job, this validation helps you to make sure sample data is both valid and well-formed. If you select this option in production, make sure to include appropriate error handling either in the Data Services job or the client application to process an error caused if a data flow in the real-time job receives data that does not validate against the imported format.
implied: Join rank	The XML message source is always the outer table in a join. You cannot change its join rank. This option is implied and does not appear in the editor.

An XML file source has these options in addition to read-only XML Schema or DTD format information:

Option	Description
XML file	The location relative to the Job Server of an XML-formatted file to use as the source.
Enable validation	A check box to turn on the comparison of the incoming data to the stored XML Schema or DTD format. When this option is enabled, the data flow throws an exception if the incoming source is not valid.
implied: Join rank	The XML file source is always the outer table in a join. You cannot change the join rank for it. This option is implied and does not appear in the editor.

An IDoc message source in a real-time job has the following options:

Option	Description
Make Port	(Optional) Select an IDoc as an input port for an embedded data flow.
IDoc test file	Browse the network to find a test file to read.
IDoc Type	(Read-only) Data Services will only process IDoc files (listed in the IDoc Test File box) if they are of this IDoc type. For example, SOPGEN01. This information is entered when you import metadata for the IDoc Type.

An IDoc file source, in a real-time job, has the following options

.

Option	Description
Make Port	(Optional) Select an IDoc as an input port for an embedded data flow.
IDoc File/s	Browse to a network file that will contain IDocs generated in SAP. Data Services reads the contents of this file/s when this data flow runs.
IDoc Type	(Read-only) Data Services will only process IDoc files (listed in the IDoc File box) if they are of this IDoc type. For example, SOPGEN01. This information is entered when you import metadata for the IDoc Type.
Join Rank	Indicates the rank of the table relative to other tables joined in a data flow. The software joins tables with higher join ranks before it joins tables with lower join ranks. Join rank specified in the Query transform editor FROM tab overrides any join rank specified in a source. Best practice is to specify the join rank only in the Query transform editor. Must be a non-negative integer. Default value is 0.
Include file name column	Determines whether to include a column in the source output that contains the source IDoc file name. Defaults to *No*. Change the value to *Yes* when you want to identify the source IDoc file in situations such as the following: ● You specified a wildcard character to read multiple source IDoc files at one time ● You load from different source IDoc files on different runs

Option	Description
Modify	If the file name is included, this button enables you to modify *File name column* and *Column size*.
File name column	If the file name is included, the name of the column that holds the source IDoc file name. Defaults to *DI_FILENAME*.
Column size	If the file name is included, the size (in characters) of the column that holds the source file name. Defaults to *100*. If the size of the file name column is not large enough to store the file name, truncation occurs from the left.
Include path	If the file name is included, determines whether to include the full path name of the source IDoc file. Defaults to *No*.

12.8.1.1.5 Table

Class

Reusable

Access

In the object library, click the *Datastores* tab.

Description

You can use a table from a non-SAP Applications datastore as a source or target in a data flow. You cannot use a table from a non-SAP Applications datastore in an ABAP data flow.

You can use an SAP application table as a source or target in an ABAP data flow or as a source in a data flow. You cannot use an SAP application table as a target in a data flow.

Tables have the following built-in attributes:

Attribute	Description
Name	The name of the object. This name appears on the object in the object library and in the calls to the object.
Description	Your description of the table.
Business_Name	Business name imported with table metadata.
Table_Usage	How the object is used when it was accessed most recently. Expect values such as Source, Target, Lookup Table, or Comparison Table.
Total_Number_Of_ Rows_Processed	The number of rows loaded into the table in the last successful load.
Date_last_loaded	The time the table was last successfully loaded by Data Services.
Number_Of_Rows_ Rejected	The number of rows rejected in the last successful load.
Number_Of_Inserts	The number of rows inserted in the last successful load.
Number_Of_Updates	The number of rows updated in the last successful load.
Date_Created	The date that the object was created.
Estimated_Row_ Count	A configurable estimate of the table size used in calculating the order tables are read to perform join operations. Used for SAP application tables only.
Number_Of_Deletes	The number of rows deleted in the last successful load.
Elapsed_Time_For_ Load	The time it took to load this table in the last successful load.
Table_Type	The type of datastore object. Most tables are type Table.
SAP_Table_Class_ Name	The table class name as designated by the SAP_Table_Class value.
SAP_Table_Class	Table type information. Used for SAP application tables only. 1 — Transparent table 2 — INTTAB 3 — Cluster

Attribute	Description
	4 — Pool 5 — View 6 — Append (Structure)

12.8.1.1.6 Target

Class

Single-use

Access

- To display target options, click the name of the target in the workspace or in the project area. This opens the object editor.
- To display target properties, right click a target and choose *Properties*.

Description

A target is an object in which Data Services loads data.

In a batch job, a target can be a flat file, a table or template table, an XML file, an IDoc file, an IDoc message, or an ABAP data flow.

In a real-time job, a target can be a file, a table, a template table, an XML file, an XML message, an IDoc file, or an IDoc message.

In an ABAP data flow, a target can be a file or a data transport object.

Target files

You can use any flat file format in a batch or ABAP data flow as a target. You can use any DTD or XML Schema format for XML file and XML message targets.

If the schema defined in the format doesn't match the schema that is input to the target, Data Services provides validation errors to identify the mismatch.

Target tables

No tables can be used in ABAP data flows as targets.

InfoSource or DataSource target

The following table contains option and description information specific to SAP NetWeaver BW InfoSource and SAP NetWeaver BW DataSource target tables.

See the *SAP Data Services Reference Guide* for option information common to all target tables.

Option	Description
Options	
Number of loaders	Loading with one loader is known as "single loader loading". Loading when the number of loaders is greater than one is known as "parallel loading" The default number of loaders is 1. You can specify any number of loaders. When parallel loading, each loader receives the number of rows indicated in the *Rows per commit* option, and applies the rows in parallel with the other loaders. For example, if you choose a *Rows per commit* of 5000 and set the *Number of Loaders* to 3: in parallel, the loaders each receive a maximum of 5000 rows; then each loader performs the necessary processing and, when complete, sends the data in a packet to the SAP NetWeaver BW system. Due to differences in processing, the loaders may not send the packets to the SAP NetWeaver BW system in sequential order. Note Parallel loading is not supported for the hierarchy type.

Target Idocs

IDoc messages can be sent from Data Services on a regular schedule or in real-time. Data Services allows you to use a batch or real-time job to configure IDoc message targets. Any number of IDoc targets can be included in a single data flow.

IDoc targets support reduced message types. When Data Services detects a reduced message type, it retrieves the appropriate metadata from SAP and creates a reduced IDoc, removing unused segments and giving unused fields the value of '/'.

Note

Reduced message type functionality is only available for some message types (e.g., DEBMAS, CREMAS, etc.).

The attributes of an IDoc target depend on the type of target and the type of data flow. To see the IDoc attributes, double-click an IDoc target object in a data flow diagram.

- IDoc message targets in a data flow of a batch job

Attribute	Description
Make Port	(Optional) Select an IDoc as an input port for an embedded data flow.
IDoc Type	(Read-only) Displays the IDoc Type you imported Data Services into for this object. For example, SOPGEN01.
Partner Number	This is an SAP term for where to send the IDoc in the SAP application. Enter the partner number of the IDoc you will be processing as a message target in Data Services. If you do not know the partner number, consult your SAP administrator.
Partner Type	This is an SAP term for an attribute of a partner number. Enter the partner type. For example, `LS` for logical system.
Message Type	This is an SAP term for an EDI message for this IDoc Type. Enter the message type.
Batch size	Specifies the number of IDoc messages to accumulate before Data Services sends the IDoc messages to the SAP server. This attribute improves performance because Data Services sends multiple IDoc messages with each transmission. Data Services sends the accumulated IDoc messages even if the number of seconds is less than the value in *Batch wait timeout*.
Do not create TID	This attribute improves performance by not creating a transaction ID for SAP transmissions. However, transaction services (such as re-transmission and checking) are not done.
Batch wait timeout	This attribute limits the wait time (in seconds) before Data Services sends the IDoc messages to the SAP server. A value of `0` specifies to wait indefinitely. This attribute improves performance because Data Services sends multiple IDoc messages with each transmission. Data Services sends the accumulated IDoc messages even if the number of messages is less than the value in *Batch size*.

- IDoc message targets in a data flow of a real-time job

Attribute	Description
Make Port	(Optional) Select an IDoc as an input port for an embedded data flow.
IDoc Test File	Browse to a network file that will contain IDocs generated in Data Services. For example: `C:/temp/`**`<filename>`**. Use this location to test the output of the IDoc message target before starting a real-time job in the Data Services Administrator. Data Services writes to this file when this real-time job is executed in test mode.
Partner Number	This is an SAP term for where to send the IDoc in SAP. Enter the partner number. If you do not know the partner number, consult your SAP administrator.

Attribute	Description
Partner Type	This is an SAP term for an attribute of a partner number. Enter the partner type. For example, `LS` for logical system.
Message Type	This is an SAP term for an EDI for this IDoc Type. Enter the message type.
Batch size	Specifies the number of IDoc messages to accumulate before Data Services sends the IDoc messages to the SAP server. This attribute improves performance because Data Services sends multiple IDoc messages with each transmission. Data Services sends the accumulated IDoc messages even if the number of seconds is less than the value in *Batch wait timeout*.
Do not create TID	This attribute improves performance by not creating a transaction ID for SAP transmissions. However, transaction services (such as re-transmission and checking) are not done.
Batch wait timeout	This attribute limits the wait time (in seconds) before Data Services sends the IDoc messages to the SAP server. A value of `0` specifies to wait indefinitely. This attribute improves performance because Data Services sends multiple IDoc messages with each transmission. Data Services sends the accumulated IDoc messages even if the number of messages is less than the value in *Batch size*.
IDoc Type	(Read-only) Data Services will only process IDoc files (listed in the IDoc Test File box) if they are of this IDoc type. For example, SOPGEN01. This information is entered when you import metadata for the IDoc Type.

- IDoc file targets in data flows

Attribute	Description
Make Port	(Optional) Select an IDoc as an input port for an embedded data flow.
IDoc File	Browse to a network file that will contain IDocs generated in Data Services. Data Services writes to this file when the data flow is executed. When you configure an IDoc File target, Data Services allows you to capture data for more than one IDoc. Each time a root segment passes into a file target (for example *IDoc File* `C:\temp\idoc`), a new file is created and named using an eight character suffix starting with `00000000.txt`. For example an *IDoc File* set to `C:\temp\idoc` could store `idoc00000000.txt` to `idoc99999999.txt`.
IDoc Type	(Read-only) The IDoc type you imported from SAP into Data Services for this object. For example, SOPGEN01.

Related Information

Reference Guide: Objects, Target [page 960]

12.8.1.2 SAP-specific objects

This section describes SAP-specific objects available in Data Services.

Object	Class	Description
ABAP data flow	Reusable	Extracts data from SAP application sources.
Custom ABAP transform	Reusable	Inserts custom ABAP logic blocks into a generated ABAP program for an ABAP data flow.
Data transport	Single-use	Identifies a file to hold a data set extracted by an ABAP data flow.
ODP source	Single-use	An ODP source is a source object that Data Services uses to read data from an SAP application.
Hierarchy	Reusable	Browse, search, and import hierarchy metadata.
IDoc file	Reusable	An intermediate document that SAP produces to move data between servers. In Data Services, an IDoc file can be used in a real-time or batch job as a source or a target.
IDoc message	Reusable	An intermediate document that SAP produces to move data between servers. In Data Services, an IDoc message can be used in a real-time job as a source or a target and in a batch job as a target.
Open Hub Table source	Single-use	A source object that Data Services uses to read data from an SAP NetWeaver Business Warehouse system.
Transport_Format	Reusable	The Transport_Format is a Data Services predefined file format object for reading flat files in SAP applications. It is automatically used to define data transport objects added to ABAP data flows.

Related Information

The Transport_Format [page 2502]
File format [page 2538]

12.8.1.2.1 ABAP data flow

Class

Reusable

Access

- To insert an existing ABAP data flow, go to the object library *Data Flows* tab, open the list of ABAP data flows, select the ABAP data flow you want to add, and drag it into the workspace.
- To insert a new ABAP data flow, select the ABAP data flow icon in the tool palette, and click in the workspace.

Description

An ABAP data flow extracts data from SAP application sources. You can insert an ABAP data flow into any other data flow (ABAP, batch, or real-time). An ABAP data flow produces a data set you can use as a source in other data flows.

You can define parameters to pass values into the ABAP data flow. If you cannot express the required extraction logic using the Data Services interface, you can embed ABAP logic into an ABAP data flow by creating a new, custom ABAP transform.

When Data Services executes ABAP data flows, it translates extraction requirements into ABAP programs and passes them to SAP to execute. An ABAP data flow can store the extracted data set in an SAP application table or in text file saved on the SAP application server. To use the data outside the ABAP data flow, save the data in a file and use a data transport object to pass the data to the parent data flow. The data transport object defines a file format and indicates how data is transferred from the SAP application server to Data Services.

When you use the ABAP data flow as a source in a join (either with other ABAP data flows, SAP sources, or with non-SAP sources), you can assign a join rank to the source. When joining sources, Data Services reads sources with higher join ranks before reading those with lower join ranks. Set join rank in the ABAP data flow properties when you first define the ABAP data flow.

> Note
>
> Join rank must be a positive integer. Zero is the default value. With a zero join rank, Data Services determines join order.

An ABAP data flow can contain the following objects:

- Sources
- Targets
- Transforms (Custom ABAP)
- Queries
- ABAP data flows

ABAP data flows have the following options on the *Options* tab.

Option	Description
Datastore	Specifies the datastore corresponding to the SAP application tables or files this ABAP data flow accesses.
Generated ABAP file name	Specifies the file name containing ABAP program code that Data Services generates from this SAP ABAP data flow. This file is written to the directory specified in the datastore definition.
ABAP program name	Specifies the name Data Services uses for the ABAP program name that runs in SAP ABAP. It must begin with Y or Z.
Job name	Specifies the name used for the job that runs in SAP. It defaults to the name of the data flow.
ABAP row limit	Limits the number of rows that will be read by this ABAP data flow. Use this option for testing purposes to limit the time that the parent batch job will run. This option can also be used to limit the number of rows read using the Designer's Data Scan feature. ABAP data flows return one file of data from scans. Individual objects inside an ABAP data flow cannot be read using Data Scan.
Join rank	Indicates the rank of the table relative to other tables joined in a data flow. The software joins tables with higher join ranks before it joins tables with lower join ranks. Join rank specified in the Query transform editor FROM tab overrides any join rank specified in a source. Best practice is to specify the join rank only in the Query transform editor. Must be a non-negative integer. Default value is 0.
Parallel process threads	Specify the number of threads for parallel processing, which can improve performance by maximizing CPU usage on the Job Server computer. For example, if you have four CPUs, enter 4 for this option.
Cache	Indicates whether Data Services should cache the data set produced by this ABAP data flow for use in other operations. If the result is part of another ABAP data flow, the cache option is ignored. Best practice is to specify the cache only in the Query transform editor. Cache specified in the Query transform editor FROM tab overrides any cache specified in a source. The default option in the Query editor is Automatic and in a table source is No. The automatic setting in the Query editor carries forward the setting from the source table. Note If any one input schema has a cache specified in the Query editor, the Data Services Optimizer considers only Query editor cache settings and ignores all source editor cache settings. *Yes*: The table is always cached unless it is the outer-most table in a join. *No*: The table is never cached. *Automatic*: Data Services determines whether to cache the table.

Option	Description
	The default option is *No*.

ABAP data flows have the following properties on the *General* tab:

Attribute	Description
Name	The name of the object. This name appears in the object library and in calls to the object.
Always execute during recovery	Indicates that Data Services should re-execute this ABAP data flow during an automatic recovery when it is part of a re-executed work flow that is a recovery unit. In this case, Data Services re-executes the ABAP data flow even if it completed successfully in an earlier run.
Description	Your description of the ABAP data flow.

Related Information

Creating custom ABAP transforms [page 2462]
Adding an ABAP data flow [page 2452]

12.8.1.2.2 Custom ABAP transform

Class

Reusable

Access

- In the object library, click the *Transforms* tab then right-click and select *New ABAP Transform*. After renaming your custom ABAP Transform, drag it into an ABAP data flow. From the *Tools* menu, select *Variables* to define parameters.
- You can reuse an existing transform by dragging and dropping the object from the *Transforms* tab.

Description

A custom ABAP transform executes a piece of ABAP logic to produce a set of rows to be used by subsequent transforms in the same ABAP data flow.

A custom ABAP transform does not take any input sets and produces one and only one output data set. It allows for any number of input parameters, but no output parameters.

A custom ABAP transform has the following properties:

Properties	Description
Name	Specifies the name for the custom ABAP program that appears in the object library and in diagrams. This name cannot contain spaces.
Description	Allows you to document the transform's operation.

A custom ABAP transform has the following options:

Option	Description
ABAP language file name	Indicates the name of the file containing the ABAP program to execute.
Join rank	Indicates the rank of the output data set relative to other data sets included in a join. The software joins data sets with higher join ranks before it joins data sets with lower join ranks. Join rank specified in the Query transform editor FROM tab overrides any join rank specified in a source. Best practice is to specify the join rank only in the Query transform editor. Must be a non-negative integer. Default value is 0. For more information, see the *Data Services Reference Guide*.
Output schema	Lists the columns in the schema produced by this ABAP program. To add a column to the schema, right-click and choose *New Column*.
Column type	Indicates the data type of the selected column. This option appears after you create a column, click outside the column name, and then select the column.

12.8.1.2.3 Data transport

Class

Single-use

Access

- To insert, open an ABAP data flow diagram in the workspace, select the data transport icon in the tool palette, and click on the workspace.

- To view options, click the name of the data transport. This opens the data transport editor.

Description

Data transports are targets in ABAP data flows. A data transport takes the data SAP extracts during an ABAP data flow and stores it in a file defined by the Transport_Format file format.

Use a data transport when you want to use the extracted data in a data flow outside the ABAP data flow. In this case, you must use the ABAP data flow as a source in the parent data flow.

Do not use a data transport when you want the extracted data kept in a file on the SAP application server or in an SAP table. In that case, use a file or SAP table as the target in the ABAP data flow.

The data transport editor shows the schema produced by the ABAP data flow and the options that define the data transport. These options specify the location of the file and indicate whether to append to or overwrite the data in the file.

You can set the delimiter SAP uses to write data to the file. The default delimiter is a tab character. Change the delimiter in the Transport_Format file format definition. Valid ascii character delimiters range from /0 to /254.

The following table lists the options in the data transport editor:

Data transport editor option	Description
File Name	The name of the saved staging file.
Working directory on SAP	The location of the saved staging file. This is the *Working directory on SAP server* specified for the datastore associated with the current ABAP data flow.
Append file	Adds the data set to the existing contents of the file.
Replace file	Clears the file before writing the data set to it.

Data transports have one attribute:

Attribute	Description
Name	The name of the object. This name appears on the object in the diagram.

12.8.1.2.4 ODP source

Class

Single-use

Access

To insert an SAP ODP source into a data flow, open the local object library, select the *Datastores* tab, select the ODP source from the SAP Applications datastore, and drag it into the workspace.

Description

An SAP ODP source is an object that SAP Data Services uses to read data from an SAP application.

Data Services automatically detects whether the ODP source uses the ODP data replication API, which provides optimal performance and changed-data capture (delta) capability. Typically you use ODP source extractors in a regular data flow, where Data Services uses RFC to call the ODP API. However if you want to do additional processing such as lookups and joins or for more advanced applications such as debugging or push-down optimization, you can use them in an ABAP data flow, where Data Services generates the ABAP that calls ODP API.

ODP source option	Description
Name	Name of the ODP source as defined in the datastore.
Type	Identifies the ODP source type as defined by SAP. Examples: TRAN: Transaction ATTR: Attribute
Method	Identifies the extraction type as defined by SAP. Examples: V: Transparent table or database view F1: Function module (complete interface) F2: Function module (simple interface)
Datastore	The SAP Applications datastore name.
Datastore type	The type of SAP datastore (SAP Applications).
Application server	Name of the remote SAP application computer to which Data Services connects.
Language	Select the login language from the possible values in the drop-down list. You can enter a customized SAP language in this option. For example, you can type S for Spanish or I for Italian.
Client number	The three-digit SAP client number. Default is 800.
System number	The two-digit SAP system number. Default is 00.
Join rank	Indicates the rank of the source relative to other tables and files in the data flow when creating a join. The software joins sources with higher join ranks before it joins sources with lower join ranks.

ODP source option	Description
Package size	Limits the number of rows brought into memory when building internal tables. By limiting the number of rows, less memory is used to construct internal tables.
Initial load	For changed-data capture (CDC), indicates whether to reload all the data. Select to return a full extraction; clear to return only changed data. If you change the filter properties for an ODP source, “reset” the job by running it with the source option *Initial load* selected. Then you can run the job with CDC filters applied (with *Initial load* cleared).
Extract from datetime	For changed-data capture (CDC), optionally enter a global variable of type datetime that defines from when to extract changed data. If the datetime value is the same as or before the value from the last execution, Data Services repeats the changed-data extraction. If the datetime value is later than the value from the last execution, Data Services returns the new data. Example: Yesterday the job ran with a datetime value of 2010.10.28 03:00:00. To reload the same data again (for example because of a problem with the execution), use the same datetime value again. To get new changes, use a later value, for example 2010.10.29 03:00:00.
Parallel process threads	For ODP sources that use the Operational Data Provider data replication API (ODP data replication API), specify the number of threads used to read the data. For example, if you have four CPUs on your Job Server computer, enter the number 4 for this option to maximize performance.

Related Information

Reading from SAP ODP sources [page 2442]

12.8.1.2.5 Hierarchy

Class

Reusable

Access

In the object library, click the *Datastores* tab and expand a datastore listing (click the plus sign next to the datastore name).

Description

Hierarchy objects allow you to browse, select, and import hierarchical information from a source database. Hierarchy objects can import the following hierarchical information:

Source application	Hierarchies extracted
SAP application	Data Services represents SAP application sets as hierarchies. In SAP applications, sets are group of objects such as cost element groups or cost center groups. The sets allow you to see an individual object or all similar objects in a related area. Hierarchy objects can import set information from SAP applications basic or single-dimension sets. In particular, you can import cost element and cost center hierarchies.

To extract hierarchical information, select a hierarchy type, import its metadata into your repository, then drag the hierarchy icon from the object library into a data flow.

SAP application hierarchies

External view

Hierarchy types are listed in the external browsing view for an SAP Applications datastore. From this view, you can choose to import a hierarchy type from a specific controlling area, or you can import a hierarchy type regardless of its association with a controlling area.

You can also import a hierarchy by specifying the hierarchy type by name. Select the datastore in the object library, right-click and choose *Import By Name*.

Imported hierarchy type

After you import the hierarchy type, it appears in the object library nested under the datastore name.

The hierarchy object has the following properties:

Property	Description
Name	The name of the hierarchy object. The name is constructed as follows: `set_table-hierarchy_group(datastore)`
Description	The description of the hierarchy type as included in the SAP application table.
Controlling_Area	The controlling area from which you imported the hierarchy type. You could specify the controlling area by selecting the hierarchy type in the controlling area view or by entering the controlling area name in the Import by Name window when you imported the hierarchy type. If you did not specify a controlling area, the value in Controlling_Area is an asterisk (*).

Property	Description
	If you import a chart of account hierarchy type, the controlling area will be inferred. The Controlling_Area value will never be NULL.
Set_Table	The table from which the hierarchy data is extracted.
Chart_Of_Account	The chart of account from which you imported this hierarchy type. This value is NULL for many hierarchy types associated with controlling areas but not chart of accounts.
Hierarchy_Group	The hierarchy type imported.
Check_Table	The location of the range of values for the hierarchy type leaf nodes.
Domain_Name	The data type and range definitions of the leaf node values.

Selecting the hierarchy in the object library and choosing *Open* displays the object properties and the source schema that results from the hierarchy extraction. Each row of the hierarchy object output describes a single relationship in the hierarchy.

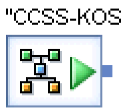
Column name	Description
Parent_id	The parent node in the relationship described by this row.
Parent_desc	A text description of the parent node.
Child_id	The child node in the relationship described by this row.
Child_desc	A text description of the child node.
Value_from	The start of the range of values associated with a leaf node. The range is found in the check table, which is recorded in the hierarchy object attributes. NULL if the row does not describes a leaf node.
Value_to	The end of the range of values associated with a leaf node. The range is found in the check table, which is recorded in the hierarchy object attributes. NULL if the row does not describes a leaf node.
Leaf_flag	A value of 1 indicates that the child node is a leaf node. A value of 0 indicates that the child node is not a leaf node.
Root_flag	A value of 1 indicates that the parent node is the root node. A value of 0 indicates that the parent node is not the root node.
Tree_level	The level of the child node in the hierarchy relative to the root node.
Cont_area	The controlling area associated with the hierarchy type. If this hierarchy type was selected without specifying a controlling area, the value of Cont_area is an asterisk (*).
Chart_of_acct	The chart of account associated with the hierarchy type.
Set_table	The table from which the hierarchy data is extracted.

Note

For every root node in the hierarchy, the hierarchy object produces a row with NULL as the root node. Depending on the final use of the hierarchy data, you may want to filter the NULL parent rows out of the hierarchy data.

Hierarchy instance

You can drag a hierarchy from the object library into an ABAP data flow definition. The hierarchy object appears in the data flow definition as follows:



The hierarchy editor displays the datastore information for the hierarchy and provides options for the instance of the hierarchy object:

Option	Description
All root nodes or Root node	Indicates that all hierarchies (root nodes) will be extracted from the specified hierarchy type. Turn off this option to specify a single hierarchy to extract. Look in the external view of the datastore to determine specific hierarchy names.
All controlling areas or Controlling area	Indicates that all hierarchy types for all controlling areas in which the groups appear will be extracted. Turn off this option to specify a single hierarchy type for a single controlling area to extract. ℹ Note For best performance, make sure to specify a single controlling area.

Related Information

Designer Guide: Datastores, Importing metadata through a database datastore [page 219]

12.8.1.2.6 IDoc file

Class

Reusable

Access

In the object library, click the *Datastores* tab, click an SAP Applications datastore, and click the list of available IDocs.

Description

IDoc file sources are handled the same way in data flows of real-time and batch jobs.

A real-time job that contains an IDoc file source processes its files one at a time. A real-time job that contains an IDoc message source can process messages one at a time or in parallel.

Multiple File Read in batch jobs

One or more IDoc files can be saved into one file or into many individual files to be processed at a later time.

When you run a real-time job in Test mode, Data Services can read multiple IDoc files at one time. To configure Data Services to read files in groups, list the names of these IDoc files or use one name with wildcard characters in the *IDoc Files* box of the source editor in the Designer.

The following list provides three examples:

- If you specify the IDoc file `D:\temp\IDOC_SAP*.txt`, Data Services will process data from all files in the D:\temp directory with names beginning with IDOC_SAP and the extension .txt.
- If you specify the IDoc file `D:\temp\IDOC_SAP?.txt`, Data Services will process data from all files in the D:\temp directory with:
  - names beginning with IDOC_SAP
  - any character before the extension
  - the extension `.txt`.
- If you specify the IDoc file `D:\temp\IDOC_01.txt`, `D:\temp\IDOC_02.txt`, `D:\temp\IDOC_03.txt`, Data Services will process data from these three IDoc files.

You can identify the source file for each row by using the Include file name column.

IDoc file sources are validated against the IDoc Name, its related hierarchy, and the SAP release.

Variable File names in batch jobs

You can also use variable file names in the *IDoc File/s* box. Define a global or local variable for an initialization script of a job. For example,

```
$SOPGEN01_<filepath> =    “D:\temp\IDOC_SAP*.txt”
```

Then enter **`<$filepath>`** in the *IDoc Files* box. This way you can avoid drilling down to each IDoc object to configure the location of source files.

Related Information

Source [page 2541]

Target [page 2548]
IDoc message [page 2564]

12.8.1.2.7 IDoc message

Class

Reusable

Access

In the object library, go to the *Datastores* tab, open the SAP Applications datastore, and open the list of available IDocs.

Description

An IDoc is an intermediate document that an SAP application produces to communicate transaction data between SAP application servers. SAP applications offers numerous IDocs that describe different transaction types. The data in an IDoc supports a particular transaction. An IDoc can contain data from multiple tables and can contain hierarchical data.

You can use an IDoc message as a source or target in a real-time job. You can use an IDoc message as a target in a batch job. You cannot use an IDoc in an ABAP data flow.

You can use the multiple file read and variable file name features with IDoc message sources in real-time jobs. However, these features can only be used when the job is run in test mode.

IDoc message sources must be configured in the Data Services Administrator as well as in Data Services Designer.

Real-time jobs that contain an IDoc message source can be processed one at a time or in parallel. To enable parallel processing, select *Administrator* > *Real-time* > *Client Interface* in the Data Services Administrator.

The *Parallel Processing* option allows you to increase the number of IDoc source messages processed per minute for the IDoc type specified. This option is disabled by default.

The parallel processing option allows the Access Server to send an IDoc to a service queue (where it waits for a service provider) and continue with the next IDoc without waiting for reply. The maximum number of outstanding IDoc requests in the queue is the number of IDocs received or 4, whichever is smaller.

> **Note**
>
> Where a strict IDoc processing sequence is required, do not use the *Parallel Processing* option.

To use IDocs, you must first import the metadata from the SAP application to your repository. Data Services imports the schema for the IDoc, maintaining hierarchical relationships among the data fields. You can display the IDoc schema by double-clicking the IDoc name in the object library.

When IDoc metadata is imported into Data Services or when IDocs are sent and received, the control data appears as the first segment for all IDoc objects. The control data is commonly prefixed with EDI_DC. The control data contains IDoc administrative information, such as IDoc number and sender or receiver information.

12.8.1.2.8 Open Hub Table source

Class

Single-use

Access

To insert an Open Hub source into an SAP Data Services data flow, open the local object library, go to the *Datastores* tab, select the Open Hub table from the SAP BW Source datastore, and drag it into the workspace.

Description

An Open Hub Table is a source object that SAP Data Services uses to read data from an SAP NetWeaver Business Warehouse system.

> Note
>
> You can only use an Open Hub Table as a source object, and it can only be used in a regular data flow. You cannot use it in an ABAP data flow.

The following options are available for an Open Hub source.

Open Hub source option	Description
Make Port	Makes the source table an embedded data flow port. For more information, see “Embedded Data Flows” in the *SAP Data Services Designer Guide*.
Join rank	Indicates the rank of the source relative to other tables and files in the data flow when creating a join. The software joins sources with higher join ranks before it joins sources with lower join ranks. Join rank specified in the Query transform editor FROM tab overrides any join rank specified in the source. Best practice is to specify the join rank only in the Query transform editor. Must be a non-negative integer. Default value is 0. For more information, see “Other Tuning Techniques” in the *Data Services Performance Optimization Guide* .
Cache	Indicates whether the software should read the required data from the source and load it into memory or pageable cache. Because an inner source of a join must be read for each row of an outer source, you might want to cache a source when it is used as an inner source in a join. There are two options: ● *Yes*: The source is always cached unless it is the outer-most source in a join. ● *No*: The source is never cached. The default is *No*. A cache setting specified in the Query transform editor FROM tab overrides any cache setting specified in a source. Best practice is to specify the cache setting only in the Query transform editor. Note For data flows that you created prior to version 11.7, the default cache type is in-memory. If the data retrieved does not fit into available memory, change the cache type to pageable in the data flow *Properties* window.
Open Hub Table	Specifies the name of the Open Hub table to read from. The default value is the name of the current Open Hub table. You can do any of the following: ● Leave the default value if different people are not using it simultaneously. ● Select another Open Hub table name from the drop-down list, but the one you select must have the same schema as the current Open Hub table. ● Select a substitution parameter from the drop-down list, but the one you select must have the same schema as the current Open Hub table. You must define the substitution parameter before creating this data flow. This capability allows you to reuse the data flow to read from another Open Hub destination that obtains its

Open Hub source option	Description
	data from the same InfoProviders with the same schema. For more details, see the Related Topics below.
Execute process chain before reading	Specifies whether or not to execute the process chain in the BW system before this Data Services data flow reads data from the Open Hub table. The process chain reads data from the BW InfoProvider objects and loads the Open Hub table from which the Data Services Open Hub source object reads the data. By default, this option is not selected. In this case, you must start the process chain with the function sap_openhub_processchain_execute in a script.
Process chain name	Specifies the name of the process chain in the BW system for this Open Hub table when *Execute process chain before reading* is selected. If you select *Execute process chain before reading*, the software fills in this option with the first process chain in the attributes for the current Open Hub table. Ensure that this is the appropriate process chain. If you change the name of the Open Hub table, you can select the corresponding process chain name from the drop-down list. You can specify a substitution parameter that you define before creating this data flow.
Parallel SAP Connections	Specifies the number of Open Hub connections to read multiple data packets from a BW system simultaneously. The default value is 0. Valid values are 0 and any positive integer. A value of 0 or 1 disables parallel reading. You can specify a substitution parameter that you define before creating this data flow.

Related Information

Creating a data flow for multiple users to read one InfoProvider [page 2519]

12.8.2 Functions

SAP Data Services does not support functions that include tables as input or output parameters except RFC and BAPI functions imported from SAP Applications.

12.8.2.1 SAP application RFC and BAPI function calls

You can call SAP application Remote Function Call (RFC) enabled functions, including Business Application Programming Interface (BAPI) functions, from queries inside data flows.

To make an RFC function available to call from Data Services data flows, import the metadata for the function from the SAP application server using an SAP Applications datastore connection. Be aware that the requirements for RFCs and BAPIs, and therefore their metadata, may be different between versions of SAP applications.

If you design data flows with BAPI calls against one version of an SAP application, then change datastores to a later version of SAP, Data Services allows this without the need to reimport the BAPI. Any new parameters added to the function call, including additional columns in table parameters, are added automatically to the call and filled with NULL values. Thus Data Services allows you to design jobs that are portable between SAP systems.

For a Data Services job to execute an RFC function, the login indicated by the datastore into which you imported the function must include the appropriate permissions required to execute the functions.

After you import the metadata for an SAP function, the function is listed in the Functions category of the SAP Applications datastore. You will also see the function in the function wizard listed under the datastore name.

When a function can provide a single output value, you can call the function in a column mapping in a query. Data Services provides a function wizard (available by clicking the *Functions* button on the *Where* tab of a query) to help you include input parameters for the function call. Input parameters can include expressions.

When a function can provide more than one output value, you can call the function by including it as an object in the output schema of a query. Data Services provides a function wizard (available through a short-cut menu) to help you include input and output parameters for the function call.

Data Services supports tables as input and output parameters for SAP RFC and BAPI functions. The function import process automatically includes the metadata for tables included as function parameters.

To specify a table as an input parameter to a function, the table must be an input to a query, either as a top-level input or nested under the top-level. The table must also be available in the FROM clause of the context where you call the function. Data Services maps columns in the input schema by name to the columns in the table used as the function input parameter. You need only supply the columns that are required by the function. At validation, if Data Services encounters type mismatches between supplied columns and the function signature, it attempts to convert the given type to the expected type. For type mismatches that it cannot resolve, Data Services produces validation errors.

One of the values that an RFC function can return is AL_RFC_RETCODE. This column contains a flag that identifies the success or failure of the function call. The possible values for AL_RFC_RETCODE are as follows:

Value	Description	Returned by
BOBJ_DI_RFC_OK	The RFC call succeeded. This value is replaced by the return value from the RFC call.	Data Services
BOBJ_DI_RFC_ENABLE_ERROR	The function is not RFC enabled.	Data Services
BOBJ_DI_RFC_NOT_ENABLED	The function is not RFC enabled.	Data Services

Value	Description	Returned by
BOBJ_DI_RFC_CALLRECEIVE_ERROR	The function call in SAP returned an error.	Data Services
BOBJ_DI_RFC_R3_CONN_EXCEPTION	The SAP Applications datastore connection cannot be created, because of a connection error, invalid user, password, system number, or host name.	Data Services
BOBJ_DI_RFC_CALL_ERROR	The connection completes, but the call fails in SAP.	Data Services
BOBJ_DI_RFC_GET_RESULT_ERROR	Data Services cannot obtain the result of the function call from SAP.	Data Services
BOBJ_DI_RFC_COMMIT_ERROR	Data Services cannot commit the work because the BAPI_TRANSACTION_COMMIT call returned an error.	Data Services
BOBJ_DI_RFC_BAPI_NOT_SAME	The Data Services repository contains a different BAPI function than in SAP.	Data Services
RFC_OK	The function call succeeded. Look for the results or errors that it returns.	SAP application
RFC_FAILURE	The function call returned an error. If the function is a BAPI, details for the cause of the error are available in the RETURN structure available as an output from the function.	SAP application
RFC_EXCEPTION	The function call returned an error. If the function is a BAPI, details for the cause of the error are available in the RETURN structure available as an output from the function.	SAP application
RFC_SYS_EXCEPTION	The function call returned an error and closed the connection to Data Services. If the function is a BAPI, details for the cause of the error are available in the RETURN structure available as an output from the function.	SAP application
RFC_CALL	The function call was received by SAP. If this value is left, the function failed to return a success flag after starting.	SAP application
RFC_INTERNAL_COM	An internal communication error occurred within SAP.	SAP application
RFC_CLOSED	The SAP application closed the connection and cancelled the function call.	SAP application

Value	Description	Returned by
RFC_EXECUTED	The SAP application already executed the function call.	SAP application
RFC_MEMORY_INSUFFICIENT	The SAP application does not have enough memory available to process the function call.	SAP application
RFC_NO_TID	The transaction ID is not available to SAP.	SAP application
RFC_RETRY	The SAP application did not process data yet. SAP will retry the function call.	SAP application
RFC_NOT_FOUND	The SAP application could not find the function.	SAP application
RFC_CALL_NOT_SUPPORTED	The SAP application does not support the function call.	SAP application
RFC_NOT_OWNER	The login in the Data Services datastore cannot connect to SAP.	SAP application
RFC_NOT_INITIALIZED	The Data Services RFC library did not initialize properly.	SAP application
RFC_SYNCHRONIZE	The SAP application is busy processing a synchronous call.	SAP application
RFC_SYSTEM_CALLED	Data Services is busy executing a call from SAP.	SAP application
RFC_VERSION_MISMATCH	The version of the function call from Data Services is incompatible with the function expected by SAP.	SAP application

The RETURN structure for BAPIs varies between releases of SAP applications:

Field	Description
TYPE	blank — success S — success E — error W — warning I — information A — abort
CODE	Error message numbers

Field	Description
MESSAGE	Error message text in the language chosen at login

This TYPE value is blank or NULL depending on the current setting of the Server option *Convert SAP null to null*. Check this option by choosing ▶ *Tools* > *Options* ◢ in the Designer. In particular when calling BAPI functions, the data you provide through the BAPI call might be different from the data that you use to test a BAPI directly in the SAP GUI interface. The SAP application interface automates data handling, where the BAPI operation undercuts the interface level.

Consider the following issues:

- All character values must be uppercase
- Padding values
- Assumed decimal values (QTY)
- Codes are language-specific
- Automatic type conversion
- SAP application version-specific behavior

To determine the data requirements of various SAP application functions, you can read the function requirements in the SAP GUI transaction screens:

- BAPI list by functional area: `bapi`
- BAPI and RFC source and input and output parameters: `se37`

You can also determine appropriate values, such as the language-specific code values, by looking at the table where the data is ultimately stored.

Reference Guide: Data Types, Type conversion [page 1039]

12.8.2.2 Data Services built-in functions

This section describes the Data Services functions that are specific to SAP.

Function	Category	Description
lookup	Lookup	Finds a value in one table or file based on values in a second table or file.
sap_extractor_delta_initialize	SAP	Sets a marker from which to return changed data.
sap_openhub_processchain_execute	SAP	• Starts the process chain that extracts data from an InfoProvider (InfoArea, InfoCube, or DataStore object) on SAP NetWeaver Business Warehouse and

Function	Category	Description
		loads the extracted data into an Open Hub Destination table. ● Monitors the process chain status and the Open Hub Destination request notification.
sap_openhub_set_read_status	SAP	Sends the read status for the Open Hub table to SAP NetWeaver BW. A read status causes SAP NetWeaver BW to release the Open Hub Destination table so that other users can access it.
substr	String	Returns a specific portion of a string starting at a given point in the string.
sy	Miscellaneous	Returns the value of an SAP system variable at run time. This function is only available through query transforms in ABAP data flows.

12.8.2.2.1 lookup

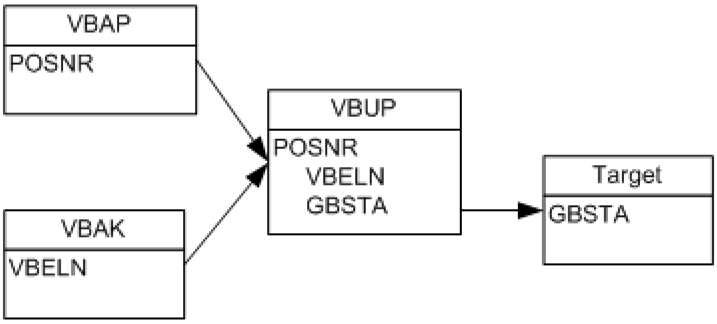
For SAP application tables, no owner value is required, but the periods are. For example: `sap_ds..KNA1`

`<cache_spec>`: The caching method the lookup operation uses. List within single quotes.

With regard to the three possible settings:

Setting	Description
NO_CACHE	Reads values from the lookup_table for every row without caching values.
PRE_LOAD_CACHE	For SAP application tables, applies the filters and loads the result_column and the compare_column into an internal SAP table. The function reads the values from the internal table. Select this option if the number of rows in the table is small or you expect to access a high percentage of the table values.
DEMAND_LOAD_CACHE	Select this option if the number of rows in the table is large and you expect to access a low percentage of the table values frequently. For SAP application tables, loads the result_column and compare_column into an internal SAP table when two or more lookups use the same translation table. So, Data Services creates a single SELECT statement to load the combined values from all the lookups into an internal SAP table. Select this option when you use the table in multiple lookups and the compare conditions are highly selective, resulting in a small subset of data.

You can use the lookup function when retrieving data from SAP application tables in an ABAP data flow. For example, suppose you are joining two tables, VBAK and VBAP, and you want to retrieve a value from a third table, VBUP.



You can create a lookup function with two **<expression>** and **<compare_column>** pairs:

```
lookup(sap_ds..VBUP, GBSTA, 'none', 'NO_CACHE', VBELN, VBAK.VBELN, POSNR,
VBAP.POSNR)
```

This function returns the value from the GBSTA column (the **<result_column>**) in the VBUP table (the **<lookup_table>**) that corresponds to the VBELN value (first **<compare_column>**) in the VBAK table (first **<expression>**) and the POSNR value in (second **<compare_column>**) the VBAP table (second **<expression>**). When no corresponding value is found, the function returns "none."

When there are multiple matching rows in the **<lookup_table>** and the lookup table is an SAP application table, the lookup function randomly selects a matching row and returns the value in the result_column for that row. To avoid random selection:

- Use the lookup_seq function if the table has a sequence column that discriminates between matching records
- Use an outer join and add criteria to the WHERE clause to discriminate between multiple matching records

12.8.2.2.2 sap_extractor_delta_initialize

Syntax

For SAP ODP sources using changed-data capture, use this function in a script to indicate to the ODP data replication API to only extract changed data (delta) for subsequent executions.

```
sap_extractor_delta_initialize (<datastore_name>, <extractor_name>, <$g1>)
```

where $g1 is a sample name for a global variable of type string. After calling the function, $g1 is empty to indicate success; otherwise, it displays E for error.

12.8.2.2.3 sap_openhub_processchain_execute

Performs the following tasks:

- Starts the process chain that extracts data from an InfoProvider (InfoArea, InfoCube, or DataStore object) on SAP NetWeaver Business Warehouse and loads the extracted data into an Open Hub Destination table.

- Monitors the process chain status and the Open Hub Destination request notification.

When the function returns successfully, an Open Hub table source in SAP Data Services can then read the data from the Open Hub Destination table.

Note

You can only use this function in a script. It is not valid in a query or audit object.

Below is the function syntax as a reference. The function wizard is explained in the next section.

Syntax

```
sap_openhub_processchain_execute('<datastore>','<open_hub_table>',
'<process_chain>',<$logid>,<$ReturnTxt>)
```

Where

`<datastore>`	Specifies the datastore name. You can specify either a constant string or a substitution parameter. The data type is varchar(256). Note The maximum length depends on the Data Services repository type. For most repository types the maximum length is 256, for MySQL the length is 64, and for MS SQL server the length is 128.
`<open_hub_table>`	Specifies the Open Hub Destination table. You can specify either a constant string or a substitution parameter. The data type is varchar(30).
`<process_chain>`	Specifies the name of the process chain that extracts data from the InfoProvider in SAP NetWeaver BW and loads the data to the Open Hub Destination table. You can specify either a constant string or a substitution parameter. The data type is varchar(30).
`<$logid >`	(Optional) Specifies a variable to obtain a value that depends on the function return value (see "Relationship between return value and value of logid variable" below). The required variable data type is varchar(25).
`<$ReturnTxt>`	(Optional) Specifies a variable to retrieve the description of the return status of the process chain.

	The required variable data type is varchar, and you can define the length you want for this variable.

Return value

varchar(1)

Returns one of the following values.

Return value	Description
B	Open Hub Destination is being read by another user.
E	Data Services error while executing the function.
R	Process chain execution failed with errors in BW system.
X	Process chain execution has been canceled in BW system.
S	Function successfully executed the Open Hub extraction Data Transfer Process (DTP) and received extraction request notification.

Relationship between return value and value of logid variable

The value of the logid output variable depends on the function return value, as the following table shows.

Return value	$logid variable value	$ReturnText variable value	Action
B	Process chain log ID of the other user that is currently reading the Open Hub Destination	Status of current Open Hub extraction	Either wait and try again or stop executing the data flow that contains the Open Hub Destination table.
E	Data Services error log number	Data Services error text	Stop executing the data flow that contains the Open Hub Destination table, and analyze the Data Services error.
R	Your process chain log ID	Error from process chain	Stop executing the data flow that contains the Open Hub Destination table, and use the log ID in the BW system to see the detail state of the process chain error.
X	Your process chain log ID	Error from process chain	Stop executing the data flow that contains the Open Hub Destination table, and use the log ID in the BW

Return value	$logid variable value	$ReturnText variable value	Action
			system to see the detail state of the process chain error.
S	Open Hub extraction request ID	Status of your Open Hub extraction	Use the request ID in the BW system to obtain detail loading statistics (such as number of packets loaded and number of records loaded).

Example

The following sample script commands check the return value, generate an exception, and print the error if the function is not successful.

```
$status = sap_openhub_processchain_execute('open_hub_datastore',
'Materials','Materials_PC',<$lpcogid>,
<$returntxt>);
If ($status != 'S') raise_exception ('Materials_PC process chain execution failed
' || $returntxt);
```

Restrictions

The following are restrictions for using Open Hub Destinations:

- Only one job at a time can read an Open Hub Destination table.
- A process chain of an Open Hub Destination can contain only one of its Data Transfer Processes (DTPs).
- A process chain cannot contain DTPs for more than one Open Hub Destination.

12.8.2.2.3.1 To define an sap_openhub_processchain_execute function

1. To access the function wizard for sap_openhub_processchain_execute from the Script Editor, click *Functions* or *...* at the top of the window.
2. Select *sap_openhub_processchain_execute* from the list of functions.
   The *Define Parameters* window opens.
3. Select an SAP BW Source datastore name from the drop-down list. You can also select a substitution variable from the list. If you type in a datastore name, put single quotes around the name.
4. Select the name of a Open Hub table from the drop-down list. Only the names of the imported Open Hub Tables appear in this list.
5. Select the name of a Process Chain from the drop-down list.
6. Specify a variable that will get the BW log ID for the process chain after the function executes. You must define the variable before you can use it.

7. Specify a variable that will get the description of the status after the function executes. You must define the variable before you can use it.

12.8.2.2.4 sap_openhub_set_read_status

Sends the read status for the Open Hub table to SAP NetWeaver BW. A successful read status causes SAP NetWeaver BW to delete the data from the Open Hub Destination table.

Syntax

```
sap_openhub_set_read_status('<datastore>','<destination>',
<status>,<$returntxt>)
```

Where

`<datastore>`	Specifies the datastore name. You can specify either a constant string or a substitution parameter. The data type is varchar(256). Note The maximum length depends on the Data Services repository type. For most repository types the maximum length is 256, for MySQL the length is 64, and for MS SQL server the length is 128.
`<destination>`	Specifies the Open Hub Destination in the BW system. You can specify either a constant string or a substitution parameter. The data type is varchar(30).
`<status>`	Specifies the read status. Possible values are either a variable or one of the following string constants: ● 'X' for Read Successful ● Any other value indicates that the Read failed. The data type is varchar(1).
`<$returntxt>`	(Optional) Specifies a variable to return the status log of the function. The required variable data type is varchar, and you can define the length you want for this variable.

Return value

varchar(1)

Returns one of the following values.

Return value	Description
S	Success
E	Error

Example

The following sample script commands sends the status of the Open Hub table read to the BW system and prints the status.

```
$status = sap_openhub_set_read_status('BR9", 'PS_BOOK_5', 'X', $returntxt):
print ('Status: ' || $status);
```

12.8.2.2.5 substr

In an ABAP data flow, the first character is position 0; in other data flows, the first character is position number 1. If **<start>** is 0 in a non-ABAP data flow, the new string begins with the first character (that is, position 1). If **<start>** is negative, the new strings begins with the first character in the string (that is, position 0 in an ABAP data flow or position 1 in a non-ABAP data flow).

12.8.2.2.6 sy

Returns the value of an SAP system variable at run time. This function is only available through query transforms in ABAP data flows.

Syntax

Syntax

```
sy('<SAP_variable>')
```

Return value

varchar(255): The value of the SAP system variable. You may need to recast the return value to the actual data type of the system variable in SAP.

Where

<SAP_variable>: A string value containing the name of the SAP system variable. This value is not case sensitive. Enclose the name in single quotation marks (').

When the sy function is executed, Data Services generates the appropriate function call in the ABAP for the ABAP data flow (appends `SY-` to the **<SAP_variable >** that you specify) and returns the result of the function call at run time.

The table SYST in SAP lists the available system variable, their data types, and descriptions.

If the given **<SAP_variable >** does not exist in SAP, Data Services produces a run-time error:

```
ABAP program <Generated ABAP Program> syntax error: <The data object "SY" has no
component called "ABC">.
```

No value is returned when this error occurs.

Example

Functions and results

Function	Results
`sy('SUBRC')`	0 if the subroutine call returned successfully
`sy('mandt')`	The client ID number of the current SAP application client
`sy('UNAME')`	The logon name of the user
`sy('DATUM')`	The current date from the SAP application server
`sy('UZEIT')`	The current time from the SAP application server
`sy('TCODE')`	The current transaction code

12.8.3 Data types

The following sections discuss SAP application data types used in Data Services.

Related Information

Reference Guide: Data types [page 1027]

12.8.3.1 Conversion to/from Data Services internal data types

The following table lists the conversions from SAP application data types to Data Services internal data types.

Source	External data type	Converts to Data Services data type
SAP application	date (D)	date
	time (T)	time
	float (F)	double
	integer (I)	int
	numeric (N)	varchar
	packed (P)	decimal
	char (C)	varchar
	hexadecimal (X)	varchar

The following table lists the conversions from Data Services internal data types to SAP application data types.

Internal data type	Is converted to SAP application data type
date	date (D)
datetime	date (D)
decimal	decimal (P)
double	float (F)
int	int (I)
interval	int (I)
numeric	char (C)
real	float (F)
time	time (T)

Internal data type	Is converted to SAP application data type
varchar	char (C)

12.8.3.2 Working with null values from SAP applications

SAP applications use a different standard for null values than Data Services or the target databases that Data Services supports. You can configure Data Services to account for the difference in one of two ways:

- Always converting the SAP equivalent of a null value to the Data Services NULL constant
- Reading the SAP null value literally

Each method has consequences for how you can use null-value tests in analytic processing. Data in a given warehouse must be loaded over time using the same method.

The default configuration for Data Services is to read the SAP value literally. You can change this configuration by navigating in the Designer to ▶ *Tools* ▶ *Options* ▶ *SAP* ▶ and selecting or deselecting the *Convert SAP null to null* option.

12.8.3.3 Design considerations for SAP application null behavior

When choosing which method to use to handle SAP application null values and when designing extraction logic in Data Services, consider the following issues:

- Primary keys built from concatenated values
  Spaces are often used in SAP applications where null values would cause an error in a primary key built from several key values concatenated together. If you choose to have Data Services automatically convert these spaces to null values, you may have to include null-value replacement logic in your data flows to avoid errors in primary keys for extracted tables.
- Null date values
  If dates are left to Data Services and the target database conventions to determine the conversion of an SAP null date value, the result may not be useful for constructing reports.
- Filters for null values

The value used to match an SAP null value depends on the data type of the value.

Data type	SAP application null value
Strings	single space
Numbers	zero
Dates	`00000000`
Times	`000000`

Related Information

Null dates [page 2582]

12.8.3.4 Null dates

The concept of a null date in SAP applications is represented by a value called INITIAL that is a property of every SAP application data element. You can see INITIAL dates displayed through SAPGUI as `00/00/0000` (month 0, day 0, year 0).

In the default configuration of Data Services (where *Convert SAP null to null* is disabled), INITIAL dates are written to an ABAP data file as NULLs. In ABAP data files, NULLs are represented by empty strings. They are then read by the parent data flow, which converts every empty string to a single space. If passed through again without data type or value change, Data Services converts the single blank into 01-JAN-1900 before loading it into a target.

The single space is not a valid date value. When Data Services encounters a single space in date conversion operations (implicit or explicit) or when evaluating an expression, the results are not predictable. To avoid unpredictable results, the data flow must explicitly convert the INITIAL date to a valid date value.

Consider these techniques to convert INITIAL dates to valid date values:

- Convert INITIAL dates to valid dates using the nvl function in the ABAP data flow
  In an ABAP data flow, Data Services produces ABAP for the nvl function that looks for an INITIAL date rather than a null value. The mapping expression can be the following:

  ```
  nvl(date_column, valid_date)
  ```

  where the valid date is a parameter passed to the data flow or a string indicating the appropriate initial date for your data warehouse.
  An example mapping expression would be:

  ```
  nvl(VBAK.ANGDT, '19901231')
  ```

- Turn on the option *Convert SAP null to null* and use nvl in regular (non-ABAP) data flows
  If an INITIAL date is extracted from SAP and loaded directly into a Data Services transport file, the INITIAL date is converted to a null value. If the Convert SAP null to null option is turned on, the null values in the transport file are brought into the data flow as null values. You can then use the nvl function in the data flow to detect the null date and substitute an appropriate valid date for it.

13 Supplement for Siebel

13.1 Overview of the SAP Data Services Siebel interface

The Data Services Siebel interface allows you to create Siebel datastores and import tables for use as sources in Data Services jobs. With this interface, you can use the Designer to:

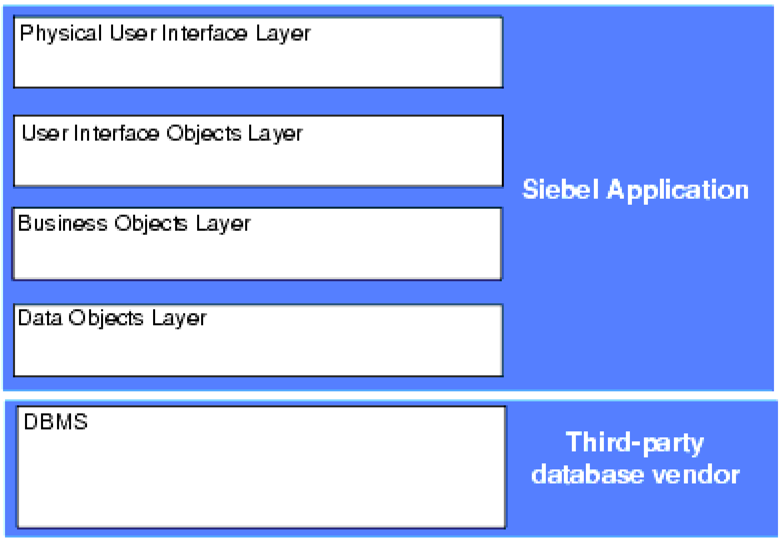
- Browse and import Siebel tables grouped by type, business component, and Siebel repository
- Browse to tables in a Siebel repository using the following path through higher level data: ▶ *applications* › *screens* › *views* › *business objects* › *business components* › *tables* ◀.
- Import function metadata

Related Information

Browsing and importing metadata [page 2585]

13.2 System requirements

The Siebel interface allows you to connect SAP Data Services with a third-party database under the Siebel application layer. You can import tables (including table and column descriptions) and function metadata. Data Services also displays information from both the logical business objects and user interface layers of Siebel applications. This makes it easier to find and import tables.



Physical User Interface Layer
User Interface Objects Layer
Business Objects Layer
Data Objects Layer
Siebel Application
DBMS
Third-party database vendor

Figure 10: Siebel Architecture

Install the drivers you need to connect your database with Data Services on the same computers on which you install the Designer and Job Server components.

The Siebel interface supports Siebel version 7.5.2 and higher compatible versions. It can be installed using the Data Services installer.

13.2.1 Security

Because SAP Data Services connects to Siebel applications through a database connection, Data Services can see all Siebel application objects that a database user can access without requiring the application's user login security information.

13.3 Datastores

SAP Data Services uses datastore connections to link with other applications or databases.

- In a design environment, use a datastore to browse or import metadata that represents external tables and other database objects.
- In a production environment, Data Services uses datastore information to move data between source and target databases and applications.

After defining a Siebel datastore in Data Services, you can browse tables by type, or drill down on business components or Siebel repositories to find the tables you want to import. You can also import tables, functions, and business components by name.

13.3.1 Defining a Siebel datastore

With a Siebel datastore connection, you can browse Siebel application metadata.

13.3.1.1 To define a Siebel datastore

1. In the object library of the Designer, go to the *Datastores* tab
2. Right-click inside the object library window and select *New*.
3. In the *Datastore Editor* window, enter a name for this datastore (`DS_SiebelApps`, for example).
4. In the *Datastore type* list, select *Siebel*.
5. Enter the connection information.
6. Click *OK*.
   The Siebel datastore appears in the object library.

13.3.2 Browsing and importing metadata

After you create a Siebel datastore, you can browse and import the metadata from the connected application.

> Note
>
> While you cannot browse functions, you can import them by name.

13.3.2.1 To browse and import metadata

1. Right-click the Siebel datastore name and select *Open*, or double-click the datastore name.

   The workspace displays a list of folders.
2. To find the tables you want to import, expand the Table by type, Business Component, or Repository folder. See the remainder of this section for a description of these folders.
3. To import table data, right-click one or more tables or business components and select *Import*.

   > Note
   >
   > When you import a table into SAP Data Services via the Siebel interface, the software does not preserve the source folder (table hierarchy). All tables display at the same level. For example, import all the tables in a Business Component, then add select statements, joins, and mappings using the Designer to create the same associations used in your Siebel application.

You can also import Siebel metadata by right-clicking a Siebel datastore in the object library and selecting *Import by name*.

Once tables are imported, you can view column names, data types, and business names for use in creating jobs.

13.3.2.2 Table - by type

Siebel applications use many table types. You can browse tables by looking at tables grouped by type.

13.3.2.2.1 Business component

Business components are sets of tables used to create a logical Siebel application object called a business object. Business components are grouped in alphabetical folders.

You can select and import one or more business components or tables.

13.3.2.2.2 Repository

Siebel repositories hold a variety of Siebel application objects. You can drill through them to find the tables you want to import.

These associations apply:

- *Seibel Repository:* Repository
- *Seibel Dynamic Commerce:* Application
- *Auctions:* Screen
- *Auction Items:* View
- *Auction Services:* Business Object
- *Auction Item Detail:* Business Component

13.3.3 Extracting data from Siebel applications

When extracting data from Siebel applications, SAP Data Services processes and converts data types appropriately.
