1 Administrator Guide

1.1 Getting Started

1.1.1 Overview of SAP Data Services

About this section

This section introduces SAP Data Services and explains its place in the SAP solution portfolio.

1.1.1.1 SAP Data Services and the SAP solution portfolio

The SAP solution portfolio delivers extreme insight through specialized end-user tools on a single, trusted business intelligence platform. This entire platform is supported by SAP Data Services. On top of SAP Data Services, the SAP solution portfolio layers the most reliable, scalable, flexible, and manageable business intelligence (BI) platform which supports the industry's best integrated end-user interfaces: reporting, query and analysis, and performance management dashboards, scorecards, and applications.

True data integration blends batch extraction, transformation, and loading (ETL) technology with real-time bi-directional data flow across multiple applications for the extended enterprise.

By building a relational datastore and intelligently blending direct real-time and batch data-access methods to access data from enterprise resource planning (ERP) systems and other sources, SAP has created a powerful, high-performance data integration product that allows you to fully leverage your ERP and enterprise application infrastructure for multiple uses.

SAP provides a batch and real-time data integration system to drive today's new generation of analytic and supply-chain management applications. Using the highly scalable data integration solution provided by SAP, your enterprise can maintain a real-time, on-line dialogue with customers, suppliers, employees, and partners, providing them with the critical information they need for transactions and business analysis.

1.1.1.2 Software benefits

Use SAP Data Services to develop enterprise data integration for batch and real-time uses. With the software:

- You can create a single infrastructure for batch and real-time data movement to enable faster and lower cost implementation.
- Your enterprise can manage data as a corporate asset independent of any single system. Integrate data across many systems and reuse that data for many purposes.
- You have the option of using pre-packaged data solutions for fast deployment and quick ROI. These solutions extract historical and daily data from operational systems and cache this data in open relational databases.

The software customizes and manages data access and uniquely combines industry-leading, patent-pending technologies for delivering data to analytic, supply-chain management, customer relationship management, and Web applications.

1.1.1.2.1 Unification with the platform

SAP Data Services provides several points of platform unification:

- Get end-to-end data lineage and impact analysis.
- Create the semantic layer (universe) and manage change within the ETL design environment.

Data Services deeply integrates the entire ETL process with the business intelligence platform so you benefit from:

- Easy metadata management
- Simplified and unified administration
- Life cycle management
- Trusted information

1.1.1.2.2 Ease of use and high productivity

SAP Data Services combines both batch and real-time data movement and management to provide a single data integration platform for information management from any information source, for any information use.

Using the software, you can:

- Stage data in an operational datastore, data warehouse, or data mart.
- Update staged data in batch or real-time modes.
- Create a single graphical development environment for developing, testing, and deploying the entire data integration platform.
- Manage a single metadata repository to capture the relationships between different extraction and access methods and provide integrated lineage and impact analysis.

1.1.1.2.3 High availability and performance

The high-performance engine and proven data movement and management capabilities of SAP Data Services include:

- Scalable, multi-instance data-movement for fast execution
- Load balancing
- Changed-data capture
- Parallel processing

1.1.1.3 Associated software

Choose from other SAP solution portfolio software options to further support and enhance the power of your SAP Data Services software.

1.1.1.3.1 SAP Metadata Management

SAP BusinessObjects Metadata Management provides an integrated view of metadata and its multiple relationships for a complete Business Intelligence project spanning some or all of the SAP solution portfolio. Use the software to:

- View metadata about reports, documents, and data sources from a single repository.
- Analyze lineage to determine data sources of documents and reports.
- Analyze the impact of changing a source table, column, element, or field on existing documents and reports.
- Track different versions (changes) to each object over time.
- View operational metadata (such as the number of rows processed and CPU utilization) as historical data with a datetime.
- View metadata in different languages.

For more information on SAP Metadata Management, contact your SAP sales representative.

1.1.1.4 Interfaces

SAP Data Services provides many types of interface components. Your version of the software may provide some or all of them.

You can use the Adapter SDK to develop adapters that read from and/or write to other applications.

In addition to the interfaces listed above, the Nested Relational Data Model (NRDM) allows you to apply the full power of SQL transforms to manipulate, process, and enrich hierarchical business documents.

For a detailed list of supported environments and hardware requirements, see the *Product Availability Matrix* available at *https://service.sap.com/PAM*. This document includes specific version and patch-level requirements for databases, applications, web application servers, web browsers, and operating systems.

Related Information

Designer Guide: Nested Data [page 342]

1.1.2 Naming Conventions

In this documentation, the following naming conventions apply:

Terminology

- “Data Services system” refers to “SAP Data Services”.
- “BI platform” refers to “SAP BusinessObjects BI platform”.

  > Note
  >
  > The BI platform components required by Data Services may also be provided by SAP BusinessObjects Information platform services (IPS).

- “CMC” refers to the Central Management Console provided by the BI or IPS platform.
- “CMS” refers to the Central Management Server provided by BI or IPS platform.

Variables

Variables	Description
`<INSTALL_DIR>`	The installation directory for the SAP software. Default location: • `C:\Program Files (x86)\SAP BusinessObjects` • `$HOME/sap businessobjects`
`<BIP_INSTALL_DIR>`	The root directory of the BI or IPS platform. Default location: • `<INSTALL_DIR>\SAP BusinessObjects Enterprise XI 4.0` • `<INSTALL_DIR>/enterprise_xi40` Note These paths are the same for both the SAP BusinessObjects BI platform and SAP BusinessObjects Information platform services.
`<LINK_DIR>`	The root directory of the Data Services system. Default location: • All platforms `<INSTALL_DIR>/Data Services` This system environment variable is created automatically during installation.

Variables	Description
<DS_COMMON_DIR>	The common configuration directory for the Data Services system. Default location: - Windows (Vista and newer) `ALLUSERSPROFILE\SAP BusinessObjects\Data Services` - Windows (Older versions) `ALLUSERSPROFILE\Application Data\SAP BusinessObjects\Data Services` - UNIX systems (for compatibility) <LINK_DIR> This system environment variable is created automatically during installation.
<DS_USER_DIR>	The user-specific configuration directory for the Data Services system. Default location: - Windows (Vista and newer) `USERPROFILE\AppData\Local\SAP BusinessObjects\Data Services` - Windows (Older versions) `USERPROFILE\Local Settings\Application Data\SAP BusinessObjects\Data Services` This user environment variable is created automatically during installation. i Note This variable is used only for Data Services client applications on Windows, such as the Designer. <DS_USER_DIR> is not used on UNIX platforms.

1.2 Data Services Architecture

1.2.1 Architecture overview

This section outlines the overall platform architecture, system, and service components that make up the SAP Data Services platform. The information helps administrators understand the system essentials and help to form a plan for the system deployment, management, and maintenance.

Data Services is designed for high performance across a broad spectrum of user and deployment scenarios. For example:

- Developers can integrate Data Services into your organization's other technology systems by using web services, Java, or .NET application programming interfaces (APIs).
- End users can access, create, edit, and interact with Data Services projects and reports using specialized tools and applications that include:
  - Designer

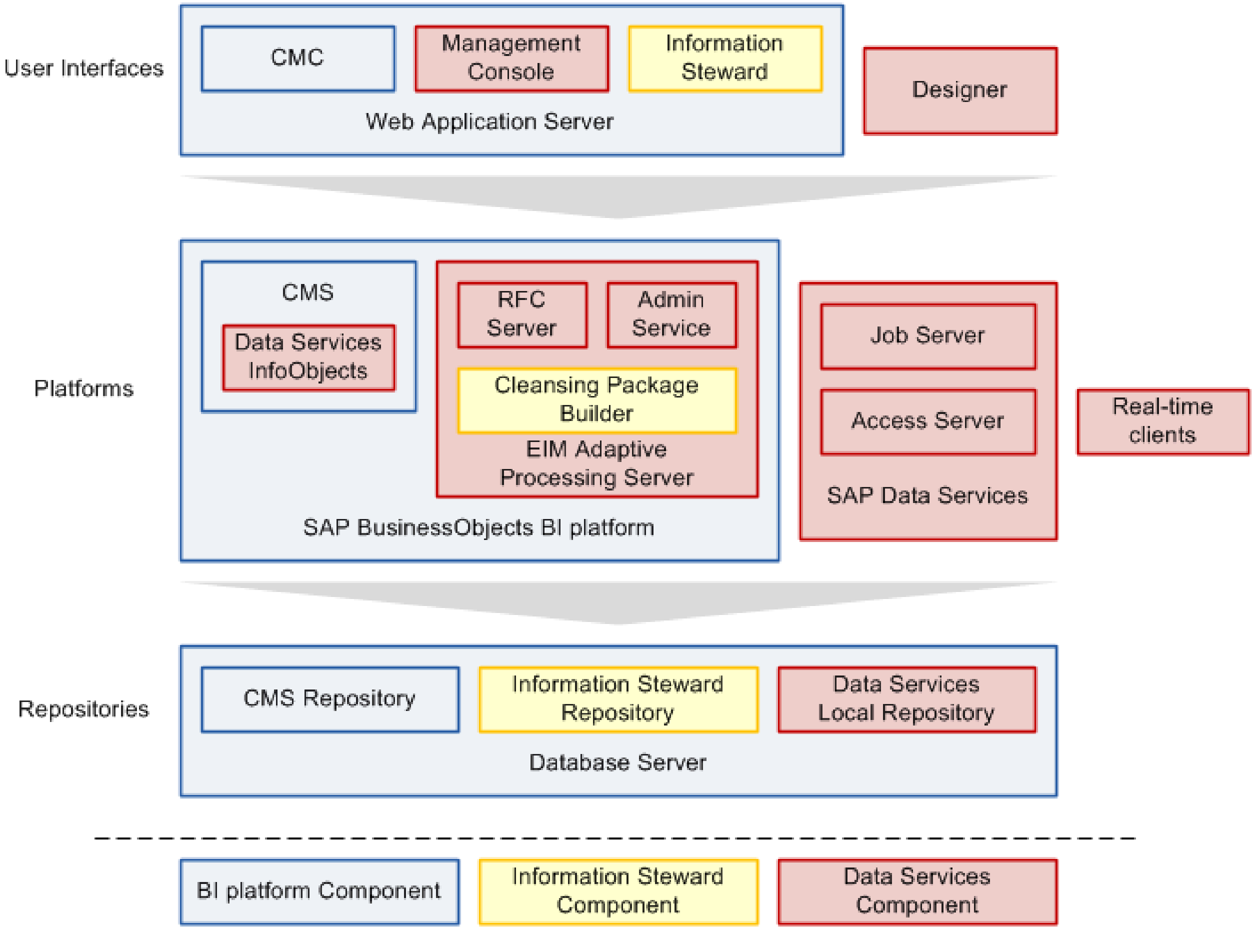
  - Management Console
    - Administrator
    - Impact and Lineage Analysis
    - Operational Dashboard
    - Auto Documentation
    - Data Validation
    - Data Quality
- IT departments can use data and system management tools that include:
  - Central Management Console (CMC)
  - Management Console
  - Server Manager
  - Repository Manager

To provide flexibility, reliability, and scalability, Data Services components can be installed on one or across many machines.

Server processes can be “vertically scaled” (where one computer runs several, or all, server-side processes) to reduce cost, or “horizontally scaled” (where server processes are distributed between two or more networked machines) to improve performance. It is also possible to run multiple, redundant versions of the same server process on more than one machine, so that processing can continue if the primary process encounters a problem.

1.2.2 Standard components

The following diagram illustrates how SAP Data Services components fit in with other software in the SAP portfolio.



Note

If you do not have a full SAP BusinessObjects BI platform installation, the basic components required by Data Services can also be provided by SAP BusinessObjects Information platform services.

For a detailed list of supported environments and hardware requirements, see the *Product Availablility Matrix* available at: *http://service.sap.com/PAM*. This information includes specific version and patch-level requirements for databases, applications, web application servers, web browsers, and operating systems.

1.2.2.1 Designer

The Designer is a development tool with an easy-to-use graphical user interface. It enables developers to define data management applications that consist of data mappings, transformations, and control logic.

Use the Designer to create applications containing work flows (job execution definitions) and data flows (data transformation definitions).

To use the Designer, create objects, then drag, drop, and configure them by selecting icons in flow diagrams, table layouts, and nested workspace pages. The objects in the Designer represent metadata. The Designer interface allows you to manage metadata stored in a repository. From the Designer, you can also trigger the Job Server to run your jobs for initial application testing.

Related Information

Repository [page 24]
Job Server [page 24]

1.2.2.2 Repository

The SAP Data Services repository is a set of tables that hold user-created and predefined system objects, source and target metadata, and transformation rules. Set up repositories on an open client/server platform to facilitate sharing metadata with other enterprise tools. Each repository must be stored on an existing RDBMS and registered in the Central Management Console (CMC).

Each repository is associated with one or more Job Servers which run the jobs you create. There are two types of repositories:

- Local repository
  A local repository is used by an application designer to store definitions of objects (like projects, jobs, work flows, and data flows) and source/target metadata.
- Central repository
  A central repository is an optional component that can be used to support multi-user development. The central repository provides a shared object library allowing developers to check objects in and out of their local repositories.
  While each user works on applications in a unique local repository, the team uses a central repository to store the master copy of the entire project. The central repository preserves all versions of an application's objects, so you can revert to a previous version if needed.
  Multi-user development includes other advanced features such as labeling and filtering to provide you with more flexibility and control in managing application objects.
  For more details, see the *Management Console Guide* and the *Designer Guide*.

1.2.2.3 Job Server

The SAP Data Services Job Server starts the data movement engine that integrates data from multiple heterogeneous sources, performs complex data transformations, and manages extractions and transactions from ERP systems and other sources. The Job Server can move data in either batch or real-time mode and uses distributed query optimization, multi-threading, in-memory caching, in-memory data transformations, and parallel processing to deliver high data throughput and scalability.

While designing a job, you can run it from the Designer which tells the Job Server to run the job. The Job Server retrieves the job from its associated repository, then starts an engine to process the job. In your production environment, the Job Server runs jobs triggered by a scheduler or by a real-time service managed by the Access Server. In production environments, you can balance job loads by creating a Job Server group (multiple Job Servers) which executes jobs according to overall system load.

Engine

When Data Services jobs are executed, the Job Server starts engine processes to perform data extraction, transformation, and movement. The engine processes use parallel processing and in-memory data transformations to deliver high data throughput and scalability.

Service

The Data Services service is installed when Job and Access Servers are installed. The service starts Job Servers and Access Servers when you restart your system. The Windows service name is `SAP Data Services`. The UNIX equivalent is a daemon named `AL_JobService`.

Related Information

Access Server [page 25]

1.2.2.4 Access Server

The SAP Data Services Access Server is a real-time, request-reply message broker that collects message requests, routes them to a real-time service, and delivers a message reply within a user-specified time frame. The Access Server queues messages and sends them to the next available real-time service across any number of computing resources. This approach provides automatic scalability because the Access Server can initiate additional real-time services on additional computing resources if traffic for a given real-time service is high. You can configure multiple Access Servers.

Service

The Data Services service is installed when Job and Access Servers are installed. The service starts Job Servers and Access Servers when you restart your system. The Windows service name is `SAP Data Services`. The UNIX equivalent is a daemon named `AL_JobService`.

1.2.2.5 Management Console

Administrator

The Administrator provides browser-based administration of SAP Data Services resources including:

- Scheduling, monitoring, and executing batch jobs.
- Configuring, starting, and stopping real-time services.
- Configuring Job Server, Access Server, and repository usage.
- Configuring and managing adapters.
- Managing users.
- Publishing batch jobs and real-time services via Web services.

Metadata Reports applications

The Metadata Reports applications provide browser-based analysis and reporting capabilities on metadata that is:

- Associated with your SAP Data Services jobs
- Associated with other SAP solution portfolio applications associated with Data Services

Metadata Reports provide several applications for exploring your metadata:

- Impact and lineage analysis
- Operational dashboards
- Auto documentation
- Data validation
- Data quality

1.2.2.5.1 Impact and Lineage Analysis reports

Impact and Lineage Analysis reports include:

- Datastore Analysis
  For each datastore connection, view overview, table, function, and hierarchy reports. SAP Data Services users can determine:
  - What data sources populate their tables
  - What target tables their tables populate
  - Whether one or more of the following SAP BusinessObjects solution portfolio reports uses data from their tables:
    - Business Views
    - Crystal Reports
    - SAP BusinessObjects Universe Builder
    - SAP BusinessObjects Web Intelligence documents
    - SAP BusinessObjects Desktop Intelligence documents
- Universe analysis
  View Universe, class, and object lineage. Universe users can determine what data sources populate their Universes and what reports use their Universes.
- Business View analysis
  View the data sources for Business Views in the Central Management Server (CMS). You can view business element and business field lineage reports for each Business View. Crystal Business View users can determine what data sources populate their Business Views and what reports use their views.

- Report analysis
  View data sources for reports in the Central Management Server (CMS). You can view table and column lineage reports for each Crystal Report and Web Intelligence Document managed by CMS. Report writers can determine what data sources populate their reports.
- Dependency analysis
  Search for specific objects in your repository and understand how those objects impact or are impacted by other SAP Data Services or SAP BusinessObjects Universe Builder objects and reports. Metadata search results provide links back into associated reports.

1.2.2.5.2 Operational Dashboard reports

Operational dashboard reports provide graphical depictions of SAP Data Services job execution statistics. This feedback allows you to view at a glance the status and performance of your job executions for one or more repositories over a given time period. You can then use this information to streamline and monitor your job scheduling and management for maximizing overall efficiency and performance.

1.2.2.5.3 Auto Documentation reports

Auto documentation reports provide a convenient and comprehensive way to create printed documentation for all of the objects you create in SAP Data Services. Auto documentation reports capture critical information for understanding your jobs so you can see at a glance the entire ETL process.

After creating a project, you can use Auto documentation reports to quickly create a PDF or Microsoft Word file that captures a selection of job, work flow, and/or data flow information including graphical representations and key mapping details.

1.2.2.5.4 Data Validation dashboard

Data Validation dashboard reports provide graphical depictions that let you evaluate the reliability of your target data based on the validation rules you created in your SAP Data Services batch jobs. This feedback allows business users to quickly review, assess, and identify potential inconsistencies or errors in source data.

1.2.2.5.5 Data Quality reports

Data Quality reports allow you to view and export Crystal Reports for batch and real-time jobs that include statistics-generating transforms. Report types include job summaries, transform-specific reports, and transform group reports.

1.2.2.6 Adapter SDK

The SAP Data Services Adapter SDK provides a Java platform for rapid development of adapters to other applications and middleware products such as EAI systems. Adapters use industry-standard XML and Java technology to ease the learning curve. Adapters provide all necessary styles of interaction including:

- Reading, writing, and request-reply from SAP Data Services to other systems.
- Request-reply from other systems to SAP Data Services.

1.2.3 Management tools

SAP Data Services has several management tools to help you manage your components.

1.2.3.1 License Manager

The License Manager displays the SAP Data Services components for which you currently have a license.

1.2.3.2 Repository Manager

The Repository Manager allows you to create, upgrade, and check the versions of local and central repositories.

1.2.3.3 Server Manager

The Server Manager allows you to add, delete, or edit the properties of Job Servers and Access Servers. It is automatically installed on each computer on which you install a Job Server or Access Server.

Use the Server Manager to define links between Job Servers and repositories. You can link multiple Job Servers on different machines to a single repository (for load balancing) or each Job Server to multiple repositories (with one default) to support individual repositories (separating test from production, for example).

The Server Manager is also where you specify SMTP server settings for the smtp_to email function.

Related Information

Reference Guide: To define and enable the smtp_to function [page 1670]

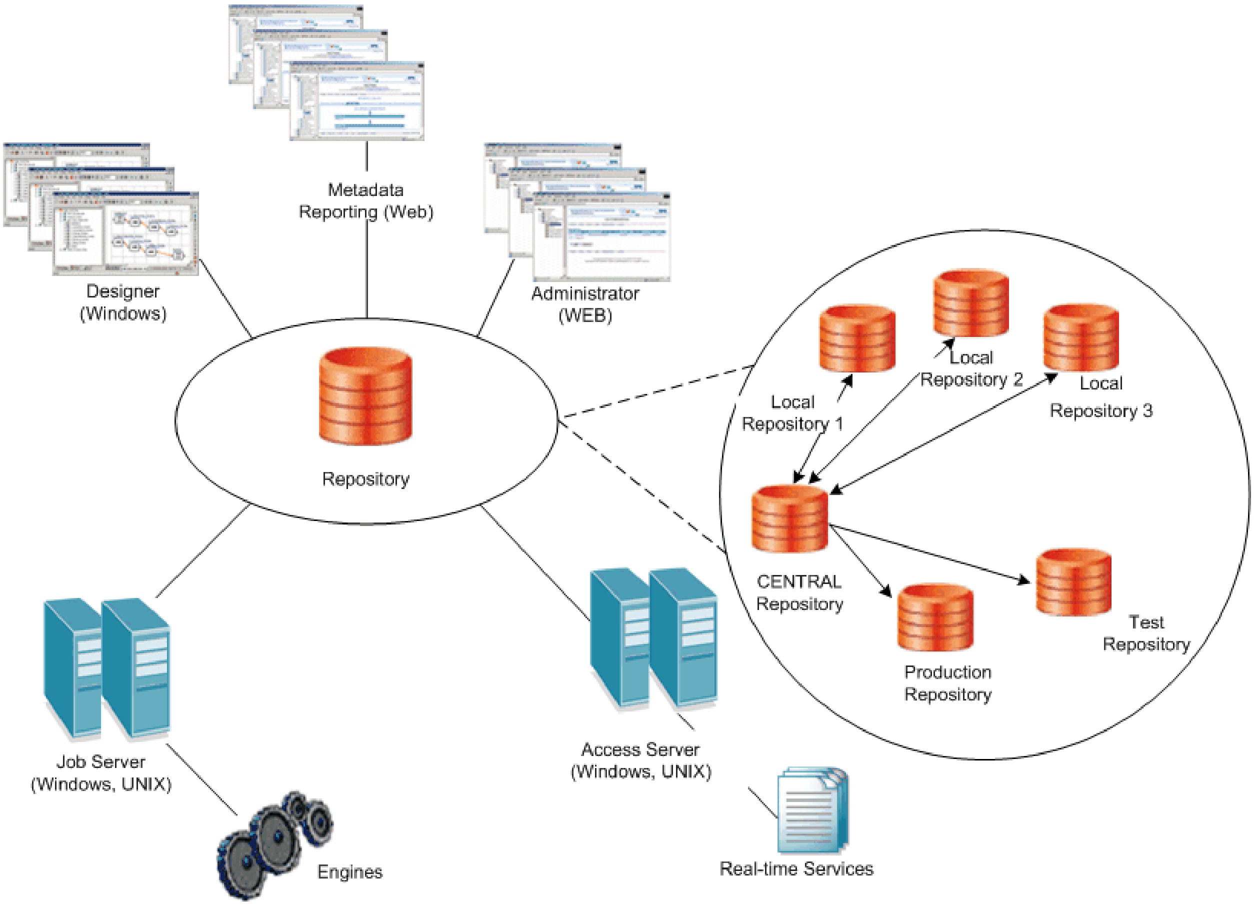
1.2.4 Operating system platforms

For a complete list of supported operating systems and hardware requirements, consult the *Product Availability Matrix* available at *http://service.sap.com/PAM*.

This document includes specific version and patch-level requirements for databases, applications, web application servers, web browsers, and operating systems.

1.2.5 Distributed architecture

SAP Data Services has a distributed architecture. An Access Server can serve multiple Job Servers and repositories. The multi-user licensed extension allows multiple Designers to work from a central repository. The following diagram illustrates both of these features.



You can distribute software components across multiple computers, subject to the following rules:

- Engine processes run on the same computer as the Job Server that spawns them.
- Adapters require a local Job Server.

Distribute components across a number of computers to best support the traffic and connectivity requirements of your network. You can create a minimally distributed system designed for developing and testing or a highly distributed system that can scale with the demands of a production environment.

1.2.5.1 Host names and port numbers

Communication between a Web application, the Access Server, the Job Server, and real-time services occurs through TCP/IP connections specified by IP addresses (or host names) and port numbers.

If your network does not use static addresses, use the name of the computer as the host name. If connecting to a computer that uses a static IP address, use that number as the host name for Access Server and Job Server configurations.

To allow for a highly scalable system, each component maintains its own list of connections. You define these connections through the Server Manager, the Administrator, the Repository Manager, and the Message Client library calls (from Web client).

For more information about the default port numbers used by Data Services, see the “Port assignments” section of the *Installation Guide*.

1.2.5.2 DSN-less and TNS-less connections

Data Services provides server name connections (also known as DSN-less and TNS-less connections) to databases that you use as a Data Services repository, source or target. Server name connections eliminate the need to configure the same DSN or TNS entries on every machine in a distributed environment.

For the Data Services repository, the following database types are supported:

- For Oracle databases, you specify the server name, database name, and port instead of the TNS name.
- For DB2, MySQL, and SAP HANA databases, you specify the server name, database name, and port instead of the DSN name.

> Note
>
> When you install Data Services, the repository defaults to a DSN-less or TNS-less connection. If you choose not to use a server name connection:
>
> - Defer repository creation to after installation.
> - Invoke the Repository Manager to subsequently create the repository.
>   - On Windows, select the option *Use TNS name* or *Use data source name (DSN)*.
>   - On UNIX, specify the `s` option to not use a server name connection.
> - Log in to the Central Management Console (CMC) to register the repository and select the repository connection type on the *Data Services Repository Properties* screen:
>   - For an Oracle database, select *Yes* in the drop-down list for *Use TNS name*.
>   - For a DB2, MySQL, or SAP HANA database, select *Yes* in the drop-down list for *Use data source name (DSN)*.

ℹ Note

This Data Services repository connection type setting on the CMC determines the connection type for logging into the Designer, running jobs, scheduling jobs, and so on.

For Data Services sources and targets, the following database types are supported for DSN-less and TNS-less connections:

- DB2 UDB
- Informix
- MySQL
- Netezza
- Oracle
- SAP HANA
- SAP Sybase IQ
- Teradata

ℹ Note

For the most current list of supported databases for server name connections, see the *Release Notes*.

Administrator Guide: To register a repository in the CMC [page 52]
Administrator Guide: To configure Job Servers [page 84]
Administrator Guide: To configure Job Servers on UNIX [page 91]
Administrator Guide: Using the Windows ODBC Driver Selector for DSN-less connections [page 79]
Administrator Guide: Configuring ODBC data sources on UNIX using DSN-less connections [page 69]

1.2.6 SAP integration

SAP Data Services integrates with your existing SAP infrastructure with the following SAP tools:

- SAP System Landscape Directory (SLD)
  The system landscape directory of SAP NetWeaver is the central source of system landscape information relevant for the management of your software life-cycle. By providing a directory comprising information about all installable software available from SAP and automatically updated data about systems already installed in a landscape, you get the foundation for tool support to plan software life-cycle tasks in your system landscape.
  The SAP Data Services installation program registers the vendor and product names and versions with the SLD, as well as server and front-end component names, versions, and location.
- SAP Solution Manager

The SAP Solution Manager is a platform that provides the integrated content, tools, and methodologies to implement, support, operate and monitor an organization's SAP and non-SAP solutions.
Non-SAP software with an SAP-certified integration is entered into a central repository and transferred automatically to your SAP System Landscape Directories (SLD). SAP customers can then easily identify which version of third-party product integration has been certified by SAP within their SAP system environment. This service provides additional awareness for third-party products besides our online catalogs for third-party products.
SAP Solution Manager is available to SAP customers at no extra charge, and includes direct access to SAP support and SAP product upgrade path information.

- CTS Transport (CTS+)
  The Change and Transport System (CTS) helps you to organize development projects in ABAP Workbench and in Customizing, and then transport the changes between the SAP systems in your system landscape. As well as ABAP objects, you can also transport Java objects (J2EE, JEE) and SAP-specific non-ABAP technologies (such as Web Dynpro Java or SAP NetWeaver Portal) in your landscape.
- Monitoring with CA Wily Introscope
  CA Wily Introscope is a web application management product that delivers the ability to monitor and diagnose performance problems that may occur within Java-based SAP modules in production, including visibility into custom Java applications and connections to back-end systems. It allows you to isolate performance bottlenecks in NetWeaver modules including individual Servlets, JSPs, EJBs, JCO's, Classes, Methods and more. It offers real-time, low-overhead monitoring, end-to-end transaction visibility, historical data for analysis or capacity planning, customizable dashboards, automated threshold alarms, and an open architecture to extend monitoring beyond NetWeaver environments.

1.3 Security

This section details the ways in which SAP Data Services addresses enterprise security concerns, thereby providing administrators and system architects with answers to typical questions regarding security.

Data Services relies on the Central Management Server (CMS) for authentication and security features. This section highlights differences and additional information specific to your Data Services system.

For complete information about the security features provided by the CMS, see the *SAP BusinessObjects BI Platform Administrator Guide* or the *SAP BusinessObjects Information Platform Services Administrator Guide*.

1.3.1 Securing administrative functions

To ensure security for your Data Services environment, use a firewall to prevent unintended remote access to administrative functions.

In a distributed installation, you need to configure your firewall so that the Data Services components are able to communicate with each other as needed.

For information about configuring ports on your firewall, see your firewall documentation. Also see the “Port assignments” topic in the Installation Guide

Related Information

Host names and port numbers [page 30]

1.3.2 Message client library

The Message Client libraries (Java and C++) used in real-time services, does not require authorization to connect. Therefore, it is important to use caution when using these libraries.

For more information about using the Message Client library, see the *SAP Data Services Integrator Guide*.

1.3.3 Temporary cache files

In Data Services, temporary cache files are generated for a variety of functions and operations. Profiling, joins, table comparison, sorting, `lookup`, and `group_by` are some examples. Because these files are not encrypted, by default, care should be taken when working with confidential or other sensitive data. Both pageable and persistent caches create data files that are not encrypted, by default.

Temporary file location

The temporary files that Data Services creates are stored in `%COMMON_DIR%/log/pCache/<repository_string>/`. These files can be secured using the appropriate permissions at the OS level.

Pageable cache and key data

The pageable cache option in a data flow stores data in temporary files that are removed automatically after a data flow finishes executing.

Persistent cache

Data Services provides a datastore called Persistent cache. The data in persistent cache is not encrypted, and it is your responsibility to secure it using OS file/directory permissions.

`long` data

When `long` data (BLOB or CLOB) data is large, the data is stored in temporary cache files.

If `long` data is cached (for a join, sort, or table comparison, for example), the cache file is deleted when the data flow finishes executing.

A `long` data cache file is also deleted when the data is out of scope. For example:

- The data is loaded into a target.
- The data is filtered out by a Query transform.
- A `long` datatype is converted to a `varchar`.

1.3.3.1 To encrypt certain temporary cache files

There are types of temporary cache files that can be encrypted, if necessary. These include:

- Persistent cache datastore files
- Pageable cache data flow files
- Functions such as lookup, search_replace, distinct, group_by, and so on.
- Transforms such as Data Quality transforms and Table Comparison

To enrypt these files:

1. Open the `DSConfig.txt` file, located in `%DS_COMMON_DIR%\conf`.
2. Set the `pageable_cache_encrypt_data` parameter, in the `String` section, to **`yes`**.
3. Save and close the file.

i Note

Encrypting these files can have a significant negative impact on performance. Remember that these files are deleted immediately after the data flow finishes executing.

1.3.4 Configuring SSL for Data Services components

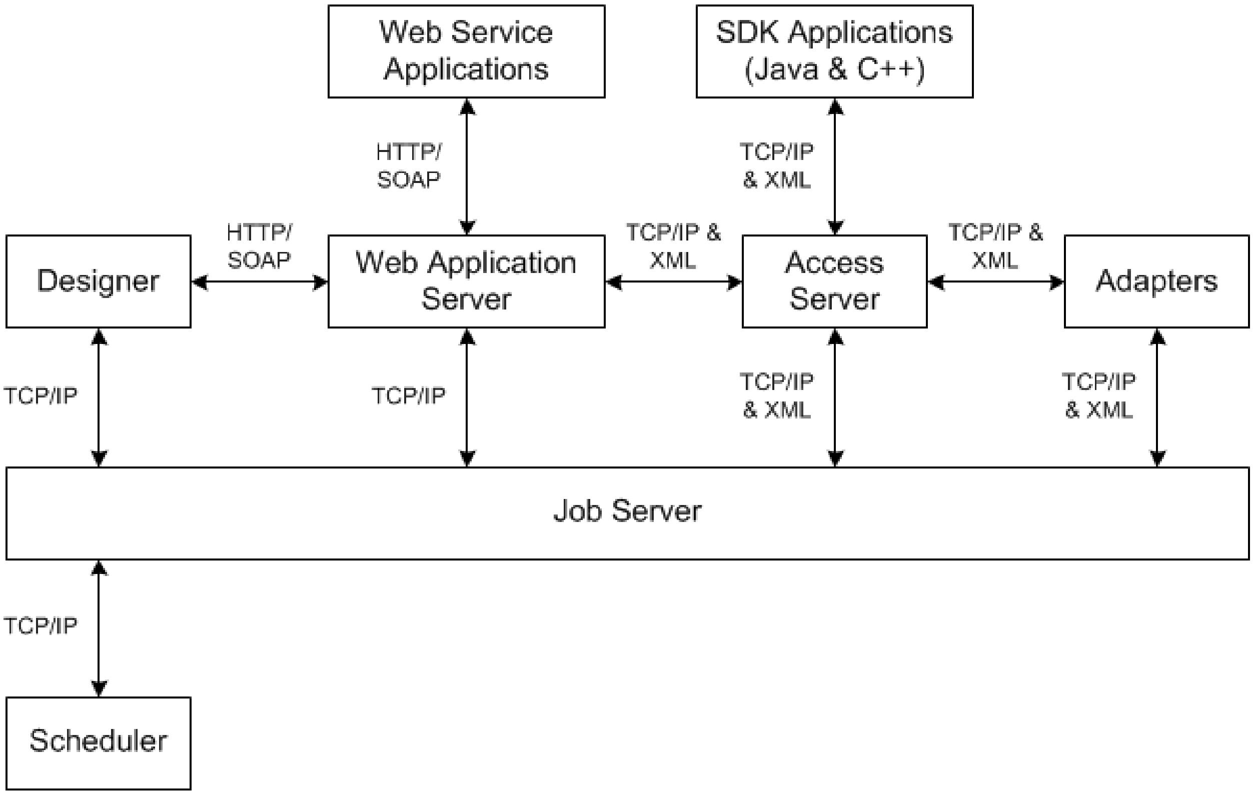
Secure Sockets Layer (SSL) is a cryptographic protocol that provides security and data integrity for communications over networks. Transport Layer Security (TLS) is the standard specification published by the IETF that is based on earlier SSL specifications.

The TLS protocol allows client/server applications to communicate across a network in a way designed to prevent eavesdropping, tampering, and message forgery. TLS provides endpoint authentication and communications confidentially over the network using cryptography.

Protected communication paths

Within the SAP Data Services platform, SSL is supported for all communication paths between components that communicate over a network.

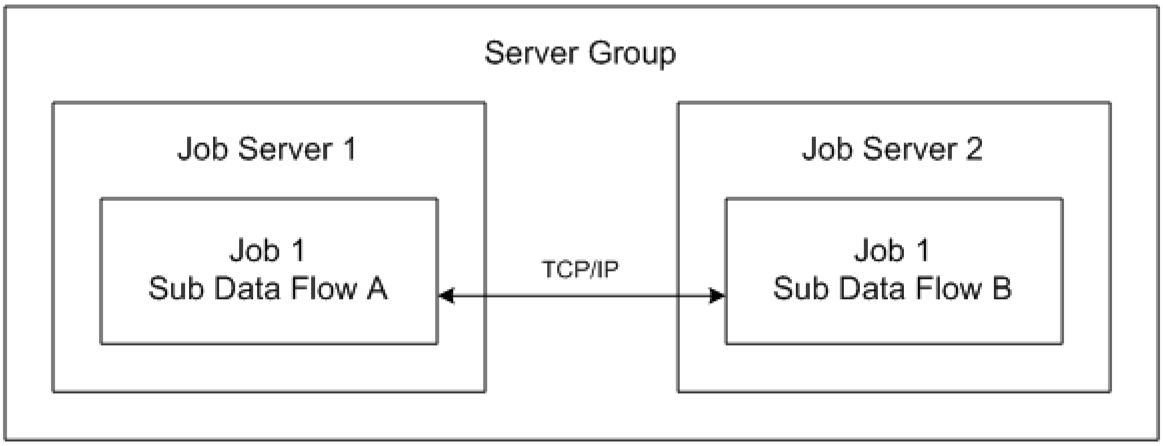
This diagram illustrates the communication channels within the Data Services architecture that support SSL.



Note

All TCP/IP communication paths support SSL/TLS. Depending on your web application server communication, clients using HTTP may switch to the HTTPS protocol.

Additionally, when you use a server group and set the distribution level to “Sub data flow”, the TCP/IP communication path between sub data flows on different job servers within the server group is also protected by SSL.



Default certificates

By default, a set of SSL certificates is created during installation for secure communication between Data Services components. You can choose to use your own certificates by configuring them after installation has finished. The default certificates use 1024-bit RSA keys and are valid for 30 years.

Related Information

To use custom certificates [page 39]
To copy certificates in a distributed installation [page 36]

1.3.4.1 To copy certificates in a distributed installation

When different Data Services components are installed on different machines and each installation has its own root and intermediate certificate authority (CA) configuration, you must manually copy the trusted certificates from one machine to all other machines.

Note

Trusted certificate files refers to root and intermediate CA certificate files. These files have a `.crt` extension, and can be located in the **`<LINK_DIR>`**`/ssl/trusted_certs` folder.

Remember

When you copy trusted certificates from one host machine to another, you must always copy the files to and from the **`<LINK_DIR>`**`/ssl/trusted_certs` folder on each respective machine.

1. If the Job Server and Access Server are installed on different machines, configure the hosts with the new certificates.
   a) Copy the trusted certificates from the Access Server to the Job Server host.
   b) On the Job Server host machine, run the following script to refresh the **<LINK_DIR>**`/ssl/trusted_certs/jssecacerts` keystore file:
      - On Windows: **<LINK_DIR>**`/bin/SetupJavaKeystore.bat`
      - On UNIX: **<LINK_DIR>**`/bin/SetupJavaKeystore.sh`

      This allows adapters that communicate with the Access Server to use the new certificates.
   c) Copy the trusted certificates from the Job Server to the Access Server host.
   d) Restart the job service on both the Job Server and Access Server host machines.
2. If the Access Server and Management Console are installed on different machines, configure the Management Console host with the new certificates.
   a) Copy the trusted certificates from the Access Server to the Management Console host.
   b) On the Management Console host machine, run the following script to refresh the **<LINK_DIR>**`/ssl/trusted_certs/jssecacerts` keystore file:
      - On Windows: **<LINK_DIR>**`/bin/SetupJavaKeystore.bat`
      - On UNIX: **<LINK_DIR>**`/bin/SetupJavaKeystore.sh`
   c) Restart the web application server that is hosting the Management Console.
3. If the Access Server and message client are installed on different machines, configure the message client host with the new certificates.
   a) Copy the trusted certificates from the Access Server to the message client host.
   b) If the message client uses Java, import the trusted certificates into the keystore used by the message client application.

      For information about creating keystores, see the JDK help for the `keytool` command.
4. If the Job Server and job launcher or external scheduler are installed on different machines, configure the job launcher or external scheduler host with the new certificates.

   Copy the trusted certificates from the Job Server to the job launcher or external scheduler host.

   > Note
   >
   > If the scheduled job connects to multiple Job Servers through a server group, copy the trusted certificates from all Job Servers within the group.

1.3.4.2 To enable or disable SSL on communication paths

Because Data Services uses multiple communication paths, there are different ways to enable or disable SSL for any given path. You may choose to enable or disable SSL for certain paths, depending on your security and performance requirements.

For adapter management

You can configure SSL for adapter management by enabling SSL support on your Job Servers. Enabling SSL for adapter management protects the communication path used between your Job Servers and adapters, and message broker clients.

To configure SSL on a Job Server, use the Server Manager.

For real-time messaging

You can configure SSL for real-time messaging by enabling SSL support on your Access Servers. Enabling SSL for real-time messaging protects the communication path used between your Access Servers and their real-time clients.

> ℹ Note
>
> By default, SSL is enabled for real-time messaging. If you disable it on an Access Server, be sure to disable it on any message clients or adapters that communicate with that Access Server.

> ℹ Note
>
> SSL can be enabled or disabled on a per-server basis. You are not required to configure it the same way for all Access Servers.

To configure SSL on an Access Server, use the Server Manager.

For peer-to-peer communication

You can configure SSL for peer-to-peer communication by configuring SSL for run-time resources. Enabling SSL for run-time resources protects the communication path used between different sub data flows running on different Job Servers.

> ℹ Note
>
> If you run multiple Job Servers within a server group, configure SSL the same way on each Job Server.

To configure SSL for run-time resources, use the Server Manager.

For other communication paths

SSL is mandatory for some communication paths within the Data Services architecture.

For example, SSL is always enabled on the communication paths between a Job Server and the following clients:

- The Administrator application in the Management Console
- Designers
- The job launcher
- Access Servers
- The job execution engine
- Other Job Servers within a server group
- The job service used for monitoring

You must ensure that each client has the correct certificates in these situations, but there is no additional configuration to perform.

> **Note**
>
> You need to copy the certificates from the Job Server to the Access Server, Management Console, and external job launcher hosts. In all other cases, the certificates are exchanged automatically.

Related Information

Using the Server Manager on Windows [page 84]
Using the Server Manager on UNIX systems [page 90]

1.3.4.3 To use custom certificates

While SAP Data Services includes a set of SSL certificates by default, you can also choose to use your own certificates. Depending on the nature of your Data Services deployment, not all steps below may be required.

1. Generate certificates as needed, and have them signed by a trusted certificate authority (CA).

   For more information, see the "To generate keys and sign certificates" section.
2. Copy all required certificates to the Data Services client machines.

   > **Note**
   >
   > Each Data Services client requires the certificates for all CAs in the certificate chain when validating the certificate of the Data Services server. The certificates within a certificate chain are called trusted certificates and must be present on the local machine. In most cases, the certificate chain is the same for all clients, and therefore the same certificates must be present on all client machines.
3. If you are using Java-based clients, use the JDK `keytool` utility to generate a keystore containing the trusted certificates.
4. Configure server certificate and keyfile paths with the Server Manager.
5. Configure certificates for the Designer.
   a) Choose *Tools* > *Options* within the Designer.
   b) Navigate to the *SSL* category under *Designer*.
   c) Specify the locations of the certificate file, the private key file, and the trusted certificates folder.

If you change any SSL options other than *Use SSL protocol for profiler*, you must restart both the Designer and any Data Services servers.

Related Information

To configure SSL paths [page 88]
To generate keys and sign certificates [page 40]

1.3.4.4 To generate keys and sign certificates

To use your own custom certificates for SSL security in Data Services, you must generate the certificates and have them signed by a trusted certificate authority (CA), such as VeriSign.

1. Generate the RSA key and certificate using the `openssl` tool.

```
openssl req -config <LINK_DIR>\ssl\conf\openssl.conf -new -newkey rsa:1024 -
nodes -keyout <mykey.pem> -out <myreq.pem>
```

   where **`<mykey.pem>`** is the name of the key file to generate, and **`<myreq.pem>`** is the name of the certificate file to generate.

   > i Note
   >
   > By default, `openssl` is installed to **`<LINK_DIR>`**`\bin`. For more information about available options and commands, see the openssl documentation.

2. Send the RSA private key and certificate files to your external CA.
3. After you receive the signed certificate from your CA, use the Server Manager to specify the path to the new certificate and private key file.

   > i Note
   >
   > Trusted certificates from an external CA must be in PEM format. The signed certificates should be copied to the **`<LINK_DIR>`**`\ssl\trusted_certs` directory.

Related Information

To configure SSL paths [page 88]
To configure SSL paths [page 96]

1.3.5 Configuring SSL for the CMS connection

You can use the Secure Sockets Layer (SSL) protocol for all network communications between SAP Data Services clients and the Central Management Server (CMS).

To set up SSL for all CMS communication, you need to perform the following steps:

- Deploy the SAP BusinessObjects BI platform or Information platform services with SSL enabled.
- Create key and certificate files for each machine in your deployment.
- Configure the location of these files in the Central Configuration Manager (CCM) and your web application server.

For Data Services, you also need to use the `sslconfig` utility configure all components that log into the CMS for SSL, including:

- Designer
- Job Servers
- External schedulers and the job launcher
- Management Console (if deployed to a different web application server than the SAP BusinessObjects BI platform or Information platform services web tier)

> Note
>
> For J2EE web application servers, configure SSL by modifying the startup script.

By default, the utility is installed in the following location:

- For Windows:
  `<INSTALL_DIR>``\SAP BusinessObjects Enterprise XI 4.0\win32_x86\sslconfig.exe`
- For UNIX:
  `<INSTALL_DIR>``/sap_bobj/enterprise_xi40/`**`<platform>`**`/boe_sslconfig`
  Where **`<platform>`** matches your UNIX platform.

For more information about using `sslconfig` and configuring the CMS and its clients for SSL, see “Configuring the SSL protocol” in the *SAP BusinessObjects BI Platform Administrator Guide* or the *SAP BusinessObjects Information Platform Services Administrator Guide*.

1.3.6 Configuring SSL for Metadata Browsing and View Data Services

You can use the Secure Sockets Layer (SSL) protocol for all network communications between the SAP Data Services backend engine and the following EIM Adaptive Processing Server services:

- Metadata Browsing Service
- View Data Service

Data Services provides these services, but they are used by other SAP software products, such as the Data Insight module of SAP Information Steward.

Data Services provides the following files by default:

- Keystore file
  The server side (Metadata Browsing Service or View Data Service) requires a Java Server keystore file which contains a single key and all the certificates that are part of the certificate chain involved in signing the key. Passwords for the keystore file and the key are also required.
  Data Services places the default keystore file and password files under the **<LINK_DIR>**`\ssl\mds` folder.
- Trusted Certificates
  These certificates are used for signing the key that is stored in the Java keystore used on the server side. The client side (the Data Services backend engine) uses these trusted certificates to communicate with the server.
  Data Services places the trusted certificates under **<LINK_DIR>**`\ssl\mds\trusted_certs` folder.

1.3.6.1 To configure SSL for Metadata Browsing and View Data Services

To enable and configure SSL communications for Metadata Browsing and View Data Services:

1. Log into the Central Management Console (CMC) as a user with administrative rights to the Data Services application.
2. Go to the “Applications” management area of the CMC.
   The “Applications” dialog box appears.
3. Right-click the Data Services application and select *Settings*.
   The “Settings” dialog box appears.
4. In the drop-down list for *Enable SSL communication for Metadata Browsing and View Data Services*, select “Yes”.
5. If you want to use the default keystore and certificates (that Data Services provides or that you generate using the Data Services tool), take the following steps:
   a) In the drop-down list for *Use Default SSL Settings*, select “Yes”.
   b) Click *Save*.
6. If you do not want to use the default keystore and certificates and generated your own outside of Data Services, take the following steps:
   a) Ensure that your keystore is a Java keystore file that contains a single key with all the certificates that are part of the certificate chain involved in signing the key. You must provide a password for the key and a password for the keystore file.
   b) Ensure that your keystore file exists in the **<LINK_DIR>**`\ssl\mds` folder and the corresponding certificate files are placed under **<LINK_DIR>**`\ssl\mds\trusted_certs` folder.
   c) If you have multiple Metadata Browsing Service or View Data Service instances associated with the same CMS server, you must copy the keystore and certificate files to all the machines where these instances are installed.
   d) In the drop-down list for *Use Default SSL Settings*, select “No”.
   e) In the *KeyStore File* box, enter the name of the KeyStore file that you want to use.
   f) Enter the KeyStore password.
   g) Enter the Key password.
   h) Click *Save*.
7. Restart the EIM.AdaptiveProcessingServer as follows:

a) Go to the “Servers” management area of the CMC
b) Expand the “Service Categories” node and select “Enterprise Information Management Services”.
c) Select “EIMAdaptiveProcessingServer” in the right pane.
d) Click *Action* > *Restart Server*.

1.3.6.2 To create a keystore file and certificates using the Data Services tool

While SAP Data Services provides a keystore file and set of SSL certificates for the Metadata Browsing Service and View Data Service, you can also create a new key and certificates using the Data Services tool.

To create a new keystore file and SSL certificates to be used as the default SSL settings for the Metadata Browsing Service and View Data Service:

1. Run the `MDSSetupJavaKeyStore` tool.
   a) In a command-line window, change directory to **`<LINK_DIR>`**`\bin`.

   ```
   cd <LINK_DIR>\bin
   ```

   b) Run "MDSSetupJavaKeyStore.bat "

   ```
   MDSSetupJavaKeyStore
   ```

   The `MDSSetupJavaKeyStore` tool creates the following files:
   - Keystore file `DSJavaKeyStore.keystore` in **`<LINK_DIR>`**`\ssl\mds` containing a single key and all the certificates that are part of the certificate chain involved in signing the key
   - File sslks.key in **`<LINK_DIR>`**`\ssl\mds` containing the key password
   - File sslstore.key in **`<LINK_DIR>`**`\ssl\mds` containing the keystore password
2. If you already configured and enabled SSL for Metadata Browsing Service and View Data Service, restart the EIM.AdaptiveProcessingServer.
   The restart picks up the new keystore and certificate files as the default ones if you selected “Yes” for the option *Use Default SSL Settings*.
3. If you have not yet configured SSL for these services, see *To configure SSL for Metadata Browsing and View Data Services* [page 42].

1.3.7 Password encryption

Within the SAP Data Services system, all passwords are encrypted using the AES algorithm with 128-bit keys.

1.3.7.1 Encryption key storage locations

Because passwords can be stored in multiple places within the Data Services system, an individual key is associated with each storage location.

Password location	Associated key location
Local repository	`REPOKEY` column in the `AL_VERSION` table
Central repository	`REPOKEY` column in the `AL_VERSION` table
Management Console	`admin.key` located in the same directory as `admin.xml`
Access Server	`AS.key` located in the same directory as `AS.xml`
Adapter SDK	**`<DS_COMMON_DIR>`**`/adapters/adapter.key`
`DSConfig.txt`	**`<DS_COMMON_DIR>`**`/conf/DSConfig.key`
Data Services-managed schedules	If the schedule uses a password file, the password is stored in the password file. If the schedule does not use a password file, the password is located in the job command line.
External scheduler command lines	If the schedule uses a password file, the password is stored in the password file. If the schedule does not use a password file, the password is located in the job command line.

⚠ Caution

For encryption keys that are stored in files, Data Services protects the security of the key file with strong OS permissions. For example, the software sets owner-only read & write access to the file (`chmod 600` on UNIX systems). You should also protect the key file by restricting user access to the server host machine when possible.

1.3.7.2 Encrypting passwords manually

In most instances, password encryption is handled automatically by the various Data Services applications and utilities. However, for some tasks, you may need to manually encrypt a password. For example, you may want to generate a data flow on the fly for use with the object creation XML toolkit. If your data flow contains a datastore that requires a password, it needs to be encrypted before you can import and run it successfully.

When you need to manually encrypt a password, you can use the `al_encrypt` command-line utility installed with the software.

Related Information

Password encryption [page 161]

1.3.8 Password protection for a Data Services repository

When you log in to the Data Services Designer or open a Data Quality report in the Management Console, by default, you are prompted to enter the user name and password for the Data Services repository you are accessing. You can turn off this default behavior by granting permissions in the BI Platform or Information platform services Central Management Console.

In the CMC, when you grant the *Allow user to retrieve repository password* right, the Data Services' repository password will be sent from the CMS to the client (Designer or Management Console: DQ reports). Although this password is encrypted, and the communication channel can be secured through SSL, sending passwords could pose a risk, and malicious users could obtain access to the password. You can selectively grant this right for repositories. For example, you may want to grant the right for development repositories but not for production repositories.

Related Information

Repository management [page 52]
Designer Guide: Logging into the Designer [page 171]
Management Console Guide: Data Quality reports [page 1994]

1.3.8.1 To set Data Services repository permissions in the CMC

Use the following steps to add permissions for users to automatically retrieve the Data Services repository password when logging on to the Designer and for accessing Data Quality reports.

1. On the Home page of the CMC, click *Data Services*.
2. On the left side of the CMC, select *Repositories*.
3. Choose ▶ *Manage* ▶ *Security* ▶ *User Security* ▶.
4. Select the *Data Services Designer Users* group (for Designer access) or the *Data Services Monitor Users* group (for Data Quality reports access), and then click the *Assign Security* button.
5. In the *Assign Security* window, click the *Advanced* tab.
6. Click *Add/Remove Rights*.
7. On the left of the *Add/Remove Rights* window, click *Application*, and select *Data Services Repository*.
8. Under *Specific Rights for Data Services Repository*, select *Granted* for either or both of the following options:
   - *Allow user to retrieve repository password*
   - *Allow user to retrieve repository password that user owns*
9. Click *OK*.

By following the preceding steps, you have given all users in the Data Services Designer Users group (or the Data Services Monitor Users group) permissions for all Data Services repositories.

Note

If you have a Data Services development or test repository, for example, to which you would like to restrict access, you can do this on a case-by-case basis. To do this, access the Add/Remove Rights window using the following steps:

1. On the Home page of the CMC, click *Data Services*.
2. On the left side of the CMC, select *Repositories*, and then select the repository that you want edit rights for.
3. Continue with step 3 above to complete your task.

1.4 User and rights management

SAP Data Services uses the Central Management Server (CMS) for user accounts and rights management.

This section covers information and procedures specific to administrating Data Services. For detailed information about user accounts and rights management, see the *SAP BusinessObjects BI Platform Administrator Guide* or the *SAP BusinessObjects Information Platform Services Administrator Guide.*

1.4.1 User management

In the *Users and Groups* management area of the Central Management Console (CMC), you can specify the details required for a user to access Data Services. In addition to creating a user account, you must also grant the user access to any repositories they need to work with.

By default, the Data Services installation program does not create any user accounts. You can use the CMC to create new user accounts, or assign existing user accounts to the Data Services group accounts.

For detailed information about creating user accounts, see “Managing Enterprise and general accounts” in the *SAP BusinessObjects BI Platform Administrator Guide* or the *SAP BusinessObjects Information Platform Services Administrator Guide*.

Related Information

Managing security settings for repositories in the CMC [page 53]

1.4.2 Group management

Groups are collections of users who share the same account privileges. Therefore, you may create groups that are based on department, role, or location. Groups enable you to change the rights for users in one place (a group) instead of modifying the rights for each user account individually. Also, you can assign object rights to a group or groups.

In the *Users and Groups* area of the Central Management Console (CMC), you can create groups that give a number of people access to the report or folder. This enables you to make changes in one place instead of modifying each user account individually.

In addition to the basic SAP BusinessObjects BI platform or Information platform services group accounts, Data Services includes several default group accounts:

Account name	Description
Data Services Administrator	Members of this group have access to all Data Services administrative functionality.
Data Services Multi-user Administrator	Members of this group are limited to managing secure central repositories. This role is a subset of the Data Services Administrator role. Multi-user administrators can: ● Add and remove secure central repositories. ● Manage users and groups. ● View secure central repository reports.
Data Services Monitor User	Members of this group have access limited to options available from the Status tabs. For example, a monitor user can abort batch jobs but cannot execute or schedule them. A monitor user can restart, abort, or shut down an Access Server, service, adapter instance, or client interface but cannot add or remove them.
Data Services Profiler Administrator	Members of this group are limited to managing profiler repositories. This role is a subset of the Administrator role. Profiler administrators can: ● Manage profiler tasks in any profiler repository. ● Manage the Profiler configuration.
Data Services Profiler User	Members of this group are limited to managing profiler tasks in the profiler repository that is configured for the user.
Data Services Operator	Members of this group have all Administrator privileges except they cannot modify repository, access, or CMS servers nor update datastore settings.
Data Services Designer	Members of this group have access to the Designer.

1.4.2.1 Detailed application rights

Application rights are assigned to each user group. The default application rights granted to each group are described in the following table.

> **i Note**
>
> The Data Services Administrator group account is granted access to all of the available Data Services application rights.

Right Name	Designer Users w/ View access	Designer Users w/ Full access	Monitor Users	Multi-user Administrator	Operator Users	Profiler Admin. Users	Profiler Users
Access to Administrator	X	X	X	X	X	X	X
Access to Auto Documentation	X	X	X	X	X	X	X
Access to Data Quality Reports	X	X	X	X	X	X	X

Related Information

Viewing application rights assigned to a group [page 51]
Managing application rights for a group [page 51]

1.4.2.2 Viewing application rights assigned to a group

Your account must be a member of the Administrators user group or a member of the Data Services Administrator Users group to be able access the CMC function for managing user security.

To view a group's currently assigned application rights:

1. On the Home page of the CMC, select *Manage > Applications*.
2. In the *Application Name* list, double-click *Data Services Application*.
3. Select *User Security* to display the user groups.
4. Highlight the user group you want to view and click *View Security*.

The *Permissions Explorer* opens and displays all of the current application rights that are assigned to your selected user group.

1.4.2.3 Managing application rights for a group

Your account must be a member of the Administrators user group or a member of the Data Services Administrator Users group to be able access the CMC function for managing user security.

To manage a group's assigned application rights:

1. On the Home page of the CMC, select *Manage > Applications*.
2. In the *Application Name* list, double-click *Data Services Application*.
3. Select *User Security* to display the configured Data Services application user groups.
4. Highlight the user group or add a user to manage their application rights.
5. Click *Assign Security*.
6. In the *Assign Security* window, select the *Advanced* tab.
7. On the *Advanced* tab, select *Add/Remove rights*.
8. In the *Add/Remove Rights* window, select to add or remove each of the specific right you want to change for this group.
9. Click *Apply* to save your changes.

Members of the modified group will be granted or denied the application rights you modified for the group the next time they log in.

1.5 Repository management

Before you can access Data Services repositories in other components such as the Designer and Management Console, you must configure them appropriately.

In general, you follow this work flow to configure a Data Services repository.

1. Create the repository in a database using the Repository Manager.
2. Register the repository in the Central Management Console (CMC).
3. Manage security settings for the repository in the CMC.

1.5.1 To register a repository in the CMC

1. Log into the Central Management Console (CMC) as a user with administrative rights to the Data Services application.
2. Go to the Data Services application:
   - Click *Data Services* from the CMC home screen OR
   - Click the Data Services icon
3. Configure a repository:
   - Choose ▶ *Manage* ▶ *Configure Repository* ◀ OR
   - Right-click *Repositories* in the navigation tree and click *Configure Repository*

   The *Add Data Services Repository* screen is displayed.
4. Specify a name and optionally a description for the repository.

   The name and description will be displayed to users when they log into applications such as the Designer and Management Console.
5. Enter the connection information for the repository database.

   The details required depend on the type of database containing the repository and the connection type you choose.

   > ➜ Tip
   >
   > For Microsoft SQL Server and SAP Sybase databases, it is recommended that you do not use `localhost` as the server name when registering the Data Services repository in the CMC. If you use `localhost`, other machines will be unable to connect to the repository.

   a) For an Oracle database, the default connection type is TNS-less. If you want to use a TNS connection, select *Yes* in the drop-down menu for *Use TNS Name* and enter the *TNS Name* if no value appears.

   If the Data Services repository was created using a TNS connection, the software fills in *TNS Name*. Otherwise, you must enter the *TNS Name*.

   > i Note
   >
   > If you created a repository on Oracle RAC, prior to registering in the CMC, you need to configure TNS Name on the local CMS machine. Then the TNS name will be filled in automatically based on the connection string provided when you register in the CMC .

b) For a DB2, MySQL or SAP HANA database, the default connection type is DSN-less. If you want to use a DSN connection, select *Yes* in the drop-down menu for *Use Data Source Name (DSN)* and enter the *Data Source Name (DSN)* if no value appears.

   If the Data Services repository was created using a DSN connection, the software fills in *Data Source Name (DSN)*. Otherwise, you must enter the *Data Source Name (DSN)*.

> i Note
>
> If you subsequently edit the properties of the Data Services repository on the CMC to change the connection type to a TNS or DSN connection, you must fill in *TNS Name* or *Data Source Name (DSN)*.

> i Note
>
> If you are using DNS or TNS connections in a distributed installation, the database connection to the repository must be configured the same on each machine as in the CMC. For example, if an Oracle repository is configured with the TNS name `Ora_DS` in the CMC, Designer and Job Server machines must also have the `Ora_DS` TNS name configured.

6. If you are registering a profiler repository, choose *Yes* for *Is Profiler Repository*.
   a) Enter the host name of the web application server hosting the profiler.
   b) Enter the port number used by the web application server hosting the profiler.
7. Click *Test Connection*.
   The application attempts to verify the connection details without adding the repository to the CMC. If the connection is not successful, review the error message and correct the repository connection information.
8. Click *Save* to add the repository to the CMC.

The Data Services application screen is displayed, and the new repository appears in the list of registered repositories.

Related Information

DSN-less and TNS-less connections [page 30]
Using the Repository Manager [page 79]

1.5.2 Managing security settings for repositories in the CMC

You can manage security settings for repositories registered in the CMC with the security options on the Manage menu. These options let you assign users and groups to the access control list for the repository, view the rights that a user or group has, and modify the rights that the user or group has to the repository.

1. Log into the Central Management Console (CMC) as a user with administrative rights to the Data Services application.
2. Navigate to the Data Services application:
   ○ Click *Data Services* on the CMC home screen OR

- Click the Data Services icon

3. Click *Repositories* in the navigation tree to display the list of registered repositories.

1.5.2.1 To view rights for a user or group on a repository

In general, you follow this work flow to view rights for a user or group on a repository.

1. Select the repository for which you want to view security settings.
2. Click *Manage* > *Security* > *User Security*.
   The *User Security* dialog box appears and displays the access control list for the repository.
3. Select a user or group from the access control list, and click *View Security*.
   The Permissions Explorer launches and displays a list of effective rights for the user or group on the repository.

1.5.2.2 To assign users and groups to an access control list for a repository

An access control list specifies the users that are granted or denied rights to a repository. In general, you follow this work flow to assign a user or group to an access control list, and to specify the rights that the user or group has to the repository.

1. Select the repository to which you want to add a user or group.
2. Click *Manage* > *Security* > *User Security*.
   The *User Security* dialog box appears and displays the access control list for the repository.
3. Click *Add Principals*.
   The *Add Principals* dialog box appears.
4. Move the users and groups you want to add from the *Available users/groups* list to the *Selected users/groups* list.
5. Click *Add and Assign Security*.
6. Select the access levels you want to grant the user or group:
   - To grant read-only access to the repository, select *View*.
   - To grant full read and write access to the repository, select *Full Control*.
   - To deny all access to the repository, select *No Access*.

1.6 Server management

1.6.1 Setting UNIX environment variables

When you install SAP Data Services on UNIX platforms, the Job Server requires that certain environment variables be set up. To set up these variables, users who run or administer Job Servers must run a script (al_env.sh).

Run this script with the syntax required by your environment. For example:

```
$ cd $LINK_DIR/bin/
$ . ./al_env.sh
```

You can also add this command to your login script so that it is always configured. For example, add the following line to the .profile:

```
. $LINK_DIR/bin/al_env.sh
```

If the script fails to run, no error messages appear. To make sure that the variables' values are properly set, check one or more of the following:

Variable	Details
$LINK_DIR	Data Services installation directory (set by the installation program).
$DS_COMMON_DIR	References $LINK_DIR for compatibility (set by the installation program).
$SHLIB_PATH	If you want to use a 64-bit Oracle client, $LINK_DIR/bin must be listed before any 64-bit Oracle shared library path.
$LD_LIBRARY_PATH	For Solaris or Linux. Must include $LINK_DIR/bin and the location of the database libraries. If you want to use a 64-bit Oracle client, $LINK_DIR/bin must be listed before any 64-bit Oracle shared library path.
$LIBPATH	For AIX. Must include $LINK_DIR/bin and the location of the database libraries. If you want to use a 64-bit Oracle client, $LINK_DIR/bin must be listed before any 64-bit Oracle shared library path.
$ORACLE_SID	Required for an Oracle source, target, or repository.
$ORACLE_HOME	Required for an Oracle source, target, or repository. If you want to use a 64-bit Oracle client, this must point to the 64-bit Oracle installation.
$DB2INSTANCE	Required for a DB2 source, target, or repository.
$DB2DIR	Required for a DB2 source, target, or repository.
$SYBASE	Required for a SAP Sybase ASE source, target, or repository.
$SYBASE_OCS	Required for a SAP Sybase ASE source, target, or repository.

Variable	Details
`$ODBCINI`	Required for ODBC sources or targets, including MySQL and SAP HANA.
`$PATH`	Must include `$LINK_DIR/bin` and **`<databasehome>`**`/bin`.

➜ Tip

Use the `echo` command to verify environment variable settings.

If the variable settings are not properly configured and you start any Data Services utility, error messages indicate that database server files are missing.

If you see such an error, verify that `al_env.sh` contains commands to set the appropriate database home locations. Run `al_env.sh` for the account used by the Job Server, or start the Job Server using an account that has all necessary environment variables defined in its `.profile`.

➜ Tip

If you want to use the RFC Server Interface in the Management Console on a 64-bit UNIX platform, see the *Management Console Guide* for additional environment configuration information.

1.6.1.1 Configuring additional database connectivity

When you install SAP Data Services on UNIX platforms, the installation setup program configures the following by default:

- DSN or TNS connections for the repository database
  To use a DSN-less or TNS-less connection, defer repository creation to after installation and when you subsequently invoke the Repository Manager, specify the `s` option to use a server name connection.
- Database connectivity for the repository only
  To access other database systems as sources and targets in your jobs, you need to add the appropriate configuration information to the `al_env.sh` file. Use the Connection Manager that is installed with Data Services to set the environment variables required for the following database types:
  - Attunity
  - DB2 on iSeries or zSeries
  - Informix
  - MySQL
  - Netezza
  - Oracle
  - SAP HANA
  - SAP Sybase ASE
  - SAP Sybase IQ
  - SAP Sybase SQL Anywhere
  - SQL Server
  - Teradata

Note

For the most current list of databases types supported by the Connection Manager, see the Supported Platforms (Product Availability Matrix) *https://service.sap.com/PAM*.

Related Information

Using the Connection Manager for UNIX systems [page 60]

Configuring ODBC drivers on UNIX for data sources using DSN-less connections [page 69]

1.6.2 Starting services automatically

On Windows

The SAP Data Services service and packaged Tomcat service start automatically when the computer restarts. The Data Services service then starts Job Servers and Access Servers on the restarted computer.

You can change service startup to *Manual* in the Windows services window.

Note

To manually log in Web applications, refer to “Configuring tracing for web applications” section in the *Information platform services Administration Guide.*

On UNIX

To start Job and Access Servers automatically when the server restarts, you must install the `actaservices` script with root privileges.

Run the `$LINK_DIR/bin/autostrt.sh` script:

```
# cd $LINK_DIR/bin/
# autostrt.sh $LINK_DIR
```

1.6.3 Setting the log retention period

The log retention period provides an automatic way to delete log files. You can view currently stored logs with the Administrator application in the Data Services Management Console .

Follow these steps to set the job server log retention period:

1. Open the Central Management Console (CMC) in a web browser and log on as a user with administrative rights.
2. Choose *Applications* from the navigation drop-down menu under the *Central Management Console* banner.
3. Right-click *Data Services Application* from the *Application Name* column and select *Settings*.
4. In the *Job Server Log Retention Period* box, type the number of days that you want to retain the following:
   - Historical batch job error, trace, and monitor logs.
   - Current service provider trace and error logs.
   - Current and historical Access Server logs.

   The software deletes all log files beyond this period. For example:

Enter	Results
1	The software displays the logs for today only. After 12:00 AM these logs clear and the software starts saving logs for the next day.
0	The software does not retain any log files.
-1	The software does not delete any log files.
1095	The software deletes log files older than approximately three years.

5. Click *Save*.

Changes you make to the log retention period occur as a background clean-up process so they do not interrupt more important message processing. Therefore, logs might not be deleted immediately when you select *Save*. Changes can take up to an hour to take effect.

For more information about viewing log files in the Administrator, see the *Management Console Guide*.

Management Console Guide: Data Quality Reports [page 1994]

1.6.4 Setting the history retention period

The log retention period provides an automatic way to delete log files. You can view currently stored logs with the Administrator application in the Data Services Management Console.

Follow these steps to set the *History Retention Period*:

1. Open the Central Management Console (CMC) in a web browser and log on as a user with administrative rights.

2. Choose *Applications* from the navigation drop-down menu under the *Central Management Console* banner.
3. Right-click *Data Services Application* from the *Application Name* column and select *Settings*.
4. In the *History Retention Period* box, type the number of days that you want to retain job execution history, which includes the following information:
   - Certification and non-certification log files.
   - Report information.

   The software deletes all log files beyond this period. For example:

Enter	Results
1	The software displays the jobs executed today only. After 12:00 AM these logs clear and the software starts saving logs for the next day.
0	The software does not retain any job history files.
-1	The software does not delete any job history files.
1095	The software deletes job history older than approximately three years.

5. Click *Save*.

Related Information

Setting the log retention period [page 57]
Designer Guide: DSF2 Augment Statistics log files [page 650]

Management Console Guide: Data Quality Reports [page 1994]

1.6.4.1 USPS-required log files and reports

If you have postal certification requirements such as CASS certification, you are required to submit log files to the postal authorities on a periodic basis. For example, if you have included the USA Regulatory Address Cleanse transform in your data flow, and you use the DSF2 and/or NCOALink functionality and have CASS enabled, you must submit certification log files to the USPS each month. With that in mind, set the log retention period so that you will not lose data prior to the creation and submission of the logs (thus submitting incomplete log files to the USPS).

The default setting of 30 days does not provide enough time for you to export and send the log files to the USPS by the monthly due date. And 30 days does not account for months that include 31 days. Therefore we recommend setting the history retention to longer (50 days for example) to ensure that you submit complete monthly logs to the USPS.

Set the number of retention days in the history retention period setting in the CMC.

In addition to sending monthly data to the USPS, you are required to have report data available for the USPS to examine for several years after the job is processed. (Make sure you are aware of current USPS rules for data retention by viewing your USPS licensing agreement.) To ensure that you retain all required reports and logs before the data is deleted from the repository, we recommend that you export the required reports and logs from the repository to a local folder on a monthly basis. This also prevents the repository contents from becoming so large that the export process “times out” due to the volume of statistics retained.

Set history retention period [page 58]
Designer Guide: DSF2 Augment Statistics log files [page 650]
Designer Guide: NCOALink logs files [page 664]

1.6.5 Using the Connection Manager for UNIX systems

Use the Connection Manager on UNIX to create, edit, or delete ODBC data sources and ODBC drivers after installation.

1. If you want to use the graphical user interface, ensure you have installed the GTK+2 library.
2. For DSN connections, set `$ODBCINI` to a file that will define the DSN. Ensure that the file is readable and writeable.
3. Invoke the Connection Manager by entering the following commands:

   ```
   $ cd $LINK_DIR/bin/
   $ ./DSConnectionManager
   ```

   The *SAP Data Services Connection Manager* window opens.

   > Note
   >
   > If the GTK+2 library is not installed, the command-line user interface starts.

4. For DSN connections, go to the *Data Sources* tab and configure data sources as needed. See the following sections for specific data sources.
5. For server name connections, go to the *Drivers* tab to configure ODBC drivers.
6. Click *Restart Services* to restart the EIM Adaptive Process Service and Data Services Job Service.

Related Information

Using the ODBC Driver Selector on Windows for server name connections [page 79]

1.6.5.1 Configuring ODBC data sources on UNIX using DSN connections

On UNIX and Linux platforms, SAP Data Services requires an ODBC driver manager library and ODBC driver library to configure ODBC data sources using data source name (DSN) connections. Some ODBC driver vendors include ODBC driver manager and ODBC driver capabilities in one single library, while others separate them into two individual libraries.

To accommodate all ODBC vendors, Data Services requires configurations in two different files for DSN connections:

1. The UNIX ODBC driver manager configuration file (**`<LINK_DIR>`**`/bin/ds_odbc.ini`).
   This file contains DSN instances that reference ODBC driver manager libraries.

   > ➡ Tip
   >
   > For natively supported ODBC databases, you do not need to manually configure `ds_odbc.ini`. Instead, use the Data Services Connection Manager to properly configure the ODBC driver manager library.

2. The ODBC vendor's configuration files (referenced by the `$ODBCINI` environment variable).
   This file contains DSN instances that reference the ODBC driver libraries, as well as the database server connection information.

   > i Note
   >
   > One ODBC configuration file can contain multiple different DSN instances. For example, a file referenced by `$ODBCINI` may contain DSNs for MySQL, Netezza, and Teradata.

1.6.5.1.1 Configuring native ODBC data sources

Data Services supports several ODBC data sources natively with DSN connections, including:

- Attunity
- DB2 on iSeries or zSeries
- Informix
- MySQL
- Netezza
- SAP HANA
- SAP Sybase ASE
- SAP Sybase IQ
- SQL Server
- Teradata

> i Note
>
> For the most current list of natively supported ODBC data sources, see the *Release Notes*.

You can use the Connection Manager to set the Data Services ODBC configuration and associated environment variables required to run a Data Services job that contains a source or target that is one of the above database types. Other generic ODBC data sources require additional manual configuration.

To run the Connection Manager to configure an ODBC source with a DSN connection:

1. Set `$ODBCINI` to a file in which the Connection Manager will define the DSN according to your input on the *Data Sources* tab. Ensure that the file is readable and writable.
   For example:

   ```
   export ODBCINI=<dir-path>/odbc.ini
   touch $ODBCINI
   ```

2. Invoke the Connection Manager by entering the following command:

   `$LINK_DIR/bin/DSConnectionManager.sh`
3. Click the *Data Sources* tab, and click *Add* to display the list of database types.
4. On the *Select Database Type* window, select the database type and click *OK*.
   The *Configuration for...* window appears with some of the connection information filled in with information that the Connection Manager detected:

   - The absolute location of the `odbc.ini` file in which the DSN will be defined
   - Driver (if relevant for database type)
   - Driver Version (if relevant for database type)
5. Provide values for additional connection properties (such as Server Name, Instance, or Port) for the specific database type.

   For a list of relevant properties for each database type, see *Properties for ODBC data sources using DSN connections* [page 63].
6. Provide the following properties (they will not be saved for further use).

   - User name
   - Password
7. If you want to test the connection, click *Test Connection*.
8. Click *Restart Services* to restart the following services:

   Restart Services

   - Both the EIM Adaptive Process Service and Data Services Job Service if Data Services is installed at the same location (machine and folder) as Information Platform Services (IPS) or BI platform. A prompt will appear for the CMS password.
   - Only the Data Services Job Service if Data Services is installed without IPS or BI platform.
9. If you will run another command such as the Repository Manager, source the `al_env.sh` script to set the environment variables.

   By default, the script is located at **`<LINK_DIR>`**`/bin/al_env.sh`.

Related Information

Configuring other ODBC data sources [page 72]
Properties for ODBC data sources using DSN connections [page 63]
The Connection Manager configures the `$ODBCINI` file based on the property values that you enter on the *Data Sources* tab. The following table lists the properties that are relevant for each database type.

1.6.5.1.2 Properties for ODBC data sources using DSN connections

The Connection Manager configures the `$ODBCINI` file based on the property values that you enter on the *Data Sources* tab. The following table lists the properties that are relevant for each database type.

Database Type	Properties on Data Sources tab
MySQL	• ODBC Ini File • DSN Name • Unix ODBC Lib Path • Driver • Driver Version • Server Name • Port • Database • User Name • Password
SQL Server	• ODBC Ini File • DSN Name • Server Name • Port • Database • User Name • Password
SAP HANA	• ODBC Ini File • DSN Name • Driver • Server Name • Instance • User Name • Password
DB2 on iSeries or zSeries	• ODBC Ini File • DSN Name • Server Name • Port • Location • Collection • Package Collection • User Name • Password
Teradata	• ODBC Ini File

Database Type	Properties on Data Sources tab
	• DSN Name • Teradata Install Path • Teradata Version • Server Name • User Name • Password
Netezza	• ODBC Ini File • DSN Name • Driver • Driver Version • Server Name • Port • Database • User Name • Password
Sybase IQ	• ODBC Ini File • DSN Name • Driver • Server Name This is also known as the host name. For example, a host name may be: vanpgc13b9 • Port • Engine Name This is also known as the server name. For example, a server name may be: vanpgc13b9_iqdemo • Database • User Name • Password
Sybase ASE	• Sybase Home Path • OCS • Server Name • Database • User Name • Password
Informix	• ODBC Ini File • DSN Name • Driver • Server Name • Database • User Name

Database Type	Properties on Data Sources tab
	● Password
Attunity	● Attunity Driver Path

1.6.5.1.3 To configure MySQL ODBC for DSN connections

Run the Connection Manager to set the Data Services ODBC configuration and associated environment variables required to run a Data Services job that contains a MySQL source or target.

1. Follow the same steps as in *Configuring native ODBC data sources* [page 61].
2. The MySQL ODBC connector driver (`libmyodbc<version>.so/sl`) has a dependency on the unixODBC driver manager(`libodbc.so`) provided by *www.unixodbc.org* .
   a) If you do not already have the unixODBC driver manager on your system, you must acquire and build the driver manager to resolve this dependency.
   b) Make sure you have the directory location of `libodbc.so` from the unixODBC installation as the first directory in the beginning of `LD_LIBRARY_PATH/LIBPATH/SHLIB_PATH`.

> ⚠ Caution
>
> If the first directory in `LD_LIBRARY_PATH/LIBPATH/SHLIB_PATH` has `libodbc.so` from a location other than the unixODBC installation, a job using MySQL as source/target/repository may not work as expected.

1.6.5.1.3.1 To install the unixODBC driver for Linux

To install the unixODBC driver, you must be using a version of Linux supported by SAP Data Services.

There are two ways to install the unixODBC libraries on Linux:

1. Install the bundled rpm unixODBC package on the Linux installation CD. For example, the the rpm package name on Redhat 5 64-bit is `unixODBC-2.2.11-7.1`.
2. Download and install the 64-bit unixODBC (x86_64) package from the following location: *http://sourceforge.net/projects/unixodbc/files/unixODBC/2.2.14/unixODBC-2.2.14-linux-x86-64.tar.gz/download*

For the latest supported versions, refer to the *Product Availability Matrix* available at *http://service.sap.com/PAM* .

1.6.5.1.3.2 To build and install the unixODBC driver for AIX

To install the unixODBC driver, you must be using a version of AIX supported by SAP Data Services, have the VisualAge C++ compiler (version 6.0 or greater), and download the unixODBC source.

1. Download and extract the unixODBC package.
   a) Download `unixODBC-2.2.12.tar.gz` from *http://www.unixodbc.org* to the `$TEMP` directory.

      > **Note**
      >
      > The downloaded file will be named `unixODBC-2.2.12.tar.tar`.

   b) Rename the unixODBC package.

      ```
      mv unixODBC-2.2.12.tar.tar unixODBC-2.2.12.tar.gz
      ```

   c) Extract the package with `gunzip` and `tar`.

      ```
      gunzip unixODBC-2.2.12.tar.gz
      tar -xvf unixODBC-2.2.12.tar
      ```

   d) Change to the newly created `unixODBC-2.2.12` directory.

      ```
      cd $TEMP/unixODBC-2.2.12
      ```

2. Make the libraries and programs.
   a) Ensure that xlC (the C++ compiler) is in the `PATH` environment variable, and add it if necessary.
      - Using ksh:

        ```
        export PATH=/usr/vacpp/bin:$PATH
        ```

      - Using csh:

        ```
        setenv PATH /usr/vacpp/bin:$PATH
        ```

   b) Configure the C compiler to be thread-enabled:

      ```
      export CC=xlc_r
      export CCC=xlC_r
      ```

   c) To compile a 64-bit version of the driver manager using the `xlc_r` compilers, set the `OBJECT_MODE` and `CFLAGS` environment variables:

      ```
      export OBJECT_MODE=64
      export CFLAGS=-q64
      ```

   d) Build the package.

      ```
      ./configure --enable-gui=no --enable-drivers=no
      make
      make install
      ```

Note

By default, the files are installed to /usr/local. You can specify a different location by altering the prefix option:

```
./configure --prefix=<new_location> --enable-gui=no --enable-drivers=no
```

where **<new_location>** is the location where you want to install the unixODBC libraries.

e) If you will be dynamically loading the driver manager from /prefix/lib, extract libodbc.a, libodbcinst.a, and libodbccr.a.

```
ar -x -X 64 libodbc.a
ar -x -X 64 libodbcinst.a
ar -x -X 64 libodbccr.a
```

f) Create the dynamically linked library.

```
ln -s libodbcinst.so.1 libodbcinst.so
```

3. Add the unixODBC library to the $LIBPATH environment variable.
For example:

```
export LIBPATH=<install_path>:$LIBPATH
```

where **<install_path>** is the location where all the unixODBC libraries are installed.

For the latest supported versions, refer to the *Product Availability Matrix* available at http://service.sap.com/PAM.

1.6.5.1.3.3 To build and install the unixODBC driver for Solaris

To install the unixODBC driver, you must be using a version of Solaris supported by SAP Data Services, have the Sun C++ compiler (version 5.5 or greater), and download the unixODBC source.

1. Download and extract the unixODBC package.

a) Download unixODBC-2.2.12.tar.gz from http://www.unixodbc.org to the $TEMP directory.

Note

The downloaded file will be named unixODBC-2.2.12.tar.tar.

b) Rename the unixODBC package.

```
mv unixODBC-2.2.12.tar.tar unixODBC-2.2.12.tar.gz
```

c) Extract the package with gunzip and tar.

```
gunzip unixODBC-2.2.12.tar.gz
tar -xvf unixODBC-2.2.12.tar
```

d) Change to the newly created `unixODBC-2.2.12` directory.

```
cd $TEMP/unixODBC-2.2.12
```

2. Make the libraries and programs.

a) Ensure that CC (the C++ compiler) is in the `PATH` environment variable, and add it if necessary.

○ Using ksh:

```
export PATH=/home4/thirdparty/software/sunonecc/8.0-sj/SUNWspro/bin/CC:
$PATH
```

○ Using csh:

```
setenv PATH /home4/thirdparty/software/sunonecc/8.0-sj/SUNWspro/bin/CC:
$PATH
```

b) Build the package using the standard GNU autoconf process.

```
./configure CFLAGS="-xarch=v9" LDFLAGS="-xarch=v9" CXXFLAGS="-xarch=v9" --
enable-gui=no
make
make install
```

> **Note**
>
> By default, the files are installed to `/usr/local`. You can specify a different location by altering the prefix option:
>
> ```
> ./configure --prefix=<new_location>/unixODBC CFLAGS="-xarch=v9" LDFLAGS="-
> xarch=v9" CXXFLAGS="-xarch=v9" --enable-gui=no
> ```
>
> where **`<new_location>`** is the location where you want to install the unixODBC libraries.

3. Add the unixODBC library to the `$LD_LIBRARY_PATH` environment variable.
For example:

```
export LD_LIBRARY_PATH=<install_path>/unixODBC/lib:$LD_LIBRARY_PATH
```

where **`<install_path>`** is the location where all the unixODBC libraries are installed.

For the latest supported versions, refer to the *Product Availability Matrix* available at *http://service.sap.com/PAM* .

1.6.5.1.4 Troubleshooting

You might need to troubleshoot the following situations:

- To determine whether all dependent libraries are set properly in the environment variables, you can use the `ldd` command on the ODBC driver manager library and the ODBC driver library.
For example:

```
ldd tdata.so
```

If you see that any dependent libraries are missing, ensure that you have added the environment settings to the session running the job service, or consult your ODBC driver vendor's documentation.

- If an error occurs when using the Connection Manager, invoke it from the command line by using the `-c` option, and use the `-d` option to show details in the log.
  For example:

  ```
  $LINK_DIR/bin/DSConnectionManager.sh -c -d
  ```

  The log file path is `$LINK_DIR/log/DSConnectionManager.log`.
  Possible errors include the following:
  - The Connection Manager cannot connect to database
  - The Data Services Job Server cannot connect to database

1.6.5.2 Configuring ODBC drivers on UNIX for data sources using DSN-less connections

On UNIX and Linux platforms, SAP Data Services requires an ODBC driver library for ODBC data sources using DSN-less connections. The UNIX ODBC driver configuration file:

- Contains driver names that reference ODBC driver libraries.
- Is an ODBC instance file referenced by the `$ODBCINST` environment variable.

> ➜ Tip
>
> For natively supported ODBC databases, you do not need to manually configure the ODBC instance file. Instead, set `$ODBCINST` to the name of the ODBC instance file and use the Data Services Connection Manager to properly configure the ODBC driver library.

1.6.5.2.1 Configuring native ODBC drivers on UNIX

Run the Connection Manager to configure the ODBC driver library and associated environment variables required to run a Data Services job that contains one of the following source or target database types using DSN-less connections:

- DB2 UDB
- Informix
- MySQL
- Netezza
- Oracle
- SAP HANA
- SAP Sybase IQ
- Teradata

> i Note
>
> For the most current list of database types supported for DSN-less connections, see the *Release Notes*.

1. For a DSN-less connection, set `$ODBCINST` to a file in which the Connection Manager will define the ODBC driver according to your input on the *Drivers* tab. Ensure that the file is readable and writable.
   For example:

   ```
   export ODBCINST=<dir-path>/odbc.inst
   touch $ODBCINST
   ```

2. Invoke the Connection Manager by entering the following command:

   `$LINK_DIR/bin/DSConnectionManager.sh`

3. Click the *Drivers* tab, and click *Add*.
   a) On the *Select Database Type* window, select the database type and click *OK*.
   The *Configuration for...* window appears with the value filled in for *ODBC Inst File*.
   b) Provide values for the driver properties. For the relevant driver properties for each database type, see *Properties for ODBC data sources using DSN-less connections* [page 70].
4. Provide values for the following properties (they will not be saved for further use).
   - Server name
   - Port (if relevant)
   - Database (if relevant)
   - User name
   - Password
5. If you want to test the connection, click *Test Connection*.
6. Click *Restart Services* to restart the following services:
   - Both the EIM Adaptive Process Service and Data Services Job Service if Data Services is installed at the same location (machine and folder) as Information Platform Services (IPS) or BI platform. A prompt will appear for the CMS password.
   - Only the Data Services Job Service if Data Services is installed without IPS or BI platform.
7. If you will run another command such as the Repository Manager, source the `al_env.sh` script to set the environment variables.

   By default, the script is located at `<LINK_DIR>/bin/al_env.sh`.

1.6.5.2.2 Properties for ODBC data sources using DSN-less connections

The Connection Manager configures the `$ODBCINST` file based on the property values that you enter on the *Drivers* tab. The following table lists the properties that are relevant for each database type.

Database Type	Properties on Drivers tab
MySQL	• ODBC Inst File • Driver Version • Unix ODBC Lib Path • Driver Name • Driver • Server Name

Database Type	Properties on Drivers tab
	• Port • Database • User Name • Password
SAP HANA	• ODBC Inst File • Driver Version • Driver Name • Driver • Server Name • Port • User Name • Password
Teradata	• ODBC Inst File • Driver Version • Driver Name • Driver • Server Name • User Name • Password
Netezza	• ODBC Inst File • Driver Version • Driver Name • Driver • Server Name • Port • Database • User Name • Password
SAP Sybase IQ	• ODBC Inst File • Driver Version • Driver Name • Driver • Server Name This is also known as the host name. For example, a host name may be: vanpgc13b9 • Port • Engine Name This is also known as the server name. For example, a server name may be: vanpgc13b9_iqdemo • Database

Database Type	Properties on Drivers tab
	• User Name • Password
Informix	• ODBC Inst File • Driver Version • Driver Name • Informix Home Path • Server Name • Database • User Name • Password
DB2 UDB	• DB2 Client Path • Driver Version • Server Name • Port • Database • User Name • Password
Oracle	• Oracle Home Path • Driver Version • Server Name • Port • SID • User Name • Password

1.6.6 Configuring other ODBC data sources

In addition to the natively-supported ODBC data sources, Data Services can access other ODBC data sources when you use the bundled DataDirect ODBC driver or another ODBC driver.

Related Information

Configuring native ODBC data sources [page 61]

1.6.6.1 To configure DataDirect ODBC

➡ Tip

It is recommended that you use the Data Services Connection Manager to configure ODBC data sources such as Microsoft SQL server and DB2 on zSeries or iSeries. The Connection Manager is an interactive user interface that simplifies the manual configuration steps of the DataDirect ODBC driver. For details about using the Connection Manager, see *Configuring native ODBC data sources* [page 61].

If you want to use the DataDirect ODBC driver to connect to ODBC data sources such as Microsoft SQL server and DB2 on zSeries or iSeries from Data Services on a Linux or Unix platform, follow these steps:

1. Add the data source to the Data Services ODBC driver manager configuration file (`<LINK_DIR>/bin/ds_odbc.ini`).
   For Microsoft SQL Server:

   ```
   [test_Microsoft_SQL_SERVER]
   Driver = <install_location>/lib/libodbc.so
   RebrandedLib = TRUE
   ```

   where `<install_location>` is the location of the DataDirect ODBC driver.

   For DB2 on zSeries or iSeries:

   ```
   [test_DB2]
   Driver = <install_location>/lib/libodbc.so
   RebrandedLib = TRUE
   ```

   where `<install_location>` is the location of the DataDirect ODBC driver.

   i Note

   `RebrandedLib = TRUE` is required when using the SAP rebranded Data Direct driver.

2. Add the data source to the ODBC vendor's configuration file (referenced by `$ODBCINI`).

   i Note

   The version number and driver filenames are subject to change with each release. Access `$LINK_DIR/DataDirect/odbc/odbc.ini` to view the current version information.

   i Note

   `EnableQuotedIdentifiers = 1` is required for Microsoft SQL server

   For Microsoft SQL Server:

   ```
   [test_Microsoft_SQL_SERVER]
   Driver=<install_location>/lib/[DA][DD]msss<xx>.so
   Description=DataDirect <current version number> SQL Server Wire Protocol
   AlternateServers=
   AnsiNPW=Yes
   ConnectionRetryCount=0
   ConnectionRetryDelay=3
   Database=<database_name>
   ```

```
EnableQuotedIdentifiers=1
HostName=<SQL_Server_host>
LoadBalancing=0
LogonID=
Password=
PortNumber=<SQL_Server_server_port>
QuotedId=No
ReportCodePageConversionErrors=0
DriverExpirationBehavior=1
```

where **`<install_location>`** is the location of the DataDirect ODBC driver.

For DB2 on zSeries or iSeries:

```
[test_DB2]
Driver=<install_location>/lib/[DD][DA]db2<xx>.so

```

where **`<install_location>`** is the location of the DataDirect ODBC driver.

3. Run the `$LINK_DIR/DataDirect/odbc/odbc.sh` script to add the environment settings to the session running the job service.

1.6.6.2 Driver manager configuration file for DSN connections

Enclose data source names in square brackets. Properties follow on subsequent lines and use PropertyName = PropertyValue. For example:

```
[test_source]
Driver     = /path/to/driver
OdbcConformanceLevel     =
LazyLoading =
ODBC64SqlHandleSize =
ODBC64SqlLenSize     =
DriverUnicodeType     =
```

In this example, test_source is the name of data source that can be loaded using the specified driver library file. Default values apply when optional properties are left blank.

Follow these guidelines when editing the **<LINK_DIR>**/bin/ds_odbc.ini file:

- Each data source name must at least have a driver property defined, which allows the driver manager to load the driver when connecting to the database.
- The pound sign (#) as the first character in any line denotes a comment.
- All leading blanks and trailing blanks in data source names and properties are ignored.

The following table lists the data source configuration parameters for ds_odbc.ini (and ds_odbc.ini.sample):

Key	Required	Valid value	Example
Driver	Yes	A full path including the ODBC driver library name. The directory containing the dependent libraries must be in the shared library path (for AIX, LIBPATH; for Solaris or Linux, LD_LIBRARY_PATH). Check vendor documentation for what you need to add to the shared library path.	Driver=/home/mysql/myodbc/lib/libmyodbc3_r.so

OdbcConformanceLevel	No	A decimal value specifying the ODBC conformance level of driver. Default value is 0, in which case the driver detects by loading 2.x followed by 3.x functions from the driver. When any value greater than or equal to 4.0 is specified, the driver manager prints a run time error.	OdbcConformanceLevel =0
			OdbcConformanceLevel =3.0

Key	Required	Valid value	Example
		Note An ODBC driver can be compliant to either 2.x or 3.x or both. The UNIX ODBC driver manager detects if the driver is 2.x or 3.x compliant and loads the respective compatible ODBC API functions. If the driver is both 2.x and 3.x compliant, then the driver manager only loads the 2.x ODBC API. You can override this behavior by specifying, for example, `OdbcConformanceLevel = 3.0`. As a result, the ODBC driver manager only loads 3.x ODBC API functions.	
`LazyLoading`	No	You can specify a Boolean `TRUE`/`YES` or `FALSE`/`NO`. Default value is `FALSE`.The UNIX ODBC Driver Manager loads the ODBC driver and instructs the operating system to load all of its dependent libraries. This flag is useful when certain dependent libraries of the ODBC driver are not required and the ODBC vendor recommends to load the library in lazy mode.	`LazyLoading=TRUE`
`ODBC64SqlHandleSize`	Yes	`32` or `64` If blank or other, the software uses the default value of `64`. The standard definition of the SQLHANDLE data type in 64-bit ODBC is 64-bit integer. However, some ODBC drivers do not conform to this standard; therefore, use this parameter to specify the actual size of SQLHANDLE. DataDirect 64-bit ODBC drivers conform to the	`ODBC64SqlHandleSize=64`

Key	Required	Valid value	Example
		standard, so ignore or set to 64 for DataDirect. For other 64-bit ODBC drivers, contact your vendor to determine the actual size of SQLHANDLE. i Note This option is required only for 64-bit platforms.	
`ODBC64SqlLenSize`	Yes	`32` or `64` If blank or other, the software uses the default value of `64`. The standard definition of the SQLLEN data type in 64-bit ODBC is 64-bit integer. However, some ODBC drivers do not conform to this standard; therefore, use this parameter to specify the actual size of SQLLEN. DataDirect 64-bit ODBC drivers conform to the standard, so ignore or set to 64 for DataDirect. For other 64-bit ODBC drivers, contact your vendor to determine the actual size of SQLLEN. i Note This option is required only for 64-bit platforms.	`ODBC64SqlLenSize=64`
`DriverUnicodeType`	Yes	`1` (for UTF16) `2` (for UTF8) If blank, other, or not detectable, the software uses the default value of `2`. This integer value specifies the ODBC driver Unicode type. DataDirect SQL Server ODBC driver only supports W functions; for this driver, specify `2`.	`DriverUnicodeType=2`

Key	Required	Valid value	Example
		ℹ Note This option is required only for ODBC drivers that only support W functions.	

1.6.6.3 To configure Neoview ODBC

To use the Neoview Transporter on UNIX, you must also install the following software components:

- Neoview Transporter Java Client
- Java JRE version 1.5 or newer
- Neoview JDBC Type 4 driver
- Neoview ODBC UNIX drivers
- Neoview Command Interface

1. Run the `dsdb_setup.sh` script to set the Data Services ODBC configuration and associated environment variables required to run a Data Services job that contains a Neoview source or target.

   You need to provide the following information when you run the script:

   - The absolute location of the `odbc.ini` file in which the Neoview DSN is defined
   - The database version
   - The location of the database client

   By default, the script is located at **`<LINK_DIR>`**`/bin/dsdb_setup.sh`.
2. Add the data source to the ODBC vendor's configuration file (referenced by `$MXODSN`). For example:

```
[test_neoview]
Driver = <install_location>/libhpodbc_drvr[64].so
Description = Default Data Source
Catalog = NEO
Schema = <schema_name>
DataLang = 0
FetchBufferSize = SYSTEM_DEFAULT
Server = TCP:<ip_address>:<port_number>
SQL_ATTR_CONNECTION_TIMEOUT = SYSTEM_DEFAULT
SQL_LOGIN_TIMEOUT = SYSTEM_DEFAULT
SQL_QUERY_TIMEOUT = NO_TIMEOUT
ServiceName = HP_DEFAULT_SERVICE
```

   where **`<install_location>`** is the location of your HP Neoview installation.
3. Run the `al_env.sh` script to set the environment variables.

   By default, the script is located at **`<LINK_DIR>`**`/bin/al_env.sh`.
4. Use the Server Manager to restart the Data Services job service.
5. Stop and restart the Central Management Server (CMS) and its services to refresh the ODBC environment.

   a) Navigate to **`<BIP_INSTALL_DIR>`**.

b) Stop the CMS and its services:

```
./stopservers
```

c) Restart the CMS and its services:

```
./startservers
```

> **Note**
>
> You must also change the regional settings to UTF-8 to process multi-byte data.

1.6.7 Using the ODBC Driver Selector on Windows for server name connections

Run the Data Services ODBC Driver Selector on Windows to configure the ODBC driver library required for a database using server name (also known as DSN-less) connections for the Data Services repository or as a source or target database in a Data Services job.

> **Note**
>
> For the most current list of database types and versions supported for DSN-less or TNS-less connections, see the Supported Platforms (Product Availability Matrix) *https://service.sap.com/PAM*.

1. Invoke the ODBC Driver Selector by opening a Command Prompt window and entering the following command:

   ```
   %LINK_DIR%/bin/ODBCDriversSelector.exe
   ```

2. Go to the database type and version in the column *Database version*, and click the cell under the column *ODBC Drivers* to display a list of existing drivers that Data Services detected and the current state of the driver.

   > **Note**
   >
   > The list of drivers in the ODBC Driver Selector is the same as the list in the Windows ODBC Data Source Administsrator for data sources using DSN connections. The state in the ODBC Driver Selector will have a state of “Installed” for these drivers. However, if you uninstall a driver, the ODBC Driver Selector state is “Not Installed”.

3. Select the ODBC Driver for your database type and click *OK*.

1.6.8 Using the Repository Manager

Use the Repository Manager to check the version, to upgrade, or to create a repository after installation.

⚠ Caution

It's recommended that you do not use database tools to attempt to quickly replicate additional repositories. By using the Repository Manager to create and seed multiple repositories individually, you can avoid potential issues related to the configuration of repository objects.

1. On Windows, choose *Start* > *Programs* > *SAP Data Services 4.2* > *Data Services Repository Manager* to open the Repository Manager.

   You can also access the Repository Manager from the command line on both Windows and UNIX platforms. For more information, see the command-line reference appendix.
2. If you are creating a new repository, ensure that you created a database for the new repository to use.
3. In the Repository Manager window, select the database type and version of your repository.
4. For a DB2, MySQL or SAP HANA database, the default connection type is DSN-less (the *Use data source name (DSN)* checkbox is not selected).
   - If you want to use a DSN-less connection, type in the *Database server name*, *Database name* (for DB2 and MySQL) and *Port*.
   - If you want to use a DSN connection, select the check box for *Use data source name (DSN)* and enter the *Data source name*.
5. For an Oracle database, the default connection type is TNS-less (the *Use TNS name* checkbox is not selected).
   - If you want to use a TNS-less connection, type in the *Hostname*, *SID*, and *Port*
   - If you want to use a TNS connection, select the check box for *Use TNS name* and enter the *TNS name*.
6. For other database types, complete the information.
7. Enter the user name and password that you want to use for your repository.
8. Select one of the following repository types:

Repository type	Description
Local	(Default) Stores definitions of objects in your local repository.
Central	Stores definitions of objects in a central repository for multiple-user users.
Profiler	Stores information generated by the Data Profiler for determining the quality of your data.

9. If you are creating a new repository, click *Create*. If you are upgrading an existing repository, click *Upgrade*.
10. If you want to create or upgrade another repository, repeat steps 1 through 6.
11. When you finish creating or upgrading repositories, click *Close*.

ℹ Note

Before you can access the repository, you must associate it with a Job Server and register it in the Central Management Console (CMC)

Related Information

To register a repository in the CMC [page 52]
Using the Server Manager on Windows [page 84]

1.6.9 Using the License Manager

License Manager lets you manage your product activation keycodes—the alphanumeric codes that are referred to each time that you run certain software. By using License Manager, you can view, add, and remove product activation keycodes for SAP solution portfolio software (such as SAP Data Services) that require them.

> **Note**
>
> License Manager accesses keycodes on the local system only; you cannot access the keycodes from a remote system. When updating keycodes, make the changes on all SAP Data Services computers by launching License Manager on each computer, including Designer and Job Server computers.

> **Note**
>
> If you are running a Windows operating system, you will not be able to add or remove license keycodes unless you have Administrator privileges. For those with non-administrator privileges, the License Manager interface will appear in read-only mode. For the command-line interface, only the `-v` and `--view` parameters are available for use.

1.6.9.1 To configure License Manager on Unix

Before you can use License Manager on UNIX platforms, you need to set the environment variable `BOE_REGISTRYHOME`. If you've already configured the SAP Data Services environment by running `al_env.sh` script, the `BOE_REGISTRYHOME` variable should already be set. If the variable has not been set, manually add it to your `.profile`, `.login`, or `.cshrc` file.

If you use Bourne shell, add product entries to your `.profile` or `.login` file.

```
BOE_REGISTRYHOME=$LINK_DIR/registry ; export BOE_REGISTRYHOME
```

If you use C shell (Berkeley), add product entries to your .cshrc file.

```
setenv BOE_REGISTRYHOME $LINK_DIR/registry
```

1.6.9.2 To start License Manager

You can run License Manager after the SAP Data Services installation has completed.

On Windows

Choose *Start* > *Programs* > *SAP Data Services 4.2* > *License Manager*.

> **Note**
>
> You can also use License Manager in command-line mode.

On UNIX

Run `LicenseManager` from the command line without specifying any options:

```
$ cd $LINK_DIR/bin
$ ./LicenseManager
```

> **Note**
>
> If X-Windows is not available, you can use License Manager in command-line mode.

1.6.9.3 To view product activation keycodes

1. Start License Manager.
   The License Manager window displays your keycode(s) sorted alphabetically.
2. Select a licensed product or feature in the *Registered Keycodes* tree to view detailed information:
   - Product or feature keycode
   - Whether the keycode is a trial version
   - Whether the keycode is expired
   - Number of days remaining until the keycode expires

Related Information

To start License Manager [page 82]

1.6.9.4 To add product activation keycodes

1. Start License Manager.
2. In the *Product Activation Keycodes* text box, enter the keycode(s) that you want to add (each keycode must be on a separate line) and click *Add*.
   The keycodes that will be added are displayed in the *Registered Keycodes* tree and highlighted.
3. When you are satisfied with the changes that will be made, click *Save*.
   The keycode highlighting is removed.

   > ➜ Tip
   >
   > If you do not want to save the keycode changes, close License Manager without saving the changes.
4. After you have saved your changes, click *Close* to exit License Manager.
5. To make sure the new keycode(s) take effect, restart the software.

Related Information

To start License Manager [page 82]

1.6.9.5 To remove product activation keycodes

1. Start License Manager.
2. In the *Registered Keycodes* tree, select the keycode(s) that you want to remove and click *Remove*.
   The keycodes that will be removed are crossed out, and any affected nodes are highlighted.
3. When you are satisfied with the changes that will be made, click *Save*.
   The crossed-out keycodes are removed.

   > ➜ Tip
   >
   > If you do not want to save the keycode changes, close License Manager without saving the changes.
4. After you have saved your changes, click *Close* to exit License Manager.
5. Restart the software.

Related Information

To start License Manager [page 82]

1.6.10 Using the Server Manager on Windows

Use the Server Manager to create, edit, or delete Job Servers and Access Servers after installation.

1. Choose *Start* > *Programs* > *SAP Data Services 4.2* > *Data Services Server Manager*.
   The Server Manager utility window opens. This window shows the Job Servers and Access Servers currently configured to run on your computer.
2. Configure Job and Access servers as needed.
3. In the Server Manager window, click *Restart*.

1.6.10.1 To configure Job Servers

1. Open the Server Manager, click the Job Server tab and click *Edit*.
2. Decide which configuration task to perform:
   - To add a new Job Server, click *Add*.
     Continue to the remaining configuration steps.
   - To edit an existing Job Server, select the Job Server and click *Edit*.
     Continue to the remaining configuration steps.
   - To remove an existing Job Server, select the Job Server and click *Delete*.
     No additional configuration steps are required.

   > Note
   >
   > If the Job Server has associated repositories, you must first delete those and then click *OK* before you can delete the Job Server.

3. In the Job Server Properties window, enter configuration information for the Job Server.
4. In the Associated Repositories section, configure any local or profiler repositories that you want to associate with the Job Server. Each Job Server must be associated with at least one local repository.
   a) If you want to use a DSN-less connection (for DB2, MySQL, SQL Anywhere, or SAP HANA database types), clear the *Use data source name (DSN)* checkbox.
   b) If you want to use a TNS-less connection for an Oracle database type, clear the *Use TNS name* checkbox.
   c) When you have finished configuring associated repositories, including one default, click *OK*.
5. Click *OK* to return to the Server Manager window.
6. Click *Restart* to restart the services with any updated configurations.

1.6.10.1.1 Job Server properties

Property	Description
Job Server name	Specifies a name that uniquely identifies the Job Server.

Property	Description
Job Server port	Specifies the TCP/IP port that the Job Server uses to receive commands from the Designer and the Access Server. If a computer hosts multiple Job Servers, each Job Server must have a unique port number. Additionally, the post number must not be used by another process on the computer. If you are unsure of which port number to use, use the default port number and increment it for each additional Job Server that you configure.
Support adapter and message broker communication	Enables communication between the Job Server and adapters. Each computer that hosts adapters must have exactly one Job Server designated to manage them.
Use SSL protocol for adapter, message broke and communication	Enables SSL security on the communication paths between the Job Server and any adapters or message brokers.
Communication port	Specifies the TCP/IP port number that the Job Server uses for communicating with adapters. The default port is 4001.

1.6.10.1.2 To configure associated repositories

Each Job Server must be associated with at least one local repository, and can be associated with other local and profiler repositories. Configure associated repositories in the Associated Repositories section of the Job Server Properties window in the Server Manager.

To add an associated repository

1. Click *Add* to associate a new local or profiler repository with the Job Server.
2. Enter the required connection information for your repository database. The details required vary depending on the database type.
3. Enter the user name and password that you want to use for your repository.
4. Check *Default repository* if this is the default repository for the Job Server. You must specify exactly one default repository.

   > Note
   >
   > Do not check *Default repository* if you are adding a profiler repository.

5. Click *Apply* to save your entries and associate the repository with the Job Server.

The associated repository entry updates with the Job Server's computer name and port number.

To edit an associated repository

1. Select the repository you want to change and click *Edit*.
2. Under Repository Information, enter the password.
3. Check or uncheck *Default repository*, indicating whether this is the default repository for the Job Server.
4. Click *Apply* to save the changes to the Job Server configuration.

> Note
>
> You can change only whether an associated repository is the default for the Job Server. If you need to make other changes, delete the existing associated repository and add a new one with the updated configuration information.

To delete an associated repository

1. Select the repository you want to delete and click *Delete*.
2. Under Repository Information, enter the password.
3. Click *Apply* to remove the associated repository from the Job Server configuration.

1.6.10.1.3 To resynchronize associated repositories

Situations when you must resynchronize the Job Server and the local repository include:

- The Job Server information is not available or not correct in the local repository.
- You have uninstalled Data Services and are reinstalling the same version without creating a new local repository.
- You created a new local repository using the Repository Manager after creating a repository and Job Server when you installed Data Services.

To resynchronize Job Servers:

1. In the Job Server Configuration Editor window, select the name of your Job Server.
2. Click *Resync with Repository*.
3. In the Job Server Properties window, select an associated local repository.
4. Click *Resync*.
5. When asked whether to update this associated repository with this local machine information, click *OK*.
6. Under *Repository Information*, enter the local repository password.
7. Click *Apply*.
8. Click *OK* on the Job Server Properties window.

1.6.10.2 To configure run-time resources

1. In the Server Manager window, click the Run-time resources tab.
2. For the *Specify a directory with enough disk space for pageable cache* option, accept the default directory (**<LINK_DIR>**`\Log\PCache`) or click the ellipses button to browse to a different directory.

   > i Note
   >
   > For memory-intensive operations such as Group By, Order By, and Detailed profiling, specify a pageable cache directory that fulfills the following criteria:

   - The directory contains enough disk space for your data. To estimate the amount of space required for pageable cache, consider factors such as:
     - Number of concurrently running jobs or data flows.
     - Amount of pageable cache required for each concurrent data flow.
   - The directory exists on a separate disk or file system from the SAP Data Services system and operating system (such as the `C:` drive on Windows, or the root file system on UNIX systems).
   - The directory limits the disk space that data flows consume. The pageable cache uses all available disk space on the file system that contains the pageable cache directory. So, to limit the disk space that data flows consume, create a file system (or partition on Windows) with a limited size. Use the new file system (partition on Windows) as the pageable cache directory.
     The software uses this directory in the following situations:
     - For pageable caching, which is the default cache type for data flows.
     - When selecting a file transfer type and Automatic is specified in the Data_Transfer transform.
3. In the *Peer-to-peer options* area, change the values for *Start port* and *End port* to restrict the number of ports used by the software. The default values for *Start port* and *End port* are `1025` and `32767`, respectively.

   The software uses these ports for peer-to-peer communications when sending data between data flows or sub data flows.

   > i Note
   >
   > If you want to enable SSL security on the communication paths between data flows and sub data flows, select *Use SSL protocol*.

4. Click *Apply* to save any configuration changes.

Related Information

Performance Optimization Guide: Caching data [page 2129]

Reference Guide: Data_Transfer [page 1071]

Performance Optimization Guide: Using grid computing to distribute data flows execution [page 2160]

1.6.10.3 To configure Access Servers

When you configure the location for an Access Server installation, SAP Data Services creates space for the Access Server log files.

1. Open the Server Manager, click the Access Server tab and click *Edit*.
2. Decide which configuration task to perform:
   - To add a new Access Server, click *Add*.
     Continue to the remaining configuration steps.
   - To edit an existing Access Server, select the Access Server and click *Edit*.
     Continue to the remaining configuration steps.
   - To remove an existing Access Server, select the Access Server and click *Delete*.
     No additional configuration steps are required.
3. In the *Access Server Properties* window, enter the Access Server configuration information and click *OK*.

Property	Description
Directory	Specifies the location of the log files for this instance of the Access Server. Click the ellipses button to browse to the Log directory under the directory where you installed the software. Do not change this value after the initial configuration.
Communication Port	Specifies the port on this computer that the Access Server uses to listen for incoming messages from clients. Make sure that this port number is unused and is unique for each Access Server.
Parameters	Specify any additional Access Server parameters. Note Additional Access Server parameters can be viewed by typing `AL_AccessServer` at the command line. For more information, see “Real Time Performance” in the *Management Console Guide*.
Use SSL protocol	Enables SSL security for real-time messaging on this Access Server.
Enable Access Server	Controls whether the Access Server is automatically started when the Data Services service starts.

4. Click *OK* to return to the Server Manager window.
5. Click *Restart* to restart the services with the updated configuration.

1.6.10.4 To configure SSL paths

Use the Server Manager to configure the paths to SSL certificates and keyfiles.

Note

By default, the paths for the SSL certificate and keyfiles are automatically configured during installation. You do not need to change them unless you want to use your own certificates.

Note

If you change the SSL certificate configuration, you must resync all repositories associated with the Job Server before you can run jobs successfully.

1. Open the Server Manager and click the SSL tab.
2. Specify the locations of the server certificate file, the server private key file, and the trusted certificates folder.

   Note

   The server certificate must be in PEM format. Valid extensions for certificates in the trusted certificates folder include `.pem`, `.crt`, and `.cer`. Regardless of the file extension, all certificate file contents must be in PEM format.
3. If you want to specify a private key password file, select *Use server private key password file* and specify the location of the password file.
4. Click *Close and Restart* to close the Server Manager and restart any Data Services servers on the machine with the updated certificate information.

Note

The certificate information specified in the Server Manager applies to all Data Services servers running on that physical machine. For example, any Job Servers, Access Servers, and so on.

1.6.10.5 Verifying that Job and Access servers are running

To verify that Job Servers are running:

1. Check in the Windows Task Manager *Processes* tab for:
   - `al_jobservice.exe` (represents the SAP Data Services service)
   - `al_jobserver.exe` (one per Job Server)
   - `AL_AccessServer.exe` (one per Access Server)
2. If you do not see all the processes expected, check for error messages in the Job Server event log in **`<LINK_DIR>`**`/log/`**`<JobServer name>`**`/server_eventlog.txt`.

   Note

   Access Server logs are in **`<AccessServerPathName>`**`/error_mm_dd_yyyy.log`

1.6.11 Using the Server Manager on UNIX systems

Use the Server Manager to create, edit, or delete Job Servers and Access Servers after installation.

The Server Manager displays the following:

Job Server information

Option	Description
Server name	This name uniquely identifies the Job Server. The Job Server name cannot be changed.
TCP/IP port number	The port number is a TCP/IP port that the Job Server uses to receive commands from the Designer and an Access Server. If a computer hosts multiple Job Servers, each Job Server must have a unique port number. Choose a port number that is not used by another process on the computer. It's recommended that you use 3500. If you are unsure of which port number to use, use the default port number and increment it for each additional Job Server you configure.
Supports adapter communication on port	If this computer hosts adapters, you must designate one (and only one) Job Server to support them. Once a Job Server is set to support adapters (a port is entered and saved), it is marked on the Job Server Configuration screen with this label.

Run-time resource information

Option	Description
Pageable cache directory	This directory contains the pageable cache that the software uses for memory-intensive operations and for file transfer types when *Automatic* is specified in the Data_Transfer transform.
Start port	The software uses this starting port number for peer-to-peer communication between data flows or sub data flows that are running on different Job Servers. The default is 1025.

Access Server information

Option	Description
Server number	This sequence number uniquely identifies the Access Server on this machine. The Access Server number cannot be changed.
Directory	The directory containing Access Server information.
Communication port	This port number is used to communicate between the Access Server and the Administrator. The default is 4000.
Parameters	Additional parameters used by the Access server.

Option	Description
	View Access Server parameters by typing **AL_AccessServer** at the command line. For more information, see "Real Time Performance" in the *Management Console Guide*.
Enable	Enter **Y** to activate the Access Server.

Job service information

Option	Description
Service executable path	The directory containing AL_JobService information.
Status	Status of the Data Services service: - Running - Not running

SMTP Server information

Option	Description
Server	The name or IP address of the SMTP server (for example, mail.company.com).
Sender	The email address that will appear in the *From* field of the email.

1.6.11.1 To configure Job Servers on UNIX

1. Ensure required environment variables are set, and run the Server Manager.

   ```
   $ cd $LINK_DIR/bin/
   $ . ./al_env.sh
   $ ./svrcfg
   ```

   The Server Manager main screen appears.
2. Enter **3** to configure a Job Server.
   The Job Server information screen appears.

   > Note
   >
   > The repository information for each configured Job Server is displayed in one of the following formats:
   >
   > ○ For a DSN or TNS connection:
   >
   > | Database Type | Format of Repository String |
   > |---|---|
   > | Oracle | **<username>**@**<TNSname_user>** |

Database Type	Format of Repository String
SAP HANA	`<username>@<DSNname_user>`
DB2	
MySQL	
SQL Anywhere	

- For a server name connection (also known as DSN-less or TNS-less connection):

Database Type	Format of Repository String
Oracle	`<username>@<server_SID_user>`
SAP HANA	`<username>@<server_port_user>`
MySQL	`<username>@<server_database_user>`
DB2	

- For SAP Sybase:
  `<username>@<server_database_user>`

3. Enter the command for the configuration task you want to perform:

Command	Configuration task
`c`	Add a new Job Server.
`e`	Edit an existing Job Server.
`d`	Delete an existing Job Server.
`a`	Add a repository connection to a Job Server.
`u`	Update a repository connection on a Job Server.
`r`	Remove a repository connection from a Job Server.
`s`	Set the default repository connection for a Job Server.
`y`	Resynchronize a Job Server configuration with a repository. You must resynchronize your Job Server and repository when: ○ You have uninstalled Data Services and are reinstalling the same version without creating a new repository. ○ You have created a new repository using the Repository Manager after installing the software. If you resynchronize your Job Server configuration with a repository, you must re-add a connection for this repository to the Administrator. For more information, see the *Management Console Guide*.

4. When you add or edit a Job Server, you must specify additional configuration details:
   a) Enter the name for the Job Server.
   b) Specify the TCP/IP port that the Job Server uses to receive commands from the Designer and the Access Server.

> i Note
>
> If a computer hosts multiple Job Servers, each Job Server must have a unique port number. Additionally, the post number must not be used by another process on the computer.

If you are unsure of which port number to use, use the default port number and increment it for each additional Job Server that you configure.

c) If you want to manage adapters with the Job Server, enter **Y**.

d) If you want to manage adapter communication with the Job Server, specify the TCP/IP port number to use.

e) If you want to enable SSL on the adapter management communication paths used by the Job Server, enter **Y**.

5. When you add or edit a repository connection, you must specify the database connection information.

a) If you want to use a DSN-less connection (for a DB2, MySQL, or SAP HANA database), enter **N** when the Server Manager asks you if you want to use an ODBC data source.

b) If you want to use a TNS-less connection for an Oracle database, enter **N** when the Server Manager asks you if you want to use a TNS name.

c) If you want to use a DSN or TNS connection, you must specify the following additional database connection information:

Database	Required information
Oracle	The TNSNAME specified in `tnsnames.ora`
MySQL	The DSN entry specified in `odbc.ini`
SAP HANA	The DSN entry specified in `odbc.ini`
DB2	The DB2 instance name
SQL Anywhere	The DSN entry specified in `odbc.ini`

d) If your database type is SAP Sybase, specify the Sybase server name specified in the Interfaces file.

Note

The Server Manager for UNIX systems does not prompt for the repository password except when creating a Job Server or adding a repository. To update the repository password in the **<DS_COMMON_DIR>**`/conf/DSConfig.txt` file, enter **u**. All options use the updated password from `DSConfig.txt` file.

6. When you are satisfied with your configuration changes, enter **q** and then **x** to exit the Server Manager.

Related Information

DSN-less and TNS-less connections [page 30]

1.6.11.2 To configure run-time resources

1. Ensure required environment variables are set, and run the Server Manager.

```
$ cd $LINK_DIR/bin/
$ . ./al_env.sh
$ ./svrcfg
```

The Server Manager main screen appears.

2. Enter `4` to configure run-time resources.
   The run-time resource information screen appears.
3. Enter `e` to edit the run-time resource configuration.
4. Accept the default *Pageable Cache Directory*, or specify a different location.

   ⚠ Restriction

   The Pageable Cache Directory path cannot exceed 70 characters.

   ℹ Note

   For memory-intensive operations such as Group By, Order By, and Detailed profiling, specify a pageable cache directory that fulfills the following criteria:

   - The directory contains enough disk space for your data. To estimate the amount of space required, consider factors such as the number of concurrently running jobs or data flows and the amount of pageable cache required by each concurrent data flow.
   - The directory exists on a separate disk or file system from the Data Services system and operating system.
   - The directory limits the disk space that data flows consume. The pageable cache uses all available disk space on the file system that contains the pageable cache directory. To limit the disk space that data flows consume, create a file system with a limited size. Use the new file system as the pageable cache directory.

   The software uses this directory in the following situations:

   - For pageable caching, the default cache type for data flows. For more information, see the *Performance Optimization Guide*.
   - When the software selects a file transfer type and *Automatic* is specified in the Data_Transfer transform.
5. Change the values for *Start port* and *End port* to restrict the number of ports used by the software for peer-to-peer communications. The default values are 1025 and 32767, respectively.

   The software uses these ports for peer-to-peer communications when sending data between data flows or sub data flows that are running on different Job Servers.
6. Specify whether you want to use the SSL security protocol on the communication paths between data flows and sub data flows.
7. Enter `q` and then `x` to exit the Server Manager.

Related Information

Performance Optimization Guide: Using grid computing to distribute data flow execution [page 2160]

1.6.11.3 To configure Access Servers

When you configure the location for an Access Server installation, SAP Data Services creates space for the Access Server log files.

1. Ensure required environment variables are set, and run the Server Manager.

   ```
   $ cd $LINK_DIR/bin/
   $ . ./al_env.sh
   $ ./svrcfg
   ```

   The Server Manager main screen appears.
2. Enter **4** to configure an Access Server.
   The Access Server information screen appears.
3. Enter the command for the configuration task you want to perform:

Command	Configuration task
c	Create a new Access Server.
e	Edit an existing Access Server.
d	Delete an existing Access Server.

4. When you create or edit an Access Server, specify additional configuration details:
   a) If you are editing an existing Access Server, enter the number of the Access Server shown in the Access Server configuration information screen.
   b) Specify the directory for the Access Server.
   c) Specify the TCP/IP port that the Access Server should use for communication.

   > Note
   >
   > You can configure more than one Access Server on the same computer, but each must have separate ports. If you enter a port number already in use, an error message appears.

   d) Specify any additional parameters for the Access Server.

   > Note
   >
   > Additional Access Server parameters can be viewed by typing `AL_AccessServer` at the command line. For more information, see "Real Time Performance" in the *Management Console Guide*.

   e) Specify whether you want to use the SSL security for real-time messaging on this Access Server.
   f) Specify whether you want to enable the Access Server.
5. When you delete an Access Server, specify the number of the Access Server to delete.

   > Note
   >
   > When you delete an Access Server, all Access Servers are stopped. When you exit the Server Manager, any remaining Access Servers restart.

6. When you are satisfied with your configuration changes, enter **q** and then **x** to exit the Server Manager.

1.6.11.4 To configure SSL paths

Use the Server Manager to configure the paths to SSL certificates and keyfiles.

> Note
>
> By default, the paths for the SSL certificate and keyfiles are automatically configured during installation. You do not need to change them unless you want to use your own certificates.

1. Ensure required environment variables are set, and run the Server Manager.

   ```
   $ cd $LINK_DIR/bin/
   $ . ./al_env.sh
   $ ./svrcfg
   ```

   The Server Manager main screen appears.
2. Enter `7` to configure SSL paths.
   The SSL configuration information screen appears.
3. Enter `e` to edit the SSL configuration.
4. Specify the SSL configuration information when prompted:
   a) The path to the server certificate file
   b) The path to the server private key file
   c) Whether you want to use a private key password file and the path to that file
   d) The directory where your trusted certificates are stored

   > Note
   >
   > The server certificate must be in PEM format. Valid extensions for certificates in the trusted certificates folder include `.pem`, `.crt`, and `.cer`. Regardless of the file extension, all certificate file contents must be in PEM format.
5. When you are satisfied with your configuration changes, enter `q` and then `x` to exit the Server Manager.

The certificate information specified in the Server Manager applies to all Data Services servers running on that physical machine (for example, any Job Servers, Access Servers, and so on.)

1.6.11.5 To start or stop the service

The SAP Data Services service (`AL_JobService`) is a daemon associated with `$LINK_DIR` that starts locally-configured Job Servers and Access Servers and then monitors them and attempts to restart them if they are not running.

After you exit the Server Manager, `AL_JobService` automatically retrieves any changes made to Job Servers or Access Servers. You do not need to restart `AL_JobService`.

1. Run the Server Manager.

   ```
   $ cd $LINK_DIR/bin/
   $ . ./al_env.sh
   $ ./svrcfg
   ```

> ℹ Note
>
> The second command sets required environment variables before `./svrcfg` starts the Server Manager.

The Server Manager main screen appears.

2. Enter **`1`** to control the service (Job service).
3. Start or stop the Job service.
   - Enter **`s`** to start the Job service.
   - Enter **`o`** to stop the Job service.
4. Enter **`q`** and then **`x`** to exit the Server Manager.

1.6.11.6 To configure SMTP email

The Server Manager can be used to specify SMTP server settings for the `smtp_to` email function. For more information, see "To define and enable the smtp_to function" in the *Reference Guide*.

1.6.12 Configuring Metadata Browsing Service and View Data Service

The installation process of Data Services configures the following services (under the server EIMAdaptiveProcessingServer) with default settings.

- Metadata Browsing Service
- View Data Service

These services are used by Information Steward to connect and view data in profiling sources. You might want to change the configuration settings to more effectively integrate Information Steward with your hardware, software, and network configurations.

1. Go to the *Servers* management area of the CMC.
2. Expand *Service Categories* in the tree panel and select *Enterprise Information Management Services*.
3. Double-click **`<computername.>`** *EIMAdaptiveProcessingServer* in the list in the right pane.
4. On the *Properties* window, find the applicable service for which you want to change settings.
5. After making desired changes in the service, click *Save* or *Save & Close*.

> ℹ Note
>
> Not all changes occur immediately. If a setting cannot change immediately, the *Properties* window displays both the current setting (in red text) and the updated setting. When you return to the *Servers* management area, the server will be marked as *Stale*. When you restart the server, it will use the updated settings from the *Properties* dialog box and the *Stale* flag is removed from the server.

Related Information

Metadata Browsing Service configuration parameters [page 98]
You can change the following properties of the Metadata Browsing Service.

View Data Services configuration parameters [page 99]
You can change the following properties of the View Data Service.

1.6.12.1 Metadata Browsing Service configuration parameters

You can change the following properties of the Metadata Browsing Service.

Server Configuration Parameter	Description	Possible Values
Service Name	Name of the service configuration.	Alphanumeric string with a maximum length of 64. The Service Name cannot contain any spaces. Default value: MetadataBrowsingService
Maximum Data Source Connections	Maximum number of data source connections that can be opened at any time under a service instance.	integer. Default value: 200
Retry attempts to launch Service Provider	Maximum number of attempts to launch a new service provider when there is contention to access a shared service provider.	Default value: 1
Stateful Connection Timeout (seconds)	Maximum duration which a stateful connection is open. Stateful connections include SAP Applications and SAP BW Source.	Default value: 1200
Stateless Connection Timeout (seconds)	Maximum duration which a stateless connection is open. Stateless connections include all relational database sources.	Default value: 1200
Recycle Threshold	Maximum number of requests that will be processed by a service before the Data Services backend engine is recycled to free memory that was allocated for metadata browsing.	Default value: 50000
Log Level	Level of logging of trace messages to the log file. Note If there is more than one instance of Metadata Browsing Service configured in the CMS, the same level of information is collected from all	Information Steward logs: ● None: Logging disabled. ● Info: Logging disabled. (same as None) ● Finer: All traces, requests, and responses.

Server Configuration Parameter	Description	Possible Values
	instances. The log level defined for the first running service is the level used.	Data Services logs: ● None: Logging disabled. ● Info: All traces. ● Finer: All traces, requests, and responses. Default level is Info.
Collect Connection Statistics	Enable or disable the collection of statistic information for each open connection.	Default is enabled.
Listener Port	Port number used to communicate with the Data Services backend engine. If you change the port number, you must restart the EIMAdaptiveProcessingServer for the change to take effect.	Four-digit port number that is not currently in use. Default value: 4010
JMX Connector Port	Port number used for the JMX Connector. If you change the port number, you must restart the EIMAdaptiveProcessingServer for the change to take effect.	Four-digit port number that is not currently in use. Default value: 4011

1.6.12.2 View Data Services configuration parameters

You can change the following properties of the View Data Service.

Server Configuration Parameter	Description	Possible Values
Service Name	Name of the service configuration.	Alphanumeric string with a maximum length of 64. The Service Name cannot contain any spaces. Default value: ViewData
Listener Port	Port number used to communicate with the Data Services backend engine. If you change the port number, you must restart the EIMAdaptiveProcessingServer for the change to take effect.	Four-digit integer. Default value: 4012
JMX Connector Port	Port number used for the JMX Connector. If you change the port number, you must restart the EIMAdaptiveProcessingServer for the change to take effect.	Four-digit integer. Default value: 4013

Server Configuration Parameter	Description	Possible Values
Batch Size (kilobytes)	Size of the data to be stored in a view data response.	Minimum value: 1000 Maximum value: 50000 Default value: 1000
Minimum Shared Service Providers	Minimum number of shared Data Services backend engines that need to be launched at the startup time of the service.	Default value: 1
Maximum Shared Service Providers	Maximum number of shared Data Services backend engines that can be launched during the time to service the view data requests.	Default value: 5
Maximum Dedicated Service Providers	Maximum number of dedicated Data Services backend engines that can be launched at any instant of time.	Default value: 10
Recycle Threshold	Maximum number of requests that will be processed by a service before the Data Services backend engine is recycled to free memory that was allocated for viewing data.	Any integer. Default value: 200
Number of attempts to launch service provider	Number of attempts to be made to try launching the Data Services backend engine instance.	Default value: 1
Maximum idle time for shared service provider (minutes)	Maximum number of minutes that a Data Services backend engine can remain without processing any requests. After this time is exceeded, the Data Services backend engine is shut down.	Default value: 120
Log Level	Level of logging of trace messages to the log file. Note If there is more than one instance of View Data Service configured in the CMS, the same level of information is collected from all instances. The log level defined for the first running service is the level used.	Information Steward logs: • None: Logging disabled. • Info: Logging disabled. (same as None) • Finer: All traces, requests, and responses. Data Services logs: • None: Logging disabled. • Info: All traces. • Finer: All traces, requests, and responses. Default level is Info.

1.6.13 Data Services CMC application settings

You can change the following settings of the Data Services Application on the CMC.

Data Services Application	Description
History Retention Period	Number of days to retain the job execution history. Default value: 30 • If you enter 0, then no job history is maintained. • If you enter a negative number, then job history is deleted.
Job Server Log Retention Period	Number of days to retain the Job Server log files. Default value: 30 • If you enter 0, then no job history is maintained. • If you enter a negative number, then job history is deleted.
Enable SSL communication for Metadata Browsing and View Data Services	Specifies whether or not to use SSL communications for Metadata Browsing Service and View Data Service of the EIM Adaptive Processing Server. Other SAP software products, such as SAP Information Steward, use the Metadata Browsing Service and View Data Service service to browse and import metadata and to view the data in connections.
Use Default SSL Settings	Specifies whether or not to use the default SSL keystore and certificates. Default value: No If you specify `No`, then you must enter values in *KeyStore File*, *KeyStore Password*, and *Key Password*.
KeyStore File	File name of the keystore that contains the key and all the certificates that are part of the certificate chain involved in signing the key. Default value: `DSJavaKeyStore.keystore`
KeyStore Password	Password to the keystore file.
Key Password	Password to the key inside the keystore file.
Encryption passphrase	Passphrase to use for encrypting passwords that are sent as part of requests to the Metadata Browsing Service and View Data Service. Other SAP software products, such as SAP HANA, use this *Encryption passphrase* to encrypt passwords when sending an open connection request. The backend engine will use this passphrase to decrypt the password and process the open connection request.

1.7 Monitoring

1.7.1 Monitoring jobs

Using the Administrator, you can monitor job execution of any batch job in a connected repository. You can monitor jobs that you run from the Administrator or from the Designer.

This section discusses how you can use the Administrator to view a batch job's overall status and statistics.

1.7.1.1 To view overall status of executed jobs

The *Batch Job Status* page lists each batch job execution. Use this list to view the overall status of each execution and to access more detailed statistics and log files.

1. Select ▶ *Batch* ▸ `<repository>` ◢.

   To view jobs in all repositories from this page, select ▶ *Batch* ▸ *All Repositories* ◢. (The All Repositories option appears under the Batch Job node if more than one repository is connected to the Administrator.)

   The *Batch Job Status* page shows each instance of job execution for the selected repository.
2. You can filter the list of batch jobs displayed by selecting a job name and/or when the job executed.

   To filter by job, select the job name from the drop-down *Job name* list. Or type the name, or type part of the name and a wildcard character (`%` or `*`), into the wildcard search string box and click *Search*. The Search field is not case sensitive and spaces are allowed.

   To filter by when the job(s) executed, select one of the following options:
   - Show last execution of a job.
   - Show status relative to today—Select the number of previous days over which to view job executions.
   - Show status as a set period—Type the date range or select the dates by clicking the calendar icons.
3. Click *Search* to update the list.
4. To sort the values in each column in ascending or descending order, click the column heading.
5. Find the overall status of a batch job execution by examining the indicator in the *Status* column.

Indicator	Description
✓	A green icon indicates that the batch job ran without error.
!	A yellow icon indicates that the batch job has one or more warnings.
✗	A red icon indicates that the batch job experienced an error.

   Check the End Time column to see if or when the job completed.
6. If a batch job execution has a red status, examine the trace, monitor, and error logs for more information.
7. To view detailed information about a particular job execution, look at the data on the Batch Job Status page.

   If the job includes a server group icon in the Job Server column, this indicates that the job was executed by a server group. You can roll your cursor over the server group icon to view the name of the server group. The Job Server listed is the Job Server in the server group that executed the job.

i Note

All jobs can be executed by an explicitly selected Job Server or by a server group. If you choose to execute a job using a server group, you can use this page to see which Job Server actually executed the job. If you explicitly select a Job Server to execute a job, then even if it is also part of a server group, the server group icon does not appear for the job in the Job Server column on this page.

Related Information

Management Console Guide: Setting the status interval [page 1877]

1.7.1.2 Statistics

For each job execution, the Administrator shows statistics. Statistics quantify the activities of the components of the job. You can view the following types of statistics:

- Job statistics such as time spent in a given component of a job and the number of data rows that streamed through the component.
- Data flow object statistics such as the cache size used by a transform within a data flow.

1.7.1.2.1 To view job statistics

To help tune the performance of a job, review job statistics.

1. Select *Batch* **`<repository>`**.
2. On the Batch Job Status page, find a job execution instance.

   Identify an instance using the page sub-title (which provides the name of the repository on which SAP Data Services stores the job) and the following column headings on this page:

Column	Description
Status	See Overall Status.
Job Name	The name that you gave the job in the Designer.
System Configuration	Name of a set of datastore configurations that the job uses to connect to source and target databases when it executes. Each value in this column is a link. Click the link to view the set of datastore configurations in the system configuration. To change the system configuration, click the *Batch Job Configuration* tab, then use the *Execute*, *Add Schedule* or *Export Execution Command* pages.
Job Server	The server that ran this job.
Start Time	The date and time that the job execution instance started.

Column	Description
End Time	The date and time that this job execution instance stopped.
Duration	The time (in seconds) that the job took to complete.
Run #	The number of times that this instance ran before completing.

3. Under *Job Information* for an instance, click *Monitor*.

   The Administrator opens the Job Server Monitor Log Viewer page. This page shows several statistics about this instance of job execution starting with the name of the monitor log file.

   After the file name, each line in the log provides the following information:

Column	Description
Path Name	Indicates which object (step in a data flow) is executing.
State	Indicates the run-time order of the processes in the execution of the transform object and the states of each process. These are not error status states. However, if a process state is *Proceed* and it never changes to *Stop*, this indicates the process ran with errors.
Initializing	Indicates that the job is initializing.
Optimizing	Indicates that the job is optimizing.
Proceed	Indicates that the process is executing.
Stop	Indicates that the process ended without error.
Row Count	Indicates the number of rows processed through this object. This value updates based on the *Monitor sample rate (# of seconds)* set as an execution option on the Execute Batch Job page.
Elapsed Time	Indicates the time (in seconds) since the object received its first row of data.
Absolute Time	Indicates the time (in seconds) since the execution of this entire data flow (including all of the transforms) began.

Related Information

To view overall status of executed jobs [page 102]

1.7.1.2.2 Data flow statistics

To help tune the performance of a data flow, review data flow statistics.

Related Information

Performance Optimization Guide: Measuring performance of jobs [page 2107]

1.7.1.3 To ignore error status

The *Batch Job Status* page includes an option to *Ignore Error Status*. Use this option if you are working through jobs with warnings or errors on this page and you want to mark a row so that you know you are finished looking at its logs.

1. On the *Batch Job Status* page, select the job or jobs that you want to ignore.
2. Click the *Ignore Error Status* button.

   The page refreshes and the rows you selected now display a green status icon.

1.7.1.4 Deleting batch job history data

The *Batch Job Status* page includes an option to delete information about how a job ran. If you want to manually delete rows from this page, select the rows that you want to delete, then select *Delete*. You can also manage this information by setting the Administrator's log retention period.

> i Note
>
> When you delete this job information, the software also clears data validation statistics from Data Validation Metadata Reports.

1.7.1.5 Stopping a running job

The *Batch Job Status* page includes an option to abort batch jobs. If a batch job is running and you need to stop it, select the check box next to the job name and click *Abort*.

1.7.1.6 To delete trace, monitor, and error logs for a batch job

You can view and delete trace, monitor, and error logs for job instances from the *Batch Job Status* page. The corresponding Job Server must be up and running to view or delete these logs.

You can set trace log options on the *Execute Batch Job* page.

You can use the *Delete* button on the *Batch Job Status* page to delete a set of batch log history files from a Job Server computer and its corresponding repository.

1. Select ▶ *Batch* ▶ `<repository>` ◀.
2. Select the job or jobs for which you want to delete logs.

   Alternately, you can click *Select All*.
3. Click *Delete*.
   The batch log history files are deleted from the Job Server computer and its corresponding repository.

1.8 Lifecycle management

1.8.1 Migration basics

About this section

Migration as it relates to SAP Data Services is the process of moving applications through multiple development phases into production. The software supports simple and complex application migration through all phases into production.

Related Information

Development phases [page 106]
Migration mechanisms and tools [page 108]

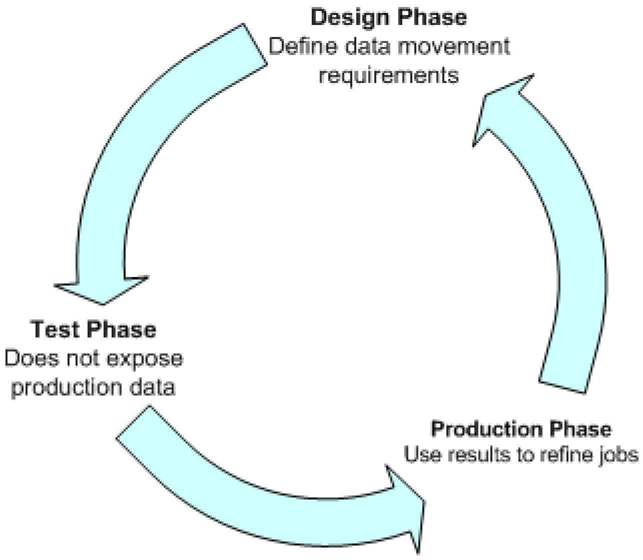
1.8.1.1 Development phases

The ETL application development process typically involves three distinct phases:

- Design phase
- Test phase
- Production phase

You can use SAP Data Services in all three phases. Because each phase might require a different repository to control environment differences, the software provides controlled mechanisms for moving objects from phase to phase.

Each phase could involve a different computer in a different environment with different security settings. For example, design and initial test may only require limited sample data and low security, while final testing may require a full emulation of the production environment including strict security.



Design Phase
Define data movement requirements
Test Phase
Does not expose production data
Production Phase
Use results to refine jobs

1.8.1.1.1 Design phase

In this phase, you define objects and build diagrams that instruct SAP Data Services in your data movement requirements. The software stores these specifications so you can reuse them or modify them as your system evolves.

Design your project with migration to testing and final production in mind. Consider these basic guidelines as you design your project:

- Construct design steps as independent, testable modules.
- Use meaningful names for each step you construct.
- Make independent modules that can be used repeatedly to handle common operations.
- Use test data that reflects all the variations in your production data.

1.8.1.1.2 Test phase

In this phase, you use SAP Data Services to test the execution of your application. At this point, you can test for errors and trace the flow of execution without exposing production data to any risk. If you discover errors during this phase, return the application to the design phase for correction, then test the corrected application.

Testing has two parts:

- The first part includes designing the data movement using your local repository.
- The second part includes fully emulating your production environment, including data volume.

The software provides feedback through trace, error, and monitor logs during both parts of this phase.

The testing repository should emulate your production environment as closely as possible, including scheduling jobs rather than manually starting them.

1.8.1.1.3 Production phase

In this phase, you set up a schedule in SAP Data Services to run your application as a job. Evaluate results from production runs and when necessary, return to the design phase to optimize performance and refine your target requirements.

After moving the software into production, monitor it in the Administrator for performance and results. During production:

- Monitor your jobs and the time it takes for them to complete.
  The trace and monitoring logs provide information about each job as well as the work flows and data flows contained within the job.
  You can customize the log details. However, the more information you request in the logs, the longer the job runs. Balance job run-time against the information necessary to analyze job performance.
- Check the accuracy of your data.

To enhance or correct your jobs:

- Make changes in your design environment.
- Repeat the object testing.
- Move changed objects back into production.

1.8.1.2 Migration mechanisms and tools

SAP Data Services provides two migration mechanisms:

- Export/import migration works best with small to medium-sized projects where a small number of developers work on somewhat independent Data Services applications through all phases of development.
- Multi-user development works best in larger projects where two or more developers or multiple teams are working on interdependent parts of Data Services applications through all phases of development.

Regardless of which migration mechanism you choose, it is recommended that you prepare for migration using one or more tools that best fit your development environment for more information). The mechanism and tools you use will depend on the needs of your development environment.

If your source data will come from multiple, homogeneous systems, it is recommended that you use Datastore and system configurations tools.

When migrating applications in a multi-user environment, it is strongly recommended that you use Naming conventions for migration.

Related Information

Export/import migration [page 109]
Designer Guide: Multi-user development [page 798]
Preparing for migration [page 110]
Datastore and system configurations [page 114]
Designer Guide: Datastores, Creating and managing multiple datastore configurations [page 239]

Naming conventions for migration [page 111]

1.8.1.2.1 Which mechanism is best?

Although SAP Data Services supports a multi-user environment, you may not need to implement this architecture on all projects. If your project is small to medium in size and only consists of one or two developers, then a Central Repository may not be a necessary solution to integrating the work of those developers.

For example, only two consultants worked on a certain HR data mart application. The Development system was designed so that while Consultant 1 managed the Master Repository, Consultant 2 worked on a new section within a complete copy of the Master Repository.

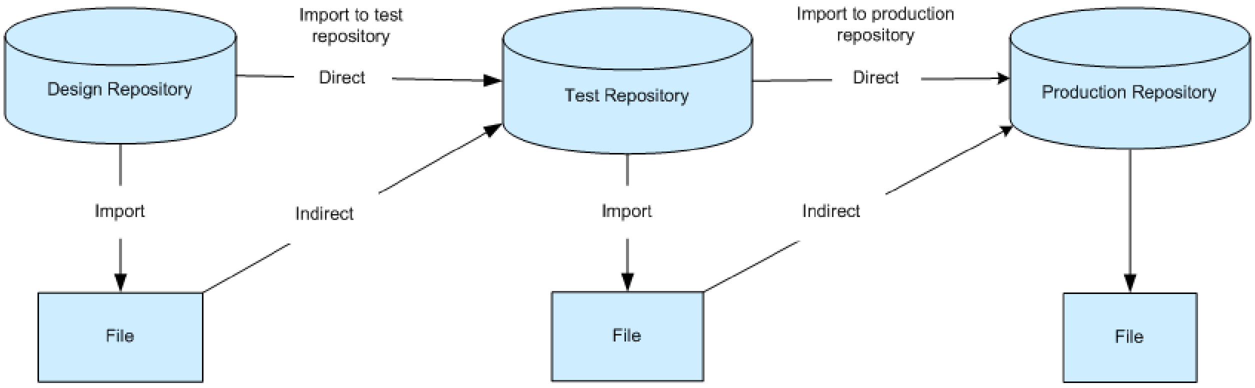
Consultant 2 then exported this new section back into the Master Repository using the export utility that allows objects to be 'Created', 'Replaced', or 'Ignored'. After updating the Master Repository, Consultant 2 took a new complete copy of the Master Repository, overwriting the previous copy.

Use the following matrix to help you determine which mechanism and tools would work best in your environment.

Situation/requirements	Migration Mechanisms		Tools	
	Export/import	Multi-user	Naming conventions	Configurations
Small to medium-sized project	X		O	O
Multiple-team project		X	X	O
Source data from multiple, homogeneous systems			X	X
Different source or target database among environments			X	X
Need a "fast and easy" migration solution	O		X	
Optimal solution: X Compatible solution: O				

1.8.1.2.2 Export/import migration

Export/import is the basic mechanism for migrating SAP Data Services applications between phases. First, you export jobs from the local repository to another local repository or to an intermediate file which you can then import into another local repository. For example, when moving from design repository to test repository, you export from the design repository to a file, then import the file to your test repository.



If you find application errors during testing, you can correct them in the development environment, then export the corrected version and import it back into the test repository for retesting.

Related Information

Export/Import [page 117]

1.8.1.2.3 Multi-user migration

You can also migrate SAP Data Services applications between phases in more complex development environments. Instead of exporting and importing applications, multi-user development provides a more secure check-in, check-out, and get mechanism, using a central repository to store the master copies of your application elements. Multi-user development includes other advanced features like labeling and filtering to provide you more flexibility and control in managing application objects.

Related Information

Designer Guide: Migrating multi-user jobs [page 824]

1.8.2 Preparing for migration

About this section

Before you develop SAP Data Services applications, it is recommended that you first set up a comprehensive structure to facilitate the migration process between development phases.

This section discusses tools that can help you build your migration structure.

It is recommended that you implement standardized naming conventions for connectivity between computer systems. Add datastore and system configurations to more easily work with multiple homogeneous systems.

Related Information

Naming conventions for migration [page 111]
Datastore and system configurations [page 114]

1.8.2.1 Naming conventions for migration

The best way to ensure fast and seamless migration is to use common naming conventions across all systems and phases of all your development environments.

Just as it is recommended that you standardize object prefixes, suffixes, and path name identifiers to simplify your projects internally, we also recommend the use of naming conventions externally for migration purposes.

To ease migration, use common naming conventions for:

- Connections to external datastores
- Directory locations
- Schema structures and owners

You want to make it as quick and easy as possible to migrate applications between users and between phases. This translates to significantly reducing or eliminating time spent reconfiguring your jobs to work in each specific environment.

While the actual data you are extracting, transforming, and loading usually differs by database, the essential structure of the data should be the same on every database with which you want the same applications to work. Therefore, it makes the most sense to standardize your database naming and structuring before starting the development process.

Related Information

Designer Guide: Naming conventions for objects in jobs [page 208]
Connections to external datastores [page 112]
Directory locations [page 113]
Schema structures and owners [page 113]

1.8.2.1.1 Connections to external datastores

Migration is the process of moving objects between local repositories, whether directly using the Export/Import method or indirectly using the Multi-user development method. Regardless of method, you must consider how the migration will impact connection configurations associated with your jobs.

Using generic naming for similar external datastore connections reduces the time you spend on reconfiguring the connections to the same database type. For example, you should choose the same logical name for all your Oracle datastore connections to the same type of database structure regardless of migration phase environment.

You can make connection names meaningful to a certain phase and specific computer system names (Test_DW, Dev_DW, Prod_DW), however if you choose this naming structure, it is recommended that you use datastore configurations for migration purposes.

Development phase	Test phase
User name: Dev_DW	User name: Test_DW
Password: Dev_DW	Password: Test_DW
Host String: Dev_DW	Host String: Test_DW

For a job to run against Test and Development, it would have to use Test_DW and Dev_DW and this would require you to create different datastore configurations for when the job runs against the Test or the Dev instance, respectively.

Alternatively, you could call the connection string DW and regardless of what instance you ran the job against, it would run without users having to create multiple datastore configurations.

Development Phase		Test Phase	
Database A	Datastore Connection	Database B	Datastore Connection
User name: DW	User name: DW	User name: DW	User name: DW
Password: DW	Password: DW	Password: DW	Password: DW
Host string: DW	Owner name: DW	Host String: DW	Owner name: DW

Examples:

- There is one Oracle source system in your company that processes order entry data. Multiple instances of this system exist for development, test, and production purposes. Therefore, you name the connection string to your Oracle source system "ORDER_SYSTEM". Then in all phases, you configure that name to point to the correct (phase-specific) instance of the system.
- Name the connection string to your target data warehouse "DW" then point it to different databases depending on whether you are in the development, test, or production environment.

When you use this generic, cross-phase naming method, you cannot access both dev and test from the same computer (since the connection string maps only to one instance). If you require access to both, use multiple datastore configurations.

Related Information

Export/Import [page 117]

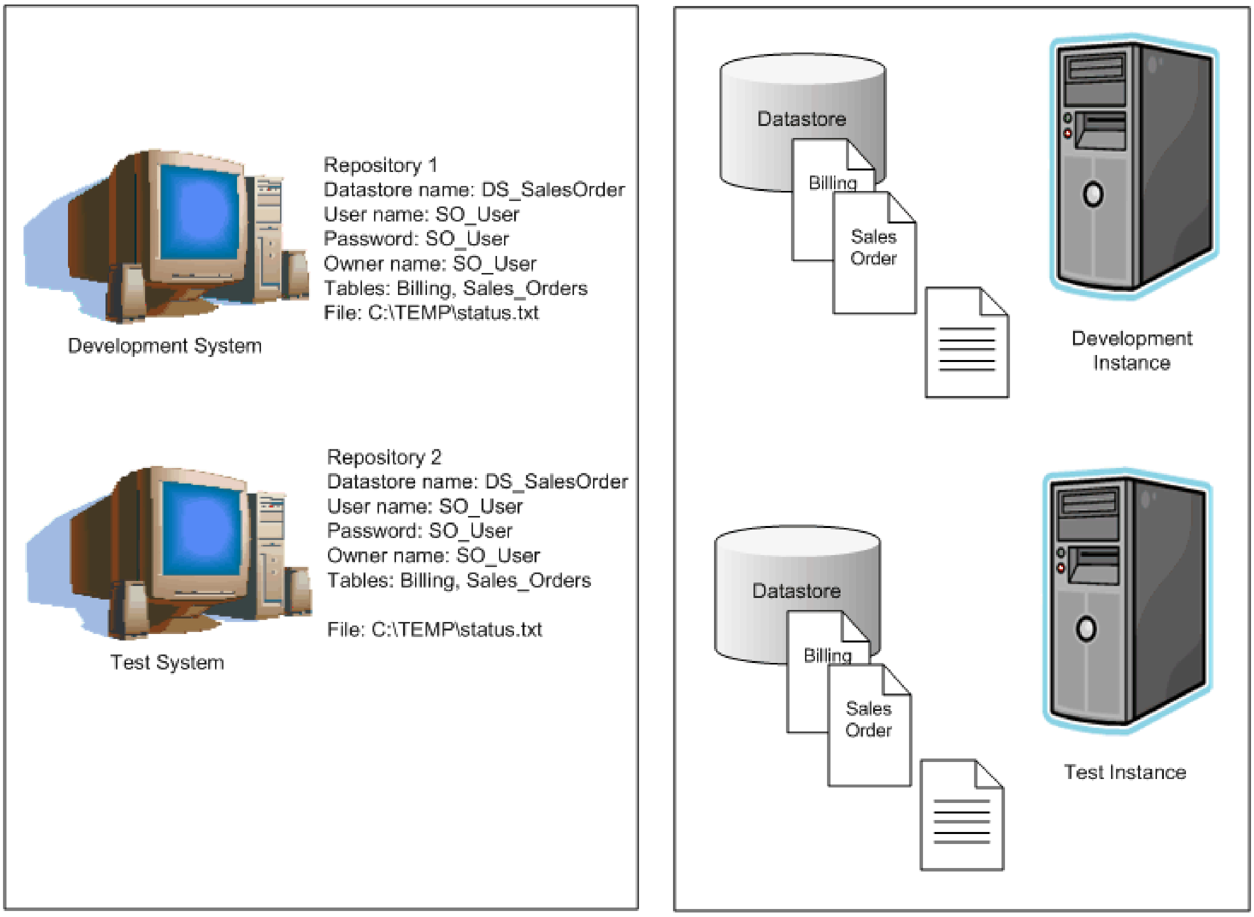
Designer Guide: Multi-user development [page 798]

1.8.2.1.2 Directory locations

It is recommended that you use logical directory names (for example, `X:\`) or point to common local drives to standardize directory location. For example, since every computer has a `C:\` drive, pointing to the directory location, `C:\TEMP` would be a safe, reproducible standard.

1.8.2.1.3 Schema structures and owners

To further facilitate a seamless structure between development phases, give all your database instances the same owner name for the same schema structures from which you are reading and to which you are loading. Regardless of name, the owner of each schema structure can vary and the software will reconcile them.



Repository 1
Datastore name: DS_SalesOrder
User name: SO_User
Password: SO_User
Owner name: SO_User
Tables: Billing, Sales_Orders
File: C:\TEMP\status.txt

Repository 2
Datastore name: DS_SalesOrder
User name: SO_User
Password: SO_User
Owner name: SO_User
Tables: Billing, Sales_Orders

File: C:\TEMP\status.txt

1.8.2.2 Datastore and system configurations

Datastore and system configurations are powerful tools for reducing the configurations required to execute the same logic against different datastore environments. With configurations, migration between development phases becomes faster and more simplified.

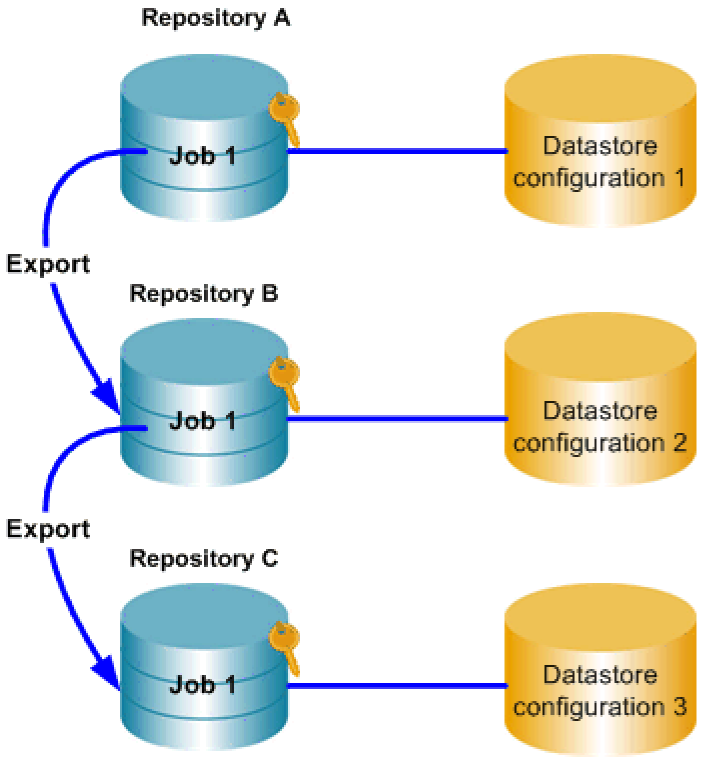
Related Information

Datastore configurations and migration [page 114]
Multiple configurations in multi-user environments [page 116]

1.8.2.2.1 Datastore configurations and migration

Without multiple configuration datastores, each time you export/import from one repository to another, you may need to spend time reconfiguring datastore connections to work with the new repository (and sometimes new host computer).

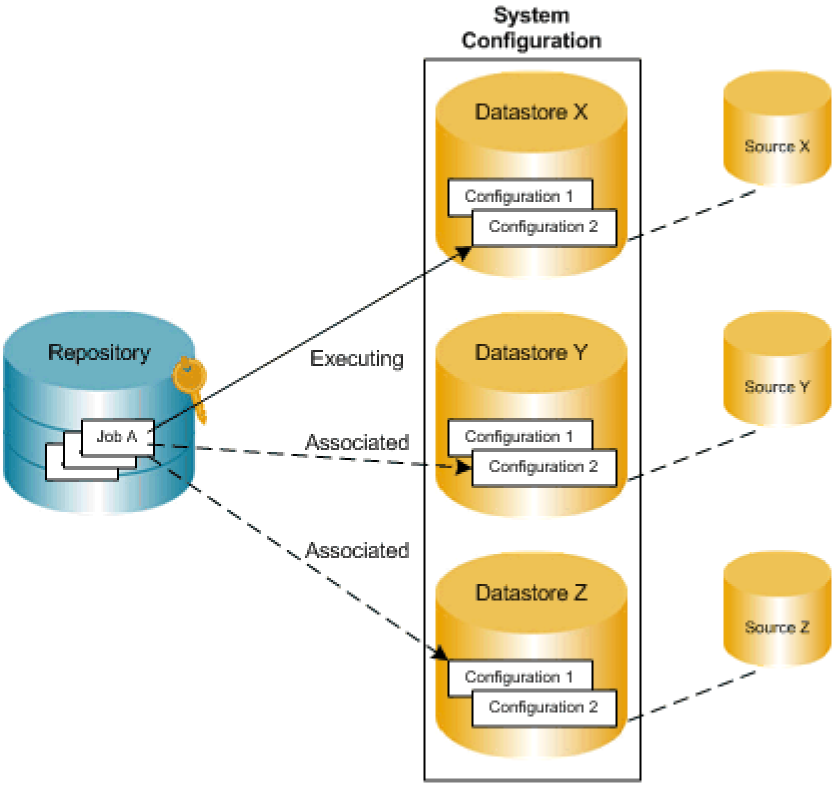
Without multiple configurations, each job in a repository can run only against one datastore configuration.



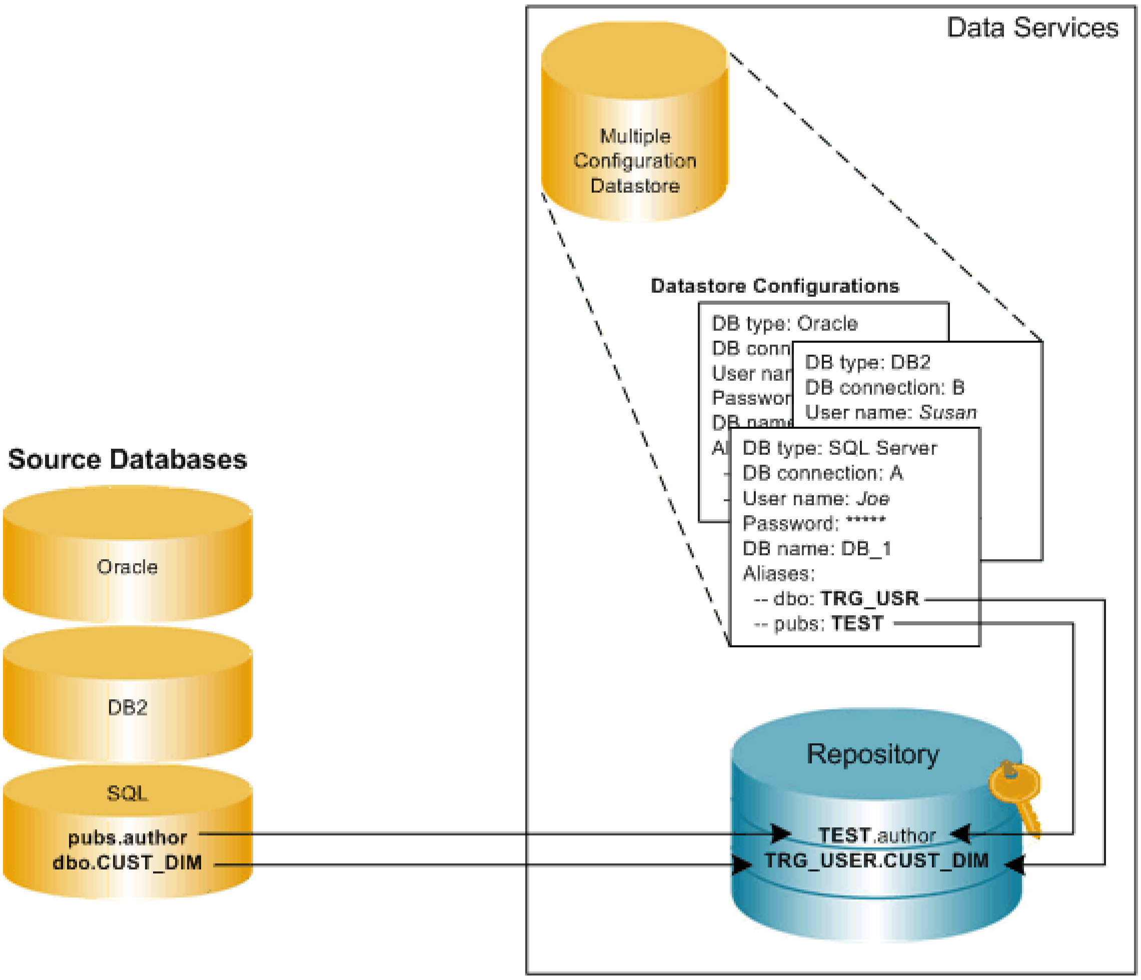
Repository A
Job 1
Datastore configuration 1
Export
Repository B
Job 1
Datastore configuration 2
Export
Repository C
Job 1
Datastore configuration 3

With multiple configurations, instead of a separate datastore (and datastore configuration) for each database instance, you can associate multiple datastore configurations with a single datastore definition.

Each system configuration defines a set of datastore configurations that you want to use together when running a job. You must create datastore configurations for the datastores in your repository before you can create system configurations.



All objects you want to import into a multiple configurations datastore must share the same owner.



Related Information

Designer Guide: Datastores, Creating and managing multiple datastore configurations [page 239]

1.8.2.2.2 Multiple configurations in multi-user environments

SAP Data Services also supports a multi-user development environment. A team can work together on an application during development, testing, and production phases. Further, different teams can work on the different phases simultaneously.

Individual users work on an application in their unique local repositories. The team uses a central repository to store, check in, and check out objects that belong to the application master copy. The central repository preserves all versions of an application's objects, allowing you to revert to a previous version if needed.

The easiest way to set up your environment to work with multi-user functionality is by establishing the exact same environment naming standards among your developers. In each developer's environment, the configuration would be different. For example a database connection string would point to their local database. However, if implementing these naming standards is not possible, you can still save time and streamline your multi-user environment by using multiple-configuration datastores.

For example, if your developers use databases with the same metadata structure but different database instances and owners, you can define a datastore configuration for each developer on your design team, mapping different owners to a common set of aliases used by all. This way, they can share and contribute to the same projects without having to set up their datastore connection information each time they check out a project from the central repository.

1.8.3 Export/Import

Overview of export/import

The simplest type of migration in Data Services is called export/import.

This section discusses the export/import method in SAP Data Services Designer.

1.8.3.1 Exporting/importing objects

The export feature gives you the flexibility to manage and migrate projects involving multiple developers and different execution environments. When you export a job from a development repository to a production repository, you can change the properties of objects being exported to match your production environment.

In particular, you can change datastore definitions—application and database locations and login information—to reflect production sources and targets.

You can export objects to another repository or a flat file (.atl or .xml). If the destination is another repository, you must be able to connect to and have write permission for that repository, and your repository versions must match.

You cannot export read-only transform configurations.

Related Information

The Designer Export editor [page 118]
Exporting objects to another repository [page 119]
Exporting objects to a file [page 121]
Exporting a repository to a file [page 121]
Importing from a file [page 122]
Export and import options [page 163]

1.8.3.1.1 The Designer Export editor

In the Designer Export editor, you specify the objects you want to export and an export location. In Designer, choose *Tools* > *Export* or select an object and right-click *Export* to open the Export editor.

To specify an object to export, drag the object from the object library into the *Objects to Export* window.

The Object to Export window shows the final list of objects to be exported. When you drag any object from the object library, the datastores, file formats, custom functions, and transform configurations included in the object definition are automatically added to the other export sections. Each object in an export window opens to show objects called by this object.

You can control which associated objects to exclude or include. For example, you can export a work flow and all tables contained in the work flow without exporting an associated data flow.

To control which objects to export, either select an object, right-click, and choose a shortcut menu option, or select the white space in the Export editor, right-click, and choose a shortcut menu option:

Option	Description
Export	Starts the export process.
Exclude	Removes only the selected object from the list of objects to be exported. The object remains in the list, but its exclusion is indicated by a red "x" on the object icon. All occurrences of the object are excluded. When you export the list, excluded objects are not copied to the destination. Objects called by this object are not removed from the list of objects to be exported, unless they are specifically excluded. i Note You cannot export read-only transform configurations, so they are automatically excluded.
Include	Adds an excluded object to the export plan. The red "x" on the icon disappears. All occurrences of the object are included. When you export, the included objects are copied to the destination.

Option	Description
Exclude Tree	Removes the selected object and all objects called by this object from the export. The objects remain in the list, but their exclusion is indicated by a red "x" on the icons—the selected object and any objects it calls are excluded. When you export the list, the excluded objects are not copied to the destination.
Include Tree	Adds the selected excluded object and the objects it calls to the export list. The red "x" on the selected object and dependents disappears. When you export the list, the included objects are copied to the destination.
Exclude Environmental Information	Removes all connections (datastores and formats) and their dependent content (tables, files, functions) from the objects in the Export editor. Note that if you exclude datastores during export, data flows that depend on those datastores will not execute properly unless your destination repository has the same set of datastores with the same database types and versions (connection strings can be different). When you export, excluded objects are not copied to the destination. From the white space in the Export editor, right-click to select Exclude environmental information from the menu. Using this option you can export jobs without connections as a way to avoid connection errors. If you decide to use this option, it is recommended that you configure datastores and formats for the new environment separately.
Clear All	Removes all objects from all sections of the editor.
Delete	Removes the selected object and objects it calls from the Export editor. Only the selected occurrence is deleted; if any of the affected objects appear in another place in the export plan, the objects are still exported. This option is available only at the top level. You cannot delete other objects; you can only exclude them.

Designer Guide: Datastores, Creating and managing multiple datastore configurations [page 239]
Reference Guide: Datastore [page 860]

1.8.3.1.2 Exporting objects to another repository

You can export objects from the current repository to another repository. However, the other repository must be the same version as the current one. The export process allows you to change environment-specific information defined in datastores and file formats to match the new environment.

1. In the object library, choose an object to export. Right-click and choose *Export*.

The Export editor opens in the workspace. To add more objects to the list of objects to export, drag the objects from the object library into the Objects to Export section of the editor.

2. Refine the list of objects to export.

   You can use the options available in the right-click menu for each object to include or exclude the object from the export list.
3. When your list is complete, right-click and choose *Export*.
4. In the *Export to repository* window, enter your user credentials for the Central Management Server (CMS).

Option	Description
System	Specify the server name and optionally the port for the CMS.
User name	Specify the user name to use to log into CMS.
Password	Specify the password to use to log into the CMS.
Authentication	Specify the authentication type used by the CMS.

5. Click *Log on*.
   The software attempts to connect to the CMS using the specified information. When you log in successfully, the list of local repositories that are available to you is displayed.
6. Select the repository you want to use as the export target.
7. Click *Next* to continue exporting to the selected repository.
8. In *Export Confirmation* window, verify the components to export.

   The Destination status column shows the status of the component in the target database and the proposed action.

Destination Status	Action
Does not exist	Create/Exclude
Exists	Replace/Exclude

   To edit an action, select any number of objects (using the SHIFT and CTRL keys) and select either *Create*, *Exclude*, or *Replace* from the Target Status list box.
9. Click *Next*.
10. In the *Datastore Export Options* window, select the datastore, change the owner of a table or the connection properties of the datastore as necessary, and click *Advanced*.
11. Change the database connection information as required by the target database and click *Next*.
12. In the *File Format Mapping* dialog, select a file and change the Destination Root Path, if necessary.

    You can change the Destination Root Path for any file formats to match the new destination.
13. Click *Finish*.

SAP Data Services copies objects in the Export editor to the target destination. When copying is complete, the objects display in the *Output* window. The *Output* window shows the number of objects exported as well as a list of any errors.

1.8.3.1.3 Exporting objects to a file

You can also export objects to a file. If you choose a file as the export destination, Data Services does not provide options to change environment-specific information.

1. Right-click an object in the object library, and click *Export*.
   The Export editor opens in the workspace. To add more objects to the list of objects to export, drag the object from the object library into the Objects to Export section of the editor.
2. Refine the list of objects to export.

   You can use the options available in the right-click menu for each object to include or exclude the object from the export list.
3. When your list is complete, right-click the editor and click *Export to ATL file* or *Export to XML file*, depending on the type of file format that you want to export.

   > 🡆 Tip
   >
   > ATL is the software's proprietary format. Using XML might make repository content easier for you to read. XML can also be used with the object creation XML toolkit. For more information, see the *Integrator Guide*.

   By default, non-executable elements are excluded from exported XML files to improve readability. For example, the exact arrangement of transforms within a data flow would not be maintained, and the transforms would be arranged automatically when imported back into the software.

   If you want to include these elements, deselect *Exclude non-executable elements from exported XML document*. This option is available in the *Designer* > *General* group in the *Tools* > *Options* menu.
4. Specify the location for the exported file.
5. Enter the case-sensitive passphrase to use to encrypt any passwords that are stored in the objects you are exporting and click *OK*.

   > ℹ Note
   >
   > You must enter the same passphrase when you import the file back into a repository. If you use an incorrect passphrase, the software will still import the objects, but any stored passwords will be removed.

This option (*Export to XML file*) allows SAP Data Quality Management SDK developer to configure Data Quality transforms within the Data Services Designer and export the settings to XML files for use with the Data Quality Management SDK.

However, if you employ Data Services as a configuration tool for the Data Quality Management SDK, Data Services does not support the creation of a change log for changes to the configuration. You can employ the Data Services central repository concept to manage changes to the Data Quality transforms, but no change log is created.

1.8.3.1.4 Exporting a repository to a file

You can also export an entire repository to a file. When you export or import a repository, jobs and their schedules (created in SAP Data Services) are automatically exported or imported as well. Schedules cannot be exported or imported without an associated job and its repository.

If you choose a file as the export destination, the software does not provide options to change environment-specific information.

1. From the object library, right-click and choose *Repository* > *Export To File*.

   A window opens to prompt you for the destination of the export file. You can browse the directory to change the location, set the file type (XML or ATL), and enter a name for the file.
2. Click *Save*.
3. Enter the case-sensitive passphrase to use to encrypt any passwords that are stored in the repository and click *Export*.

   > Note
   >
   > You must enter the same passphrase when you import the file back into a repository. If you use an incorrect passphrase, the software will still import the objects, but any stored passwords will be removed.

   The repository is exported to the file.

1.8.3.1.5 Importing from a file

Importing objects or an entire repository from a file overwrites existing objects with the same names in the destination repository.

1. There are two ways to import repository files into another repository. Use *Tools* > *Import from file*, or in the object library, right-click and choose *Repository* > *Import from File*.

   A window opens for you to specify the file to import. You can import individual files or the whole repository using either an ATL, XML, DMT, or FMT file type. (ATL is the software's internal scripting language. DMT and FMT are files exported from the SAP Data Quality Management or IQ8 products.)
2. Select a file to import and click *Open*.
3. Enter the passphrase that was used to encrypt passwords when the file was exported and click *Import*.

   > Note
   >
   > If the passphrase does not match the passphrase you used to export the file, the import will continue, but any passwords will be emptied and need to be reset manually.
4. Perform any additional steps that may vary depending on the type of the file you are importing.
   - If you attempt to import an ATL file saved from an earlier version of SAP Data Services, a warning displays indicating that the version of the ATL file is lower than the repository version and that the ATL file you are about to import might contain objects that do not make optimal use of your upgraded repository. For example, new options for some features might not be available. To update an ATL file, import it into a repository of the same version then upgrade that repository. To abort the import, click *No*. To continue with the import, click *Yes*.
   - If you attempt to import an ATL file saved from a repository that is later than your current version, an error message displays indicating that the version of the ATL file is higher than the repository version and cannot be imported. Click *OK*.
   - If you attempt to import a DMT or FMT file, the software displays the File Format Editor to allow you to allow you to complete missing values for the properties of the file. Also, because DMT and FMT formats

support field names longer than 60 characters, you must uniquely rename any field names longer than 60 characters prior to importing the file.

1.8.3.2 Backing up repositories

Use your DBMS utilities to back up your repositories regularly. For information, refer to your DBMS documentation.

1.8.3.3 Maintaining Job Server performance

If you are designing jobs, typically you might use the same computer for your Designer, repository, and Job Server. In addition, you might use the same datastore for both your repository and your target database.

However, when you migrate your jobs into a test environment, the Job Server could move to a separate computer (typically from a Windows to a UNIX platform). The SAP Data Services Job Server computer uses source, target, and repository database client libraries to extract, transform, and load data according to a job's design. Therefore, the Job Server computer must have a database client installed for each database you are using to run a job. In addition, you can localize source and target databases using locale and code page settings.

When migrating jobs between different Job Servers verify that the code page used by each source and target database is the same as the code page set for the corresponding database client on the Job Server's computer.

The database client code page used by a Job Server on a Windows might be different from the one used on UNIX. For example, the Oracle client code page MS1252 on Windows should be changed to the ISO88591 code page on UNIX.

The software allows different code pages to be used in sources and targets. Mismatched locale settings do not cause errors and the software attempts to treat equivalent settings without any transcoding. However, mismatches may result in performance degradation from transcoding done by the software during job execution.

If your jobs do not require the use of different locales, you can increase performance by ensuring that default locales are not mismatched. After migration, if you notice a significant difference between the speed of design and test environments, check locale settings. In the Designer, check to see that datastore code pages for sources and targets match client code pages on the Job Server computer.

Related Information

Reference Guide: Locales and Multi-Byte Functionality [page 1793]

1.8.4 The Enhanced Change and Transport System

The Change and Transport System (CTS) transports changes between SAP systems in your system landscape. The Enhanced CTS (CTS+) promotes non-SAP (non-ABAP) contents across repositories, i.e. enables you to transport application objects between systems in your system landscape, if required, alongside ABAP objects. You can administer non-ABAP systems in a CTS transport domain in SAP NetWeaver Application Server ABAP. You transport these objects in a transport requests. When you run imports in Transport Management System (TMS), the system performs the appropriate copying of objects in an automatic and controlled manner.

The enhanced CTS functions are available with Support Package Stack (SPS) 15 of SAP NetWeaver 7.0. You also require an SAP Application Server Java with the same Support Package level.

For more information, see *SAP Note 1003674*

1.8.4.1 Transporting changes: Business context

Very often Data Services is installed in multi-tier system landscapes. Typically the Data Services customer development is done in a development Data Services system, the changes then are consolidated in a test/consolidation Data Services system and at the end the changes are brought to the production Data Services system.

To support controlled transport from the development system to the follow-up systems the SAP NetWeaver CTS transport management system was developed. With Enhanced CTS (CTS+) this is extended to Non-ABAP transports, for example for Data Services change files.

The integration of Data Services CTS+ transport management allows to provide all development changes made in the Development System to the Quality System and then to the Production System in a system controlled way.

With the transport of Data Services changes using a CTS+ system the following goals are achieved:

- Trace changes performed in an application system landscape.
- Avoid multiple erroneous manual modifications on different dependent repositories, when changes are done in a development system, tested in a test system and used in a production system.
- Transport changes through a customer-defined multi-tier application system landscape is possible.
- Guarantee similarity or even equality of all systems on the transport route in the application system landscape, regarding the application customer development.

1.8.4.2 Background information

Change and Transport System: Overview (BC-CTS)

The first reference to be consulted is the standard Change and Transport system documentation - CTS Reference Manual: *http://help.sap.com/saphelp_nw70/helpdata/EN/3b/dfba3692dc635ce10000009b38f839/frameset.htm*

The SP stack levels of the CTS system mentioned in this guide refer to the SP stacks of SAP NetWeaver. Keep in mind that SP stack levels for SAP Solution Manager are different and do not contain the same functionality as an SP stack for SAP NetWeaver. Take a look at the basis release and SP stack of SAP NetWeaver that your Solution Manager is using.

SAP Note: 1003674 Central Note on enhanced CTS.

Transporting Non-ABAP Objects in Change and Transport System

The documentation on non-ABAP Transports in the Change and Transport System can be found in the following manual: *http://help.sap.com/saphelp_nw70/helpdata/en/45/EC25370FDC3481E10000000A1553F6/frameset.htm*

Configuring TMS

Information about configuration of the transport management system (TMS) you find here: *http://help.sap.com/saphelp_nw70/helpdata/en/44/b4a09a7acc11d1899e0000e829fbbd/frameset.htm*

Transport Organizer Web UI

The Transport Organizer Web UI is used to manage the CTS+ change requests. Read the CTS+ User Reference Manual – Transport Organizer Web UI: *http://help.sap.com/saphelp_nw70/helpdata/EN/46/028ec7469204abe10000000a114a6b/frameset.htm*

CTS+ Command Line Tool

The CTS+ command line tool allows handling CTS+ requests from a command batch file. For details about the use, see SAP Note 1278181.

How-To Guide: Best Practices for Implementing CTS+

This document provides an overview about the CTS+ configuration and the CTS+ landscape setup. *https://www.sdn.sap.com/irj/sdn/go/portal/prtroot/docs/library/uuid/10456aac-44f7-2a10-1fbe-8b7bcd7bcd58*

Solution Manager 7.0 Change Request Management (ChaRM)

Change Request Management (ChaRM) enables you to manage your maintenance, implementation, template, and upgrade projects: Starting with change management and project planning, through resource management and cost control, to physical transports of changes from the development environment into the productive environment. The processes supported by Change Request Management include urgent corrections for implementing fast and direct changes in the productive environment, and activities for maintenance projects, and implementation, upgrade, or template projects. Cross-system and cross-component changes are supported.

ChaRM is the logical management of all changes, for example the transport requests of PCM systems. This includes the management and control of periods or situations, in which transport requests are approved and imported into target systems. Change Request Management works with the underlying TMS/CTS system. It also defines and controls emergency correction procedures and personnel responsible and authorized to participate in the change processes etc.

1.8.4.3 Setting up your Data Services change files

You can send files, exported from Data Services, through the CTS+ system. These files can be in XML or ATL format, and can represent any of the following objects:

- Repositories
- Jobs
- work flows
- Datastores
- Transform configurations
- Any other object in the Object Library

These files will need to be exported to a directory that CTS+ will be able to access during import to the CTS+ system. Similarly, you may also want to create a directory that will house the files you will receive from CTS+ that you import into your repository.

You will use the normal Data Services import and export procedures to produce these files and update your objects. You may also want to implement a file naming convention to help keep track of the files.

Example

Creating a source directory

You may want to create a directory structure in the Data Services install location, such as **<LINK_DIR>**`\cts\source` to specify that the folder contains files ready to be output to CTS+. When you set up a source system in CTS+, you will point to this directory.

Example

Creating a target directory

You may want to create a directory structure in the Data Services install location, such as **<LINK_DIR>**`\cts\target` to specify that the folder contains files received from CTS+. When you set up a target system in CTS+, you will point to this directory.

Related Information

Export/Import [page 117]

1.8.4.4 Configuring the Transport Organizer Web UI

CTS+ provides an ABAP Web Dynpro application called the Transport Organizer (CTS_BROWSER) that you use to create transport requests and to attach transportable objects. You must perform configuration steps to run and use this application.

For more information, see: *http://help.sap.com/saphelp_nw70/helpdata/en/ea/6213584a3f49119eccd7d739e55d5d/frameset.htm*

Activate all of the services that are required to run ABAP Web Dynpro applications as well as the web service CTS_BROWSER using transaction SICF (Maintain Services). This includes all services for ABAP WDA outlined in *SAP Note 517484* and *SAP Note 1088717*. If after the activation of services the Transport Organizer cannot be called and the response displays error messages as outlined in *SAP Note 1088717* (for example, Service is not active or equivalent), activate the services displayed in the error messages and retry.

1.8.4.4.1 Configuring the Transport Landscape

Create the systems of your Data Services system landscape as non-ABAP systems in TMS. Follow the steps outlined in this documentation. In TMS, as is true for any SAP ABAP and SAP Java based system, systems are represented by a three alphanumeric character identifier, called system identifier or SID. This SID is representing the system not only in TMS, but also in other managing applications, for example the SAP System Landscape Directory, the SAP Solution Manager, etc. Please provide your Data Services with a SID, for example DSD for the development system, DSQ for the test system, DSP for the production system. If you use the System Landscape Directory (SLD) to register Data Services systems, please use the same SIDs as reported to SLD. Systems are thereafter connected to so called transport routes. They provide a clear understanding to the Data Services administrators who are using the Transport Organizer Web UI and TMS to manage and control the transport requests.

For details, refer to reference manual (Defining and Configuring Non-ABAP Systems): *http://help.sap.com/saphelp_nw70/helpdata/en/45/f64a3dbc1a04a9e10000000a114a6b/frameset.htm*

1.8.4.4.1.1 Define the System Landscape

1. Log on to the CTS+ system and start transaction STMS (Transport Management System).
2. Choose *System Overview* to get the list of all systems defined in the CTS system.

1.8.4.4.1.2 Create the source system

In this step, you will need to define Data Services as a new non-ABAP System.

1. Choose ▶ *SAP System* ▶ *Create* ▶ *Non-ABAP System.* ◀
   The *TMS: Configure Non-ABAP System* window is displayed.

2. Create the Data Services System with a system ID (using the system's SID) and a description
3. Select the CTS+ system as the communication system.
4. Define the Data Services system as a source system by selecting the *Activate Transport Organizer* option.
5. Enter the client where you want to use the Transport Organizer.
6. Save your settings and confirm that you want to distribute the TMS configuration.
7. Add location information for the common file share for Data Services output/CTS+ inbox by selecting the newly created system from the list and double-clicking it.
8. In the *Transport Tool* tab, add the additional parameter: NON_ABAP_WBO_INBOX for the development system.
   For example, **`<LINK_DIR>`**`\cts\source`.

   > **Note**
   >
   > Alternatively, you may upload rom a local machine (client) in the Transport WebUI.

   For more information, see *http://help.sap.com/saphelp_nw70/helpdata/EN/6f/90813e26b1443d9d3642bb5cd8234c/frameset.htm*

1.8.4.4.1.3 Create the target system

In this step you will create a target systems (test and production) in the same way you created the source system.

1. Choose *SAP System* > *Create* > *Non-ABAP System.*
   The *TMS: Configure Non-ABAP System* window is displayed.
2. Create the Data Services System with a system ID (using the system's SID) and a description.
3. Select the CTS+ system as the communication system.
4. Define the Data Services system as a target system by selecting the *Activate Deployment Service* option.
5. Select the *File* checkbox as your preferred deployment method.
6. In the *Directory* field, enter the file share where CTS+ is providing the change data to the target system.
   For example, **`<LINK_DIR>`**`\cts\target`.
   This value then appears in the DEPLOY_OUTBOX parameter in the *Transport Tool* tab. For more information, see *http://help.sap.com/saphelp_nw70/helpdata/EN/2e/674953194c4299abae253152544fab/frameset.htm*.
7. Save your settings and confirm that you want to distribute the TMS configuration.

1.8.4.4.2 Defining transport routes

You systems are now ready to be included in a transport route in CTS.

To define transport routes, you will use the Graphical Editor in STMS. To do this, log on to Domain Controller (in client 000), start transaction STMS, and click the *Transport Routes* icon.

Create one standard transport layer, which is the default.

Using the Graphical Editor for definition of transport routes is explained in the following manual: *http://help.sap.com/saphelp_nw70/helpdata/en/44/b4a2a27acc11d1899e0000e829fbbd/frameset.htm*.

Now the Data Services systems are defined in the transport system landscape, and a transport route is defined from a development Data Services system to a production Data Services system.

1.8.4.5 Providing changes to CTS+ transport system

After the changes performed in the Data Services development system are extracted (exported), the next step is to provide the change file to the CTS+ Transport Control System. To do this, you will need to create a new transport request and import the change file into the new CTS+ transport request. You can do this in one of two ways:

- Using the Transport Organizer Web UI
- Using the CTS+ Command Line Tool

> Note
>
> The installation and setup of the CTS+ system and the CTS+ Transport Organizer Web UI are not part of this manual. Links to this documentation (including the CTS+ command line tool) can be found in the *Background information* [page 124] topic.

1.8.4.5.1 Change file attachment with CTS Transport Organizer Web UI

The CTS+ Transport Organizer Web UI is the UI that allows you to create and administrate Data Services change requests. It also provides the functionality to attach the change file to the change request.

For sharing with CTS, you need to define a shared folder on the CTS host where exported Data Services change files can be accessed from the CTS host. In this documentation, we use the following example share for data exchange: `\\`**`<CTSServer>`**`\DSOutbox` - a shared folder that is physically stored on the same server where the CTS application server is implemented. This folder is used as shared folder for the source Data Services change extraction output. (In customer installations this should be the **`<LINK_DIR>`**`\cts\source` folder)

1.8.4.5.1.1 Provide change data via NON_ABAP_WBO_INBOX

The change files from **`<LINK_DIR>`**`\cts\source` have to be accessible by CTS+ by sharing this folder either with the CTS+ system or with your local desktop. To directly access it from CTS host the parameter NON_ABAP_WBO_INBOX has to be defined to point to the share where Data Services puts its exported data (Parameter NON_ABAP_WBO_INBOX == \\<CTSServer>\DSOutbox).

1.8.4.5.1.2 Start the Transport Organizer Web UI

1. Log in to the Domain Controller, within the client as specified when creating the source system.
2. Start transaction STMS.
   Now the Transport Organizer Web UI can be started via Environment > Transport Organizer Web UI.
3. Enter the SID of the Data Services source system.

1.8.4.5.1.3 Create a new transport in CTS

1. Click the *Create Request* button to begin the creation of the new CTS+ change request.
2. Enter a short description and check for the correct owner.
3. Click *Create*.

A new transport request is created, and it appears in the *Requests* column.

1.8.4.5.1.4 Attach change file to the transport request

1. Select the transport request, then click the *Object List* tab to see if there are already attached objects.
2. To attach the change file, click the *Attach* button.
   The *Attach file object* window appears.
3. Select *Other* in the *Application* option.
4. Select *Client* if the change file is on the same local client that the Transport Organizer Web UI is running. If the Data Services Outbound folder is shared on the CTS server, select *Server*.
5. Click *Browse* to find the shared file and to upload it to the CTS+ system.
6. Select the correct change file, and click *Open*.
7. Click *OK* to upload the file to the transport request and to CTS.

1.8.4.6 Transport in the System Landscape

After you have attached all of the Data Services files that you want to transport with one transport request, you have to release your transport request and start the import to the target system, which is the next system in your transport route. During the import, the files are copied to the Data Services inbound folder.

In the CTS+ configuration, you can specify whether the Import Queue is handled automatically or if the queued transports have to be imported manually.

The deployment of a Data Services-specific transport orders in the current version is done with provisioning the change files to the CTS+ outbox folder defined for the Data Services target system, where the Data Services administrator has to pick it up for manual deployment.

1.8.4.6.1 Release transport request

1. Open the Transport Organizer Web UI.
2. Select the transport request to be released.
3. Click the *Release* button.

The transport request is now assigned a status of *Released*.

> **Note**
>
> If any issues occur with the release process, you may find helpful details in the Logs tab in the Transport Organizer Web UI.

1.8.4.6.2 Starting the import from the Import Queue

Processing the import will send the attached change file to the CTS outbox (or Data Services Inbound from a Data Services perspective, parameter DEPLOY_OUTBOX).

1. Start the transaction STMS, and click the *Import Overview* icon.
2. Select the target system to see the import queue for this target sytem. In the selected row, you see the icon (with a plus sign) that specifies that there are imports to be processed.
3. Double-click the target system to open the import queue.

   If you do not see the new transport request, click *Refresh*.
4. Select the transport order, and click the *Import Request* icon.

   Check the CTS+ DEPLOY_OUTBOX folder in the target sytem before and after the import and you will see a new directory with the name of the transport order.

   The*Import Transport Request* window appears.
5. Select an option to import immediately or at a later time.
6. Click *Yes* to import.

Because a file sharing between the CTS+ outbound and the Data Services Inbound has been defined for the target system (CTS+ Parameter DEPLOY_OUTBOX), the imported change file in now also accessible on the file share server you assigned.

If you encounter issues when importing, you will find details in import logs. You can mark the request in question and choose *Request* > *Display* > *Logs* .

For more information about performing transports, see *http://help.sap.com/saphelp_nw70/helpdata/en/44/b4a3507acc11d1899e0000e829fbbd/frameset.htm*.

1.8.5 Data Services Object Promotion Management

1.8.5.1 About object promotion

1.8.5.1.1 Overview of Data Services Object Promotion Management

The *Object Promotion* tool in the Data Services Administrator enables you to move one or more Data Services objects from a development environment to a QA environment, or directly to a production environment. To ensure security, these environments typically do not have direct access to one another. Object promotion in Data Services is accomplished over secure FTP or over a shared directory that only an Administrator or a user with an account assigned to the Data Services Administrator group can configure for this purpose, maintaining security in both source and target environments.

Users with *View* access to a repository can export its objects from a development environment to a shared directory created by authorized users. Users who have *Full Control* access to the repository can import objects after an Administrator or a user with an account assigned to the Data Services Administrator group has granted them the new *Manage Object Promotion Import* user application right.

> Note
>
> The user who starts the Server Intelligence Agent (SIA) on the server that has access to the shared directories that are used for exporting and importing promoted objects must have full read and write access to those shared directories. If the server is started by a user who does not have full access to the shared directory, all configurations for export and import operations for that shared directory will fail validation, and the configurations cannot be completed until the issue is resolved. To validate this, an authorized user or the Administrator can validate the configuration by testing the connection or re-saving the configuration to check. If another user without full read write privileges to the shared directory starts SIA after a configuration has been successfully validated, all export and import operations from that configuration will fail until SIA is restarted by a user with the required credentials.

If objects with the same name and types are selected for import, the objects are imported sequentially based on the date of export. When you view the list of exported objects in the *Import Configuration* page in the Administrator, the exported objects are grouped together with objects of the same type and object name, listed in order by the date they were exported. If the same object and types are exported multiple times, depending on the export date, you can import these objects the same objects and these objects will be imported sequentially, based on the export date.

1.8.5.1.2 Requirements for object promotion

The following requirements apply when using the SAP Data Services Object Promotion Management tool in the *Administrator* in Management Console to promote Data Services objects:

- The source and target repositories must both be running the same version of Data Services before attempting to promote objects to or from them.

- The user who starts the Server Intelligence Agent (SIA) on the server that has access to the shared directories that are used for exporting and importing promoted objects must have full read and write access to those shared directories.
  If the server is started by a user who does not have full access to the shared directory, all configurations for export and import operations for that shared directory will fail validation, and the configurations cannot be completed until the issue is resolved. To validate this, go to configuration page and click *Test*, or try to save the configuration again.
  If another user without full read write privileges to the shared directory starts the SIA on the server after export and import configurations have been successfully validated and saved, all of those export and import configurations will fail to successfully run until the SIA is restarted by a user with the required credentials.
- When a Data Services object is promoted, all of its dependent objects are also promoted, with the exception of its datastores. Typically, datastores in a development environment contain data that is used only for testing, and that data is not typically used in a production environment. If you need to promote a datastore from a development environment to a production environment, the datastore must be promoted separately.
- When a datastore is promoted, its password is not included in the import or export operation, so the password field for the promoted datastore is left blank. This is intentional and provides a safeguard to prevent the unintended use of a development or QA datastore in a production environment. It also provides another level of security, because only the owner of a datastore should know its password.
  After a datastore promotion is completed, be sure to reconfigure the datastore under *Administration > Management > Datastore* in SAP Data Services Management Console. Set a password for the promoted datastore in its new location, and if needed, modify the location of the database it uses. If the datastore used in the production environment is different from the one used in development or QA, be sure to update them. If a valid datastore password is not entered after the datastore has been imported into another environment, all of the jobs that depend on that datastore will fail to run until you enter the password.
- Only a user whose account is assigned to the Data Services Administrator group account can create and edit the configurations used for exporting or importing objects. An Administrator or a user who is assigned to the Data Services Administrator group can assign to another user who is not part of that group the *Manage Object Promotion Configurations* right to allow that user to modify the configurations through the Administrator in Master Console.
- Only users with, at a minimum, *View* access to a repository can export its objects to the shared directory configured by an Administrator or a Data Services Administrator group user.
- Only Data Services Administrator group users can import objects into a repository. An Administrator or a user whose account is a member of the Data Services Administrator group can assign another user who is not part of that group the right to *Manage Object Promotion Import*, which grants that user the authorization to import objects into a repository. That user must also have *Full Control* access to the repository to be able to import its objects.
- Each top-level object import is run sequentially. If one object fails to import, it will revert back, then the import continues to the next top-level object.

The following table summarizes the required user rights for each stage of the Object Promotion Management process.

Type of user	Configure export and import	Export objects from repository (source)	Import objects from shared directory (target)
Administrator	Yes	Yes	Yes
Data Services Administrator group	Yes	Yes	Yes
Regular Data Services user, without additional rights	No	Yes	No

Type of user	Configure export and import	Export objects from repository (source)	Import objects from shared directory (target)
		Must also have, at minimum, *View* access to export objects from the repository	
Regular Data Services user, with *Manage Object Promotion Configurations* right	Yes	Yes Must also have, at minimum, *View* access to export objects from the repository	No
Regular Data Services user, with *Manage Object Promotion Import* right	No	Yes Must also have the required *Full Control* access to the shared directory	Yes

Related Information

Managing application rights for a group [page 51]

1.8.5.1.3 Object promotion user interface

The Data Services Object Promotion Management tool is found in the Management Console, under the *Administrator*. To view the choices, select or expand the *Object Promotion* menu.

When you select the title for the *Object Promotion* menu, the *Object Promotion* page appears, with choices to access and run existing export and import configurations.

- *Export objects* manages the export of specific object types from specific repositories. After you select a repository and object type, and select *Next*, a table appears with details for each object of the selected type that resides on that repository and is available to export.
- *Export Substitution Parameters* manages the export of one or more substitution parameters, which are listed by the repository in which they reside. After you select a substitution parameter and select *Next*, a table appears with details for each substitution parameter.
- *Export System Configurations* manages the export of one or more individual system configurations from the local repository. After you select a system configuration and select *Next*, a table appears with details for each system configuration.
- *Import* displays details for objects that have been exported from the repository and are available to import. A search tool provides a way to narrow the displayed list. From the displayed results, you can select one or more objects to import.

Each of the pages displayed for these choices include an indication of whether an export or import has ever been run on the displayed object(s).

Field	Value = Yes	Value = No
Exported	One or more export operations have been run on this repository object. The status of these operations could be success or failure.	No export operations have ever been run on this repository object.
Imported	One or more import operations have been run on this repository object. The status of these operations could be success or failure.	No import operations have ever been run on this repository object.

When you expand the *Object Promotion* menu, there are two choices:

- *Export Configuration* lists all of the export configurations that have been created by authorized users.
- *Import Configuration* lists all of the import configurations that have been created by authorized users.

The export and import configurations are displayed and are available for selection in the list on the *Object Promotion* page, which is displayed when you select either choice.

> i Note
>
> Users whose accounts are not members of the Data Services Administrator group or who have not been granted specific permissions by a member of that group cannot create or edit export and import configurations, nor can they run the import configurations created by an authorized user.
>
> - To edit an export or import configuration, users outside the Data Services Administrator group must be granted the *Manage Object Promotion Configurations* right.
> - To run an import configuration to import objects, users outside the Data Services Administrator group must be granted the *Manage Object Promotion Import* right, and they must also have *Full Control* access to the repository.

1.8.5.2 Configuring object promotion

1.8.5.2.1 Setting up an export configuration

The following specific requirements and recommendations apply when setting up an export configuration:

- Only a user whose account is assigned to the Data Services Administrator group account can create and edit the configurations used for exporting or importing objects. An Administrator or a user who is assigned to the Data Services Administrator group can assign to another user who is not part of that group the *Manage Object Promotion Configurations* right to allow that user to modify the configurations through the Administrator in Master Console.
- For security reasons, only a system administrator can create a shared directory to which objects can be exported to or imported from. If a shared directory has not yet been created but you have been granted permission to configure exports and imports, the only available transport option you will see for your configuration is FTP.
- If you are configuring an export to use FTP to promote objects to a UNIX system, be sure to configure the FTP server to have full read and write access to the shared directory that was set up to receive exported objects.

- If you need to clear space on the shared directory, you can safely delete the exported .ATL and .manifest files after you have finished importing them. If you create a separate export configuration for each release, it will be easier to identify the groups of files you can safely archive or delete.
- A repository can be associated with multiple, different export configurations.
- For information about the general requirements for object promotion, see the related topics.

You can use object promotion to create a configuration than can be used to export an object and its dependent objects over secure FTP or directly to a shared directory:

1. In Data Services Management Console, expand the *Object Promotion* menu, then select *Export Configuration*.
2. In the *Export Configuration* page, click *Add*.
3. To create an export configuration to transport objects over FTP:
   a) On the FTP tab, enter information in each of the required fields.
   b) Choose whether to enable Secure FTP.
   c) Select one or more entries in the *Available Repositories* list to associate with this configuration. You can only export objects from the repositories that are selected for the *Associated Repositories* list.
   d) Optionally, click *Test* to ensure that the configuration can access the repositories and the *Target Directory* you associated with this configuration.
   e) Save the configuration.
4. To create an export configuration to transport objects directly to an existing shared directory:
   a) On the *Shared Directory* tab, enter a name for the configuration and a target directory to which the objects should be exported on the shared directory.
   b) Select one or more entries in the *Available Repositories* list to associate with this configuration. You can only export objects from the repositories that are selected for the *Associated Repositories* list.
   c) Save the configuration.

When you test or save the configuration, the Object Promotion Management tool validates whether the SIA service can save (read and write) content to the shared directory. If the configuration can access the repositories with which it has been associated and the SIA service validates access to the shared directory, the configuration is saved with the name you specified. After it is saved, the named configuration will appear as a choice on the *Export Configuration* page, and as an *Object Name* choice when you choose *Export Objects*, *Export System Configuration*, or *Export Substitution Parameters*.

To modify an export configuration, return to the *Export Configuration* and select the *Object Name* of the configuration you want to modify.

To remove an export configuration, select it in the *Export Configuration* and click *Remove*.

Related Information

Requirements for object promotion [page 132]

Exporting an object [page 137]

1.8.5.2.2 Setting up an import configuration

The following specific requirements apply when setting up an import configuration:

- The object and all of its dependent objects must have already been exported before you run the import configuration.
- An import configuration can be associated with only one repository.
- A target repository must be configured to a shared directory where ATL files have been exported.
- Only a user whose account is assigned to the Data Services Administrator group account can create and edit the configurations used for exporting or importing objects. An Administrator or a user who is assigned to the Data Services Administrator group can assign to another user who is not part of that group the *Manage Object Promotion Configurations* right to allow that user to modify the configurations through the Administrator in Master Console.
- For information about the general requirements for object promotion, see the related topics.

You use object promotion to create a configuration than can be used to import an object and its dependent objects from a shared directory:

1. In Data Services Management Console, expand the *Object Promotion* menu, then select *Import Configuration*.
2. On the *Import Configuration* page, click *Add*.
3. Select the *Repository* from which the objects were configured to be exported, and in the *Source Directory* field, enter the directory path to where the export configuration deposited the objects.

   After you configure the *Repository*, it cannot be configured with a different path, because that repository will no longer show up in the list of choices.
4. Save the configuration.

If the import configuration can access the shared directory to where the objects are exported, the configuration is saved with the name of the target repository. The configuration will appear as a choice on the *Import Configuration* page, and as an *Object Name* choice when you choose *Import*.

To modify an import configuration, return to the *Import Configuration* page and select the *Object Name* of the configuration you want to modify.

To remove an import configuration, select it in the *Import Configuration* and click *Remove*.

If you imported a datastore, after it is imported you must reconfigure the datastore under *Administration > Management > Datastore* in SAP Data Services Management Console and assign it a password.

After you import a collection of substitution parameters, if needed, you can update the paths for the substitution parameters after they are imported to their new location.

Related Information

Requirements for object promotion [page 132]
Importing an object [page 140]

1.8.5.3 Promoting objects

1.8.5.3.1 Exporting an object

The following specific requirements apply when exporting an object:

- The source and target repositories must be running the same version of SAP Data Services.
- You can export from a local repository or a central repository.
- If a datastore is a dependent object of the object you are exporting, the datastore must be exported separately.
- When a datastore is promoted, its password is not included in the import or export operation, so the password field for the promoted datastore is left blank. This is intentional and provides a safeguard to prevent the unintended use of a development or QA datastore in a production environment.
  After a datastore promotion is completed, be sure to reconfigure the datastore under *Administration > Management > Datastore* in SAP Data Services Management Console. Set a password for the promoted datastore in its new location, and if needed, modify the location of the database it uses.
- The repository you are exporting objects from must be associated with an export configuration.
- For information about the general requirements for object promotion, see the related topics.

You can use object promotion to export the following types of objects from their current repository to a shared directory:

- Project
- Job
- Work flow
- Data flow
- Function
- File format
- Datastore
- System configurations
- Substitution parameters

1. In Data Services Management Console, select *Object Promotion*.
2. Select one of the following choices in the *Objects* list, then click *Next*.
   - Export objects
   - Export system configurations
   - Export substitution parameters
3. Select a repository (local or central) and if you chose *Export objects*, choose an object type, then click *Next*.
   The *Export* page appears, with a list of the latest version of all the objects you specified that are available in your chosen repository.

   There are 23 entries listed on each page. You can include up to 23 of the entries listed on a given *Export* page in a single export operation. Click the page links to view any subsequent pages of available objects.
4. If you chose *Export system configurations* or *Export substitution parameters* in the *Objects* list, to narrow the list to display only the objects you want to export, use the *Search* field to look for objects that completely or partially match the export configuration for the objects you want to export. The *Search* field supports wildcards.
5. If you chose *Export objects* in the *Objects* list, to narrow the list to display only the objects you want to export, filter the list:
   a) Enter specific text to search for that appears in the *Object name* field. You can use an asterisk as a wildcard to expand your search to objects that partially match or are part of a common naming scheme.
   b) If the selected *Object Type* is *Job*, select a specific *Project* (the default is *All Projects*).
   c) If you are exporting from the central repository, additional filter choices are available:

If the selected *Object Type* is *Project*, select a different version in the *Get* list (the default is *Latest Version*).

When you submit the query, it matches the parent object's label with the associated version. If the label for a child of an object does not match with the specified label, when a parent object is exported, the latest version of the child object will be exported.

To ensure that you have total control over which version of an object's dependencies are exported, be sure to always label your objects when you check them in. Label child objects with the same label you assigned to the parent object.

d) Click *Search* to use your selections to search for objects that match your choices.

6. Individually choose up to 23 *Object Name* entries displayed on the current page, or choose *Select All* to import all 23 objects on the currently displayed page.
7. Choose the export method.
8. Click *Export* to start exporting the objects you selected.

For each object, an ATL file and a manifest file are written to the *Target Directory* specified in the export configuration.

A *Confirmation* page displays progress for the export, and the *Status* is automatically refreshed every five seconds. When the export is completed, the automatic refresh ends, the ending *Status* information is displayed (success or failure), and log information is stored in the repository under the *AL_EXPORT_HISTORY* table. To view the log information while you have the *Confirmation* page open, select *view log* under the *Status* column of the displayed report. Details about the job are on the *Trace* tab. If there were any issues with the export, messages are recorded to the *Error* tab.

A unique confirmation ID is assigned to each export attempt. The confirmation ID is used for a unique ID in the *AL_EXPORT_HISTORY* table. The confirmation ID is used to pass information when you import the exported objects. The confirmation ID contains the following information:

```
<Timestamp-in-milliseconds>-<six-digit random number>-<number of export attempts>
```

To convert the time stamp that is displayed in milliseconds to date format, copy the integers displayed next to *Confirmation#* up to the first dash, and paste them into any available conversion tool.

> **Note**
>
> Make a note of the unique confirmation number displayed on the *Confirmation* page, and copy any information from the log that you want to preserve. You cannot return to this *Confirmation* page after you dismiss it. A copy of the log is also written to the repository under the *AL_EXPORT_HISTORY* table, so you can query the table to find the log information later.

If you exported a datastore, after it is imported you must reconfigure the datastore under *Administration > Management > Datastore* in SAP Data Services Management Console and assign it a password.

If you exported substitution parameters, if needed, you can update the paths for the substitution parameters after they are imported to their new location. To edit substitution parameters, you must either be an Administrator or your account is a member of the Data Services Administrator group, or either of these users can grant you the *Manage datastore and substitution param configurations*.

Related Information

Requirements for object promotion [page 132]
Setting up an export configuration [page 135]
Managing application rights for a group [page 51]

1.8.5.3.2 Importing an object

The following requirements apply when importing an object to another repository:

- The source and target repositories must be running the same version of SAP Data Services.
- Your user account must be a member of the Data Services *Administrator* group, or a member of that group must have granted your user account the *Manage Object Promotion Import* right and you have Full Control permissions for the repository.
- You can only import objects to a local repository.
- When a datastore is promoted, its password is not included in the import or export operation, so the password field for the promoted datastore is left blank. This is intentional and provides a safeguard to prevent the unintended use of a development or QA datastore in a production environment.
  After a datastore promotion is completed, be sure to reconfigure the datastore under *Administration > Management > Datastore* in SAP Data Services Management Console. Set a password for the promoted datastore in its new location, and if needed, modify the location of the database it uses.
- For information about the general requirements for object promotion, see the related topics.

You can use object promotion to securely import objects into a production environment from the source directory for the import configuration.

1. In Data Services Management Console, select *Object Promotion*.
2. Select a target repository from which to import objects, then click *Next*.
   The *Import* page appears, with a list of exported objects that are available in the target repository. These entries contain information about objects that are associated with a corresponding export configuration, and contains information about where to find the exported objects.

   There are 23 entries listed on each page. You can include up to 23 of the entries listed on a given *Import* page in a single import operation. Click the page links to view any subsequent pages of available objects
3. To narrow the list to display only the objects you want to import, use the *Filter* choices to filter the displayed entries in the list or search for objects that completely or partially match the export configuration for the objects you want to import. The *Search* field supports wildcards.
4. Individually choose up to 23 entries displayed on the current page, or choose *Select All* to import all 23 objects displayed on the current page.
5. Click *Import* to start importing the selected objects.

The *Confirmation* page displays progress for the import, and the Status is automatically refreshed every five seconds. When the import is completed, the automatic refresh ends, the ending *Status* information is displayed (success or failure), and log information is stored in the repository under the *AL_IMPORT_HISTORY* table. To view the log information while you have the *Confirmation* page open, select *view log* under the *Status* column of the displayed report. Details about the job are on the *Trace* tab. If there were any issues with the export, messages are recorded to the *Error* tab.

A unique confirmation ID is assigned to each import attempt. The confirmation ID is used for a unique ID in the *AL_IMPORT_HISTORY* table. The confirmation ID contains the following information:

```
<Timestamp-in-milliseconds>-<six-digit random number>-<number of import attempts>
```

To convert the time stamp that is displayed in milliseconds to date format, copy the integers displayed next to *Confirmation#* up to the first dash, and paste them into any available conversion tool.

> i Note
>
> Make a note of the unique confirmation number displayed on the *Confirmation* page, and copy any information from the log that you want to preserve. You cannot return to this *Confirmation* page after you dismiss it. A copy of the log is also written to the repository under the *AL_IMPORT_HISTORY* table, so you can query the table to find the log information later.

If you imported a datastore, after it is imported you must reconfigure the datastore under *Administration > Management > Datastore* in SAP Data Services Management Console and assign it a password.

If you imported substitution parameters, if needed, you can update the paths for the substitution parameters after they are imported to their new location. To edit substitution parameters, you must either be an Administrator or your account is a member of the Data Services Administrator group, or either of these users can grant you the *Manage datastore and substitution param configurations*.

1.9 Integration with SAP and SAP Solution Manager

1.9.1 Integration overview

Data Services can be integrated into a number of SAP solutions to take advantage of their features. The System Landscape Directory and Solution Manager Diagnostics products help you manage, monitor, and maintain your Data Services deployment.

SAP System Landscape Directory (SLD)

The system landscape directory of SAP NetWeaver is the central source of system landscape information relevant for the management of your software life-cycle. By providing a directory comprising information about all installable software available from SAP and automatically updated data about systems already installed in a landscape, you get the foundation for tool support to plan software life-cycle tasks in your system landscape.

The SAP Data Services installation program registers the vendor and product names and versions with the SLD, as well as server and front-end component names, versions, and location.

Solution Manager Diagnostics (SMD)

The SMD component of SAP Solution Manager provides all functionality to centrally analyze and monitor a complete system landscape. Data Services can be monitored by the SMD server if an SMD Agent is installed. The SMD Agent gathers information for the SMD which can then be used for root cause analysis.

Data Services provides support for this performance monitoring through CA/Wily Introscope in Solution Manager Diagnostics through an integration with the NCS library, which is installed automatically with Data Services.

1.9.2 SLD and SAP Solution Manager integration checklist

The following table summarizes what components are required to enable SLD and SAP Solution Manager to provide support for Data Services.

Support for...	Required for SAP Data Services
SLD registration	• SAPHOSTAGENT must be installed to enable registration of Data Services servers. i Note The Data Services installer will automatically register servers if SAPHOSTAGENT is already installed. • Must create a `slddest.cfg.key` and `slddest.cfg` file for the SLDReg data supplier reporting on the back-end servers.
SMD integration	Must download and install SMD Agent (DIAGNOSTICS.AGENT) on all hosts of Data Services servers.
Performance instrumentation	• SMD Agent must be installed. • Introscope Agent must be configured to connect to Introsope Enterprise Manager. Use the Data Services Server Manager (Windows) or ServerConfig utility (UNIX) to configure the NCS options.

1.9.3 Managing System Landscape Directory registration

1.9.3.1 Registration of Data Services in the System Landscape

The System Landscape Directory (SLD) is a central repository of system landscape information that is relevant for the management of the software lifecycle. The SLD contains a description of the system landscape—the systems and software components that are currently installed.

SLD data suppliers (SLDReg) register the systems on the SLD server and keep the information up-to-date. Management and business applications access the information stored in the SLD to perform tasks in a collaborative computing environment.

SLDReg is installed when you install the SAPHOSTAGENT. Once SLDREG has been installed, you need to create a `slddest.cfg` and `slddest.cfg.key` file to enable it to connect to the SLD server.

The data supplier is provided for every installation of Data Services to report on the following components:

- Server components (job server, access server)
- Services deployed on the Business Intelligence Platform (RFC Server, View Data and Metadata Browsing Service, Administrator Service)
- Web applications deployed on an application server (Management Console)

> Note
>
> SAP NetWeaver has a built-in SLD-DS supplier that registers the NetWeaver application server as well as hosted web applications and services. This SLD-DS is relevant for Data Services deployments that are integrated within an SAP NetWeaver environment.

For information on how to configure the specific data supplier for WebSphere, see the *SAP Web Application Deployment Guide*.

During the installation of Data Services, information required for registering Data Services is stored in a configuration file. This file contains information used by the SLDReg to connect to the Data Services database.

1.9.3.2 To create a slddest.cfg.key file for the SLDReg

Before creating a `slddest.cfg.key` file for the SLD data supplier, you need to download and install the SAPHOSTAGENT.

> Note
>
> If you selected to add SLD during the Data Services installation, you do not need to create this file. If you are choosing to activate SLD after installing Data Services, follow this procedure.

The `slddest.cfg.key` file is required for SLD registration with the data supplier that reports on Data Services servers.

> Note
>
> This procedure creates both the `slddest.cfg` and the `slddest.cfg.key` file. Both of these files are required for SLD integration to work.

1. Open a command line console.
2. Navigate to the default SAPHOSTAGENT install path.
   - On Windows: `Program Files\SAP\hostctrl\exe`
   - On UNIX: `/usr/sap/hostctrl/exe`
3. Run the following command:

   ```
   sldreg -configure slddest.cfg
   ```
4. Enter the following configuration details:
   - User name
   - Password
   - Host
   - Port number
   - Specify to use HTTP

The `sldreg` tool will create the `slddest.cfg.key` file that will automatically be used by the data supplier to push information to the SLD server.

SLDReg needs to be running in the **`<LINK_DIR>`**`/sldreg` directory, or these files need to be manually copied to this directory for SLD integration to work.

1.9.3.3 When is SLD registration triggered?

The Data Services service invokes SLDReg (the data supplier for Data Services) to handle SLD registration.

1.9.4 Performance and availability monitoring

1.9.4.1 Solution Manager Diagnostics (SMD) overview

The Solution Manager Diagnostics (SMD) component of SAP Solution Manager provides all functionality to centrally analyze and monitor a complete system landscape. Data Services can be monitored by the SMD server if an SMD Agent is installed. The SMD Agent gathers information for the SMD which can then be used for root cause analysis. Information collected and sent to the SMD server includes back-end server configurations and the location of server log files.

Data Services provides support for performance and availability monitoring through CA Wily Introscope in Solution Manager Diagnostics through an integration with the NCS library, which is installed automatically with Data Services.

Components of SMD

- *SAP Solution Manager:* You must have Solution Manager 7.01 SP26 or later installed. For more information, see *https://service.sap.com/solutionmanager*.
- *SMD Agent:* A local agent (`DIAGNOSTICS.AGENT`) that collects and sends the information to the SMD server. This agent must be downloaded and installed on each Job Server that you want to monitor. The Data Services installation does not install this agent for you.

  Information on installing and configuring the agent is available at: *https://service.sap.com/diagnostics*.
- *CA Wily Introscope:* An application performance management framework. Introscope Enterprise Server is part of Solution Manager. There is no need to perform a separate installation. For more information, see *https://service.sap.com/diagnostics*
- *SAPOSCOL:* The SAP Operating System Collector provides operating system data to the SMD and Introscope.

All of these components are available for download from *http://service.sap.com/swdc*.

1.9.4.2 SMD agent guidelines

The SMD Agent is a local agent (`DIAGNOSTICS.AGENT`) that collects and sends the information to the SMD server.

All of these components are available for download from *http://service.sap.com/swdc*.

Guidelines for working with the SMD Agent

The following are provided as guidelines for using SMD agents to monitor Data Services:

- The installation order of the monitored system and agent is not critical. You can install the SMD Agent before or after installing and deploying Data Services.
- If the servers are deployed on a distributed system, you should install an SMD Agent on every machine hosting a server.

Related Information

http://service.sap.com/diagnostics

1.9.4.3 Configuring your system for SMD

There are a few settings and files to configure to get SMD working properly on your system.

- You must enable the feature in the Server Manager for each of the Job Servers for which you want to get performance metrics.
- If you have problems, you can edit the `ncs.conf` file. This file controls the information sent to the SMD Agent. Normally, you can keep the default settings. Descriptions of the options are included in the file. It is located in the **`<LINK_DIR>`**`\bin` directory of your Data Services installation.
- SMD Agent files. There are two files in your SMD Agent installation location: `SapAgentConfig.xml` and `IntroscopeSapAgent.profile`. Configuring these files is necessary to provide information to the Solution Manager server.

1.9.4.4 To enable performance instrumentation on Windows

Before you can monitor performance on a Job Server, you must enable it.

1. Open the Data Services Server Manager.
2. Click the *Native Component Supportability* tab.
3. Select *Enable instrumentation in NCS (Native Component Supportability) library*.

In most circumstances, you can leave the default settings for the rest of the options.

1.9.4.4.1 Server Manager: Native Component Supportability options

Option	Description
Enable instrumentation in NCS (Native Component Supportablility) library	Select to enable performance monitoring of the jobs run on this server.
Tracing level threshold	Indicates the tracing level that the instrumented code needs to go under to produce a trace: 0: Use the value from ncs.conf configuration file 1-5: No tracing (NONE) 6-10: Tracing major points (MAJOR) 11-15: Tracing minor points (MINOR) 16-20: Tracing fine details (FINE) >20: Max details (FINEST)
Execution interval	Indicates execution interval for CPU usage/process memory metrics to be sent to Wily Enterprise Manager in seconds. 0 means that the default NCS scheduler will be used.
Execution time offset	Indicates execution time offset with regard to the interval in seconds.

Option	Description
	For example, if the interval is 3600 (every one hour) and the offset is 1800 (every half an hour), the information will be sent to SMD agent at 3:30, 4:30, 5:30, and so on. If the interval is smaller than the NCS library scheduler interval defined in parameter "datasending_interval", the offset parameter will be bypassed.
Tracing level	This option is not currently used.
Application passport	This option is not currently used.

1.9.4.5 To enable performance instrumentation on UNIX and Linux

If you are running Data Services on a UNIX or Linux platform, you will need to edit the `DSConfig.txt` file to enable instrumentation.

1. Navigate to **`<DS_COMMON_DIR>`**`/conf`.
2. Open the `DSConfig.txt` file.
3. Set the Wily_instrumentation parameter to **`True`**.

The other parameters (found in the Engine section) can be left with the default values.

```
Wily_instrumentation=TRUE

Wily_instrumentation_Level_Threshold=0

Wily_instrumentation_Interval=0

Wily_instrumentation_Offset=

Wily_instrumentation_TraceLevel=3487

Wily_instrumentation_App_Passport=
```

1.9.4.6 Heartbeat monitoring

Availability monitoring (heartbeat) lets you use the SAP Solution Manager to check whether a component such as a Job Server or Access Server is up and running. You can also get information about real-time services for Access Servers.

From CA Wily Introscope under the *Status* node, you can view each monitored Job Server or Access Server's status. For heartbeat, a value of 1 indicates the server is running; 0 indicates it is not.

In addition, you can view an Access Server's real-time service status. The status indicators are:

0	not running
1	starting

2	started
3	shutting down
4	warning
5	error
9	disabled

1.9.4.7 Alert monitoring

Alerts let you view critical errors in the SAP Solution Manager. From Data Services, Job Servers send alerts when a job fails.

From CA Wily Introscope under the *Status* node, you can view each monitored Job Server's status. For alerts, a value of 1 indicates a job has failed in that Job Server's repository.

1.10 Command line administration

1.10.1 Command lines overview

This section lists the command-line options that control the behavior of each Data Services component.

Throughout this section, values provided in square brackets [ ] are optional.

i Note

The following tables list the supported command-line options. Data Services components use a number of internal options that are not listed in these tables. These internal options should not be modified.

1.10.2 License Manager

License Manager includes a command-line mode that you can use if you don't want to use the graphical interface, or need to script License Manager operations.

Syntax

```
LicenseManager [-v | -a <keycode> | -r <keycode> [-l <location>]]
```

Parameter	Description

-v or **--view**	Displays the stored product activation keycodes in a format similar to the License Manager graphical interface. For example:
	`------ Registered Keycodes ------`
	` EIM Titan`
	`  Suite 12.0`
	`   Data Services XI 3.1 Premium`
	`    Keycode: 00000-0000000-0000000-0000`
	`    Trial Option: Yes`
	`    Expired: No`
	`    Days Remaining: 54`

-a or **--add <keycode>**	Adds the specified license keycode, and displays the stored keycodes in a format similar to the License Manager graphical interface. Returns status messages for the following conditions: - An internal error occurred. - Successfully added the keycode. - Successfully added the keycode and replaced a trial version. - Keycode not added because it is invalid. - Keycode not added because it is a duplicate.
-r or **--remove <keycode> [-l <location>]**	Removes the specified product activation keycode, and displays the stored keycodes in a format similar to the License Manager graphical interface. If **<location>** is specified, the removal is restricted to that node. Returns status messages for the following conditions: - An internal error occurred. - Removed one keycode. - Removed multiple keycodes. - Keycode not removed because it is invalid. - Keycode not removed because it was not found.

1.10.3 Connection Manager (Unix)

The Connection Manager (DSConnectionManager) is a graphical interface used to configure ODBC databases and ODBC drivers that you want to use for Data Services repositories, sources and targets after installation on Unix platforms. The Connection Manager includes a command-line mode that you can use if you do not want to use the graphical interface, or need to troubleshoot errors.

To use `DSConnectionManager.sh` from the command line, use the `-c` parameter which must be the first parameter.

If an error occurs when using the Connection Manager, use the `-d` option to show details in the log

For example:

```
$LINK_DIR/bin/DSConnectionManager.sh -c -d
```

1.10.4 Repository Manager (Windows)

You can use RepoManBatch.exe to create or update repositories from the command line on Windows platforms. By default, RepoManBatch.exe is installed to the **<LINK_DIR>**\bin directory.

Specify parameters using a command prompt.

```
C:\Program Files\SAP BusinessObjects\Data Services\bin>RepoManBatch.exe

Usage:
     -U<User>          : Repository login user
     -P<Password>      : Repository login password
     -s                : Use Server name based connection
     -S<Server>        : Repository server name
     -p<PortNo>        : Repository server port number
     -N<DatabaseType> : Repository database type
     -Q<Database>      : Repository database
     -V<Database_version>    : Repository database server version
     -g                : Repository using Windows Authentication (Microsoft
                            SQL Server only)
     -t<Type>          : Repository type: local, central, profiler
     -c                : Repository create
     -u                : Repository upgrade
     -v                : Repository version
     -d                : Show details
     -a                : Repository security

C:\Program Files\SAP BusinessObjects\Data Services\bin>
```

For example:

```
RepoManBatch -Usa -P -NMicroSoft_SQL_Server -SServer -QJake -c -tcentral -d
```

or

```
RepoManBatch -UJake -PJake -NOracle -Sdbsvr -v
```

Usage:

Flag	Description
-U	Repository login user This parameter is required for all database types.
-P	Repository login password This parameter is required for all database types.
-s	Specify this parameter to use a server name (also known as DSN-less or TNS-less) connection to the repository. If you specify this parameter, you must specify the -p and -V parameters.
-S	Repository server name: • For DB2: data source • For MySQL: ODBC data source name • For Microsoft SQL Server: database server name • For Oracle: database connection name • For SAP HANA: ODBC data source name • For SAP Sybase SQL Anywhere: ODBC data source name • For SAP Sybase ASE: server

Flag	Description
	This parameter is required for all database types.
`-p`	Repository database port number This parameter is required if you specified `-s` for a server name connection.
`-N`	Repository database type: ● `DB2` ● `HANA` ● `Microsoft_SQL_Server` ● `MySQL` ● `Oracle` ● `SQL_Anywhere` ● `Sybase` This parameter is required for all database types.
`-Q`	Repository database name This parameter is required only for Microsoft SQL Server and Sybase ASE.
`-V`	Repository database version This parameter is required if you specified `-s` for a server name connection.
`-g`	Specify this parameter to use Windows authentication to connect to this repository (Microsoft SQL Server only).
`-t`	Repository type: ● `local` ● `central` ● `profiler`
`-c`	Create repository
`-u`	Upgrade repository
`-v`	Get repository version
`-d`	Show details
`-a`	Central repository security

1.10.5 Repository Manager (Unix)

You can use the executable called `repoman` to create or update repositories from the command line on Unix platforms. By default, `repoman` is installed to the **`<LINK_DIR>`**`/bin` directory.

Specify parameters using a command prompt.

```
$ ./repoman
```

```
Usage:
     -U<User>         : Repository login user
     -P<Password>     : Repository login password
     -S<Server>       : Repository server name
     -N<DatabaseType> : Repository database type: SQL_Anywhere, Sybase, MySQL, HANA,
                           DB2, Oracle
     -Q<Database>     : Repository database
     -s               : Connect Repository database by DSN-less (ODBC) or
                           TNS-less for Oracle
     -V<databaseVersion> : Repository database version (only available
                           with -s):
                              MYSQL 5.0, MYSQL 5.1 (default)
                              HANA 1.X (default)
                              DB2 UDB 9.X
                              ORACLE 11G, ORACLE 10G

                                  SQL Anywhere 12.X
     -p<port>         : Repository database port
     -t<Type>         : Repository type: local, central,
                           profiler
     -b               : Check database connectivity
     -c               : Repository create
     -u               : Repository upgrade
     -v               : Repository version
     -d               : Show details
     -a               : Repository security
     -l               : Create log file
     -z               : Create error file
                           (local, central, profiler modes)
```

For example:

```
./repoman -Usa -P -NDB2 -SServer -QJake -c -tcentral -d
```

or

```
./repoman -UJake -PJake -NOracle -Sdbsvr -v
```

Usage:

Flag	Description
`-U`	Repository login user This parameter is required for all database types.
`-P`	Repository login password This parameter is required for all database types.
`-s`	Specify this parameter to use a server name (also known as DSN-less or TNS-less) connection to the repository. If you specify this parameter, you must specify the `-p` and `-V` parameters.
`-S`	Repository server name: • For DB2: data source • For MySQL: ODBC data source name • For Oracle: TNSNAME defined in `tnsnames.ora` • For SAP HANA: ODBC data source name • For SAP Sybase SQL Anywhere: ODBC data source name • For SAP Sybase ASE: server This parameter is required for all database types.

Flag	Description
`-p`	Repository database port number This parameter is required if you specified `-s` for a server name connection.
`-N`	Repository database type: • `DB2` • `HANA` • `MySQL` • `Oracle` • `SQL_Anywhere` • `Sybase` This parameter is required for all database types.
`-Q`	Repository database name This parameter is required only for Sybase ASE.
`-V`	Repository database version This parameter is required if you specified `-s` for a server name connection.
`-t`	Repository type: • `local` • `central` • `profiler`
`-c`	Operation mode: Creates repository
`-u`	Operation mode: Upgrades repository
`-v`	Operation mode: Gets repository version
`-d`	Operation mode: Shows details
`-a`	Central repository security
`-o`	Overwrite existing repository

1.10.6 Server Manager (Windows)

The Server Manager (`AWServerConfig.exe`) is used to create, edit, or delete Job Servers and Access Servers after installation on Windows platforms. In addition to the default graphical user interface, `AWServerConfig.exe` also supports command-line parameters for several tasks:

- Adding a Job Server
- Adding an Access Server
- Adding run-time resources

Note

On Windows platforms, there is no command-line option to start or stop the Data Services service using `AWServerConfig.exe` because it is installed as a Windows service. The Data Services service can be started and stopped using the standard `net` command.

Example

Start Data Services services

```
net start "SAP Data Services"
```

Example

Stop Data Services services

```
net stop "SAP Data Services"
```

1.10.6.1 To add an Access Server

To use `AWServerConfig.exe` to add an Access Server from the command line, use the `-n` parameter, along with additional Access Server-specific parameters. `-n` must be the first argument.

Access Server parameters

Parameter	Description
`-R`**`<access_server_dir>`**	Specifies the directory path for the Access Server. Replace **`<access_server_dir>`** with the Access Server directory path.
`-A`**`<port>`**	Specifies the port assigned to the Access Server. Replace **`<port>`** with the desired port number. The port number may have a value between 1024 and 49151, and must be unique and not in use.
`-E`	Indicates that the Access Server should be enabled. If not specified, the Access Server is created but not enabled.
`-T`**`<param>`**	Specifies a parameter for the Access Server. Replace **`<param>`** with the desired parameter.

Example

Create and enable an Access Server on port 4000

```
AWServerConfig.exe -n -RC:\DataServices\AccessServer -A4000 -E
```

1.10.6.2 To add a Job Server

To use `AWServerConfig.exe` to add a Job Server from the command line, use the `-n` parameter, along with additional Job Server-specific parameters. `-n` must be the first parameter.

Job Server parameters

Parameter	Description
`-J`**`<server_name>`**	Specifies the name of the Job Server. Replace **`<server_name>`** with the desired name for the Job Server. The specified name may not contain `@@` and must be unique.
`-P`**`<port_number>`**	Specifies the listening port for the Job Server. Replace **`<port_number>`** with the desired port number. The port number may have a value between 1024 and 49151, and must be unique and not in use.
`-a`	Indicates that the Job Server will manage an adapter. If not specified, the new Job Server will not manage adapters.
`-B`**`<broker_port>`**	Specifies the adapter manager port. Replace **`<broker_port>`** with the desired port number. The port number may have a value between 1024 and 49151, and must be unique and not in use.
`-s`	Indicates that SNMP is enabled for the Job Server. If not specified, SNMP is disabled.
`-d`	Indicates that this is the default repository for the Job Server.
`-U`**`<username>`**	Specifies the username used to connect to the repository. Replace **`<username>`** with the repository username.
`-W`**`<password>`**	Specifies the password used to connect to the repository. Replace **`<password>`** with the repository password.
`-N`**`<db_type>`**	Specifies the type of database used for the repository. Replace **`<db_type>`** with a valid value: ● `DB2` ● `Microsoft_SQL_Server` ● `MySQL` ● `Oracle` ● `SQL_Anywhere` ● `Sybase`

Parameter	Description
-S**<server_name>**	Specifies the database service name or server name used to connect to the repository. Replace **<server_name>** with the appropriate information for the database type: ● For Oracle, the database service name as specified in tnsnames.ora. ● For DB2, the database instance name. ● For Microsoft SQL Server, the database server name. ● For Sybase, the database server name. ● For MySQL, the database source name as specified in the system DSN. ● For SAP Sybase SQL Anywhere, the database server name.
-Q**<database_name>**	Specifies the database name for the repository. Replace **<database_name>** with the name of the repository database. Note This parameter is required only for repositories on Sybase and Microsoft SQL Server.
-g	Indicates that Windows authentication will be used for the connection to the repository. Note This parameter is applicable only for repositories on Microsoft SQL Server.

Example

Add a Job Server with an Oracle repository

```
AWServerConfig.exe -n -JNewJobServer -P3500 -Uuser -Wpass -NOracle -SORCLPROD
```

1.10.6.3 To add run-time resources

To use `AWServerConfig.exe` to add run-time resources from the command line, use the `-n` parameter, along with additional run-time resource-specific parameters. `-n` must be the first parameter.

Run-time resource parameters

Parameter	Description
-C**<cache_dir>**	Specifies the directory for the pageable cache. Replace **<cache_dir>** with the desired directory.
-PF**<from_port>**	Specifies the starting port number. Replace **<from_port>** with the desired port number. The port number may have a value between 1025 and 32766, and must be unique and not in use.
-PT**<to_port>**	Specifies the ending port number. Replace **<to_port>** with the desired port number. The port number may have a value between 1026 and 32767, and must be unique and not in use. The ending port value must be greater than the starting port value.

Example

Add a pageable cache resource on ports 2000-2550

```
AWServerConfig.exe -n -C"%LINK_DIR%\log\Pcache" -PF2000 -PT2550
```

1.10.7 Server Manager (Unix)

The Server Manager (`svrcfg`) is used to create, edit, or delete Job Servers and Access Servers after installation on Unix platforms. In addition to the console-based interface, `svrcfg` also supports command-line parameters for several tasks:

- Adding a Job Server
- Adding an Access Server
- Adding run-time resources
- Starting Data Services services
- Stopping Data Services services

Common parameters

`svrcfg` supports one common parameter for all operations. Other available parameters depend on the operation.

Parameter	Description
-T**<task>**	Specifies the configuration task to perform. Available values for **<task>** include:

Parameter	Description
	• `JS` - Add a Job Server • `AS` - Add an Access Server • `R` - Add run-time resources • `START` - Start services • `STOP` - Stop services

ℹ Note

When starting or stopping the Data Services services, `svrcfg` requires no additional parameters.

Example

Start Data Services services

```
svrcfg -TSTART
```

Example

Stop Data Services services

```
svrcfg -TSTOP
```

Output

When using `svrcfg` to perform tasks from the command line, output is directed to the console (or `stdout`). The last line of the output indicates whether the task execution succeeded or failed. Possible statuses include:

- `Success`
- `Failure`

1.10.7.1 To add an Access Server

To use `svrcfg` to add an Access Server from the command line, use the `-TAS` parameter, along with additional Access Server-specific parameters.

Access Server parameters

Parameter	Description
-A**<path>**	Specifies the path for the access server. Replace **<path>** with the desired path.
-O**<port>**	Specifies the port assigned to the Access Server. Replace **<port>** with the desired port number. The port number may have a value between 1024 and 49151, and must be unique and not in use.
-R**<param>**	Specifies a parameter for the Access Server. Replace **<param>** with the desired parameter.
-E	Indicates that the Access Server should be enabled. If not specified, the Access Server is created but not enabled.

Example

Create and enable an Access Server on port 4000

```
svrcfg -TAS -A/home/bods/AStest -O4000 -E
```

1.10.7.2 To add a Job Server

To use `svrcfg` to add a Job Server from the command line, use the `-TJS` parameter, along with additional Job Server-specific parameters.

Job Server parameters

Parameter	Description
-J**<server_name>**	Specifies the name of the Job Server. Replace **<server_name>** with the desired name for the Job Server. The specified name may not contain `@@` and must be unique.
-p**<port_number>**	Specifies the listening port for the Job Server. Replace **<port_number>** with the desired port number. The port number may have a value between 1024 and 49151, and must be unique and not in use.
-a	Indicates that the Job Server will manage an adapter. If not specified, the new Job Server will not manage adapters.

Parameter	Description
`-b`**`<broker_port>`**	Specifies the adapter manager port. Replace **`<broker_port>`** with the desired port number. The port number may have a value between 1024 and 49151, and must be unique and not in use.
`-e`	Indicates that SNMP is enabled for the Job Server. If not specified, SNMP is disabled.
`-D`**`<db_type>`**	Specifies the type of database used for the repository. Replace **`<db_type>`** with a valid value: ● `DB2` ● `HANA` ● `MySQL` ● `Oracle` ● `SQL_Anywhere` ● `SYBASE`
`-C`**`<connect_string>`**	Specifies the connection string to use to connect to the repository. Replace **`<connect_string>`** with appropriate information for the database type: ● For DB2, the database instance name. ● For MySQL, the data source name as specified in the `odbc.ini` file referenced by `$ODBCINI`. ● For Oracle, the service name as specified in `tnsnames.ora`. ● For SAP HANA, the data source name as specified in the `odbc.ini` file referenced by `$ODBCINI`. ● For SAP Sybase SQL Anywhere, the database server name. ● For Sybase, the database server name.
`-d`**`<database>`**	Specifies the database name for the repository. Replace **`<database>`** with the name of the repository database. ℹ Note This parameter is required only for repositories on Sybase.
`-U`**`<username>`**	Specifies the username used to connect to the repository. Replace **`<username>`** with the repository username.
`-P`**`<password>`**	Specifies the password used to connect to the repository. Replace **`<password>`** with the repository password.

Example

Add a Job Server with an Oracle repository

```
svrcfg -TJS -JJobServer_1 -p3500 -DOracle -CORCL -Uuser -Ppassword
```

1.10.7.3 To add run-time resources

To use `svrcfg` to add run-time resources from the command line, use the `-TR` parameter, along with additional run-time resource-specific parameters.

Run-time resource parameters

Parameter	Description
`-i<cache_dir>`	Specifies the directory for the pageable cache. Replace `<cache_dir>` with the desired directory.
`-t<port>`	Specifies the starting port number. Replace `<port>` with the desired port number. The port number may have a value between 1025 and 32766, and must be unique and not in use.
`-n<port>`	Specifies the ending port number. Replace `<port>` with the desired port number. The port number may have a value between 1026 and 32767, and must be unique and not in use. The ending port value must be greater than the starting port value.

Example

Add a pageable cache resource on ports 2000-3000

```
svrcfg -TR -i$LINK_DIR\Log\Cache2 -t2000 -n3000
```

1.10.8 Password encryption

You can use `al_encrypt` to encrypt a password by using either an encryption key or a passphrase.

Additionally, you can use `al_encrypt` to return the base64 encoding of any text. This may be useful if you need to modify a command line that contains global variable or substitution variable data, which must be encoded in base64 form.

By default, `al_encrypt` is installed to the **`<LINK_DIR>`**`/bin` directory.

Syntax

```
al_encrypt -e <plain_password> [-k <key string> | -p <passphrase>]
```

```
al_encrypt "<text to encode>"
```

Parameter	Description
`-e <password>`	Specifies the plain-text password to encrypt.
`-k <key string>`	Specifies the encryption key to use to encrypt the password.
`-p <passphrase>`	Specifies the passphrase to use to encrypt the password.
`<text to encode>`	When you run `al_encrypt` with no parameters, it returns the base64 encoding of any following optionally-quoted text.

Example

Encrypt a password using a passphrase

```
al_encrypt -e mypassword -p thepassphrase >
+0100000000120303000803E83F55088B0C987CD715006C02938825530E8691DFD9DDB4198AFFC5C194C
D8CE6D338FDE470E2
```

Example

Encode text using base64 encoding

```
al_encrypt "encode this as base64" > ZW5jb2RlIHRoaXMgYXMgYmFzZTY0
```

1.10.9 al_engine

`al_engine` is a core Data Services process. It is responsible for executing jobs, importing and exporting repository objects, and so on.

Common options

`al_engine` supports options that are common to many different operations.

Parameter	Description
`-U<Username>`	Specifies the username used to log into the repository.
`-P<Password>`	Specifies the password used to log into the repository.
`-S<ServerName>`	Specifies the repository server name. For a DSN connection to a DB2, SAP HANA SAP Sybase, or SAP Sybase SQL Anywhere repository, use ODBC connection name.

Parameter	Description
-N**<DatabaseType>**	Specifies the repository database type Acceptable values include: ● Oracle ● Microsoft_SQL_Server ● DB2 ● MySQL ● Sybase ● HANA ● SQL_Anywhere
-Q**<DatabaseName_or_SID>**	Specifies the repository database name or SID (for Oracle). For a DSN-less connection to a DB2, SAP Sybase, or SAP Sybase SQL Anywhere repository, use database name.
-Kserver	Specify this parameter to use a server name (also known as DSN-less or TNS-less) connection to the repository. If you specify this parameter, you must specify the -Kport and -Kversion parameters.
-Kport**<PortNumber>**	Repository port number for server name connection. This parameter is required if you specified -Kserver for a server name connection.
-Kversion**<VersionNumber>**	Repository database server version for server name connection. This parameter is required if you specified -Kserver for a server name connection. For example, -Kversion"MySQL 5.1"
-g	Specifies Windows Authentication as the repository connection type. This parameter is valid only for repositories on Microsoft SQL Server.
-v	Returns the version number of the Data Services engine.

1.10.9.1 Export and import options

al_engine supports options that are used only for export and import operations. al_engine can import and export repository information in two formats: XML and ATL, the software's internal scripting language.

Parameter	Description
-X	Exports the entire repository in ATL format to repo_export.atl.
-XKserver	Exports repository server name connection (for MySQL, SAP HANA, ORACLE, and DB2).
-XKport**<PortNumber>**	Exports repository port number for server name connection. This parameter must be used with -XKserver parameter.

Parameter	Description
-XKversion**<VersionNumber>**	Exports repository database server version for server name connection. This parameter must be used with the –XKserver parameter. For example, -XKversion"MySQL 5.1"
-Xp@**<ObjectType>**@**<FileName>**	Exports all repository objects of the specified type to the specified file in ATL format.
-Xp@**<ObjectType>**@**<FileName>**@**<ObjectName>**	Exports the specified repository object to the specified file in ATL format.
–Xp@**<ObjectType>**@**<FileName>**@**<ObjectName>**@DE	Exports the specified repository object and its dependents to the specified file in ATL format, including datastore information.
-Xp@**<ObjectType>**@**<FileName>**@**<ObjectName>**@D	Exports the specified repository object and its dependents to the specified file in ATL format, excluding datastore information.
-XX[L]	Exports the entire repository in XML format to export.xml.
-XX[L]@**<ObjectType>**@**<FileName>**	Exports all repository objects of the specified type to the specified file in XML format.
–XX[L]@**<ObjectType>**@**<FileName>**@**<ObjectName>**	Exports the specified repository object to the specified file in XML format.
–XX[L]@**<ObjectType>**@**<FileName>**@**<ObjectName>**@DE	Exports the specified repository object and its dependents to the specified file in XML format, including datastore information.
–XX[L]@**<ObjectType>**@**<FileName>**@**<ObjectName>**@D	Exports the specified repository object and its dependents to the specified file in XML format, excluding datastore information.
-f**<filename.atl>**	Imports information from **<filename.atl>** into the repository.
-XI**<filename.xml>**	Imports information from **<filename.xml>** into the repository.
-passphrase**<passphrase>**	Specifies a plain-text passphrase to use to encrypt any passwords when exporting objects or decrypt any passwords when importing objects.
-epassphrase**<passphrase>**	Specifies a base64-encoded passphrase to use to encrypt any passwords when exporting objects or decrypt any passwords when importing objects. This parameter can be used to use a passphrase that contains special characters. Note You must transcode the passphrase to the UTF8 character set before encoding it into base64.

Note

For all –XX parameters, the optional addition [L] specifies a lean XML format for export. The lean XML format excludes all non-executable elements from the exported XML to improve readability. For example, the exact arrangement of transforms within a data flow in the Designer workspace area would not be maintained. When imported back into the software, the transforms would be arranged automatically.

Note

When you export objects, you must specify a passphrase with either the -passphrase parameter or the –epassphrase parameter. When you import objects, the passphrase is optional. However, if you do not specify a passphrase, or the specified passphrase is incorrect, any encrypted passwords in the imported objects will be removed.

Available object type codes

Code	Object type
P	Projects
J	Jobs
W	work flows
D	data flows
T	Idocs
F	User-defined file formats
X	XML and DTD message formats
S	Datastores
C	Custom functions
B	COBOL Copybooks
E	Excel workbooks
p	System profiles
v	Substitution parameter configurations
K	SDK-type transform configurations

Example

Export all data flows in lean XML format

```
al_engine -Uuser -Ppassword -Slocalhost -NMySQL -QTheRepository -
XXL@D@exported_dataflows.xml -passphraseMypassphrase
```

2 Designer Guide

2.1 Introduction

2.1.1 Welcome to SAP Data Services

2.1.1.1 Welcome

SAP Data Services delivers a single enterprise-class solution for data integration, data quality, data profiling, and text data processing that allows you to integrate, transform, improve, and deliver trusted data to critical business processes. It provides one development UI, metadata repository, data connectivity layer, run-time environment, and management console—enabling IT organizations to lower total cost of ownership and accelerate time to value. With SAP Data Services, IT organizations can maximize operational efficiency with a single solution to improve data quality and gain access to heterogeneous sources and applications.

2.1.1.2 Documentation set for SAP Data Services

You should become familiar with all the pieces of documentation that relate to your SAP Data Services product. The latest Data Services documentation can be found on the *SAP Help Portal*.

Document	What this document provides
Adapter SDK Guide	Information about installing, configuring, and running the Data Services Adapter SDK
Administrator Guide	Information about administrative tasks such as monitoring, lifecycle management, security, and so on.
Customer Issues Fixed	Information about customer issues fixed in this release. Note In some releases, this information is displayed the Release Notes.
Designer Guide	Information about how to use Data Services Designer.
Documentation Map	Information about available Data Services books, languages, and locations.
Installation Guide for Windows	Information about and procedures for installing Data Services in a Windows environment.
Installation Guide for UNIX	Information about and procedures for installing Data Services in a UNIX environment.
Integrator Guide	Information for third-party developers to access Data Services functionality using web services and APIs.

Document	What this document provides
Master Guide	Information about the application, its components and scenarios for planning and designing your system landscape. Information about SAP Information Steward is also provided in this guide.
Management Console Guide	Information about how to use Data Services Administrator and Data Services Metadata Reports.
Performance Optimization Guide	Information about how to improve the performance of Data Services.
Reference Guide	Detailed reference material for Data Services Designer.
Release Notes	Important information you need before installing and deploying this version of Data Services.
Technical Manuals	A compiled, searchable, “master” PDF of core Data Services books: ● *Administrator Guide* ● *Designer Guide* ● *Reference Guide* ● *Management Console Guide* ● *Performance Optimization Guide* ● *Integrator Guide* ● *Supplement for J.D. Edwards* ● *Supplement for Oracle Applications* ● *Supplement for PeopleSoft* ● *Supplement for Salesforce.com* ● *Supplement for Siebel* ● *Supplement for SAP* ● *Workbench Guide*
Text Data Processing Extraction Customization Guide	Information about building dictionaries and extraction rules to create your own extraction patterns to use with Text Data Processing transforms.
Text Data Processing Language Reference Guide	Information about the linguistic analysis and extraction processing features that the Text Data Processing component provides, as well as a reference section for each language supported.
Tutorial	A step-by-step introduction to using Data Services.
Upgrade Guide	Information to help you upgrade from previous releases of Data Services and release-specific product behavior changes from earlier versions of Data Services to the latest release.
What's New	Highlights of new key features in this SAP Data Services release. This document is not updated for support package or patch releases.
Workbench Guide	Provides users with information about how to use the Workbench to migrate data and database schema information between different database systems.

In addition, you may need to refer to several Supplemental Guides.

Document	What this document provides
Supplement for SAP	Information about interfaces between Data Services, SAP Applications, SAP Master Data Services, SAP NetWeaver BW, and SAP Master Data Services.
Supplement for SuccessFactors	Information about interfaces between Data Services and SuccessFactors.
Supplement for Salesforce.com	Information about how to install, configure, and use the SAP Data Services Salesforce.com Adapter Interface.
Supplement for J.D. Edwards	Information about interfaces between Data Services and J.D. Edwards World and J.D. Edwards OneWorld.
Supplement for Oracle Applications	Information about the interface between Data Services and Oracle Applications.
Supplement for PeopleSoft	Information about interfaces between Data Servicesand PeopleSoft.
Supplement for Siebel	Information about the interface between Data Services and Siebel.

We also include these manuals for information about SAP BusinessObjects Information platform services.

Document	What this document provides
Information platform services Administrator Guide	Information for administrators who are responsible for configuring, managing, and maintaining an Information platform services installation.
Information platform services Installation Guide for UNIX	Installation procedures for SAP BusinessObjects Information platform services on a UNIX environment.
Information platform services Installation Guide for Windows	Installation procedures for SAP BusinessObjects Information platform services on a Windows environment.

2.1.1.3 Accessing documentation

You can access the complete documentation set for SAP Data Services in several places.

2.1.1.3.1 Accessing documentation on Windows

After you install SAP Data Services, you can access the documentation from the Start menu.

1. Choose *Start* > *Programs* > *SAP Data Services 4.2* > *Data Services Documentation* > *All Guides* .
2. Click the appropriate shortcut for the document that you want to view.

2.1.1.3.2 Accessing documentation on UNIX

After you install SAP Data Services, you can access the documentation by going to the directory where the printable PDF files were installed.

1. Go to **<LINK_DIR>**`/doc/book/en/`.
2. Using Adobe Reader, open the PDF file of the document that you want to view.

2.1.1.3.3 Accessing documentation from the Web

You can access the complete documentation set for SAP Data Services from the SAP Business Users Support site.

To do this, go to *http://help.sap.com/bods*.

You can view the PDFs online or save them to your computer.

2.1.1.4 SAP information resources

A global network of SAP technology experts provides customer support, education, and consulting to ensure maximum information management benefit to your business.

Useful addresses at a glance:

Address	Content
Customer Support, Consulting, and Education services *http://service.sap.com/*	Information about SAP support programs, as well as links to technical articles, downloads, and online forums. Consulting services can provide you with information about how SAP can help maximize your information management investment. Education services can provide information about training options and modules. From traditional classroom learning to targeted e-learning seminars, SAP can offer a training package to suit your learning needs and preferred learning style.
Product documentation *http://help.sap.com/bods/*	SAP product documentation.
Supported Platforms (Product Availability Matrix) *https://service.sap.com/PAM*	Get information about supported platforms for SAP Data Services. Use the search function to search for Data Services. Click the link for the version of Data Services you are searching for.
SAP Data Services Community Network *http://scn.sap.com/community/data-services*	Get online and timely information about SAP Data Services, including forums, tips and tricks, additional downloads, samples, and much more. All content is to and from the community, so feel free to join in and contact us if you have a submission.
Blueprints *http://scn.sap.com/docs/DOC-8820*	Blueprints for you to download and modify to fit your needs. Each blueprint contains the necessary SAP Data Services project, jobs, data flows, file formats, sample data, template

Address	Content
	tables, and custom functions to run the data flows in your environment with only a few modifications.
SAPTerm *https://portal.wdf.sap.corp/go/sapterm*	SAP's terminology database, the central repository for defining and standardizing the use of specialist terms.

2.1.2 Overview of this guide

Welcome to the *Designer Guide*. The Data Services Designer provides a graphical user interface (GUI) development environment in which you define data application logic to extract, transform, and load data from databases and applications into a data warehouse used for analytic and on-demand queries. You can also use the Designer to define logical paths for processing message-based queries and transactions from Web-based, front-office, and back-office applications.

2.1.2.1 About this guide

The guide contains two kinds of information:

- Conceptual information that helps you understand the Data Services Designer and how it works
- Procedural information that explains in a step-by-step manner how to accomplish a task

You will find this guide most useful:

- While you are learning about the product
- While you are performing tasks in the design and early testing phase of your data-movement projects
- As a general source of information during any phase of your projects

2.1.2.2 Who should read this guide

This and other Data Services product documentation assumes the following:

- You are an application developer, consultant, or database administrator working on data extraction, data warehousing, data integration, or data quality.
- You understand your source data systems, RDBMS, business intelligence, and messaging concepts.
- You understand your organization's data needs.
- You are familiar with SQL (Structured Query Language).
- If you are interested in using this product to design real-time processing, you should be familiar with:
  - DTD and XML Schema formats for XML files
  - Publishing Web Services (WSDL, REST, HTTP, and SOAP protocols, etc.)
- You are familiar Data Services installation environments—Microsoft Windows or UNIX.

2.2 Logging into the Designer

You must have access to a local repository to log into the software. Typically, you create a repository during installation. However, you can create a repository at any time using the Repository Manager, and configure access rights within the Central Management Server.

Additionally, each repository must be associated with at least one Job Server before you can run repository jobs from within the Designer. Typically, you define a Job Server and associate it with a repository during installation. However, you can define or edit Job Servers or the links between repositories and Job Servers at any time using the Server Manager.

When you log in to the Designer, you must log in as a user defined in the Central Management Server (CMS).

1. Enter your user credentials for the CMS.

Option	Description
System	Specify the server name and optionally the port for the CMS.
User name	Specify the user name to use to log into CMS.
Password	Specify the password to use to log into the CMS.
Authentication	Specify the authentication type used by the CMS.

2. Click *Log on*.
   The software attempts to connect to the CMS using the specified information. When you log in successfully, the list of local repositories that are available to you is displayed.
3. Select the repository you want to use.
4. Click *OK* to log in using the selected repository.
   When you click *OK*, you are prompted to enter the password for the Data Services repository. This default behavior can be changed by adding the necessary rights to the repository in the CMC. See the *Administrator Guide* for more information.

Related Information

Administrator Guide: Password protection for a Data Services repository [page 45]
Administrator Guide: Managing security settings for repositories in the CMC [page 53]

2.2.1 Version restrictions

Your repository version must be associated with the same major release as the Designer and must be less than or equal to the version of the Designer.

During login, the software alerts you if there is a mismatch between your Designer version and your repository version.

After you log in, you can view the software and repository versions by selecting *Help* > *About Data Services*.

Some features in the current release of the Designer might not be supported if you are not logged in to the latest version of the repository.

2.2.2 Resetting users

Occasionally, more than one person may attempt to log in to a single repository. If this happens, the Reset Users window appears, listing the users and the time they logged in to the repository.

From this window, you have several options. You can:

- *Reset Users* to clear the users in the repository and set yourself as the currently logged in user.
- *Continue* to log in to the system regardless of who else might be connected.
- *Exit* to terminate the login attempt and close the session.

Note

Only use *Reset Users* or *Continue* if you know that you are the only user connected to the repository. Subsequent changes could corrupt the repository.

2.3 Designer User Interface

This section provides basic information about the Designer's graphical user interface.

2.3.1 Objects

All "entities" you define, edit, or work with in Designer are called objects. The local object library shows objects such as source and target metadata, system functions, projects, and jobs.

Objects are hierarchical and consist of:

- Options, which control the operation of objects. For example, in a datastore, the name of the database to which you connect is an option for the datastore object.
- Properties, which document the object. For example, the name of the object and the date it was created are properties. Properties describe an object, but do not affect its operation.

The software has two types of objects: Reusable and single-use. The object type affects how you define and retrieve the object.

2.3.1.1 Reusable objects

You can reuse and replicate most objects defined in the software.

After you define and save a reusable object, the software stores the definition in the local repository. You can then reuse the definition as often as necessary by creating calls to the definition. Access reusable objects through the local object library.

A reusable object has a single definition; all calls to the object refer to that definition. If you change the definition of the object in one place, you are changing the object in all other places in which it appears.

A data flow, for example, is a reusable object. Multiple jobs, like a weekly load job and a daily load job, can call the same data flow. If the data flow changes, both jobs use the new version of the data flow.

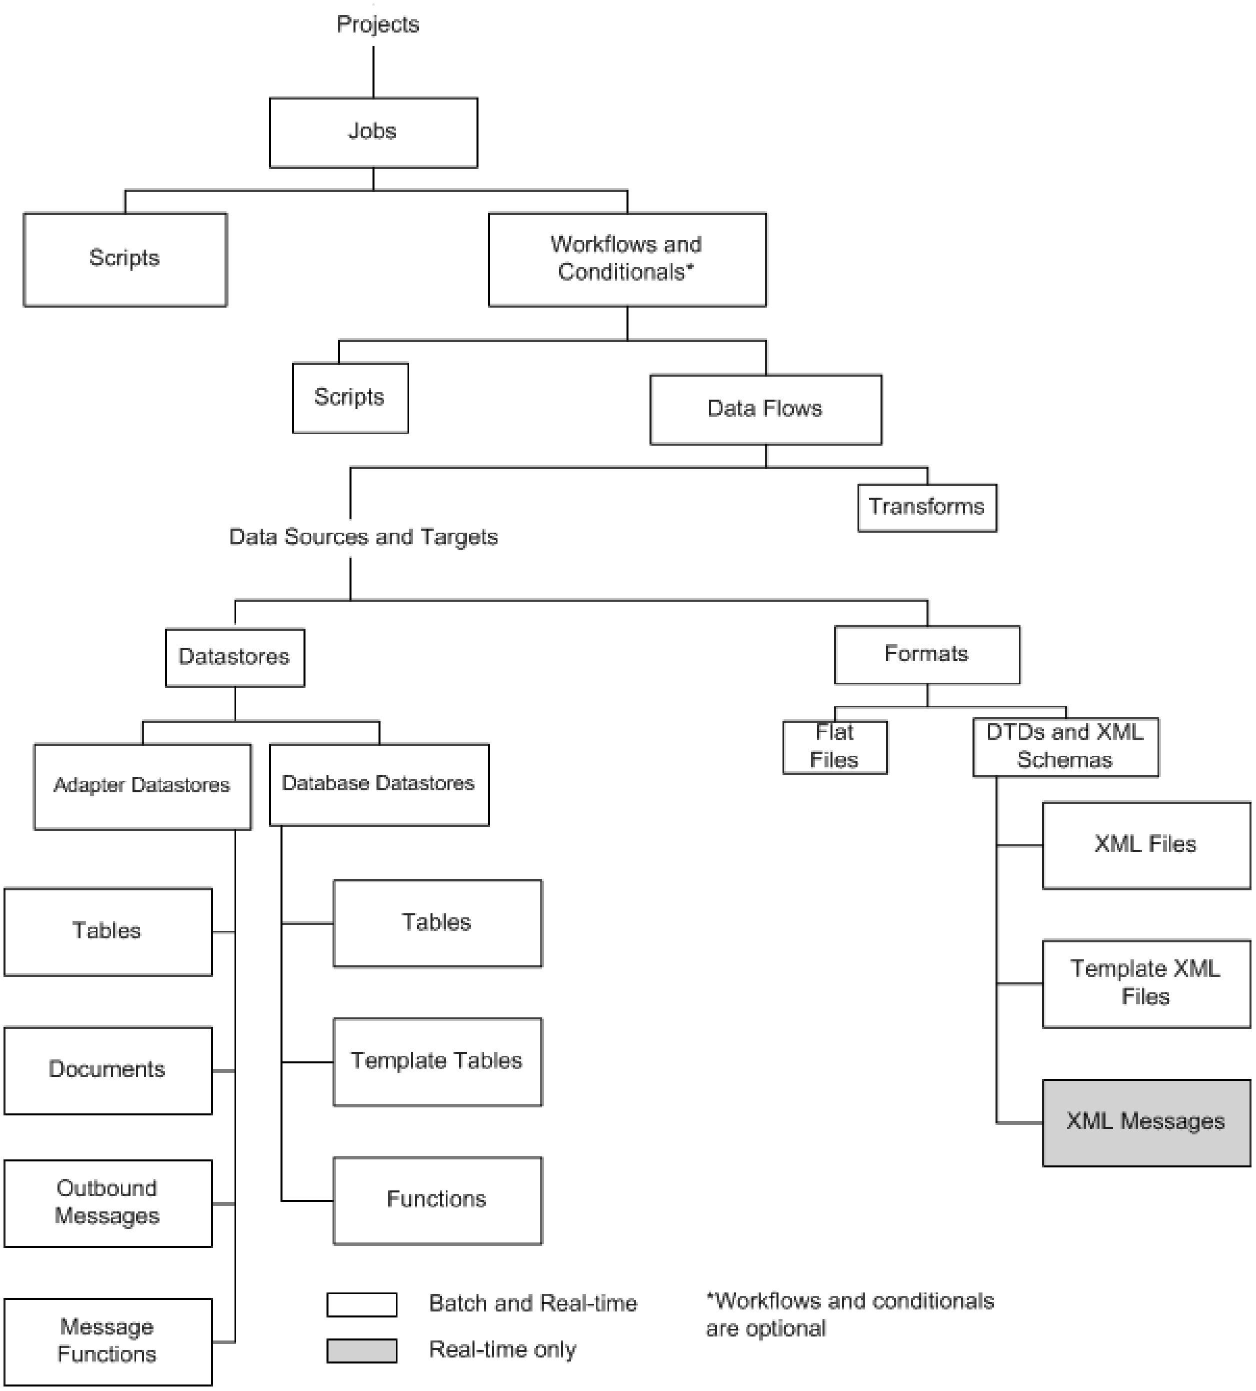
The object library contains object definitions. When you drag and drop an object from the object library, you are really creating a new reference (or call) to the existing object definition.

2.3.1.2 Single-use objects

Some objects are defined only within the context of a single job or data flow, for example scripts and specific transform definitions.

2.3.1.3 Object hierarchy

Object relationships are hierarchical. The following figure shows the relationships between major object types:



2.3.2 Menu bar

This section contains a brief description of the Designer's menus.

2.3.2.1 Project menu

The project menu contains standard Windows as well as software-specific options.

Option	Description
New	Define a new project, batch job, real-time job, work flow, data flow, transform, datastore, file format, DTD, XML Schema, or custom function.
Open	Open an existing project.
Close	Close the currently open project.
Delete	Delete the selected object.
Save	Save the object open in the workspace.
Save All	Save all changes to objects in the current Designer session.
Print	Print the active workspace.
Print Setup	Set up default printer information.
Exit	Exit Designer.

2.3.2.2 Edit menu

The Edit menu provides standard Windows commands with a few restrictions.

Option	Description
Undo	Undo the last operation.
Cut	Cut the selected objects or text and place it on the clipboard.
Copy	Copy the selected objects or text to the clipboard.
Paste	Paste the contents of the clipboard into the active workspace or text box.
Delete	Delete the selected objects.
Recover Last Deleted	Recover deleted objects to the workspace from which they were deleted. Only the most recently deleted objects are recovered.
Select All	Select all objects in the active workspace.
Clear All	Clear all objects in the active workspace (no undo).

2.3.2.3 View menu

A check mark indicates that the tool is active.

Option	Description
Toolbar	Display or remove the toolbar in the Designer window.
Status Bar	Display or remove the status bar in the Designer window.
Palette	Display or remove the floating tool palette.
Enabled Descriptions	View descriptions for objects with enabled descriptions.
Refresh	Redraw the display. Use this command to ensure the content of the workspace represents the most up-to-date information from the repository.

2.3.2.4 Tools menu

An icon with a different color background indicates that the tool is active.

Option	Description
Object Library	Open or close the object library window.
Project Area	Display or remove the project area from the Designer window.
Variables	Open or close the Variables and Parameters window.
Output	Open or close the Output window. The Output window shows errors that occur such as during job validation or object export.
Profiler Monitor	Display the status of Profiler tasks.
Run Match Wizard	Display the Match Wizard to create a match data flow. Select a transform in a data flow to activate this menu item. The transform(s) that the Match Wizard generates will be placed downstream from the transform you selected.
Match Editor	Display the Match Editor to edit Match transform options.
Associate Editor	Display the Associate Editor to edit Associate transform options.
User-Defined Editor	Display the User-Defined Editor to edit User-Defined transform options.
Custom Functions	Display the Custom Functions window.
System Configurations	Display the System Configurations editor.
Substitution Parameter Configurations	Display the Substitution Parameter Editor to create and edit substitution paramters and configurations.
Profiler Server Login	Connect to the Profiler Server.
Export	Export individual repository objects to another repository or file. This command opens the Export editor in the workspace. You can drag objects from the object library into the editor for export. To export your whole repository, in the object library right-click and select *Repository* > *Export to file*.

Option	Description
Import From File	Import objects into the current repository from a file. The default file types are ATL, XML, DMT, and FMT. For more information on DMT and FMT files, see the *Upgrade Guide*.
Metadata Exchange	Import and export metadata to third-party systems via a file.
BusinessObjects Universes	Export (create or update) metadata in BusinessObjects Universes.
Central Repositories	Create or edit connections to a central repository for managing object versions among multiple users.
Options	Display the Options window.
Data Services Management Console	Display the Management Console.

2.3.2.5 Debug menu

The only options available on this menu at all times are *Show Filters/Breakpoints* and *Filters/Breakpoints*. The *Execute* and *Start Debug* options are only active when a job is selected. All other options are available as appropriate when a job is running in the Debug mode.

Option	Description
Execute	Opens the Execution Properties window which lets you execute the selected job.
Start Debug	Opens the Debug Properties window which lets you run a job in the debug mode.

Option	Description
View Design-Time Data	Opens data panes in the transform editor, which let you view and analyze the input and output for a data set in real time as you design a transform.
View Automatically	Let you view input and output data automatically after you modify a transform.
Filter Input Dataset	To filter the number of data rows displayed in the Design-Time Data Viewer panes.
Options	Opens a window in which you can configure the number of data rows displayed and the time allowed for updates before a time out.
Show Filters/Breakpoints	Shows and hides filters and breakpoints in workspace diagrams.
Filters/Breakpoints	Opens a window you can use to manage filters and breakpoints.

Related Information

Using the interactive debugger [page 701]
Using the Design-Time Data Viewer [page 699]
Filters and Breakpoints window [page 711]

2.3.2.6 Validation menu

The Designer displays options on this menu as appropriate when an object is open in the workspace.

Option	Description
Validate	Validate the objects in the current workspace view or all objects in the job before executing the application.
Show ATL	View a read-only version of the language associated with the job.
Display Optimized SQL	Display the SQL that Data Services generated for a selected data flow.

Related Information

Performance Optimization Guide: Maximizing Push-Down Operations, To view SQL [page 2121]

2.3.2.7 Window menu

The Window menu provides standard Windows options.

Option	Description
Back	Move back in the list of active workspace windows.
Forward	Move forward in the list of active workspace windows.
Cascade	Display window panels overlapping with titles showing.
Tile Horizontally	Display window panels one above the other.
Tile Vertically	Display window panels side by side.
Close All Windows	Close all open windows.

A list of objects open in the workspace also appears on the Windows menu. The name of the currently-selected object is indicated by a check mark. Navigate to another open object by selecting its name in the list.

2.3.2.8 Help menu

The Help menu provides standard help options.

Option	Description
Release Notes	Displays the *Release Notes* for this release.
What's New	Displays a summary of new features for this release.
Technical Manuals	Displays the *Technical Manuals* CHM file, a compilation of many of the Data Services technical documents. You can also access the same documentation from the <LINKDIR>\Doc \Books directory.
Tutorial	Displays the *Data Services Tutorial*, a step-by-step introduction to using SAP Data Services.
Data Services Community	Get online and timely information about SAP Data Services, including tips and tricks, additional downloads, samples, and much more. All content is to and from the community, so feel free to join in and contact us if you have a submission.
Forums on SCN (SAP Community Network)	Search the SAP forums on the SAP Community Network to learn from other SAP Data Services users and start posting questions or share your knowledge with the community.
Blueprints	Blueprints for you to download and modify to fit your needs. Each blueprint contains the necessary SAP Data Services project, jobs, data flows, file formats, sample data, template tables, and custom functions to run the data flows in your environment with only a few modifications.
Show Start Page	Displays the home page of the Data Services Designer.

Option	Description
About Data Services	Display information about the software including versions of the Designer, Job Server and engine, and copyright information.

2.3.3 Toolbar

In addition to many of the standard Windows tools, the software provides application-specific tools, including:

Icon	Tool	Description
	Close all windows	Closes all open windows in the workspace.
	Local Object Library	Opens and closes the local object library window.
	Central Object Library	Opens and closes the central object library window.
	Variables	Opens and closes the variables and parameters creation window.
	Project Area	Opens and closes the project area.
	Output	Opens and closes the output window.
	View Enabled Descriptions	Enables the system level setting for viewing object descriptions in the workspace.
	Validate Current View	Validates the object definition open in the workspace. Other objects included in the definition are also validated.
	Validate All Objects in View	Validates the object definition open in the workspace. Objects included in the definition are also validated.
✓	Audit Objects in Data Flow	Opens the Audit window to define audit labels and rules for the data flow.
	View Where Used	Opens the Output window, which lists parent objects (such as jobs) of the object currently open in the workspace (such as a data flow). Use this command to find other jobs that use the same data flow, before you decide to make design changes. To see if an object in a data flow is reused elsewhere, right-click one and select *View Where Used*.
←	Go Back	Move back in the list of active workspace windows.

Icon	Tool	Description
⇨	Go Forward	Move forward in the list of active workspace windows.
	Management Console	Opens and closes the Management Console window.
?	Contents	Opens the *Technical Manuals* PDF for information about using the software.

Use the tools to the right of the About tool with the interactive debugger.

Related Information

Debug menu options and tool bar [page 711]

2.3.4 Project area

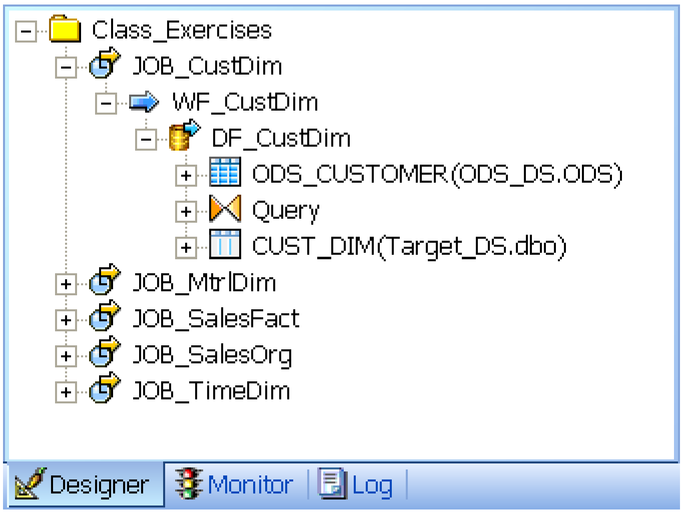
The project area provides a hierarchical view of the objects used in each project. Tabs on the bottom of the project area support different tasks. Tabs include:

Designer	Create, view and manage projects. Provides a hierarchical view of all objects used in each project.
Monitor	View the status of currently executing jobs. Selecting a specific job execution displays its status, including which steps are complete and which steps are executing. These tasks can also be done using the Administrator.
Log	View the history of complete jobs. Logs can also be viewed with the Administrator.

To control project area location, right-click its gray border and select/deselect *Docking*, or select *Hide* from the menu.

- When you select *Docking*, you can click and drag the project area to dock at and undock from any edge within the Designer window. When you drag the project area away from a Designer window edge, it stays undocked. To quickly switch between your last docked and undocked locations, just double-click the gray border.
When you deselect Allow Docking, you can click and drag the project area to any location on your screen and it will not dock inside the Designer window.
- When you select *Hide*, the project area disappears from the Designer window. To unhide the project area, click its toolbar icon.

Here's an example of the Project window's *Designer* tab, which shows the project hierarchy:



```
Class_Exercises
  JOB_CustDim
    WF_CustDim
      DF_CustDim
        ODS_CUSTOMER(ODS_DS.ODS)
        Query
        CUST_DIM(Target_DS.dbo)
  JOB_MtrlDim
  JOB_SalesFact
  JOB_SalesOrg
  JOB_TimeDim
```

As you drill down into objects in the Designer workspace, the window highlights your location within the project hierarchy.

2.3.5 Tool palette

The tool palette is a separate window that appears by default on the right edge of the Designer workspace. You can move the tool palette anywhere on your screen or dock it on any edge of the Designer window.

The icons in the tool palette allow you to create new objects in the workspace. The icons are disabled when they are not allowed to be added to the diagram open in the workspace.

To show the name of each icon, hold the cursor over the icon until the tool tip for the icon appears, as shown.

When you create an object from the tool palette, you are creating a new definition of an object. If a new object is reusable, it will be automatically available in the object library after you create it.

For example, if you select the data flow icon from the tool palette and define a new data flow, later you can drag that existing data flow from the object library, adding a call to the existing definition.

The tool palette contains the following icons:

Icon	Tool	Description (class)	Available
	Pointer	Returns the tool pointer to a selection pointer for selecting and moving objects in a diagram.	Everywhere
	Work flow	Creates a new work flow. (reusable)	Jobs and work flows
	Data flow	Creates a new data flow. (reusable)	Jobs and work flows
	ABAP data flow	Used only with the SAP application.	

Icon	Tool	Description (class)	Available
⋈	Query transform	Creates a template for a query. Use it to define column mappings and row selections. (single-use)	Data flows
▦	Template table	Creates a table for a target. (single-use)	Data flows
⇄	Template XML	Creates an XML template. (single-use)	Data flows
⇆	Data transport	Used only with the SAP application.	
📜	Script	Creates a new script object. (single-use)	Jobs and work flows
≺	Conditional	Creates a new conditional object. (single-use)	Jobs and work flows
○	Try	Creates a new try object. (single-use)	Jobs and work flows
◉	Catch	Creates a new catch object. (single-use)	Jobs and work flows
🗒	Annotation	Creates an annotation. (single-use)	Jobs, work flows, and data flows

2.3.6 Designer keyboard accessibility

The following keys are available for navigation in the Designer. All dialogs and views support these keys.

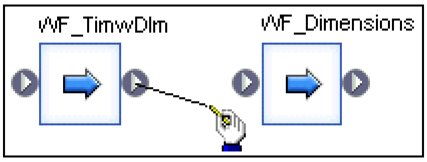
To	Press
Enter edit mode.	*F2*
Close a menu or dialog box or cancel an operation in progress.	*ESC*
Close the current window.	*CTRL+F4*
Cycle through windows one window at a time.	*CTRL+TAB*
Display a system menu for the application window.	*ALT+SPACEBAR*
Move to the next page of a property sheet.	*CTRL+PAGE DOWN*
Move to the previous page of a property sheet.	*CTRL+PAGE UP*
Move to the next control on a view or dialog.	*TAB*
Move to the previous control on a view or dialog.	*SHIFT+TAB*
Press a button when focused.	*ENTER* or *SPACE*
Enable the context menu (right-click mouse operations).	*SHIFT+F10* or *Menu Key*

To	Press
Expand or collapse a tree (+).	*Right Arrow* or *Left Arrow*
Move up and down a tree.	*Up Arrow* or *Down Arrow*
Show focus.	*ALT*
Hot Key operations.	*ALT+<LETTER>*

2.3.7 Workspace

When you open or select a job or any flow within a job hierarchy, the workspace becomes "active" with your selection. The workspace provides a place to manipulate system objects and graphically assemble data movement processes.

These processes are represented by icons that you drag and drop into a workspace to create a workspace diagram. This diagram is a visual representation of an entire data movement application or some part of a data movement application.



2.3.7.1 Moving objects in the workspace area

Use standard mouse commands to move objects in the workspace.

To move an object to a different place in the workspace area:

1. Click to select the object.
2. Drag the object to where you want to place it in the workspace.

2.3.7.2 Connecting objects

You specify the flow of data through jobs and work flows by connecting objects in the workspace from left to right in the order you want the data to be moved.

To connect objects:

1. Place the objects you want to connect in the workspace.
2. Click and drag from the triangle on the right edge of an object to the triangle on the left edge of the next object in the flow.

2.3.7.3 Disconnecting objects

To disconnect objects:

1. Click the connecting line.
2. Press the *Delete* key.

2.3.7.4 Describing objects

You can use descriptions to add comments about objects. You can use annotations to explain a job, work flow, or data flow. You can view object descriptions and annotations in the workspace. Together, descriptions and annotations allow you to document an SAP Data Services application. For example, you can describe the incremental behavior of individual jobs with numerous annotations and label each object with a basic description.

This job loads current categories and expenses and produces tables for analysis.

Related Information

Creating descriptions [page 192]
Creating annotations [page 194]

2.3.7.5 Scaling the workspace

You can control the scale of the workspace. By scaling the workspace, you can change the focus of a job, work flow, or data flow. For example, you might want to increase the scale to examine a particular part of a work flow, or you might want to reduce the scale so that you can examine the entire work flow without scrolling.

To change the scale of the workspace

1. In the drop-down list on the tool bar, select a predefined scale or enter a custom value (for example, 100%).
2. Alternatively, right-click in the workspace and select a desired scale.

> i Note
>
> You can also select *Scale to Fit* and *Scale to Whole*:

- Select *Scale to Fit* and the Designer calculates the scale that fits the entire project in the current view area.
- Select *Scale to Whole* to show the entire workspace area in the current view area.

2.3.7.6 Arranging workspace windows

The Window menu allows you to arrange multiple open workspace windows in the following ways: cascade, tile horizontally, or tile vertically.

2.3.7.7 Closing workspace windows

When you drill into an object in the project area or workspace, a view of the object's definition opens in the workspace area. The view is marked by a tab at the bottom of the workspace area, and as you open more objects in the workspace, more tabs appear. (You can show/hide these tabs from the *Tools* > *Options* menu. Go to *Designer* > *General* options and select/deselect *Show tabs in workspace*.)

> **Note**
>
> These views use system resources. If you have a large number of open views, you might notice a decline in performance.

Close the views individually by clicking the close box in the top right corner of the workspace. Close all open views by selecting *Window* > *Close All Windows* or clicking the *Close All Windows* icon on the toolbar.

Related Information

General and environment options [page 198]

2.3.8 Local object library

The local object library provides access to reusable objects. These objects include built-in system objects, such as transforms, and the objects you build and save, such as datastores, jobs, data flows, and work flows.

The local object library is a window into your local repository and eliminates the need to access the repository directly. Updates to the repository occur through normal software operation. Saving the objects you create adds them to the repository. Access saved objects through the local object library.

To control object library location, right-click its gray border and select/deselect *Docking*, or select *Hide* from the menu.

- When you select *Docking*, you can click and drag the object library to dock at and undock from any edge within the Designer window. When you drag the object library away from a Designer window edge, it stays undocked. To quickly switch between your last docked and undocked locations, just double-click the gray border.
  When you deselect *Allow Docking*, you can click and drag the object library to any location on your screen and it will not dock inside the Designer window.
- When you select *Hide*, the object library disappears from the Designer window. To unhide the object library, click its toolbar icon.

Related Information

Designer Guide: Multi-user Development, Central versus local repository [page 798]

2.3.8.1 To open the object library

Choose ▶ *Tools* ▶ *Object Library* ◀, or click the object library icon in the icon bar.

The object library gives you access to the object types listed in the following table. The table shows the tab on which the object type appears in the object library and describes the context in which you can use each type of object.

Tab	Description
Projects	Projects are sets of jobs available at a given time.
Jobs	Jobs are executable work flows. There are two job types: batch jobs and real-time jobs.
Work Flows	Work flows order data flows and the operations that support data flows, defining the interdependencies between them.
Data Flows	Data flows describe how to process a task.
Transforms	Transforms operate on data, producing output data sets from the sources you specify. The object library lists both built-in and custom transforms.
Datastores	Datastores represent connections to databases and applications used in your project. Under each datastore is a list of the tables, documents, and functions imported into the software.
Formats	Formats describe the structure of a flat file, XML file, or XML message.
Custom Functions	Custom Functions are functions written in the software's Scripting Language. You can use them in your jobs.

2.3.8.2 To display the name of each tab as well as its icon

1. Make the object library window wider until the names appear.

   or
2. Hold the cursor over the tab until the tool tip for the tab appears.

2.3.8.3 To sort columns in the object library

Click the column heading.

For example, you can sort data flows by clicking the Data Flow column heading once. Names are listed in ascending order. To list names in descending order, click the Data Flow column heading again.

2.3.9 Object editors

To work with the options for an object, in the workspace click the name of the object to open its editor. The editor displays the input and output schemas for the object and a panel below them listing options set for the object. If there are many options, they are grouped in tabs in the editor.

A schema is a data structure that can contain columns, other nested schemas, and functions (the contents are called schema elements). A table is a schema containing only columns.

In an editor, you can:

- Undo or redo previous actions performed in the window (right-click and choose *Undo* or *Redo*)
- Find a string in the editor (right-click and choose *Find*)
- Drag-and-drop column names from the input schema into relevant option boxes
- Use colors to identify strings and comments in text boxes where you can edit expressions (keywords appear blue; strings are enclosed in quotes and appear pink; comments begin with a pound sign and appear green)

> Note
>
> You cannot add comments to a mapping clause in a Query transform. For example, the following syntax is not supported on the Mapping tab:

```
table.column # comment
```

The job will not run and you cannot successfully export it. Use the object description or workspace annotation feature instead.

Related Information

Query Editor [page 311]

[page 314]

2.3.10 Working with objects

This section discusses common tasks you complete when working with objects in the Designer. With these tasks, you use various parts of the Designer—the toolbar, tool palette, workspace, and local object library.

2.3.10.1 Creating new reusable objects

You can create reusable objects from the object library or by using the tool palette. After you create an object, you can work with the object, editing its definition and adding calls to other objects.

2.3.10.1.1 To create a reusable object (in the object library)

1. Open the object library by choosing *Tools* ▸ *Object Library*.
2. Click the tab corresponding to the object type.
3. Right-click anywhere except on existing objects and choose *New*.
4. Right-click the new object and select *Properties*. Enter options such as name and description to define the object.

2.3.10.1.2 To create a reusable object (using the tool palette)

1. In the tool palette, left-click the icon for the object you want to create.
2. Move the cursor to the workspace and left-click again.

   The object icon appears in the workspace where you have clicked.

2.3.10.1.3 To open an object's definition

You can open an object's definition in one of two ways:

1. From the workspace, click the object name. The software opens a blank workspace in which you define the object.
2. From the project area, click the object.

You define an object using other objects. For example, if you click the name of a batch data flow, a new workspace opens for you to assemble sources, targets, and transforms that make up the actual flow.

2.3.10.1.4 To add an existing object (create a new call to an existing object)

1. Open the object library by choosing *Tools* ▸ *Object Library*.
2. Click the tab corresponding to any object type.
3. Select an object.
4. Drag the object to the workspace.

Note

Objects dragged into the workspace must obey the hierarchy logic. For example, you can drag a data flow into a job, but you cannot drag a work flow into a data flow.

Related Information

Object hierarchy [page 173]

2.3.10.2 Changing object names

You can change the name of an object from the workspace or the object library. You can also create a copy of an existing object.

Note

You cannot change the names of built-in objects.

1. To change the name of an object in the workspace
   a) Click to select the object in the workspace.
   b) Right-click and choose *Rename*.
   c) Edit the text in the name text box.
   d) Click outside the text box or press Enter to save the new name.
2. To change the name of an object in the object library
   a) Select the object in the object library.
   b) Right-click and choose *Properties*.
   c) Edit the text in the first text box.
   d) Click *OK*.
3. To copy an object
   a) Select the object in the object library.
   b) Right-click and choose *Replicate*.
   c) The software makes a copy of the top-level object (but not of objects that it calls) and gives it a new name, which you can edit.

2.3.10.3 Viewing and changing object properties

You can view (and, in some cases, change) an object's properties through its property page.

2.3.10.3.1 To view, change, and add object properties

1. Select the object in the object library.
2. Right-click and choose *Properties*. The *General* tab of the Properties window opens.
3. Complete the property sheets. The property sheets vary by object type, but General, Attributes and Class Attributes are the most common and are described in the following sections.
4. When finished, click *OK* to save changes you made to the object properties and to close the window.

   Alternatively, click Apply to save changes without closing the window.

2.3.10.3.2 General tab

The *General* tab contains two main object properties: name and description.

From the General tab, you can change the object name as well as enter or edit the object description. You can add object descriptions to single-use objects as well as to reusable objects. Note that you can toggle object descriptions on and off by right-clicking any object in the workspace and selecting/clearing *View Enabled Descriptions*.

Depending on the object, other properties may appear on the *General* tab. Examples include:

- *Execute only once*
- *Recover as a unit*
- *Degree of parallelism*
- *Use database links*
- *Cache type*

Related Information

Linked datastores [page 231]

Performance Optimization Guide: Using Parallel Execution [page 2137]

Recovery Mechanisms [page 720]

Creating and defining data flows [page 284]

2.3.10.3.3 Attributes tab

The *Attributes* tab allows you to assign values to the attributes of the current object.

To assign a value to an attribute, select the attribute and enter the value in the *Value* box at the bottom of the window.

Some attribute values are set by the software and cannot be edited. When you select an attribute with a system-defined value, the *Value* field is unavailable.

2.3.10.3.4 Class Attributes tab

The *Class Attributes* tab shows the attributes available for the type of object selected. For example, all data flow objects have the same class attributes.

To create a new attribute for a class of objects, right-click in the attribute list and select *Add*. The new attribute is now available for all of the objects of this class.

To delete an attribute, select it then right-click and choose *Delete*. You cannot delete the class attributes predefined by Data Services.

2.3.10.4 Creating descriptions

Use descriptions to document objects. You can see descriptions on workspace diagrams. Therefore, descriptions are a convenient way to add comments to workspace objects.

A description is associated with a particular object. When you import or export that repository object (for example, when migrating between development, test, and production environments), you also import or export its description.

The Designer determines when to show object descriptions based on a system-level setting and an object-level setting. Both settings must be activated to view the description for a particular object.

The system-level setting is unique to your setup. The system-level setting is disabled by default. To activate that system-level setting, select *ViewEnabled Descriptions*, or click the *View Enabled Descriptions* button on the toolbar.

The object-level setting is saved with the object in the repository. The object-level setting is also disabled by default unless you add or edit a description from the workspace. To activate the object-level setting, right-click the object and select *Enable object description*.

An ellipses after the text in a description indicates that there is more text. To see all the text, resize the description by clicking and dragging it. When you move an object, its description moves as well. To see which object is associated with which selected description, view the object's name in the status bar.

2.3.10.4.1 To add a description to an object

1. In the project area or object library, right-click an object and select *Properties*.
2. Enter your comments in the *Description* text box.
3. Click *OK*.

   The description for the object displays in the object library.

2.3.10.4.2 To display a description in the workspace

1. In the project area, select an existing object (such as a job) that contains an object to which you have added a description (such as a work flow).
2. From the *View* menu, select *Enabled Descriptions*.

   Alternately, you can select the View Enabled Descriptions button on the toolbar.
3. Right-click the work flow and select *Enable Object Description*.

   The description displays in the workspace under the object.

2.3.10.4.3 To add a description to an object from the workspace

1. From the *View* menu, select *Enabled Descriptions*.
2. In the workspace, right-click an object and select *Properties*.
3. In the Properties window, enter text in the *Description* box.
4. Click *OK*.

   The description displays automatically in the workspace (and the object's Enable Object Description option is selected).

2.3.10.4.4 To hide an object's description

1. In the workspace diagram, right-click an object.

   Alternately, you can select multiple objects by:
   - Pressing and holding the Control key while selecting objects in the workspace diagram, then right-clicking one of the selected objects.
   - Dragging a selection box around all the objects you want to select, then right-clicking one of the selected objects.
2. In the pop-up menu, deselect *Enable Object Description*.

   The description for the object selected is hidden, even if the View Enabled Descriptions option is checked, because the object-level switch overrides the system-level switch.

2.3.10.4.5 To edit object descriptions

1. In the workspace, double-click an object description.
2. Enter, cut, copy, or paste text into the description.
3. In the *Project* menu, select *Save*.

Alternately, you can right-click any object and select Properties to open the object's Properties window and add or edit its description.

> **Note**
>
> If you attempt to edit the description of a reusable object, the software alerts you that the description will be updated for every occurrence of the object, across all jobs. You can select the *Don't show this warning next time* check box to avoid this alert. However, after deactivating the alert, you can only reactivate the alert by calling Technical Support.

2.3.10.5 Creating annotations

Annotations describe a flow, part of a flow, or a diagram in a workspace. An annotation is associated with the job, work flow, or data flow where it appears. When you import or export that job, work flow, or data flow, you import or export associated annotations.

2.3.10.5.1 To annotate a workspace diagram

1. Open the workspace diagram you want to annotate.

   You can use annotations to describe any workspace such as a job, work flow, data flow, catch, conditional, or while loop.
2. In the tool palette, click the annotation icon.
3. Click a location in the workspace to place the annotation.

   An annotation appears on the diagram.

   You can add, edit, and delete text directly on the annotation. In addition, you can resize and move the annotation by clicking and dragging. You can add any number of annotations to a diagram.

2.3.10.5.2 To delete an annotation

1. Right-click an annotation.
2. Select *Delete*.

   Alternately, you can select an annotation and press the Delete key.

2.3.10.6 Copying objects

Objects can be cut or copied and then pasted on the workspace where valid. Multiple objects can be copied and pasted either within the same or other data flows, work flows, or jobs. Additionally, calls to data flows and works flows can be cut or copied and then pasted to valid objects in the workspace.

References to global variables, local variables, parameters, and substitution parameters are copied; however, you must be define each within its new context.

> Note
>
> The paste operation duplicates the selected objects in a flow, but still calls the original objects. In other words, the paste operation uses the original object in another location. The replicate operation creates a new object in the object library.

To cut or copy and then paste objects:

1. In the workspace, select the objects you want to cut or copy.

   You can select multiple objects using Ctrl-click, Shift-click, or Ctrl+A.
2. Right-click and then select either *Cut* or *Copy*.
3. Click within the same flow or select a different flow. Right-click and select *Paste*.

   Where necessary to avoid a naming conflict, a new name is automatically generated.

   > Note
   >
   > The objects are pasted in the selected location if you right-click and select *Paste*.
   >
   > The objects are pasted in the upper left-hand corner of the workspace if you paste using any of the following methods:
   >
   > ○ click the *Paste* icon.
   >
   > ○ click ▶ *Edit* › *Paste* ◀.
   >
   > ○ use the Ctrl+V keyboard short-cut.
   >
   > If you use a method that pastes the objects to the upper left-hand corner, subsequent pasted objects are layered on top of each other.

2.3.10.7 Saving and deleting objects

Saving an object in the software means storing the language that describes the object to the repository. You can save reusable objects; single-use objects are saved only as part of the definition of the reusable object that calls them.

You can choose to save changes to the reusable object currently open in the workspace. When you save the object, the object properties, the definitions of any single-use objects it calls, and any calls to other reusable objects are recorded in the repository. The content of the included reusable objects is not saved; only the call is saved.

The software stores the description even if the object is not complete or contains an error (does not validate).

2.3.10.7.1 To save changes to a single reusable object

1. Open the project in which your object is included.

2. Choose ▸ *Project* ▸ *Save* ◂.
   This command saves all objects open in the workspace.

Repeat these steps for other individual objects you want to save.

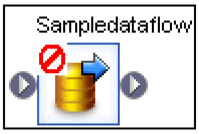
2.3.10.7.2 To save all changed objects in the repository

1. Choose ▸ *Project* ▸ *Save All* ◂.
   The software lists the reusable objects that were changed since the last save operation.
2. (optional) Deselect any listed object to avoid saving it.
3. Click *OK*.

> **Note**
>
> The software also prompts you to save all objects that have changes when you execute a job and when you exit the Designer. Saving a reusable object saves any single-use object included in it.

2.3.10.7.3 To delete an object definition from the repository

1. In the object library, select the object.
2. Right-click and choose *Delete*.
   - If you attempt to delete an object that is being used, the software provides a warning message and the option of using the *View Where Used* feature.
   - If you select *Yes*, the software marks all calls to the object with a red “deleted” icon to indicate that the calls are invalid. You must remove or replace these calls to produce an executable job.



> **Note**
>
> Built-in objects such as transforms cannot be deleted from the object library.

Related Information

Using View Where Used [page 686]

2.3.10.7.4 To delete an object call

1. Open the object that contains the call you want to delete.
2. Right-click the object call and choose *Delete*.

If you delete a reusable object from the workspace or from the project area, only the object call is deleted. The object definition remains in the object library.

2.3.10.8 Searching for objects

From within the object library, you can search for objects defined in the repository or objects available through a datastore.

2.3.10.8.1 To search for an object

1. Right-click in the object library and choose *Search*.

   The software displays the Search window.
2. Enter the appropriate values for the search.

   Options available in the Search window are described in detail following this procedure.
3. Click *Search*.

   The objects matching your entries are listed in the window. From the search results window you can use the context menu to:

   - *Open* an item
   - *View* the attributes (*Properties*)
   - *Import* external tables as repository metadata

   You can also drag objects from the search results window and drop them in the desired location.

The Search window provides you with the following options:

Option	Description
Look in	Where to search. Choose from the repository or a specific datastore. When you designate a datastore, you can also choose to search the imported data (*Internal Data*) or the entire datastore (*External Data*).
Object type	The type of object to find. When searching the repository, choose from Tables, Files, Data flows, Work flows, Jobs, Hierarchies, IDOCs, and Domains. When searching a datastore or application, choose from object types available through that datastore.

Option	Description
Name	The object name to find. If you are searching in the repository, the name is not case sensitive. If you are searching in a datastore and the name is case sensitive in that datastore, enter the name as it appears in the database or application and use double quotation marks (") around the name to preserve the case. You can designate whether the information to be located *Contains* the specified name or *Equals* the specified name using the drop-down box next to the *Name* field.
Description	The object description to find. Objects imported into the repository have a description from their source. By default, objects you create in the Designer have no description unless you add a one. The search returns objects whose description attribute contains the value entered.

The Search window also includes an *Advanced* button where, you can choose to search for objects based on their attribute values. You can search by attribute values only when searching in the repository.

The *Advanced* button provides the following options:

Option	Description
Attribute	The object attribute in which to search.
Value	The attribute value to find.
Match	The type of search performed. Select *Contains* to search for any attribute that contains the value specified. Select *Equals* to search for any attribute that contains only the value specified.

2.3.11 General and environment options

To open the *Options* window, select ▶ *Tools* ▸ *Options* ◢. The window displays option groups for Designer, Data, and Job Server options.

Expand the options by clicking the plus icon. As you select each option group or option, a description appears on the right.

2.3.11.1 Designer — Environment

Table 1: Default Administrator for Metadata Reporting

Option	Description
Administrator	Select the Administrator that the metadata reporting tool uses. An Administrator is defined by host name and port.

Table 2: Default Job Server

Option	Description
Current	Displays the current value of the default Job Server.
New	Allows you to specify a new value for the default Job Server from a drop-down list of Job Servers associated with this repository. Changes are effective immediately.

If a repository is associated with several Job Servers, one Job Server must be defined as the default Job Server to use at login.

> Note
>
> Job-specific options and path names specified in Designer refer to the current default Job Server. If you change the default Job Server, modify these options and path names.

Table 3: Designer Communication Ports

Option	Description
Allow Designer to set the port for Job Server communication	If checked, Designer automatically sets an available port to receive messages from the current Job Server. The default is checked. Uncheck to specify a listening port or port range.
From *To*	Enter port numbers in the port text boxes. To specify a specific listening port, enter the same port number in both the *From* port and *To* port text boxes. Changes will not take effect until you restart the software. Only activated when you deselect the previous control. Allows you to specify a range of ports from which the Designer can choose a listening port. You may choose to constrain the port used for communication between Designer and Job Server when the two components are separated by a firewall.
Interactive Debugger	Allows you to set a communication port for the Designer to communicate with a Job Server while running in Debug mode.
Server group for local repository	If the local repository that you logged in to when you opened the Designer is associated with a server group, the name of the server group appears.

Related Information

Changing the interactive debugger port [page 704]

2.3.11.2 Designer — General

Option	Description
View data sampling size (rows)	Controls the sample size used to display the data in sources and targets in open data flows in the workspace. View data by clicking the magnifying glass icon on source and target objects.
Number of characters in workspace icon name	Controls the length of the object names displayed in the workspace. Object names are allowed to exceed this number, but the Designer only displays the number entered here. The default is 17 characters.
Maximum schema tree elements to auto expand	The number of elements displayed in the schema tree. Element names are not allowed to exceed this number. Enter a number for the *Input schema* and the *Output schema*. The default is 100.
Default parameters to variables of the same name	When you declare a variable at the work-flow level, the software automatically passes the value as a parameter with the same name to a data flow called by a work flow.
Automatically import domains	Select this check box to automatically import domains when importing a table that references a domain.
Perform complete validation before job execution	If checked, the software performs a complete job validation before running a job. The default is unchecked. If you keep this default setting, you should validate your design manually before job execution.
Open monitor on job execution	Affects the behavior of the Designer when you execute a job. With this option enabled, the Designer switches the workspace to the monitor view during job execution; otherwise, the workspace remains as is. The default is on.
Automatically calculate column mappings	Calculates information about target tables and columns and the sources used to populate them. The software uses this information for metadata reports such as impact and lineage, auto documentation, or custom reports. Column mapping information is stored in the AL_COLMAP table (ALVW_MAPPING view) after you save a data flow or import objects to or export objects from a repository. If the option is selected, be sure to validate your entire job before saving it because column mapping calculation is sensitive to errors and will skip data flows that have validation problems.
Show dialog when job is completed	Allows you to choose if you want to see an alert or just read the trace messages.

Option	Description
Show tabs in workspace	Allows you to decide if you want to use the tabs at the bottom of the workspace to navigate.
Single window in workspace	Allows you to view only one window in the workspace area (for example, a job or transform). If you open another window, the previous window closes and the new window opens.
Show Start Page at startup	Allows you to view the Designer start page when you open the Designer.
Enable Object Description when instantiate	Enables element descriptions for elements that you place in your flow (for example, a reader or transform that you put into a job, workflow, or data flow).
Exclude non-executable elements from export to XML Document	Excludes elements not processed during job execution from exported XML documents. For example, Designer workspace display coordinates would not be exported.

Related Information

Using View Data [page 688]

Management Console Guide: Refresh Usage Data tab [page 1974]

2.3.11.3 Designer — Graphics

Choose and preview stylistic elements to customize your workspaces. Using these options, you can easily distinguish your job/work flow design workspace from your data flow design workspace.

Option	Description
Workspace flow type	Switch between the two workspace flow types (Job/Work Flow and Data Flow) to view default settings. Modify settings for each type using the remaining options.
Line Type	Choose a style for object connector lines.
Line Thickness	Set the connector line thickness.
Background style	Choose a plain or tiled background pattern for the selected flow type.
Color scheme	Set the background color to blue, gray, or white.
Use navigation watermark	Add a watermark graphic to the background of the flow type selected. Note that this option is only available with a plain background style.

2.3.11.4 Designer — Attribute values

When re-importing, Data Services preserves or clears the old value for some table and column attributes.

You can control what Data Services does on re-import for the following attributes:

Attribute	Object type	Description
Associated_Dimension	Column	The name of the dimension attached to the detail. Used to support the metadata exchanged between SAP Data Services and SAP Universe Builder.
Business_Description	Column and Table	A business-level description of a table or column.
Business_Name	Column and Table	A logical field. This attribute defines and runs jobs that extract, transform, and load physical data while the Business Name data remains intact.
Column_Usage	Column	Supports metadata exchanged between SAP Data Services and SAP Universe Builder.
Content_Type	Column	Defines the type of data in a column.
Description	Column and Table	Description of the column or table.
Estimated_Row_Count	Table	An estimate of the table size used in calculating the order in which tables are read to perform join operations.
ObjectLabel	Column and Table	A label used to describe an object.
Table_Usage	Table	A label field used to mark a table as fact or dimension, for example.

2.3.11.5 Designer — Central Repository Connections

Option	Description
Central Repository Connections	Displays the central repository connections and the active central repository. To activate a central repository, right-click one of the central repository connections listed and select *Activate*.
Reactivate automatically	Select if you want the active central repository to be reactivated whenever you log in to the software using the current local repository.

2.3.11.6 Designer — Language

These options provide you with locales, other than English (the default locale), for viewing the Data Services user interface and any text that the user interface generaties in other languages.

You can select the locale for both the user interface and the displayed data.

Option	Description
Product locale	Specifies the user interface language and all product messages.
Preferred viewing locale	Specifies the locale that the user data should be presented in. For example, date formatting should be presented in the preferred viewing locale.

2.3.11.7 Designer — SSL

By default, the paths for the SSL certificate and keyfiles are automatically configured during installation. You do not need to change them unless you want to use your own certificates.

Note

If you change any SSL options other than *Use SSL protocol for profiler*, you must restart both the Designer and any Data Services servers.

Option	Description
Server certificate file	The path to the server certificate file. The server certificate must be in PEM format.
Server private key file	The path to the server private key file.
Use server private key password file	Select this option and specify the location of the password file if you want to use a private key password file.
Trusted certificates folder	Specify the location of the trusted certificates folder. Valid extensions for certificates in the trusted certificates folder include .pem, .crt, and .cer. Regardless of the file extension, all certificate file contents must be in PEM format.
Use SSL protocol for profiler	Select this option to use SSL protocol for communications between the Designer and the profiler server.

2.3.11.8 Data — General

Option	Description
Century Change Year	Indicates how the software interprets the century for two-digit years. Two-digit years greater than or equal to this value are interpreted as 19##. Two-digit years less than this value are interpreted as 20##. The default value is 15. For example, if the *Century Change Year* is set to 15:

<table>
<tr><th>Option</th><th>Description</th></tr>
<tr><td></td><td><table><tr><th>Two-digit year</th><th>Interpreted as</th></tr><tr><td>99</td><td>1999</td></tr><tr><td>16</td><td>1916</td></tr><tr><td>15</td><td>1915</td></tr><tr><td>14</td><td>2014</td></tr></table></td></tr>
<tr><td><i>Convert blanks to nulls for Oracle bulk loader</i></td><td>Converts blanks to NULL values when loading data using the Oracle bulk loader utility and:
● the column is not part of the primary key
● the column is nullable</td></tr>
</table>

2.3.11.9 Job Server — Environment

Option	Description
Maximum number of engine processes	Sets a limit on the number of engine processes that this Job Server can have running concurrently.

2.3.11.10 Job Server — General

Use this window to reset Job Server options or with guidance from SAP Technical customer Support.

Related Information

Changing Job Server options [page 428]

2.4 Projects and Jobs

Project and job objects represent the top two levels of organization for the application flows you create using the Designer.

2.4.1 Projects

A project is a reusable object that allows you to group jobs. A project is the highest level of organization offered by the software. Opening a project makes one group of objects easily accessible in the user interface.

You can use a project to group jobs that have schedules that depend on one another or that you want to monitor together.

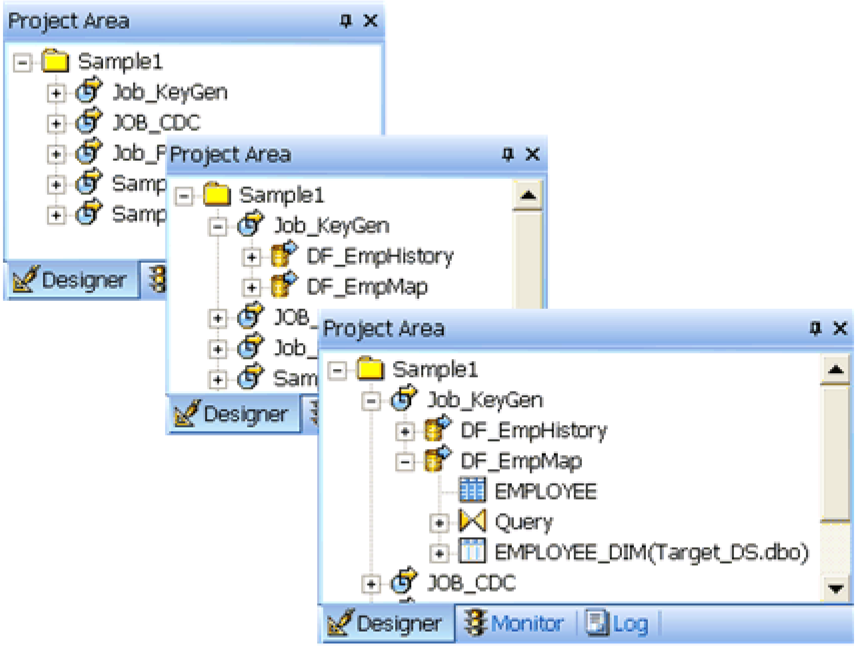
Projects have common characteristics:

- Projects are listed in the object library.
- Only one project can be open at a time.
- Projects cannot be shared among multiple users.

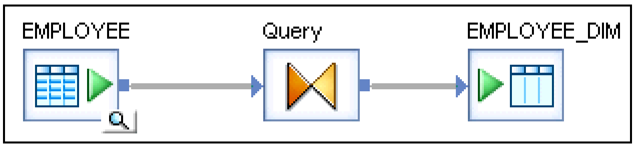
2.4.1.1 Objects that make up a project

The objects in a project appear hierarchically in the project area. If a plus sign (+) appears next to an object, expand it to view the lower-level objects contained in the object. The software shows you the contents as both names in the project area hierarchy and icons in the workspace.

In the following example, the Job_KeyGen job contains two data flows, and the DF_EmpMap data flow contains multiple objects.



Each item selected in the project area also displays in the workspace:



2.4.1.2 Creating a new project

1. Choose ▶ *Project* ▶ *New* ▶ *Project* ◀.
2. Enter the name of your new project.

   The name can include alphanumeric characters and underscores (_). It cannot contain blank spaces.
3. Click *Create*.

The new project appears in the project area. As you add jobs and other lower-level objects to the project, they also appear in the project area.

2.4.1.3 Opening existing projects

2.4.1.3.1 To open an existing project

1. Choose ▶ *Project* ▶ *Open* ◀.
2. Select the name of an existing project from the list.
3. Click *Open*.

> i Note
>
> If another project was already open, the software closes that project and opens the new one.

2.4.1.4 Saving projects

2.4.1.4.1 To save all changes to a project

1. Choose ▶ *Project* ▶ *Save All* ◀.

   The software lists the jobs, work flows, and data flows that you edited since the last save.
2. (optional) Deselect any listed object to avoid saving it.
3. Click *OK*.

   > i Note
   >
   > The software also prompts you to save all objects that have changes when you execute a job and when you exit the Designer. Saving a reusable object saves any single-use object included in it.

2.4.2 Jobs

A job is the only object you can execute. You can manually execute and test jobs in development. In production, you can schedule batch jobs and set up real-time jobs as services that execute a process when the software receives a message request.

A job is made up of steps you want executed together. Each step is represented by an object icon that you place in the workspace to create a job diagram. A job diagram is made up of two or more objects connected together. You can include any of the following objects in a job definition:

- Data flows
    - Sources
    - Targets
    - Transforms
- Work flows
    - Scripts
    - Conditionals
    - While Loops
    - Try/catch blocks

If a job becomes complex, organize its content into individual work flows, then create a single job that calls those work flows.

Real-time jobs use the same components as batch jobs. You can add work flows and data flows to both batch and real-time jobs. When you drag a work flow or data flow icon into a job, you are telling the software to validate these objects according the requirements of the job type (either batch or real-time).

There are some restrictions regarding the use of some software features with real-time jobs.

Related Information

Work Flows [page 328]

Real-time Jobs [page 372]

2.4.2.1 Creating jobs

2.4.2.1.1 To create a job in the project area

1. In the project area, select the project name.
2. Right-click and choose *New Batch Job* or *Real Time Job*.
3. Edit the name.

The name can include alphanumeric characters and underscores (_). It cannot contain blank spaces.

The software opens a new workspace for you to define the job.

2.4.2.1.2 To create a job in the object library

1. Go to the *Jobs* tab.
2. Right-click *Batch Jobs* or *Real Time Jobs* and choose *New*.
3. A new job with a default name appears.
4. Right-click and select Properties to change the object's name and add a description.

   The name can include alphanumeric characters and underscores (_). It cannot contain blank spaces.
5. To add the job to the open project, drag it into the project area.

2.4.2.2 Naming conventions for objects in jobs

We recommend that you follow consistent naming conventions to facilitate object identification across all systems in your enterprise. This allows you to more easily work with metadata across all applications such as:

- Data-modeling applications
- ETL applications
- Reporting applications
- Adapter software development kits

Examples of conventions recommended for use with jobs and other objects are shown in the following table.

Prefix	Suffix	Object	Example
DF_	n/a	Data flow	DF_Currency
EDF_	_Input	Embedded data flow	EDF_Example_Input
EDF_	_Output	Embedded data flow	EDF_Example_Output
RTJob_	n/a	Real-time job	RTJob_OrderStatus
WF_	n/a	Work flow	WF_SalesOrg
JOB_	n/a	Job	JOB_SalesOrg
n/a	_DS	Datastore	ORA_DS
DC_	n/a	Datastore configuration	DC_DB2_production
SC_	n/a	System configuration	SC_ORA_test
n/a	_Memory_DS	Memory datastore	Catalog_Memory_DS
PROC_	n/a	Stored procedure	PROC_SalesStatus

Although the Designer is a graphical user interface with icons representing objects in its windows, other interfaces might require you to identify object types by the text alone. By using a prefix or suffix, you can more easily identify your object's type.

In addition to prefixes and suffixes, you might want to provide standardized names for objects that identify a specific action across all object types. For example: DF_OrderStatus, RTJob_OrderStatus.

In addition to prefixes and suffixes, naming conventions can also include path name identifiers. For example, the stored procedure naming convention can look like either of the following:

<datastore>.<owner>.<PROC_Name>

<datastore>.<owner>.<package>.<PROC_Name>

2.5 Datastores

This section describes different types of datastores, provides details about the Attunity Connector datastore, and instructions for configuring datastores.

2.5.1 What are datastores?

Datastores represent connection configurations between the software and databases or applications. These configurations can be direct or through adapters. Datastore configurations allow the software to access metadata from a database or application and read from or write to that database or application while the software executes a job.

SAP Data Services datastores can connect to:

- Databases and mainframe file systems.
- Applications that have pre-packaged or user-written adapters.
- J.D. Edwards One World and J.D. Edwards World, Oracle Applications, PeopleSoft, SAP Applications, SAP Master Data Services, SAP NetWeaver BW, and Siebel Applications. See the appropriate supplement guide.

> Note
>
> The software reads and writes data stored in flat files through flat file formats. The software reads and writes data stored in XML documents through DTDs and XML Schemas.

The specific information that a datastore object can access depends on the connection configuration. When your database or application changes, make corresponding changes in the datastore information in the software. The software does not automatically detect the new information.

> Note
>
> Objects deleted from a datastore connection are identified in the project area and workspace by a red "deleted" icon. 🚫 This visual flag allows you to find and update data flows affected by datastore changes.

You can create multiple configurations for a datastore. This allows you to plan ahead for the different environments your datastore may be used in and limits the work involved with migrating jobs. For example, you can add a set of configurations (DEV, TEST, and PROD) to the same datastore name. These connection settings stay with the datastore during export or import. You can group any set of datastore configurations into a system configuration. When running or scheduling a job, select a system configuration, and thus, the set of datastore configurations for your current environment.

Related Information

Database datastores [page 210]
Adapter datastores [page 233]
File Formats [page 254]
Formatting XML documents [page 345]
Creating and managing multiple datastore configurations [page 239]

2.5.2 Database datastores

Database datastores can represent single or multiple connections with:

- Legacy systems using Attunity Connect
- IBM DB2, HP Neoview, Informix, Microsoft SQL Server, Oracle, SQL Anywhere, Sybase ASE, Sybase IQ, MySQL, Netezza, SAP HANA, SAP Data Federator, SQL Anywhere and Teradata databases (using native connections)
- Other databases (through ODBC)
- A repository, using a memory datastore or persistent cache datastore

You can create a connection to most of the data sources using the server name instead of the DSN (Data Source Name) or TNS (Transparent Network Substrate) name. Server name connections (also known as DSN-less and TNS-less connections) eliminate the need to configure the same DSN or TNS entries on every machine in a distributed environment.

Related Information

Administrator Guide: DSN-less and TNS-less connections [page 30]

2.5.2.1 Mainframe interface

The software provides the Attunity Connector datastore that accesses mainframe data sources through Attunity Connect. The data sources that Attunity Connect accesses are in the following list. For a complete list of sources, refer to the Attunity documentation.

- Adabas
- DB2 UDB for OS/390 and DB2 UDB for OS/400
- IMS/DB

- VSAM
- Flat files on OS/390 and flat files on OS/400

2.5.2.1.1 Prerequisites for an Attunity datastore

Attunity Connector accesses mainframe data using software that you must manually install on the mainframe server and the local client (Job Server) computer. The software connects to Attunity Connector using its ODBC interface.

It is not necessary to purchase a separate ODBC driver manager for UNIX and Windows platforms.

Servers

Install and configure the Attunity Connect product on the server (for example, an zSeries computer).

Clients

To access mainframe data using Attunity Connector, install the Attunity Connect product. The ODBC driver is required. Attunity also offers an optional tool called Attunity Studio, which you can use for configuration and administration.

Configure ODBC data sources on the client (SAP Data Services Job Server).

When you install a Job Server on UNIX, the installer will prompt you to provide an installation directory path for Attunity connector software. In addition, you do not need to install a driver manager, because the software loads ODBC drivers directly on UNIX platforms.

For more information about how to install and configure these products, refer to their documentation.

2.5.2.1.2 Configuring an Attunity datastore

To use the Attunity Connector datastore option, upgrade your repository to SAP Data Services version 6.5.1 or later.

To create an Attunity Connector datastore:

1. In the *Datastores* tab of the object library, right-click and select *New*.
2. Enter a name for the datastore.
3. In the *Datastore type* box, select *Database*.
4. In the *Database type* box, select *Attunity Connector*.
5. Type the Attunity data source name, location of the Attunity daemon (*Host location*), the Attunity daemon port number, and a unique Attunity server workspace name.

6. To change any of the default options (such as *Rows per Commit* or *Language*), click the *Advanced* button.
7. Click *OK*.

   You can now use the new datastore connection to import metadata tables into the current repository.

2.5.2.1.3 Specifying multiple data sources in one Attunity datastore

You can use the Attunity Connector datastore to access multiple Attunity data sources on the same Attunity Daemon location. If you have several types of data on the same computer, for example a DB2 database and VSAM, you might want to access both types of data using a single connection. For example, you can use a single connection to join tables (and push the join operation down to a remote server), which reduces the amount of data transmitted through your network.

To specify multiple sources in the Datastore Editor:

1. Separate data source names with semicolons in the Attunity data source box using the following format:

   ```
   AttunityDataSourceName;AttunityDataSourceName
   ```

   For example, if you have a DB2 data source named DSN4 and a VSAM data source named Navdemo, enter the following values into the Data source box:

   ```
   DSN4;Navdemo
   ```
2. If you list multiple data source names for one Attunity Connector datastore, ensure that you meet the following requirements:
   - All Attunity data sources must be accessible by the same user name and password.
   - All Attunity data sources must use the same workspace. When you setup access to the data sources in Attunity Studio, use the same workspace name for each data source.

2.5.2.1.4 Data Services naming convention for Attunity tables

Data Services' format for accessing Attunity tables is unique to Data Services. Because a single datastore can access multiple software systems that do not share the same namespace, the name of the Attunity data source must be specified when referring to a table. With an Attunity Connector, precede the table name with the data source and owner names separated by a colon. The format is as follows:

```
AttunityDataSource:OwnerName.TableName
```

When using the Designer to create your jobs with imported Attunity tables, Data Services automatically generates the correct SQL for this format. However, when you author SQL, be sure to use this format. You can author SQL in the following constructs:

- SQL function
- SQL transform
- Pushdown_sql function
- Pre-load commands in table loader
- Post-load commands in table loader

Note

For tables in Data Services, the maximum length of the owner name for most repository types is 256 (MySQL is 64 and MS SQL server is 128). In the case of Attunity tables, the maximum length of the Attunity data source name and actual owner name is 63 (the colon accounts for 1 character).

2.5.2.1.5 Limitations

All Data Services features are available when you use an Attunity Connector datastore except the following:

- Bulk loading
- Imported functions (imports metadata for tables only)
- Template tables (creating tables)
- The datetime data type supports up to 2 sub-seconds only
- Data Services cannot load timestamp data into a timestamp column in a table because Attunity truncates varchar data to 8 characters, which is not enough to correctly represent a timestamp value.
- When running a job on UNIX, the job could fail with following error:

  ```
  [D000] Cannot open file /usr1/attun/navroot/def/sys System error 13: The file
  access permissions do not allow the specified action.; (OPEN)
  ```

  This error occurs because of insufficient file permissions to some of the files in the Attunity installation directory. To avoid this error, change the file permissions for all files in the Attunity directory to 777 by executing the following command from the Attunity installation directory:

  ```
  $ chmod -R 777 *
  ```

2.5.2.2 Defining a database datastore

Define at least one database datastore for each database or mainframe file system with which you are exchanging data.

To define a datastore, get appropriate access privileges to the database or file system that the datastore describes.

For example, to allow the software to use parameterized SQL when reading or writing to DB2 databases, authorize the user (of the datastore/database) to create, execute, and drop stored procedures. If a user is not authorized to create, execute, and drop stored procedures, jobs will still run. However, the jobs will produce a warning message and will run less efficiently.

2.5.2.2.1 To define a Database datastore

1. In the *Datastores* tab of the object library, right-click and select *New*.
2. Enter the name of the new datastore in the *Datastore Name* field.

   The name can contain any alphabetical or numeric characters or underscores (_). It cannot contain spaces.
3. Select the *Datastore type*.

   When you select a Datastore Type, the software displays other options relevant to that type.
4. Select the *Database type*.
5. If you selected Oracle, the default connection type is TNS-less (the *Use TNS name* checkbox is not selected).
   - If you want to use a TNS-less connection, type in the *Hostname*, *SID*, and *Port*
   - If you want to use a TNS connection, select the check box for *Use TNS name* and type in the *TNS name*.
6. If you selected a database type that supports DSN-less connections (such as DB2, Informix, MySQL, Netezza, or SAP HANA), the default connection type is DSN-less (the *Use data source name (DSN)* checkbox is not selected).
   - If you want to use a DSN-less connection, type in the *Database server name*, *Database name* (for DB2 and MySQL) and *Port*.

     > Note
     >
     > If you selected Informix, you must specify the server instance name (not the host name) in *Database server name*. If Data Services is on a different computer than the Informix server, follow the next step.
   - If you want to use a DSN connection, select the check box for *Use data source name (DSN)* and type in the *Data source name*.

   For the most current list of supported databases for DSN-less connections, see the *Release Notes*.
7. If you selected Informix, want to use DSN-less connections, and Data Services is on a different computer than the Informix server, you must identify the Informix host as follows:

   a) Go to your Informix client installation folder.
   For example: `C:\Program Files\IBM\Informix\Client-SDK\bin`

   b) Run **`setnet32.exe`** and go to the *Server Information* tab.

   c) Enter the IBM Informix Server name, Host name, and other required information.

   d) Click *Make Default Server*, and then click *OK*.

   For DSN-less connections to an Informix database, the Designer can now obtain the Informix host name for the Informix server name you provided.
8. If you selected Data Federator, you must also specify the catalog name and the schema name in the URL. If you do not, you may see all of the tables from each catalog.

   a) Select *ODBC Admin* and then the *System DSN* tab.

   b) Highlight Data Federator, and then click *Configure*.

   c) In the URL option, enter the catalog name and the schema name; for example, `jdbc:leselect://localhost/`**`<catalogname>`**`;schema=`**`<schemaname>`**.
9. For other database types, enter the appropriate information for the selected database type.
10. The *Enable automatic data transfer* check box is selected by default when you create a new datastore and choose `Database` for *Datastore type*. This check box displays for all databases except Attunity Connector, Data Federator, Memory, and Persistent Cache.

Keep Enable automatic data transfer selected to enable transfer tables in this datastore that the Data_Transfer transform can use to push down subsequent database operations.

11. At this point, you can save the datastore or add more information to it:
    - To save the datastore and close the Datastore Editor, click *OK*.
    - To add more information, select *Advanced*.
      To enter values for each configuration option, click the cells under each configuration name.
      For the datastore as a whole, the following buttons and options are available:

Buttons	Description
Import unsupported data types as VARCHAR of size	The data types that the software supports are documented in the Reference Guide. If you want the software to convert a data type in your source that it would not normally support, select this option and enter the number of characters that you will allow.
Edit	Opens the Configurations for Datastore dialog. Use the tool bar on this window to add, configure, and manage multiple configurations for a datastore.
Show ATL	Opens a text window that displays how the software codes the selections you make for this datastore in its scripting language.
OK	Saves selections and closes the Datastore Editor (Create New Datastore) window.
Cancel	Cancels selections and closes the Datastore Editor window.
Apply	Saves selections.

12. Click *OK*.

> Note
>
> On versions of Data Integrator prior to version 11.7.0, the correct database type to use when creating a datastore on Netezza was ODBC. SAP Data Services 11.7.1 provides a specific Netezza option as the *Database type* instead of ODBC. When using Netezza as the database with the software, we recommend that you choose the software's Netezza option as the *Database type* rather than ODBC.

Creating and managing multiple datastore configurations [page 239]

Ways of importing metadata [page 221]

2.5.2.3 Configuring ODBC data sources on UNIX

To use ODBC data sources on UNIX platforms, you may need to perform additional configuration.

Data Services provides the Connection Manager to simplify configuration of natively-supported ODBC data sources such as MySQL and Teradata. Other ODBC data sources may require manual configuration.

Related Information

Administrator's Guide: Configuring ODBC data sources on UNIX [page 61]

2.5.2.4 Changing a datastore definition

Like all objects, datastores are defined by both options and properties:

- Options control the operation of objects. For example, the name of the database to connect to is a datastore option.
- Properties document the object. For example, the name of the datastore and the date on which it was created are datastore properties. Properties are merely descriptive of the object and do not affect its operation.

2.5.2.4.1 To change datastore options

1. Go to the *Datastores* tab in the object library.
2. Right-click the datastore name and choose *Edit*.

   The Datastore Editor appears (the title bar for this dialog displays Edit Datastore). You can do the following tasks:

   - Change the connection information for the current datastore configuration.
   - Click *Advanced* and change properties for the current configuration.
   - Click *Edit* to add, edit, or delete additional configurations. The Configurations for Datastore dialog opens when you select *Edit* in the Datastore Editor. After you add a new configuration to an existing datastore, you can use the fields in the grid to change connection values and properties for the new configuration.
3. Click *OK*.

   The options take effect immediately.

Related Information

Reference Guide: Database datastores [page 868]

2.5.2.4.2 To change datastore properties

1. Go to the datastore tab in the object library.
2. Right-click the datastore name and select *Properties*.

   The Properties window opens.
3. Change the datastore properties.
4. Click *OK*.

Related Information

Reference Guide: Datastore [page 860]

2.5.2.5 Browsing metadata through a database datastore

The software stores metadata information for all imported objects in a datastore. You can use the software to view metadata for imported or non-imported objects and to check whether the metadata has changed for objects already imported.

2.5.2.5.1 To view imported objects

1. Go to the *Datastores* tab in the object library.
2. Click the plus sign (+) next to the datastore name to view the object types in the datastore. For example, database datastores have functions, tables, and template tables.
3. Click the plus sign (+) next to an object type to view the objects of that type imported from the datastore. For example, click the plus sign (+) next to tables to view the imported tables.

2.5.2.5.2 To sort the list of objects

Click the column heading to sort the objects in each grouping and the groupings in each datastore alphabetically. Click again to sort in reverse-alphabetical order.

2.5.2.5.3 To view datastore metadata

1. Select the *Datastores* tab in the object library.
2. Choose a datastore, right-click, and select *Open*. (Alternatively, you can double-click the datastore icon.)

The software opens the datastore explorer in the workspace. The datastore explorer lists the tables in the datastore. You can view tables in the external database or tables in the internal repository. You can also search through them.

3. Select *External metadata* to view tables in the external database.

   If you select one or more tables, you can right-click for further options.

Command	Description
Open (Only available if you select one table.)	Opens the editor for the table metadata.
Import	Imports (or re-imports) metadata from the database into the repository.
Reconcile	Checks for differences between metadata in the database and metadata in the repository.

4. Select *Repository metadata* to view imported tables.

   If you select one or more tables, you can right-click for further options.

Command	Description
Open (Only available if you select one table)	Opens the editor for the table metadata.
Reconcile	Checks for differences between metadata in the repository and metadata in the database.
Reimport	Reimports metadata from the database into the repository.
Delete	Deletes the table or tables from the repository.
Properties (Only available if you select one table)	Shows the properties of the selected table.
View Data	Opens the View Data window which allows you to see the data currently in the table.

Related Information

To import by searching [page 223]

2.5.2.5.4 To determine if a schema has changed since it was imported

1. In the browser window showing the list of repository tables, select *External Metadata*.

2. Choose the table or tables you want to check for changes.
3. Right-click and choose *Reconcile*.

   The Changed column displays YES to indicate that the database tables differ from the metadata imported into the software. To use the most recent metadata from the software, reimport the table.

   The Imported column displays YES to indicate that the table has been imported into the repository.

2.5.2.5.5 To browse the metadata for an external table

1. In the browser window showing the list of external tables, select the table you want to view.
2. Right-click and choose *Open*.

   A table editor appears in the workspace and displays the schema and attributes of the table.

2.5.2.5.6 To view the metadata for an imported table

1. Select the table name in the list of imported tables.
2. Right-click and select *Open*.

   A table editor appears in the workspace and displays the schema and attributes of the table.

2.5.2.5.7 To view secondary index information for tables

Secondary index information can help you understand the schema of an imported table.

1. From the datastores tab in the Designer, right-click a table to open the shortcut menu.
2. From the shortcut menu, click *Properties* to open the Properties window.
3. In the Properties window, click the *Indexes* tab. The left portion of the window displays the Index list.
4. Click an index to see the contents.

2.5.2.6 Importing metadata through a database datastore

For database datastores, you can import metadata for tables and functions.

2.5.2.6.1 Imported table information

The software determines and stores a specific set of metadata information for tables. After importing metadata, you can edit column names, descriptions, and data types. The edits are propagated to all objects that call these objects.

Metadata	Description
Table name	The name of the table as it appears in the database. Note The maximum length depends on the Data Service repository type. For most repository types the maximum length is 256, for MySQL the length is 64, and for MS SQL server the length is 128.
Table description	The description of the table.
Column name	The name of the column.
Column description	The description of the column.
Column data type	The data type for the column. If a column is defined as an unsupported data type, the software converts the data type to one that is supported. In some cases, if the software cannot convert the data type, it ignores the column entirely.
Column content type	The content type identifies the type of data in the field.
Primary key column	The column(s) that comprise the primary key for the table. After a table has been added to a data flow diagram, these columns are indicated in the column list by a key icon next to the column name.
Table attribute	Information the software records about the table such as the date created and date modified if these values are available.
Owner name	Name of the table owner. Note The owner name for MySQL and Netezza data sources corresponds to the name of the database or schema where the table appears.

Varchar and Column Information from SAP Data Federator tables

Any decimal column imported to Data Serves from an SAP Data Federator data source is converted to the decimal precision and scale(28,6).

Any varchar column imported to the software from an SAP Data Federator data source is varchar(1024).

You may change the decimal precision or scale and varchar size within the software after importing from the SAP Data Federator data source.

2.5.2.6.2 Imported stored function and procedure information

The software can import stored procedures from DB2, MS SQL Server, Oracle, SAP HANA, SQL Anywhere, Sybase ASE, Sybase IQ, and Teredata databases. You can also import stored functions and packages from Oracle. You can use these functions and procedures in the extraction specifications you give Data Services.

Information that is imported for functions includes:

- Function parameters
- Return type
- Name, owner

Imported functions and procedures appear on the *Datastores* tab of the object library. Functions and procedures appear in the *Function* branch of each datastore tree.

You can configure imported functions and procedures through the function wizard and the smart editor in a category identified by the datastore name.

Related Information

Reference Guide: About procedures [page 1697]

2.5.2.6.3 Ways of importing metadata

This section discusses methods you can use to import metadata.

2.5.2.6.3.1 To import by browsing

ℹ Note

Functions cannot be imported by browsing.

1. Open the object library.
2. Go to the *Datastores* tab.
3. Select the datastore you want to use.
4. Right-click and choose *Open*.

   The items available to import through the datastore appear in the workspace.

   In some environments, the tables are organized and displayed as a tree structure. If this is true, there is a plus sign (+) to the left of the name. Click the plus sign to navigate the structure.

   The workspace contains columns that indicate whether the table has already been imported into the software (Imported) and if the table schema has changed since it was imported (Changed). To verify whether the repository contains the most recent metadata for an object, right-click the object and choose Reconcile.
5. Select the items for which you want to import metadata.

   For example, to import a table, you must select a table rather than a folder that contains tables.
6. Right-click and choose *Import*.
7. In the object library, go to the *Datastores* tab to display the list of imported objects.

2.5.2.6.3.2 To import by name

1. Open the object library.
2. Click the *Datastores* tab.
3. Select the datastore you want to use.
4. Right-click and choose *Import By Name*.
5. In the Import By Name window, choose the type of item you want to import from the *Type* list.

   If you are importing a stored procedure, select Function.
6. To import tables:
   a) Enter a table name in the *Name* box to specify a particular table, or select the *All* check box, if available, to specify all tables.
      If the name is case-sensitive in the database (and not all uppercase), enter the name as it appears in the database and use double quotation marks (") around the name to preserve the case.
   b) Enter an owner name in the *Owner* box to limit the specified tables to a particular owner. If you leave the owner name blank, you specify matching tables regardless of owner (that is, any table with the specified table name).
7. To import functions and procedures:
   - In the *Name* box, enter the name of the function or stored procedure.
     If the name is case-sensitive in the database (and not all uppercase), enter the name as it appears in the database and use double quotation marks (") around the name to preserve the case. Otherwise, the software will convert names into all upper-case characters.
     You can also enter the name of a package. An Oracle package is an encapsulated collection of related program objects (e.g., procedures, functions, variables, constants, cursors, and exceptions) stored together in the database. The software allows you to import procedures or functions created within packages and use them as top-level procedures or functions.

If you enter a package name, the software imports all stored procedures and stored functions defined within the Oracle package. You cannot import an individual function or procedure defined within a package.

  - Enter an owner name in the *Owner* box to limit the specified functions to a particular owner. If you leave the owner name blank, you specify matching functions regardless of owner (that is, any function with the specified name).
  - If you are importing an Oracle function or stored procedure and any of the following conditions apply, clear the *Callable from SQL expression* check box. A stored procedure cannot be pushed down to a database inside another SQL statement when the stored procedure contains a DDL statement, ends the current transaction with COMMIT or ROLLBACK, or issues any ALTER SESSION or ALTER SYSTEM commands.

8. Click *OK*.

2.5.2.6.3.3 To import by searching

> ℹ Note
>
> Functions cannot be imported by searching.

1. Open the object library.
2. Click the *Datastores* tab.
3. Select the name of the datastore you want to use.
4. Right-click and select *Search*.

   The Search window appears.
5. Enter the entire item name or some part of it in the *Name* text box.

   If the name is case-sensitive in the database (and not all uppercase), enter the name as it appears in the database and use double quotation marks (") around the name to preserve the case.
6. Select *Contains* or *Equals* from the drop-down list to the right depending on whether you provide a complete or partial search value.

   Equals qualifies only the full search string. That is, you need to search for owner.table_name rather than simply table_name.
7. (Optional) Enter a description in the *Description* text box.
8. Select the object type in the *Type* box.
9. Select the datastore in which you want to search from the *Look In* box.
10. Select *External* from the drop-down box to the right of the *Look In* box.

    External indicates that the software searches for the item in the entire database defined by the datastore.

    Internal indicates that the software searches only the items that have been imported.
11. Go to the *Advanced* tab to search using the software's attribute values.

    The advanced options only apply to searches of imported items.
12. Click *Search*.

    The software lists the tables matching your search criteria.

13. To import a table from the returned list, select the table, right-click, and choose *Import*.

2.5.2.6.4 Reimporting objects

If you have already imported an object such as a datastore, function, or table, you can reimport it, which updates the object's metadata from your database (reimporting overwrites any changes you might have made to the object in the software).

To reimport objects in previous versions of the software, you opened the datastore, viewed the repository metadata, and selected the objects to reimport. In this version of the software, you can reimport objects using the object library at various levels:

- Individual objects — Reimports the metadata for an individual object such as a table or function
- Category node level — Reimports the definitions of all objects of that type in that datastore, for example all tables in the datastore
- Datastore level — Reimports the entire datastore and all its dependent objects including tables, functions, IDOCs, and hierarchies

2.5.2.6.4.1 To reimport objects from the object library

1. In the object library, click the *Datastores* tab.
2. Right-click an individual object and click *Reimport*, or right-click a category node or datastore name and click *Reimport All*.

   You can also select multiple individual objects using Ctrl-click or Shift-click.
3. Click *Yes* to reimport the metadata.
4. If you selected multiple objects to reimport (for example with *Reimport All*), the software requests confirmation for each object unless you check the box *Don't ask me again for the remaining objects*.

   You can skip objects to reimport by clicking No for that object.

   If you are unsure whether to reimport (and thereby overwrite) the object, click View Where Used to display where the object is currently being used in your jobs.

2.5.2.7 Memory datastores

The software also allows you to create a database datastore using *Memory* as the *Database type*. Memory datastores are designed to enhance processing performance of data flows executing in real-time jobs. Data (typically small amounts in a real-time job) is stored in memory to provide immediate access instead of going to the original source data.

A memory datastore is a container for memory tables. A datastore normally provides a connection to a database, application, or adapter. By contrast, a memory datastore contains memory table schemas saved in the repository.

Memory tables are schemas that allow you to cache intermediate data. Memory tables can cache data from relational database tables and hierarchical data files such as XML messages and SAP IDocs (both of which contain nested schemas).

Memory tables can be used to:

- Move data between data flows in real-time jobs. By caching intermediate data, the performance of real-time jobs with multiple data flows is far better than it would be if files or regular tables were used to store intermediate data. For best performance, only use memory tables when processing small quantities of data.
- Store table data in memory for the duration of a job. By storing table data in memory, the LOOKUP_EXT function and other transforms and functions that do not require database operations can access data without having to read it from a remote database.

The lifetime of memory table data is the duration of the job. The data in memory tables cannot be shared between different real-time jobs. Support for the use of memory tables in batch jobs is not available.

2.5.2.7.1 Creating memory datastores

You can create memory datastores using the Datastore Editor window.

2.5.2.7.1.1 To define a memory datastore

1. From the *Project* menu, select *New* > *Datastore* .
2. In the *Name* box, enter the name of the new datastore.

   Be sure to use the naming convention "Memory_DS". Datastore names are appended to table names when table icons appear in the workspace. Memory tables are represented in the workspace with regular table icons. Therefore, label a memory datastore to distinguish its memory tables from regular database tables in the workspace.
3. In the *Datastore type* box keep the default *Database*.
4. In the *Database Type* box select *Memory*.

   No additional attributes are required for the memory datastore.
5. Click *OK*.

2.5.2.7.2 Creating memory tables

When you create a memory table, you do not have to specify the table's schema or import the table's metadata. Instead, the software creates the schema for each memory table automatically based on the preceding schema, which can be either a schema from a relational database table or hierarchical data files such as XML messages. The first time you save the job, the software defines the memory table's schema and saves the table. Subsequently, the table appears with a table icon in the workspace and in the object library under the memory datastore.

2.5.2.7.2.1 To create a memory table

1. From the tool palette, click the template table icon.
2. Click inside a data flow to place the template table.

   The Create Table window opens.
3. From the Create Table window, select the memory datastore.
4. Enter a table name.
5. If you want a system-generated row ID column in the table, click the *Create Row ID* check box.
6. Click *OK*.

   The memory table appears in the workspace as a template table icon.
7. Connect the memory table to the data flow as a target.
8. From the *Project* menu select *Save*.

   In the workspace, the memory table's icon changes to a target table icon and the table appears in the object library under the memory datastore's list of tables.

Related Information

Create Row ID option [page 227]

2.5.2.7.3 Using memory tables as sources and targets

After you create a memory table as a target in one data flow, you can use a memory table as a source or target in any data flow.

Related Information

Real-time Jobs [page 372]

2.5.2.7.3.1 To use a memory table as a source or target

1. In the object library, click the *Datastores* tab.
2. Expand the memory datastore that contains the memory table you want to use.
3. Expand *Tables*.

   A list of tables appears.

4. Select the memory table you want to use as a source or target, and drag it into an open data flow.
5. Connect the memory table as a source or target in the data flow.

   If you are using a memory table as a target, open the memory table's target table editor to set table options.
6. Save the job.

Related Information

Memory table target options [page 227]

2.5.2.7.4 Update Schema option

You might want to quickly update a memory target table's schema if the preceding schema changes. To do this, use the Update Schema option. Otherwise, you would have to add a new memory table to update a schema.

2.5.2.7.4.1 To update the schema of a memory target table

1. Right-click the memory target table's icon in the work space.
2. Select *Update Schema*.

   The schema of the preceding object is used to update the memory target table's schema. The current memory table is updated in your repository. All occurrences of the current memory table are updated with the new schema.

2.5.2.7.5 Memory table target options

The *Delete data from table before loading* option is available for memory table targets. The default is on (the box is selected). To set this option, open the memory target table editor. If you deselect this option, new data will append to the existing table data.

2.5.2.7.6 Create Row ID option

If the *Create Row ID* is checked in the Create Memory Table window, the software generates an integer column called *DI_Row_ID* in which the first row inserted gets a value of 1, the second row inserted gets a value of 2, etc. This new column allows you to use a LOOKUP_EXT expression as an iterator in a script.

> Note
>
> The same functionality is available for other datastore types using the SQL function.

Use the *DI_Row_ID* column to iterate through a table using a `lookup_ext` function in a script. For example:

```
$NumOfRows = total_rows (memory_DS..table1)
$I = 1;
$count=0
while ($count < $NumOfRows)
begin
  $data =
     lookup_ext([memory_DS..table1, 'NO_CACHE','MAX'],[A],[O],[DI_Row_ID,'=',$I]);
  $1 = $I + 1;
  if ($data != NULL)
  begin
  $count = $count + 1;
  end
end
```

In the preceding script, `table1` is a memory table. The table's name is preceded by its datastore name (memory_DS), a dot, a blank space (where a table owner would be for a regular table), then a second dot. There are no owners for memory datastores, so tables are identified by just the datastore name and the table name as shown.

Select the LOOKUP_EXT function arguments (line 7) from the function editor when you define a LOOKUP_EXT function.

The TOTAL_ROWS(DatastoreName.Owner.TableName) function returns the number of rows in a particular table in a datastore. This function can be used with any type of datastore. If used with a memory datastore, use the following syntax: TOTAL_ROWS(**`<DatastoreName..TableName>`**)

The software also provides a built-in function that you can use to explicitly expunge data from a memory table. This provides finer control than the active job has over your data and memory usage. The TRUNCATE_TABLE(**`<DatastoreName..TableName>`**) function can only be used with memory tables.

Related Information

Reference Guide: Functions and Procedures, Descriptions of built-in functions [page 1515]

2.5.2.7.7 Troubleshooting memory tables

- One possible error, particularly when using memory tables, is that the software runs out of virtual memory space. The software exits if it runs out of memory while executing any operation.
- A validation and run time error occurs if the schema of a memory table does not match the schema of the preceding object in the data flow.
  To correct this error, use the Update Schema option or create a new memory table to match the schema of the preceding object in the data flow.
- Two log files contain information specific to memory tables: `trace_memory_reader` log and `trace_memory_loader` log.

2.5.2.8 Persistent cache datastores

The software also allows you to create a database datastore using *Persistent cache* as the *Database type*. Persistent cache datastores provide the following benefits for data flows that process large volumes of data.

- You can store a large amount of data in persistent cache which the software quickly loads into memory to provide immediate access during a job. For example, you can access a lookup table or comparison table locally (instead of reading from a remote database).
- You can create cache tables that multiple data flows can share (unlike a memory table which cannot be shared between different real-time jobs). For example, if a large lookup table used in a lookup_ext function rarely changes, you can create a cache once and subsequent jobs can use this cache instead of creating it each time.

A persistent cache datastore is a container for cache tables. A datastore normally provides a connection to a database, application, or adapter. By contrast, a persistent cache datastore contains cache table schemas saved in the repository.

Persistent cache tables allow you to cache large amounts of data. Persistent cache tables can cache data from relational database tables and files.

> ℹ Note
>
> You cannot cache data from hierarchical data files such as XML messages and SAP IDocs (both of which contain nested schemas). You cannot perform incremental inserts, deletes, or updates on a persistent cache table.

You create a persistent cache table by loading data into the persistent cache target table using one data flow. You can then subsequently read from the cache table in another data flow. When you load data into a persistent cache table, the software always truncates and recreates the table.

2.5.2.8.1 Creating persistent cache datastores

You can create persistent cache datastores using the *Datastore Editor* window.

2.5.2.8.1.1 To define a persistent cache datastore

1. From the *Project* menu, select *New* > *Datastore*.
2. In the *Name* box, enter the name of the new datastore.

   Be sure to use a naming convention such as "Persist_DS". Datastore names are appended to table names when table icons appear in the workspace. Persistent cache tables are represented in the workspace with regular table icons. Therefore, label a persistent cache datastore to distinguish its persistent cache tables from regular database tables in the workspace.
3. In the *Datastore type* box, keep the default *Database*.
4. In the *Database Type* box, select *Persistent cache*.

5. In the *Cache directory* box, you can either type or browse to a directory where you want to store the persistent cache.
6. Click *OK*.

2.5.2.8.2 Creating persistent cache tables

When you create a persistent cache table, you do not have to specify the table's schema or import the table's metadata. Instead, the software creates the schema for each persistent cache table automatically based on the preceding schema. The first time you save the job, the software defines the persistent cache table's schema and saves the table. Subsequently, the table appears with a table icon in the workspace and in the object library under the persistent cache datastore.

You create a persistent cache table in one of the following ways:

- As a target template table in a data flow
- As part of the Data_Transfer transform during the job execution

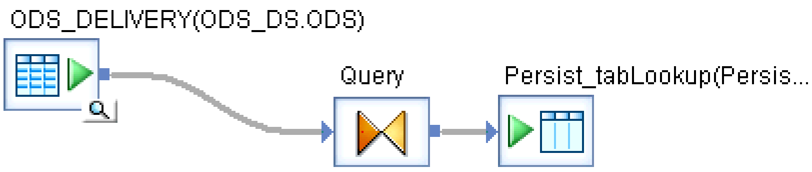
Related Information

Reference Guide: Data_Transfer [page 1071]

2.5.2.8.2.1 To create a persistent cache table as a target in a data flow

1. Use one of the following methods to open the Create Template window:
   - From the tool palette:
     1. Click the template table icon.
     2. Click inside a data flow to place the template table in the workspace.
     3. On the Create Template window, select the persistent cache datastore.
   - From the object library:
     1. Expand a persistent cache datastore.
     2. Click the template table icon and drag it to the workspace.
2. On the Create Template window, enter a table name.
3. Click *OK*.

   The persistent cache table appears in the workspace as a template table icon.
4. Connect the persistent cache table to the data flow as a target (usually a Query transform).



5. In the Query transform, map the Schema In columns that you want to include in the persistent cache table.
6. Open the persistent cache table's target table editor to set table options.
7. On the Options tab of the persistent cache target table editor, you can change the following options for the persistent cache table.
   - *Column comparison* — Specifies how the input columns are mapped to persistent cache table columns. There are two options:
     - Compare_by_position — The software disregards the column names and maps source columns to target columns by position.
     - Compare_by_name — The software maps source columns to target columns by name. This option is the default.
   - *Include duplicate keys* — Select this check box to cache duplicate keys. This option is selected by default.
8. On the Keys tab, specify the key column or columns to use as the key in the persistent cache table.
9. From the *Project* menu select *Save*. In the workspace, the template table's icon changes to a target table icon and the table appears in the object library under the persistent cache datastore's list of tables.

Related Information

Reference Guide:Target persistent cache tables [page 961]

2.5.2.8.3 Using persistent cache tables as sources

After you create a persistent cache table as a target in one data flow, you can use the persistent cache table as a source in any data flow. You can also use it as a lookup table or comparison table.

Related Information

Reference Guide: Persistent cache source [page 951]

2.5.2.9 Linked datastores

Various database vendors support one-way communication paths from one database server to another. Oracle calls these paths database links. In DB2, the one-way communication path from a database server to another database server is provided by an information server that allows a set of servers to get data from remote data sources. In Microsoft SQL Server, linked servers provide the one-way communication path from one database server to another. These solutions allow local users to access data on a remote database, which can be on the local or a remote computer and of the same or different database type.

For example, a local Oracle database server, called Orders, can store a database link to access information in a remote Oracle database, Customers. Users connected to Customers however, cannot use the same link to access data in Orders. Users logged into database Customers must define a separate link, stored in the data dictionary of database Customers, to access data on Orders.

The software refers to communication paths between databases as database links. The datastores in a database link relationship are called linked datastores. The software uses linked datastores to enhance its performance by pushing down operations to a target database using a target datastore.

Related Information

Performance Optimization Guide: Database link support for push-down operations across datastores [page 2124]

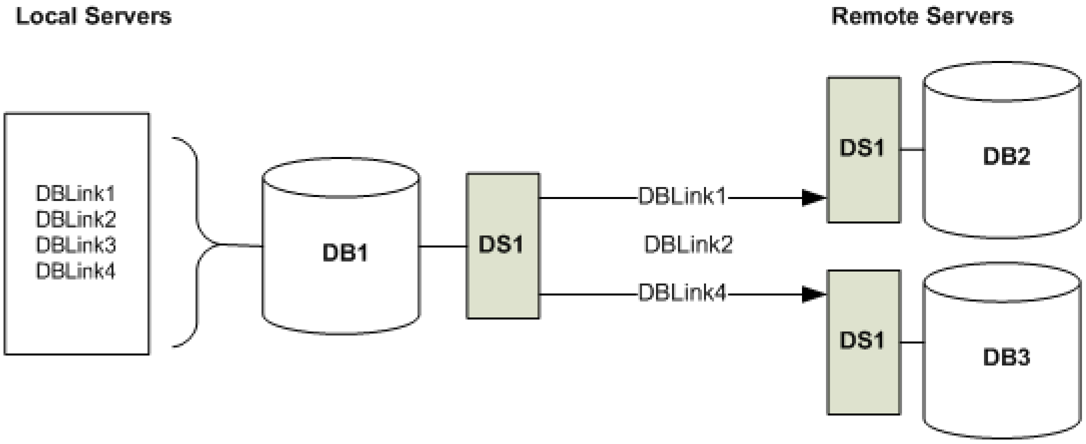
2.5.2.9.1 Relationship between database links and datastores

A database link stores information about how to connect to a remote data source, such as its host name, database name, user name, password, and database type. The same information is stored in an SAP Data Services database datastore.You can associate the datastore to another datastore and then import an external database link as an option of a datastore. The datastores must connect to the databases defined in the database link.

Additional requirements are as follows:

- A local server for database links must be a target server in the software
- A remote server for database links must be a source server in the software
- An external (exists first in a database) database link establishes the relationship between any target datastore and a source datastore
- A Local datastore can be related to zero or multiple datastores using a database link for each remote database
- Two datastores can be related to each other using one link only

The following diagram shows the possible relationships between database links and linked datastores:



Four database links, DBLink 1 through 4, are on database DB1 and the software reads them through datastore Ds1.

- Dblink1 relates datastore Ds1 to datastore Ds2. This relationship is called linked datastore Dblink1 (the linked datastore has the same name as the external database link).
- Dblink2 is not mapped to any datastore in the software because it relates Ds1 with Ds2, which are also related by Dblink1. Although it is not a regular case, you can create multiple external database links that connect to the same remote source. However, the software allows only one database link between a target datastore and a source datastore pair. For example, if you select DBLink1 to link target datastore DS1 with source datastore DS2, you cannot import DBLink2 to do the same.
- Dblink3 is not mapped to any datastore in the software because there is no datastore defined for the remote data source to which the external database link refers.
- Dblink4 relates Ds1 with Ds3.

2.5.3 Adapter datastores

Depending on the adapter implementation, adapters allow you to:

- Browse application metadata
- Import application metadata into a repository
- Move batch and real-time data between the software and applications

SAP offers an Adapter Software Development Kit (SDK) to develop your own custom adapters. Also, you can buy the software pre-packaged adapters to access application metadata and data in any application. For more information on these products, contact your SAP sales representative.

Adapters are represented in Designer by adapter datastores. Jobs provide batch and real-time data movement between the software and applications through an adapter datastore's subordinate objects:

Subordinate Objects	Use as	Used for
Tables	Source or target	Batch data movement
Documents	Source or target	
Functions	Function call in query	
Message functions	Function call in query	Real-time data movement
Outbound messages	Target only	

Adapters can provide access to an application's data and metadata or just metadata. For example, if the data source is SQL-compatible, the adapter might be designed to access metadata, while the software extracts data from or loads data directly to the application.

Related Information

Management Console Guide: Adapters [page 1938]
Source and target objects [page 286]
Real-time source and target objects [page 381]

2.5.3.1 Defining an adapter datastore

You need to define at least one datastore for each adapter through which you are extracting or loading data.

To define a datastore, you must have appropriate access privileges to the application that the adapter serves.

2.5.3.1.1 To define an adapter datastore

To create an adapter datastore, you must first install the adapter on the Job Server computer, configure the Job Server to support local adapters using the Server Manager utility, and ensure that the Job Server's service is running.

1. In the Object Library, click to select the *Datastores* tab.
2. Right-click and select *New*.

   The Create New Datastore window opens.
3. Enter a unique identifying name for the datastore.

   The datastore name appears in the Designer only. It can be the same as the adapter name.
4. In the *Datastore type* list, select *Adapter*.
5. Select a *Job server* from the list.

   Adapters residing on the Job Server computer and registered with the selected Job Server appear in the Job server list.
6. Select an adapter instance from the *Adapter instance name* list.
7. Enter all adapter information required to complete the datastore connection.

   > Note
   >
   > If the developer included a description for each option, the software displays it below the grid. The adapter documentation should list all information required for a datastore connection.

   For the datastore as a whole, the following buttons are available:

Buttons	Description
Edit	Opens the Configurations for Datastore dialog. Use the tool bar on this window to add, configure, and manage multiple configurations for a datastore.

Buttons	Description
Show ATL	Opens a text window that displays how the software will code the selections you make for this datastore in its scripting language.
OK	Saves selections and closes the Datastore Editor (Create New Datastore) window.
Cancel	Cancels selections and closes the Datastore Editor window.
Apply	Saves selections.

8. Click *OK*.

   The datastore configuration is saved in your metadata repository and the new datastore appears in the object library.

After you create a datastore connection, you can browse and/or import metadata from the data source through the adapter.

2.5.3.1.2 To change an adapter datastore's configuration

1. Right-click the datastore you want to browse and select *Edit* to open the Datastore Editor window.
2. Edit configuration information.

   When editing an adapter datastore, enter or select a value. The software looks for the Job Server and adapter instance name you specify. If the Job Server and adapter instance both exist, and the Designer can communicate to get the adapter's properties, then it displays them accordingly. If the Designer cannot get the adapter's properties, then it retains the previous properties.
3. Click *OK*.

   The edited datastore configuration is saved in your metadata repository.

2.5.3.1.3 To delete an adapter datastore and associated metadata objects

1. Right-click the datastore you want to delete and select *Delete*.
2. Click *OK* in the confirmation window.

   The software removes the datastore and all metadata objects contained within that datastore from the metadata repository.

   If these objects exist in established flows, they appear with a deleted icon ⊘.

2.5.3.2 Browsing metadata through an adapter datastore

The metadata you can browse depends on the specific adapter.

2.5.3.2.1 To browse application metadata

1. Right-click the datastore you want to browse and select *Open*.

   A window opens showing source metadata.
2. Scroll to view metadata name and description attributes.
3. Click plus signs [+] to expand objects and view subordinate objects.
4. Right-click any object to check importability.

2.5.3.3 Importing metadata through an adapter datastore

The metadata you can import depends on the specific adapter. After importing metadata, you can edit it. Your edits propagate to all objects that call these objects.

2.5.3.3.1 To import application metadata while browsing

1. Right-click the datastore you want to browse, then select *Open*.
2. Find the metadata object you want to import from the browsable list.
3. Right-click the object and select *Import*.
4. The object is imported into one of the adapter datastore containers (documents, functions, tables, outbound messages, or message functions).

2.5.3.3.2 To import application metadata by name

1. Right-click the datastore from which you want metadata, then select *Import by name*.

   The Import by name window appears containing import parameters with corresponding text boxes.
2. Click each import parameter text box and enter specific information related to the object you want to import.
3. Click *OK*. Any object(s) matching your parameter constraints are imported to one of the corresponding categories specified under the datastore.

2.5.4 Web service datastores

Web service datastores represent a connection from Data Services to an external web service-based data source.

2.5.4.1 Defining a web service datastore

You need to define at least one datastore for each web service with which you are exchanging data.

To define a datastore, you must have the appropriate access priveliges to the web services that the datastore describes.

2.5.4.1.1 To define a web services datastore

1. In the *Datastores* tab of the object library, right-click and select *New*.
2. Enter the name of the new datastore in the *Datastore name* field.

   The name can contain any alphabetical or numeric characters or underscores (_). It cannot contain spaces.
3. Select the *Datastore type*.

   Choose a web service option. When you select a Datastore Type, Data Services displays other options relevant to that type.
4. Specify the *Web Service URL*.

   The URL must accept connections and return the WSDL. For REST web services, you can either enter a URL or the path to the local WADL file. See "Web services technologies" in the *Integrator Guide* for more information about WSDL and WADL files.
5. Click *OK*.
   The datastore configuration is saved in your metadata repository and the new datastore appears in the object library.

After you complete your datastore connection, you can browse and/or import metadata from the web service through the datastore.

2.5.4.1.2 To change a web service datastore's configuration

1. Right-click the datastore you want to browse and select *Edit* to open the Datastore Editor window.
2. Edit configuration information.
3. Click *OK*.
   The edited datastore configuration is saved in your metadata repository.

2.5.4.1.3 To delete a web service datastore and associated metadata objects

1. Right-click the datastore you want to delete and select *Delete*.
2. Click *OK* in the confirmation window.
   Data Services removes the datastore and all metadata objects contained within that datastore from the metadata repository. If these objects exist in established data flows, they appear with a deleted icon.

2.5.4.2 Browsing WSDL and WADL metadata through a web service datastore

Data Services stores metadata information for all imported objects in a datastore. You can use Data Services to view metadata for imported or non-imported objects and to check whether the metadata has changed for objects already imported.

See "Web services technologies" in the *Integrator Guide* for more information about WSDL and WADL files.

2.5.4.2.1 To view imported objects

1. Go to the *Datastores* tab in the object library.
2. Click the plus sign (+) next to the datastore name to view the object types in the datastore. Web service datastores have functions.
3. Click the plus sign (+) next to an object type to view the objects of that type imported from the datastore.

2.5.4.2.2 To sort the list of objects

Click the column heading to sort the objects in each grouping and the groupings in each datastore alphabetically. Click again to sort in reverse-alphabetical order.

2.5.4.2.3 To view WSDL and WADL metadata

1. Select the *Datastores* tab in the object library.
2. Choose a datastore, right-click, and select *Open*. (Alternatively, you can double-click the datastore icon.)
   Data Services opens the datastore explorer in the workspace. The datastore explorer lists the web service ports and operations in the datastore. You can view ports and operations in the external web service or in the internal repository. You can also search through them.
3. Select *External metadata* to view web service ports and operations from the external WSDL or WADL file. See "Web services technologies" in the *Integrator Guide* for more information about WSDL and WADL files.

If you select one or more operations, you can right-click for further options.

Command	Description
Import	Imports (or re-imports) operations from the database into the repository.

4. Select Repository metadata to view imported web service operations.
   If you select one or more operations, you can right-click for further options.

Command	Description
Delete	Deletes the operation or operations from the repository.
Properties	Shows the properties of the selected web service operation.

2.5.4.3 Importing metadata through a web service datastore

For web service datastores, you can import metadata for web service operations.

2.5.4.3.1 To import web service operations

1. Right-click the datastore you want to browse, then select *Open*.
2. Find the web service operation you want to import from the browsable list.
3. Right-click the operation and select *Import*.
   The operation is imported into the web service datastore's function container.

2.5.5 Creating and managing multiple datastore configurations

Creating multiple configurations for a single datastore allows you to consolidate separate datastore connections for similar sources or targets into one source or target datastore with multiple configurations. Then, you can select a set of configurations that includes the sources and targets you want by selecting a system configuration when you execute or schedule the job. The ability to create multiple datastore configurations provides greater ease-of-use for job portability scenarios, such as:

- OEM (different databases for design and distribution)
- Migration (different connections for DEV, TEST, and PROD)
- Multi-instance (databases with different versions or locales)
- Multi-user (databases for central and local repositories)

Related Information

Portability solutions [page 244]

2.5.5.1 Definitions

Refer to the following terms when creating and managing multiple datastore configurations:

Table 4:

Term	Definition
Datastore configuration	Allows you to provide multiple metadata sources or targets for datastores. Each configuration is a property of a datastore that refers to a set of configurable options (such as database connection name, database type, user name, password, and locale) and their values.
Default datastore configuration	The datastore configuration that the software uses for browsing and importing database objects (tables and functions) and executing jobs if no system configuration is specified. If a datastore has more than one configuration, select a default configuration, as needed. If a datastore has only one configuration, the software uses it as the default configuration.
Current datastore configuration	The datastore configuration that the software uses to execute a job. If you define a system configuration, the software will execute the job using the system configuration. Specify a current configuration for each system configuration. If you do not create a system configuration, or the system configuration does not specify a configuration for a datastore, the software uses the default datastore configuration as the current configuration at job execution time.
Database objects	The tables and functions that are imported from a datastore. Database objects usually have owners. Some database objects do not have owners. For example, database objects in an ODBC datastore connecting to an Access database do not have owners.
Owner name	Owner name of a database object (for example, a table) in an underlying database. Also known as database owner name or physical owner name.
Alias	A logical owner name. Create an alias for objects that are in different database environments if you have different owner names in those environments. You can create an alias from the datastore editor for any datastore configuration.
Dependent objects	Dependent objects are the jobs, work flows, data flows, and custom functions in which a database object is used. Dependent object information is generated by the where-used utility.

2.5.5.2 Why use multiple datastore configurations?

By creating multiple datastore configurations, you can decrease end-to-end development time in a multi-source, 24x7, enterprise data warehouse environment because you can easily port jobs among different database types, versions, and instances.

For example, porting can be as simple as:

1. Creating a new configuration within an existing source or target datastore.
2. Adding a datastore alias then map configurations with different object owner names to it.
3. Defining a system configuration then adding datastore configurations required for a particular environment. Select a system configuration when you execute a job.

2.5.5.3 Creating a new configuration

You can create multiple configurations for all datastore types except memory datastores. Use the Datastore Editor to create and edit datastore configurations.

Related Information

Reference Guide: Descriptions of objects, Datastore [page 860]

2.5.5.3.1 To create a new datastore configuration

1. From the Datastores tab of the object library, right-click any existing datastore and select *Edit*.
2. Click *Advanced* to view existing configuration information.

   Each datastore must have at least one configuration. If only one configuration exists, it is the default configuration.

3. Click *Edit* to open the Configurations for Datastore window.
4. Click the *Create New Configuration* icon on the toolbar.

   The Create New Configuration window opens.

5. In the Create New Configuration window:
   a) Enter a unique, logical configuration *Name*.
   b) Select a *Database type* from the drop-down menu.
   c) Select a *Database version* from the drop-down menu.
   d) In the Values for table targets and SQL transforms section, the software pre-selects the *Use values from* value based on the existing database type and version. The Designer automatically uses the existing SQL transform and target values for the same database type and version.

Further, if the database you want to associate with a new configuration is a later version than that associated with other existing configurations, the Designer automatically populates the Use values from with the earlier version.

However, if database type and version are not already specified in an existing configuration, or if the database version is older than your existing configuration, you can choose to use the values from another existing configuration or the default for the database type and version.

e) Select or clear the *Restore values if they already exist* option.

When you delete datastore configurations, the software saves all associated target values and SQL transforms. If you create a new datastore configuration with the same database type and version as the one previously deleted, the Restore values if they already exist option allows you to access and take advantage of the saved value settings.)

- If you keep this option (selected as default) the software uses customized target and SQL transform values from previously deleted datastore configurations.
- If you deselect *Restore values if they already exist*, the software does not attempt to restore target and SQL transform values, allowing you to provide new values.

f) Click *OK* to save the new configuration.

If your datastore contains pre-existing data flows with SQL transforms or target objects, the software must add any new database type and version values to these transform and target objects. Under these circumstances, when you add a new datastore configuration, the software displays the *Added New Values - Modified Objects* window which provides detailed information about affected data flows and modified objects. These same results also display in the Output window of the Designer.

For each datastore, the software requires that one configuration be designated as the default configuration. The software uses the default configuration to import metadata and also preserves the default configuration during export and multi-user operations. Your first datastore configuration is automatically designated as the default; however after adding one or more additional datastore configurations, you can use the datastore editor to flag a different configuration as the default.

When you export a repository, the software preserves all configurations in all datastores including related SQL transform text and target table editor settings. If the datastore you are exporting already exists in the target repository, the software overrides configurations in the target with source configurations. The software exports system configurations separate from other job related objects.

2.5.5.4 Adding a datastore alias

From the datastore editor, you can also create multiple aliases for a datastore then map datastore configurations to each alias.

2.5.5.4.1 To create an alias

1. From within the datastore editor, click *Advanced*, then click *Aliases (Click here to create)*.

   The Create New Alias window opens.
2. Under *Alias Name in Designer*, use only alphanumeric characters and the underscore symbol (_) to enter an alias name.

3. Click *OK*.

   The *Create New Alias* window closes and your new alias appears underneath the Aliases category

When you define a datastore alias, the software substitutes your specified datastore configuration alias for the real owner name when you import metadata for database objects. You can also rename tables and functions after you import them.

Related Information

Renaming table and function owner [page 249]

2.5.5.5 Functions to identify the configuration

The software provides six functions that are useful when working with multiple source and target datastore configurations.

Function	Category	Description
db_type	Miscellaneous	Returns the database type of the current datastore configuration.
db_version	Miscellaneous	Returns the database version of the current datastore configuration.
db_database_name	Miscellaneous	Returns the database name of the current datastore configuration if the database type is MS SQL Server or Sybase ASE.
db_owner	Miscellaneous	Returns the real owner name that corresponds to the given alias name under the current datastore configuration.
current_configuration	Miscellaneous	Returns the name of the datastore configuration that is in use at runtime.
current_system_configuration	Miscellaneous	Returns the name of the current system configuration. If no system configuration is defined, returns a NULL value.

The software links any SQL transform and target table editor settings used in a data flow to datastore configurations. You can also use variable interpolation in SQL text with these functions to enable a SQL transform to perform successfully regardless of which configuration the Job Server uses at job execution time.

Use the Administrator to select a system configuration as well as view the underlying datastore configuration associated with it when you:

- Execute batch jobs

- Schedule batch jobs
- View batch job history
- Create services for real-time jobs

To use multiple configurations successfully, design your jobs so that you do not need to change schemas, data types, functions, variables, and so on when you switch between datastore configurations. For example, if you have a datastore with a configuration for Oracle sources and SQL sources, make sure that the table metadata schemas match exactly. Use the same table names, alias names, number and order of columns, as well as the same column names, data types, and content types.

Job portability tips [page 248]

2.5.5.6 Portability solutions

Set multiple source or target configurations for a single datastore if you want to quickly change connections to a different source or target database. The software provides several different solutions for porting jobs.

Related Information

Designer Guide: Multi-user Development [page 798]
Designer Guide: Multi-user Environment Setup [page 802]

2.5.5.6.1 Migration between environments

When you must move repository metadata to another environment (for example from development to test or from test to production) which uses different source and target databases, the process typically includes the following characteristics:

- The environments use the same database type but may have unique database versions or locales.
- Database objects (tables and functions) can belong to different owners.
- Each environment has a unique database connection name, user name, password, other connection properties, and owner mapping.
- You use a typical repository migration procedure. Either you export jobs to an ATL file then import the ATL file to another repository, or you export jobs directly from one repository to another repository.

Because the software overwrites datastore configurations during export, you should add configurations for the target environment (for example, add configurations for the test environment when migrating from development to test) to the source repository (for example, add to the development repository before migrating to the test environment). The Export utility saves additional configurations in the target environment, which means that you do not have to edit datastores before running ported jobs in the target environment.

This solution offers the following advantages:

- Minimal production down time: You can start jobs as soon as you export them.
- Minimal security issues: Testers and operators in production do not need permission to modify repository objects.

Related Information

Administrator Guide: Export/Import [page 117]

2.5.5.6.2 Loading multiple instances

If you must load multiple instances of a data source to a target data warehouse, the task is the same as in a migration scenario except that you are using only one repository.

2.5.5.6.2.1 To load multiple instances of a data source to a target data warehouse

1. Create a datastore that connects to a particular instance.
2. Define the first datastore configuration. This datastore configuration contains all configurable properties such as database type, database connection name, user name, password, database version, and locale information.

   When you define a configuration for an Adapter datastore, make sure that the relevant Job Server is running so the Designer can find all available adapter instances for the datastore.
3. Define a set of alias-to-owner mappings within the datastore configuration. When you use an alias for a configuration, the software imports all objects using the metadata alias rather than using real owner names. This allows you to use database objects for jobs that are transparent to other database instances.
4. Use the database object owner renaming tool to rename owners of any existing database objects.
5. Import database objects and develop jobs using those objects, then run the jobs.
6. To support executing jobs under different instances, add datastore configurations for each additional instance.
7. Map owner names from the new database instance configurations to the aliases that you defined in an earlier step.
8. Run the jobs in all database instances.

Related Information

Renaming table and function owner [page 249]

2.5.5.6.3 OEM deployment

If you design jobs for one database type and deploy those jobs to other database types as an OEM partner, the deployment typically has the following characteristics:

- The instances require various source database types and versions.
- Since a datastore can only access one instance at a time, you may need to trigger functions at run-time to match different instances. If this is the case, the software requires different SQL text for functions (such as lookup_ext and sql) and transforms (such as the SQL transform). The software also requires different settings for the target table (configurable in the target table editor).
- The instances may use different locales.
- Database tables across different databases belong to different owners.
- Each instance has a unique database connection name, user name, password, other connection properties, and owner mappings.
- You export jobs to ATL files for deployment.

2.5.5.6.3.1 To deploy jobs to other database types as an OEM partner

1. Develop jobs for a particular database type following the steps described in the *Loading multiple instances* [page 245] scenario.

   To support a new instance under a new database type, the software copies target table and SQL transform database properties from the previous configuration to each additional configuration when you save it.

   If you selected a bulk loader method for one or more target tables within your job's data flows, and new configurations apply to different database types, open your targets and manually set the bulk loader option (assuming you still want to use the bulk loader method with the new database type). The software does not copy bulk loader options for targets from one database type to another.

   When the software saves a new configuration it also generates a report that provides a list of targets automatically set for bulk loading. Reference this report to make manual changes as needed.
2. If the SQL text in any SQL transform is not applicable for the new database type, modify the SQL text for the new database type.

   If the SQL text contains any hard-coded owner names or database names, consider replacing these names with variables to supply owner names or database names for multiple database types. This way, you will not have to modify the SQL text for each environment.
3. Because the software does not support unique SQL text for each database type or version of the sql(), lookup_ext(), and pushdown_sql() functions, use the db_type() and similar functions to get the database type and version of the current datastore configuration and provide the correct SQL text for that database type and version using the variable substitution (interpolation) technique.

Related Information

Reference Guide: SQL [page 1469]

2.5.5.6.4 Multi-user development

If you are using a central repository management system, allowing multiple developers, each with their own local repository, to check in and check out jobs, the development environment typically has the following characteristics:

- It has a central repository and a number of local repositories.
- Multiple development environments get merged (via central repository operations such as check in and check out) at times. When this occurs, real owner names (used initially to import objects) must be later mapped to a set of aliases shared among all users.
- The software preserves object history (versions and labels).
- The instances share the same database type but may have different versions and locales.
- Database objects may belong to different owners.
- Each instance has a unique database connection name, user name, password, other connection properties, and owner mapping.

In the multi-user development scenario you must define aliases so that the software can properly preserve the history for all objects in the shared environment.

2.5.5.6.4.1 Porting jobs in a multi-user environment

When porting jobs in a multi-user environment, consider these points:

- Rename table owners and function owners to consolidate object database object owner names into aliases.
    - Renaming occurs in local repositories. To rename the database objects stored in the central repository, check out the datastore to a local repository and apply the renaming tool in the local repository.
    - If the objects to be renamed have dependent objects, the software will ask you to check out the dependent objects.
    - If all the dependent objects can be checked out, renaming will create a new object that has the alias and delete the original object that has the original owner name.
    - If all the dependent objects cannot be checked out (data flows are checked out by another user), the software displays a message, which gives you the option to proceed or cancel the operation. If you cannot check out some of the dependent objects, the renaming tool only affects the flows that you can check out. After renaming, the original object will co-exist with the new object. The number of flows affected by the renaming process will affect the Usage and Where-Used information in the Designer for both the original object and the new object.
- You are responsible for checking in all the dependent objects that were checked out during the owner renaming process. Checking in the new objects does not automatically check in the dependent objects that were checked out.
    - The software does not delete original objects from the central repository when you check in the new objects.

  - Use caution because checking in datastores and checking them out as multi-user operations can override datastore configurations.
  - Maintain the datastore configurations of all users by not overriding the configurations they created. Instead, add a configuration and make it your default configuration while working in your own environment.
    - When your group completes the development phase, It is recommended that the last developer delete the configurations that apply to the development environments and add the configurations that apply to the test or production environments.

2.5.5.7 Job portability tips

- The software assumes that the metadata of a table or function is the same across different database types and versions specified in different configurations in the same datastore. For instance, if you import a table when the default configuration of the datastore is Oracle, then later use the table in a job to extract from DB2, your job will run.
- Import metadata for a database object using the default configuration and use that same metadata with all configurations defined in the same datastore.
- The software supports options in some database types or versions that it does not support in others For example, the software supports parallel reading on Oracle hash-partitioned tables, not on DB2 or other database hash-partitioned tables. If you import an Oracle hash-partitioned table and set your data flow to run in parallel, the software will read from each partition in parallel. However, when you run your job using sources from a DB2 environment, parallel reading will not occur.
- The following features support job portability:
  - Enhanced SQL transform
    With the enhanced SQL transform, you can enter different SQL text for different database types/versions and use variable substitution in the SQL text to allow the software to read the correct text for its associated datastore configuration.
  - Enhanced target table editor
    Using enhanced target table editor options, you can configure database table targets for different database types/versions to match their datastore configurations.
  - Enhanced datastore editor
    Using the enhanced datastore editor, when you create a new datastore configuration you can choose to copy the database properties (including the datastore and table target options as well as the SQL transform text) from an existing configuration or use the current values.
- When you design a job that will be run from different database types or versions, name database tables, functions, and stored procedures the same for all sources. If you create configurations for both case-insensitive databases and case-sensitive databases in the same datastore, It is recommended that you name the tables, functions, and stored procedures using all upper-case characters.
- Table schemas should match across the databases in a datastore. This means the number of columns, the column names, and column positions should be exactly the same. The column data types should be the same or compatible. For example, if you have a VARCHAR column in an Oracle source, use a VARCHAR column in the Microsoft SQL Server source too. If you have a DATE column in an Oracle source, use a DATETIME column in the Microsoft SQL Server source. Define primary and foreign keys the same way.
- Stored procedure schemas should match. When you import a stored procedure from one datastore configuration and try to use it for another datastore configuration, the software assumes that the signature of the stored procedure is exactly the same for the two databases. For example, if a stored procedure is a stored

function (only Oracle supports stored functions), then you have to use it as a function with all other configurations in a datastore (in other words, all databases must be Oracle). If your stored procedure has three parameters in one database, it should have exactly three parameters in the other databases. Further, the names, positions, data types, and in/out types of the parameters must match exactly.

Advanced Development Guide: Multi-user Environment Setup [page 802]

2.5.5.8 Renaming table and function owner

The software allows you to rename the owner of imported tables, template tables, or functions. This process is called owner renaming.

Use owner renaming to assign a single metadata alias instead of the real owner name for database objects in the datastore. Consolidating metadata under a single alias name allows you to access accurate and consistent dependency information at any time while also allowing you to more easily switch between configurations when you move jobs to different environments.

When using objects stored in a central repository, a shared alias makes it easy to track objects checked in by multiple users. If all users of local repositories use the same alias, the software can track dependencies for objects that your team checks in and out of the central repository.

When you rename an owner, the instances of a table or function in a data flow are affected, not the datastore from which they were imported.

2.5.5.8.1 To rename the owner of a table or function

1. From the Datastore tab of the local object library, expand a table, template table, or function category.
2. Right-click the table or function and select *Rename Owner*.
3. Enter a New *Owner Name* then click *Rename*.

   When you enter a New Owner Name, the software uses it as a metadata alias for the table or function.

   > Note
   >
   > If the object you are renaming already exists in the datastore, the software determines if that the two objects have the same schema. If they are the same, then the software proceeds. If they are different, then the software displays a message to that effect. You may need to choose a different object name.

The software supports both case-sensitive and case-insensitive owner renaming.

- If the objects you want to rename are from a case-sensitive database, the owner renaming mechanism preserves case sensitivity.

- If the objects you want to rename are from a datastore that contains both case-sensitive and case-insensitive databases, the software will base the case-sensitivity of new owner names on the case sensitivity of the default configuration. To ensure that all objects are portable across all configurations in this scenario, enter all owner names and object names using uppercase characters.

During the owner renaming process:

- The software updates the dependent objects (jobs, work flows, and data flows that use the renamed object) to use the new owner name.
- The object library shows the entry of the object with the new owner name. Displayed Usage and Where-Used information reflect the number of updated dependent objects.
- If the software successfully updates all the dependent objects, it deletes the metadata for the object with the original owner name from the object library and the repository.

2.5.5.8.2 Using the Rename window in a multi-user scenario

This section provides a detailed description of Rename Owner window behavior in a multi-user scenario.

Using an alias for all objects stored in a central repository allows the software to track all objects checked in by multiple users. If all local repository users use the same alias, the software can track dependencies for objects that your team checks in and out of the central repository.

When you are checking objects in and out of a central repository, depending upon the check-out state of a renamed object and whether that object is associated with any dependent objects, there are several behaviors possible when you select the *Rename* button.

Case 1

Object is not checked out, and object has no dependent objects in the local or central repository.

Behavior: When you click *Rename*, the software renames the object owner.

Case 2

Object is checked out, and object has no dependent objects in the local or central repository.

Behavior: Same as Case 1.

Case 3

Object is not checked out, and object has one or more dependent objects (in the local repository).

Behavior: When you click *Rename*, the software displays a second window listing the dependent objects (that use or refer to the renamed object).

If you click *Continue*, the software renames the objects and modifies the dependent objects to refer to the renamed object using the new owner name. If you click *Cancel*, the Designer returns to the Rename Owner window.

> **Note**
>
> An object might still have one or more dependent objects in the central repository. However, if the object to be renamed is not checked out, the Rename Owner mechanism (by design) does not affect the dependent objects in the central repository.

Case 4

Object is checked out and has one or more dependent objects.

Behavior: This case contains some complexity.

- If you are not connected to the central repository, the status message reads:

  ```
  This object is checked out from central repository <X>. Please select Tools |
  Central Repository… to activate that repository before renaming.
  ```

- If you are connected to the central repository, the Rename Owner window opens.
  When you click Rename, a second window opens to display the dependent objects and a status indicating their check-out state and location. If a dependent object is located in the local repository only, the status message reads:

  ```
  Used only in local repository. No check out necessary.
  ```

- If the dependent object is in the central repository, and it is not checked out, the status message reads:

  ```
  Not checked out
  ```

- If you have the dependent object checked out or it is checked out by another user, the status message shows the name of the checked out repository. For example: `Oracle.production.user1`
  As in Case 2, the purpose of this second window is to show the dependent objects. In addition, this window allows you to check out the necessary dependent objects from the central repository, without having to go to the Central Object Library window.
  Click the *Refresh List* button to update the check out status in the list. This is useful when the software identifies a dependent object in the central repository but another user has it checked out. When that user checks in the dependent object, click *Refresh List* to update the status and verify that the dependent object is no longer checked out.
  To use the Rename Owner feature to its best advantage, check out associated dependent objects from the central repository. This helps avoid having dependent objects that refer to objects with owner names that do not exist. From the central repository, select one or more objects, then right-click and select Check Out.
  After you check out the dependent object, the Designer updates the status. If the check out was successful, the status shows the name of the local repository.

Case 4a

You click *Continue*, but one or more dependent objects are not checked out from the central repository.

In this situation, the software displays another dialog box that warns you about objects not yet checked out and to confirm your desire to continue.

Click *No* to return to the previous dialog box showing the dependent objects. Click *Yes* to proceed with renaming the selected object and to edit its dependent objects. The software modifies objects that are not checked out in the local repository to refer to the new owner name. It is your responsibility to maintain consistency with the objects in the central repository.

Case 4b

You click *Continue*, and all dependent objects are checked out from the central repository.

The software renames the owner of the selected object, and modifies all dependent objects to refer to the new owner name. Although to you, it looks as if the original object has a new owner name, in reality the software has not modified the original object; it created a new object identical to the original, but uses the new owner name. The original object with the old owner name still exists. The software then performs an "undo checkout" on the original object. It becomes your responsibility to check in the renamed object.

When the rename operation is successful, in the *Datastore* tab of the local object library, the software updates the table or function with the new owner name and the Output window displays the following message:

```
Object <Object_Name>: Owner name <Old_Owner> successfully renamed to <New_Owner>,
including references from dependent objects.
```

If the software does not successfully rename the owner, the Output window displays the following message:

```
Object <Object_Name>: Owner name <Old_Owner> could not be renamed to <New_Owner>.
```

2.5.5.9 Defining a system configuration

What is the difference between datastore configurations and system configurations?

Datastore configurations	Each datastore configuration defines a connection to a particular database from a single datastore.
System configurations	Each system configuration defines a set of datastore configurations that you want to use together when running a job. You can define a system configuration if your repository contains at least one datastore with multiple configurations. You can also associate substitution parameter configurations to system configurations.

When designing jobs, determine and create datastore configurations and system configurations depending on your business environment and rules. Create datastore configurations for the datastores in your repository before you create system configurations to organize and associate them.

Select a system configuration to use at run-time. In many enterprises, a job designer defines the required datastore and system configurations and then a system administrator determines which system configuration to use when scheduling or starting a job.

The software maintains system configurations separate from jobs. You cannot check in or check out system configurations in a multi-user environment. However, you can export system configurations to a separate flat file which you can later import.

Related Information

Creating a new configuration [page 241]

2.5.5.9.1 To create a system configuration

1. From the Designer menu bar, select *Tools* ▸ *System Configurations*.

   The *Edit System Configurations* window displays.
2. To add a new system configuration, do one of the following:
   - Click the *Create New Configuration* icon to add a configuration that references the default configuration of the substitution parameters and each datastore connection.
   - Select an existing configuration and click the *Duplicate Configuration* icon to create a copy of the selected configuration.
     You can use the copy as a template and edit the substitution parameter or datastore configuration selections to suit your needs.
3. If desired, rename the new system configuration.
   a) Select the system configuration you want to rename.
   b) Click the *Rename Configuration* icon to enable the edit mode for the configuration name field.
   c) Type a new, unique name and click outside the name field to accept your choice.

   It is recommended that you follow a consistent naming convention and use the prefix `SC_` in each system configuration name so that you can easily identify this file as a system configuration. This practice is particularly helpful when you export the system configuration.
4. From the list, select a substitution parameter configuration to associate with the system configuration.
5. For each datastore, select the datastore configuration you want to use when you run a job using the system configuration.

   If you do not map a datastore configuration to a system configuration, the Job Server uses the default datastore configuration at run-time.
6. Click *OK* to save your system configuration settings.

Related Information

Associating a substitution parameter configuration with a system configuration [page 418]

2.5.5.9.2 To export a system configuration

1. In the object library, select the Datastores tab and right-click a datastore.
2. Select ▶ *Repository* ▶ *Export System Configurations* ◀.

   It is recommended that you add the SC_ prefix to each exported system configuration .atl file to easily identify that file as a system configuration.
3. Click *OK*.

2.6 File Formats

This section discusses file formats, how to use the file format editor, and how to create a file format in the software.

Related Information

Reference Guide: File format [page 920]

2.6.1 Understanding file formats

A file format is a set of properties describing the structure of a flat file (ASCII). File formats describe the metadata structure. A file format describes a specific file. A file format template is a generic description that can be used for multiple data files.

The software can use data stored in files for data sources and targets. A file format defines a connection to a file. Therefore, you use a file format to connect to source or target data when the data is stored in a file rather than a database table. The object library stores file format templates that you use to define specific file formats as sources and targets in data flows.

To work with file formats, perform the following tasks:

- Create a file format template that defines the structure for a file.
- Create a specific source or target file format in a data flow. The source or target file format is based on a template and specifies connection information such as the file name.

File format objects can describe files of the following types:

- Delimited: Characters such as commas or tabs separate each field.
- Fixed width: You specify the column width.
- SAP transport: Use to define data transport objects in SAP application data flows.
- Unstructured text: Use to read one or more files of unstructured text from a directory.
- Unstructured binary: Use to read one or more binary documents from a directory.

Related Information

Supplement for SAP: Connecting to SAP Applications, File formats [page 254]

2.6.2 File format editor

Use the file format editor to set properties for file format templates and source and target file formats. Available properties vary by the mode of the file format editor:

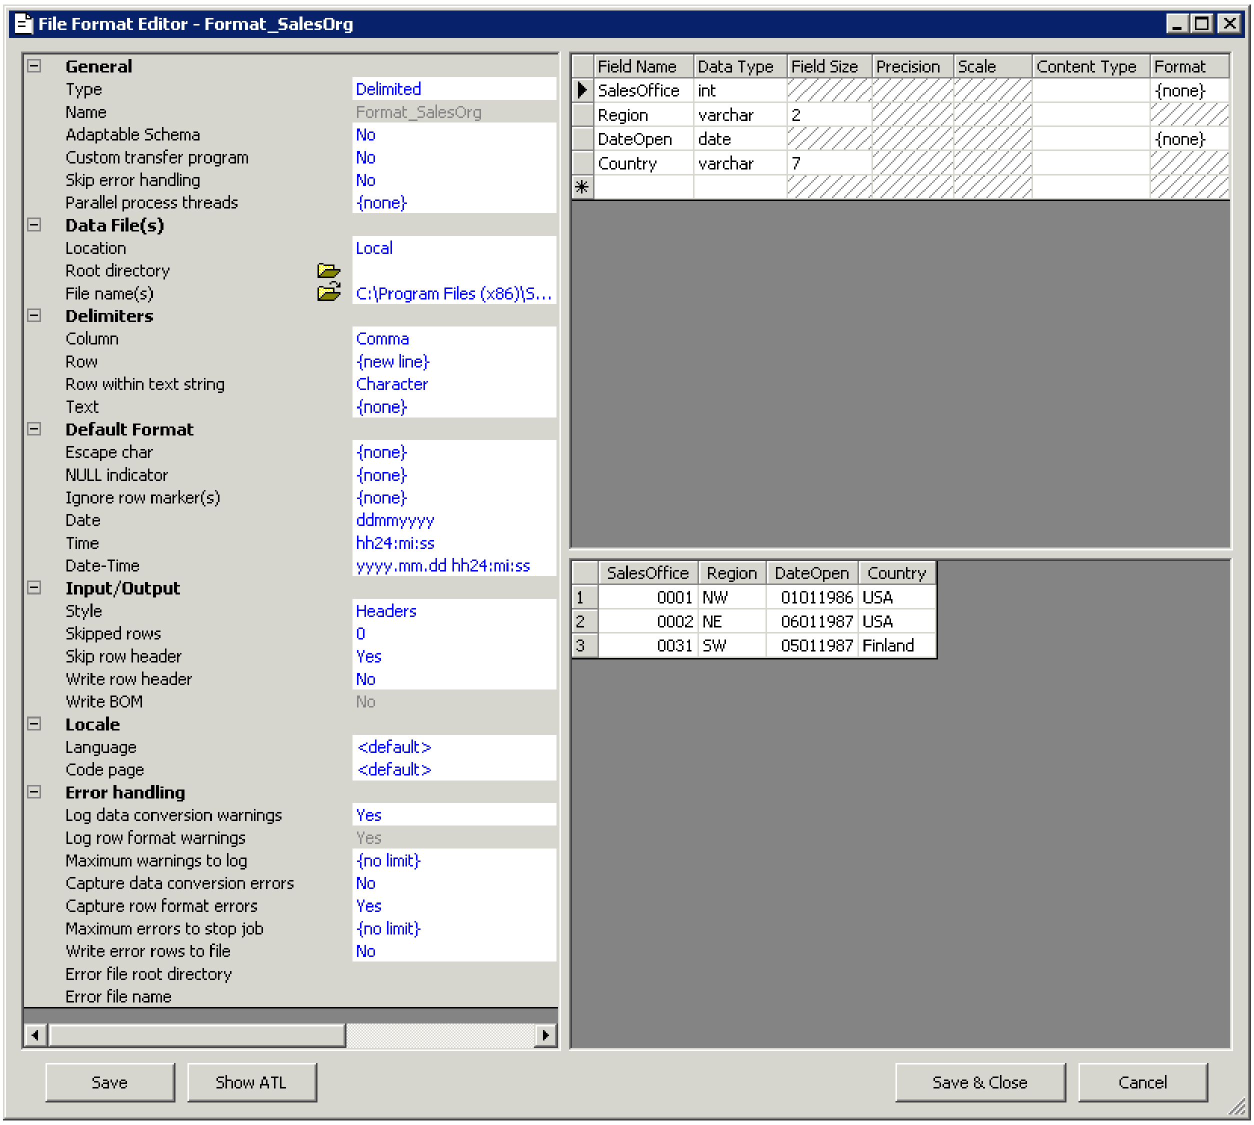
Mode	Description
New mode	Create a new file format template
Edit mode	Edit an existing file format template
Source mode	Edit the file format of a particular source file
Target mode	Edit the file format of a particular target file

The file format editor has three work areas:

Work area	Description
Properties-Values	Edit the values for file format properties. Expand and collapse the property groups by clicking the leading plus or minus.
Column Attributes	Edit and define the columns or fields in the file. Field-specific formats override the default format set in the Properties-Values area.
Data Preview	View how the settings affect sample data.

The file format editor contains "splitter" bars to allow resizing of the window and all the work areas. You can expand the file format editor to the full screen size.

The properties and appearance of the work areas vary with the format of the file.



File Format Editor - Format_SalesOrg

General	
Type	Delimited
Name	Format_SalesOrg
Adaptable Schema	No
Custom transfer program	No
Skip error handling	No
Parallel process threads	{none}
Data File(s)	
Location	Local
Root directory	
File name(s)	C:\Program Files (x86)\S...
Delimiters	
Column	Comma
Row	{new line}
Row within text string	Character
Text	{none}
Default Format	
Escape char	{none}
NULL indicator	{none}
Ignore row marker(s)	{none}
Date	ddmmyyyy
Time	hh24:mi:ss
Date-Time	yyyy.mm.dd hh24:mi:ss
Input/Output	
Style	Headers
Skipped rows	0
Skip row header	Yes
Write row header	No
Write BOM	No
Locale	
Language	<default>
Code page	<default>
Error handling	
Log data conversion warnings	Yes
Log row format warnings	Yes
Maximum warnings to log	{no limit}
Capture data conversion errors	No
Capture row format errors	Yes
Maximum errors to stop job	{no limit}
Write error rows to file	No
Error file root directory	
Error file name	

Field Name	Data Type	Field Size	Precision	Scale	Content Type	Format
SalesOffice	int					{none}
Region	varchar	2				
DateOpen	date					{none}
Country	varchar	7				

	SalesOffice	Region	DateOpen	Country
1	0001	NW	01011986	USA
2	0002	NE	06011987	USA
3	0031	SW	05011987	Finland

You can navigate within the file format editor as follows:

- Switch between work areas using the Tab key.
- Navigate through fields in the Data Preview area with the Page Up, Page Down, and arrow keys.
- Open a drop-down menu in the Properties-Values area by pressing the *ALT*-down arrow key combination.
- When the file format type is fixed-width, you can also edit the column metadata structure in the Data Preview area.

Note

The *Show ATL* button displays a view-only copy of the Transformation Language file generated for your file format. You might be directed to use this by SAP Business User Support.

Related Information

Reference Guide: File format [page 920]

2.6.3 Creating file formats

To specify a source or target file, you create a file format template that defines the structure for a file. When you drag and drop the file format into a data flow; the format represents a file that is based on the template and specifies connection information such as the file name.

2.6.3.1 To create a new file format

1. In the local object library, go to the *Formats* tab, right-click *Flat Files*, and select *New*.
2. For *Type*, select:
   - *Delimited*: For a file that uses a character sequence to separate columns.
   - *Fixed width*: For a file that uses specified widths for each column.
   - *SAP transport*: For data transport objects in SAP application data flows.
   - *Unstructured text*: For one or more files of unstructured text from a directory. The schema is fixed for this type.
   - *Unstructured binary*: For one or more unstructured text and binary documents from a directory. The schema is fixed for this type.

   The options change in the editor based on the type selected.
3. For *Name*, enter a name that describes this file format template.

   After you save this file format template, you cannot change the name.
4. For Delimited and Fixed width files, you can read and load files using a third-party file-transfer program by selecting *Yes* for *Custom transfer program*.
5. Complete the other properties to describe files that this template represents.

   Look for properties available when the file format editor is in source mode or target mode.
6. For source files, some file formats let you specify the structure of the columns in the Column Attributes work area (the upper-right pane):

   a) Enter field name.

   b) Set data types.

   c) Enter field sizes for data types.

   d) Enter scale and precision information for decimal and numeric and data types.

   e) Enter the *Content Type*. If you have added a column while creating a new format, the content type might be provided for you based on the field name. If an appropriate content type is not available, it defaults to blank.

   f) Enter information in the *Format* field for appropriate data types if desired. This information overrides the default format set in the Properties-Values area for that data type.

   You can model a file format on a sample file.

ℹ Note

You do not need to specify columns for files used as targets. If you do specify columns and they do not match the output schema from the preceding transform, the software writes to the target file using the transform's output schema.

ℹ Note

For a decimal or real data type, if you only specify a source column format and the column names and data types in the target schema do not match those in the source schema, the software cannot use the source column format specified. Instead, it defaults to the format used by the code page on the computer where the Job Server is installed.

7. Click *Save & Close* to save the file format template and close the file format editor.

Related Information

Reference Guide: Locales and Multi-byte Functionality [page 1793]
File transfers [page 269]
Reference Guide: File format [page 920]

2.6.3.2 Modeling a file format on a sample file

1. From the *Formats* tab in the local object library, create a new flat file format template or edit an existing flat file format template.
2. Under *Data File(s)*:
   - If the sample file is on your Designer computer, set *Location* to *Local*. Browse to set the *Root directory* and *File(s)* to specify the sample file.

     ℹ Note

     During design, you can specify a file located on the computer where the Designer runs or on the computer where the Job Server runs. Indicate the file location in the Location property. During execution, you must specify a file located on the Job Server computer that will execute the job.

   - If the sample file is on the current Job Server computer, set *Location* to *Job Server*. Enter the *Root directory* and *File(s)* to specify the sample file. When you select *Job Server*, the *Browse* icon is disabled, so you must type the path to the file. You can type an absolute path or a relative path, but the Job Server must be able to access it. For example, a path on UNIX might be `/usr/data/abc.txt`. A path on Windows might be `C:\DATA\abc.txt`.

     ℹ Note

     In the Windows operating system, files are not case-sensitive; however, file names are case sensitive in the UNIX environment. (For example, abc.txt and aBc.txt would be two different files in the same UNIX directory.)

To reduce the risk of typing errors, you can telnet to the Job Server (UNIX or Windows) computer and find the full path name of the file you want to use. Then, copy and paste the path name from the telnet application directly into the Root directory text box in the file format editor. You cannot use the Windows Explorer to determine the exact file location on Windows.

3. If the file type is delimited, set the appropriate column delimiter for the sample file. You can choose from the drop-down list or specify Unicode delimiters by directly typing the Unicode character code in the form of /XXXX, where XXXX is a decimal Unicode character code. For example, /44 is the Unicode character for the comma (,) character.
4. Under *Input/Output*, set *Skip row header* to *Yes* if you want to use the first row in the file to designate field names.

   The file format editor will show the column names in the Data Preview area and create the metadata structure automatically.
5. Edit the metadata structure as needed.

   For both delimited and fixed-width files, you can edit the metadata structure in the Column Attributes work area:

   a) Right-click to insert or delete fields.
   b) Rename fields.
   c) Set data types.
   d) Enter field lengths for the *Blob* and *VarChar* data type.
   e) Enter scale and precision information for *Numeric* and *Decimal* data types.
   f) Enter *Format* field information for appropriate data types, if desired. This format information overrides the default format set in the Properties-Values area for that data type.
   g) Enter the *Content Type* information. You do not need to specify columns for files used as targets. If you have added a column while creating a new format, the content type may auto-fill based on the field name. If an appropriate content type cannot be automatically filled, then it will default to blank.

   For fixed-width files, you can also edit the metadata structure in the Data Preview area:

   a) Click to select and highlight columns.
   b) Right-click to insert or delete fields.

   > Note
   >
   > The Data Preview pane cannot display blob data.
6. Click *Save & Close* to save the file format template and close the file format editor.

2.6.3.3 Replicating and renaming file formats

After you create one file format schema, you can quickly create another file format object with the same schema by replicating the existing file format and renaming it. To save time in creating file format objects, replicate and rename instead of configuring from scratch.

2.6.3.3.1 To create a file format from an existing file format

1. In the Formats tab of the object library, right-click an existing file format and choose *Replicate* from the menu.

   The File Format Editor opens, displaying the schema of the copied file format.
2. Double-click to select the *Name* property value (which contains the same name as the original file format object).
3. Type a new, unique name for the replicated file format.

   > Note
   >
   > You must enter a new name for the replicated file. The software does not allow you to save the replicated file with the same name as the original (or any other existing File Format object). Also, this is your only opportunity to modify the Name property value. Once saved, you cannot modify the name again.
4. Edit other properties as desired.

   Look for properties available when the file format editor is in source mode or target mode.
5. To save and view your new file format schema, click *Save*.

   To terminate the replication process (even after you have changed the name and clicked Save), click Cancel or press the Esc button on your keyboard.
6. Click *Save & Close*.

Related Information

Reference Guide: File format [page 920]

2.6.3.4 To create a file format from an existing flat table schema

1. From the Query editor, right-click a schema and select *Create File format*.

   The File Format editor opens populated with the schema you selected.
2. Edit the new schema as appropriate and click *Save & Close*.

   The software saves the file format in the repository. You can access it from the Formats tab of the object library.

2.6.3.5 To create a specific source or target file

1. Select a flat file format template on the *Formats* tab of the local object library.
2. Drag the file format template to the data flow workspace.

3. Select *Make Source* to define a source file format, or select *Make Target* to define a target file format.
4. Click the name of the file format object in the workspace to open the file format editor.
5. Enter the properties specific to the source or target file.

   Look for properties available when the file format editor is in source mode or target mode.

   Under File name(s), be sure to specify the file name and location in the File and Location properties.

   > Note
   >
   > You can use variables as file names.
6. Connect the file format object to other objects in the data flow as appropriate.

Related Information

Reference Guide: File format [page 920]
Setting file names at run-time using variables [page 413]

2.6.4 Editing file formats

You can modify existing file format templates to match changes in the format or structure of a file. You cannot change the name of a file format template.

For example, if you have a date field in a source or target file that is formatted as mm/dd/yy and the data for this field changes to the format dd-mm-yy due to changes in the program that generates the source file, you can edit the corresponding file format template and change the date format information.

For specific source or target file formats, you can edit properties that uniquely define that source or target such as the file name and location.

> ⚠ Caution
>
> If the template is used in other jobs (usage is greater than 0), changes that you make to the template are also made in the files that use the template.

2.6.4.1 To edit a file format template

1. In the object library *Formats* tab, double-click an existing flat file format (or right-click and choose *Edit)*.

   The file format editor opens with the existing format values.
2. Edit the values as needed.

   Look for properties available when the file format editor is in source mode or target mode.

> ⚠ Caution
>
> If the template is used in other jobs (usage is greater than 0), changes that you make to the template are also made in the files that use the template.

3. Click *Save*.

Related Information

Reference Guide: File format [page 920]

2.6.4.2 To edit a source or target file

1. From the workspace, click the name of a source or target file.

   The file format editor opens, displaying the properties for the selected source or target file.
2. Edit the desired properties.

   Look for properties available when the file format editor is in source mode or target mode.

   To change properties that are not available in source or target mode, you must edit the file's file format template. Any changes you make to values in a source or target file editor override those on the original file format.
3. Click *Save*.

Related Information

Reference Guide: File format [page 920]

2.6.4.3 Change multiple column properties

Use these steps when you are creating a new file format or editing an existing one.

1. Select the *Format* tab in the Object Library.
2. Right-click on an existing file format listed under Flat Files and choose *Edit*.
   The *File Format Editor* opens.
3. In the column attributes area (upper right pane) select the multiple columns that you want to change.
   - To choose a series of columns, select the first column and press the keyboard *Shift* key and select the last column.
   - To choose non-consecutive columns hold down the keyboard *Control* key and select the columns.

4. Right click and choose *Properties*.
   The *Multiple Columns Properties* window opens.
5. Change the Data Type and/or the Content Type and click *OK*.
   The Data Type and Content Type of the selected columns change based on your settings.

2.6.5 File format features

The software offers several capabilities for processing files.

2.6.5.1 Reading multiple files at one time

The software can read multiple files with the same format from a single directory using a single source object.

2.6.5.1.1 To specify multiple files to read

1. Open the editor for your source file format
2. Under *Data File(s)* in the file format editor, set the *Location* of the source files to *Local* or *Job Server*.
3. Set the root directory in *Root directory*.

   > i Note
   >
   > If your Job Server is on a different computer than the Designer, you cannot use Browse to specify the root directory. You must type the path. You can type an absolute path or a relative path, but the Job Server must be able to access it.

4. Under *File name(s)*, enter one of the following:
   - A list of file names separated by commas, or
   - A file name containing a wild card character (* or ?).
     For example:
     1999????.txt might read files from the year 1999
     *.txt reads all files with the txt extension from the specified Root directory

2.6.5.2 Identifying source file names

You might want to identify the source file for each row in your target in the following situations:

- You specified a wildcard character to read multiple source files at one time
- You load from different source files on different runs

2.6.5.2.1 To identify the source file for each row in the target

1. Under *Source Information* in the file format editor, set *Include file name* to *Yes*. This option generates a column named DI_FILENAME that contains the name of the source file.
2. In the Query editor, map the DI_FILENAME column from Schema In to Schema Out.
3. When you run the job, the DI_FILENAME column for each row in the target contains the source file name.

2.6.5.3 Number formats

The dot (.) and the comma (,) are the two most common formats used to determine decimal and thousand separators for numeric data types. When formatting files in the software, data types in which these symbols can be used include Decimal, Numeric, Float, and Double. You can use either symbol for the thousands indicator and either symbol for the decimal separator. For example: `2,098.65` or `2.089,65`.

	Field Name	Data Type	Field Size	Precision	Scale	Format
✎	Sales Office	int				{none}
	Region	varchar	2			
	Date open	date				
	Country	varchar	7			
*						

Format	Description
{none}	The software expects that the number contains only the decimal separator. The reading of the number data and this decimal separator is determined by Data Service Job Server Locale Region. Comma (,) is the decimal separator when is Data Service Locale is set to a country that uses commas (for example, Germany or France). Dot (.) is the decimal separator when Locale is set to country that uses dots (for example, USA, India, and UK). In this format, the software will return an error if a number contains a thousand separator. When the software writes the data, it only uses the Job Server Locale decimal separator. It does not use thousand separators.
#,##0.0	The software expects that the decimal separator of a number will be a dot (.) and the thousand separator will be a comma (,). When the software loads the data to a flat file, it uses a comma (,) as the thousand separator and a dot (.) as decimal separator.
#.##0,0	The software expects that the decimal separator of a number will be a comma (,) and the thousand separator will be dot (.). When the software loads the data to a flat file, it uses a dot (.) as the thousand separator and comma (,) as decimal separator.

Leading and trailing decimal signs are also supported. For example: `+12,000.00` or `32.32-`.

2.6.5.4 Ignoring rows with specified markers

The file format editor provides a way to ignore rows containing a specified marker (or markers) when reading files. For example, you might want to ignore comment line markers such as `#` and `//`.

Associated with this feature, two special characters — the semicolon (;) and the backslash (\) — make it possible to define multiple markers in your ignore row marker string. Use the semicolon to delimit each marker, and use the backslash to indicate special characters as markers (such as the backslash and the semicolon).

The default marker value is an empty string. When you specify the default value, no rows are ignored.

2.6.5.4.1 To specify markers for rows to ignore

1. Open the file format editor from the Object Library or by opening a source object in the workspace.
2. Find *Ignore row marker(s)* under the *Format* Property.
3. Click in the associated text box and enter a string to indicate one or more markers representing rows that the software should skip during file read and/or metadata creation.

   The following table provides some ignore row marker(s) examples. (Each value is delimited by a semicolon unless the semicolon is preceded by a backslash.)

Marker value(s)	Row(s) ignored
	None (this is the default value)
`abc`	Any that begin with the string `abc`
`abc;def;hi`	Any that begin with `abc` or `def` or `hi`
`abc;\;`	Any that begin with `abc` or `;`
`abc;\\;\;`	Any that begin with `abc` or `\` or `;`

2.6.5.5 Date formats at the field level

You can specify a date format at the field level to overwrite the default date, time, or date-time formats set in the Properties-Values area.

For example, when the *Data Type* is set to Date, you can edit the value in the corresponding *Format* field to a different date format such as:

- yyyy.mm.dd
- mm/dd/yy
- dd.mm.yy

2.6.5.6 Parallel process threads

Data Services can use parallel threads to read and load files to maximize performance.

To specify parallel threads to process your file format:

1. Open the file format editor in one of the following ways:
   - In the Formats tab in the Object Library, right-click a file format name and click *Edit*.
   - In the workspace, double-click the source or target object.
2. Find *Parallel process threads* under the *General* Property.
3. Specify the number of threads to read or load this file format.
   For example, if you have four CPUs on your Job Server computer, enter the number 4 in the *Parallel process threads* box.

Related Information

Performance Optimization Guide: Using Parallel Execution, File multi-threading [page 2150]

2.6.5.7 Error handling for flat-file sources

During job execution, the software processes rows from flat-file sources one at a time. You can configure the File Format Editor to identify rows in flat-file sources that contain the following types of errors:

- Data-type conversion errors — For example, a field might be defined in the File Format Editor as having a data type of integer but the data encountered is actually varchar.
- Row-format errors — For example, in the case of a fixed-width file, the software identifies a row that does not match the expected width value.

These error-handling properties apply to flat-file sources only.

Related Information

Reference Guide: File format [page 920]

2.6.5.7.1 Error-handling options

In the File Format Editor, the *Error Handling* set of properties allows you to choose whether or not to have the software perform the following actions:

- check for either of the two types of flat-file source error
- write the invalid row(s) to a specified error file

- stop processing the source file after reaching a specified number of invalid rows
- log data-type conversion or row-format warnings to the error log; if so, you can limit the number of warnings to log without stopping the job

2.6.5.7.2 About the error file

If enabled, the error file will include both types of errors. The format is a semicolon-delimited text file. You can have multiple input source files for the error file. The file resides on the same computer as the Job Server.

Entries in an error file have the following syntax:

```
source file path and name; row number in source file; Data Services error; column
number where the error occurred; all columns from the invalid row
```

The following entry illustrates a row-format error:

```
d:/acl_work/in_test.txt;2;-80104: 1-3-A column delimiter was seen after column
number <3> for row number <2> in file <d:/acl_work/in_test.txt>. The total number
of columns defined is <3>, so a row delimiter should be seen after column number
<3>. Please check the file for bad data, or redefine the input schema for the file
by editing the file format in the UI.;3;defg;234;def
```

where `3` indicates an error occurred after the third column, and `defg;234;def` are the three columns of data from the invalid row.

> i Note
>
> If you set the file format's *Parallel process thread* option to any value greater than *0* or *{none}*, the row number in source file value will be `-1`.

2.6.5.7.3 Configuring the File Format Editor for error handling

2.6.5.7.3.1 To capture data-type conversion or row-format errors

1. In the object library, click the *Formats* tab.
2. Expand *Flat Files*, right-click a format, and click *Edit*.
3. The File Format Editor opens.
4. To capture data-type conversion errors, under the *Error Handling* properties for *Capture data conversion errors*, click *Yes*.
5. To capture errors in row formats, for *Capture row format errors* click *Yes*.
6. Click *Save* or *Save & Close*.

2.6.5.7.3.2 To write invalid rows to an error file

1. In the object library, click the *Formats* tab.
2. Expand *Flat Files,* right-click a format, and click *Edit*.

   The File Format Editor opens.
3. Under the *Error Handling* properties, click *Yes* for either or both of the *Capture data conversion errors* or *Capture row format errors* properties.
4. For *Write error rows to file*, click *Yes*.

   Two more fields appear: Error file root directory and Error file name.
5. Type an *Error file root directory* in which to store the error file.

   If you type a directory path here, then enter only the file name in the Error file name property.
6. Type an *Error file name*.

   If you leave Error file root directory blank, then type a full path and file name here.
7. Click *Save* or *Save & Close*.

For added flexibility when naming the error file, you can enter a variable that is set to a particular file with full path name. Use variables to specify file names that you cannot otherwise enter such as those that contain multibyte characters

2.6.5.7.3.3 To limit to the number of invalid rows processed before stopping the job

1. In the object library, click the *Formats* tab.
2. Expand *Flat Files*, right-click a format, and click *Edit*.

   The File Format Editor opens.
3. Under the *Error Handling* properties, click *Yes* for either or both the *Capture data conversion errors* or *Capture row format errors* properties.
4. For *Maximum errors to stop job*, type a number.

   > Note
   >
   > This property was previously known as Bad rows limit.
5. Click *Save* or *Save & Close*.

2.6.5.7.3.4 To log data-type conversion warnings in the error log

1. In the object library, click the *Formats* tab.

2. Expand *Flat Files*, right-click a format, and click *Edit*.

   The File Format Editor opens.
3. Under the *Error Handling* properties, for *Log data conversion warnings*, click *Yes*.
4. Click *Save* or *Save & Close*.

2.6.5.7.3.5 To log row-format warnings in the error log

1. In the object library, click the *Formats* tab.
2. Expand *Flat Files*, right-click a format, and click *Edit*.

   The File Format Editor opens.
3. Under the *Error Handling* properties, for *Log row format warnings*, click *Yes*.
4. Click *Save* or *Save & Close*.

2.6.5.7.3.6 To limit to the number of warning messages to log

If you choose to log either data-type or row-format warnings, you can limit the total number of warnings to log without interfering with job execution.

1. In the object library, click the *Formats* tab.
2. Expand *Flat Files*, right-click a format, and click *Edit*.

   The File Format Editor opens.
3. Under the *Error Handling* properties, for *Log row format warnings* or *Log data conversion warnings* (or both),click *Yes*.
4. For *Maximum warnings to log*, type a number.
5. Click *Save* or *Save & Close*.

2.6.6 File transfers

The software can read and load files using a third-party file transfer program for flat files. You can use third-party (custom) transfer programs to:

- Incorporate company-standard file-transfer applications as part of the software job execution
- Provide high flexibility and security for files transferred across a firewall

The custom transfer program option allows you to specify:

- A custom transfer program (invoked during job execution)
- Additional arguments, based on what is available in your program, such as:
  - Connection data

- Encryption/decryption mechanisms
- Compression mechanisms

2.6.6.1 Custom transfer system variables for flat files

When you set custom transfer options for external file sources and targets, some transfer information, like the name of the remote server that the file is being transferred to or from, may need to be entered literally as a transfer program argument. You can enter other information using the following system variables:

Data entered for:	Is substituted for this variable if it is defined in the Arguments field
User name	$AW_USER
Password	$AW_PASSWORD
Local directory	$AW_LOCAL_DIR
File(s)	$AW_FILE_NAME

By using these variables as custom transfer program arguments, you can collect connection information entered in the software and use that data at run-time with your custom transfer program.

For example, the following custom transfer options use a Windows command file (Myftp.cmd) with five arguments. Arguments 1 through 4 are system variables:

- User and Password variables are for the external server
- The Local Directory variable is for the location where the transferred files will be stored in the software
- The File Name variable is for the names of the files to be transferred

Argument 5 provides the literal external server name.

> **Note**
>
> If you do not specify a standard output file (such as `ftp.out` in the example below), the software writes the standard output into the job's trace log.

```
@echo off

set USER=%1
set PASSWORD=%2
set LOCAL_DIR=%3
set FILE_NAME=%4
set LITERAL_HOST_NAME=%5

set INP_FILE=ftp.inp

echo %USER%>%INP_FILE%
echo %PASSWORD%>>%INP_FILE%
echo lcd %LOCAL_DIR%>>%INP_FILE%
echo get %FILE_NAME%>>%INP_FILE%
echo bye>>%INP_FILE%

ftp -s%INPT_FILE% %LITERAL_HOST_NAME%>ftp.out
```

2.6.6.2 Custom transfer options for flat files

Of the custom transfer program options, only the *Program executable* option is mandatory.

Entering *User Name*, *Password,* and *Arguments* values is optional. These options are provided for you to specify arguments that your custom transfer program can process (such as connection data).

You can also use *Arguments* to enable or disable your program's built-in features such as encryption/decryption and compression mechanisms. For example, you might design your transfer program so that when you enter –`sSecureTransportOn` or `-CCompressionYES` security or compression is enabled.

> Note
>
> Available arguments depend on what is included in your custom transfer program. See your custom transfer program documentation for a valid argument list.

You can use the *Arguments* box to enter a user name and password. However, the software also provides separate *User name* and *Password* boxes. By entering the $ **`<AW_USER>`** and $ **`<AW_PASSWORD>`** variables as *Arguments* and then using the *User* and *Password* boxes to enter literal strings, these extra boxes are useful in two ways:

- You can more easily update users and passwords in the software both when you configure the software to use a transfer program and when you later export the job. For example, when you migrate the job to another environment, you might want to change login information without scrolling through other arguments.
- You can use the mask and encryption properties of the *Password* box. Data entered in the *Password* box is masked in log files and on the screen, stored in the repository, and encrypted by Data Services.

  > Note
  >
  > The software sends password data to the custom transfer program in clear text. If you do not allow clear passwords to be exposed as arguments in command-line executables, then set up your custom program to either:

  - Pick up its password from a trusted location.
  - Inherit security privileges from the calling program (in this case, the software).

2.6.6.3 Setting custom transfer options

The custom transfer option allows you to use a third-party program to transfer flat file sources and targets. You can configure your custom transfer program in the File Format Editor window. Like other file format settings, you can override custom transfer program settings if they are changed for a source or target in a particular data flow. You can also edit the custom transfer option when exporting a file format.

2.6.6.3.1 To configure a custom transfer program in the file format editor

1. Select the *Formats* tab in the object library.
2. Right-click *Flat Files* in the tab and select *New*.

   The File Format Editor opens.
3. Select either the *Delimited* or the *Fixed width* file type.

   > Note
   >
   > While the custom transfer program option is not supported by SAP application file types, you can use it as a data transport method for an SAP ABAP data flow.
4. Enter a format name.
5. Select *Yes* for the *Custom transfer program* option.
6. Expand *Custom Transfer* and enter the custom transfer program name and arguments.
7. Complete the other boxes in the file format editor window.

   In the Data File(s) section, specify the location of the file in the software.

   To specify system variables for Root directory and File(s) in the Arguments box:
   - Associate the system variable $ **`<AW_LOCAL_DIR>`** with the local directory argument of your custom transfer program.
   - Associate the system variable $ **`<AW_FILE_NAME>`** with the file name argument of your custom transfer program.

   For example, enter: -l$AW_LOCAL_DIR\$AW_FILE_NAME

   When the program runs, the Root directory and File(s) settings are substituted for these variables and read by the custom transfer program.

   > Note
   >
   > The flag -l used in the example above is a custom program flag. Arguments you can use as custom program arguments in the software depend upon what your custom transfer program expects.
8. Click *Save*.

Related Information

2.6.6.4 Design tips

Keep the following concepts in mind when using the custom transfer options:

- Variables are not supported in file names when invoking a custom transfer program for the file.
- You can only edit custom transfer options in the File Format Editor (or Datastore Editor in the case of SAP application) window before they are exported. You cannot edit updates to file sources and targets at the data flow level when exported. After they are imported, you can adjust custom transfer option settings at the data flow level. They override file format level settings.

When designing a custom transfer program to work with the software, keep in mind that:

- The software expects the called transfer program to return 0 on success and non-zero on failure.
- The software provides trace information before and after the custom transfer program executes. The full transfer program and its arguments with masked password (if any) is written in the trace log. When "Completed Custom transfer" appears in the trace log, the custom transfer program has ended.
- If the custom transfer program finishes successfully (the return code = 0), the software checks the following:
    - For an ABAP data flow, if the transport file does not exist in the local directory, it throws an error and the software stops.
    - For a file source, if the file or files to be read by the software do not exist in the local directory, the software writes a warning message into the trace log.
- If the custom transfer program throws an error or its execution fails (return code is not 0), then the software produces an error with return code and `stdout`/`stderr` output.
- If the custom transfer program succeeds but produces standard output, the software issues a warning, logs the first 1,000 bytes of the output produced, and continues processing.
- The custom transfer program designer must provide valid option arguments to ensure that files are transferred to and from the local directory (specified in the software). This might require that the remote file and directory name be specified as arguments and then sent to the Designer interface using system variables.

2.6.7 Creating COBOL copybook file formats

When creating a COBOL copybook format, you can:

- Create just the format, then configure the source after you add the format to a data flow, or
- Create the format and associate it with a data file at the same time.

This section also describes how to:

- Create rules to identify which records represent which schemas using a field ID option.
- Identify the field that contains the length of the schema's record using a record length field option.

Related Information

Reference Guide: Import or Edit COBOL copybook format options [page 850]
Reference Guide: COBOL copybook source options [page 854]
Reference Guide: Data Types, Conversion to or from internal data types [page 1040]

2.6.7.1 To create a new COBOL copybook file format

1. In the local object library, click the *Formats* tab, right-click *COBOL copybooks*, and click *New*.

   The Import COBOL copybook window opens.
2. Name the format by typing a name in the *Format name* field.
3. On the *Format* tab for *File name*, specify the COBOL copybook file format to import, which usually has the extension .cpy.

   During design, you can specify a file in one of the following ways:
   - For a file located on the computer where the Designer runs, you can use the *Browse* button.
   - For a file located on the computer where the Job Server runs, you must type the path to the file. You can type an absolute path or a relative path, but the Job Server must be able to access it.
4. Click *OK*.

   The software adds the COBOL copybook to the object library.
5. The *COBOL Copybook schema name(s)* dialog box displays. If desired, select or double-click a schema name to rename it.
6. Click *OK*.

When you later add the format to a data flow, you can use the options in the source editor to define the source.

Related Information

Reference Guide: COBOL copybook source options [page 854]

2.6.7.2 To create a new COBOL copybook file format and a data file

1. In the local object library, click the *Formats* tab, right-click *COBOL copybooks*, and click *New*.

   The Import COBOL copybook window opens.
2. Name the format by typing a name in the *Format name* field.
3. On the *Format* tab for *File name*, specify to the COBOL copybook file format to import, which usually has the extension .cpy.

During design, you can specify a file in one of the following ways:

- For a file located on the computer where the Designer runs, you can use the Browse button.
- For a file located on the computer where the Job Server runs, you must type the path to the file. You can type an absolute path or a relative path, but the Job Server must be able to access it.

4. Click the *Data File* tab.
5. For *Directory*, type or browse to the directory that contains the COBOL copybook data file to import.

   If you include a directory path here, then enter only the file name in the Name field.
6. Specify the COBOL copybook data file *Name*.

   If you leave Directory blank, then type a full path and file name here.

   During design, you can specify a file in one of the following ways:

   - For a file located on the computer where the Designer runs, you can use the Browse button.
   - For a file located on the computer where the Job Server runs, you must type the path to the file. You can type an absolute path or a relative path, but the Job Server must be able to access it.
7. If the data file is not on the same computer as the Job Server, click the *Data Access* tab. Select *FTP* or *Custom* and enter the criteria for accessing the data file.
8. Click *OK*.
9. The *COBOL Copybook schema name(s)* dialog box displays. If desired, select or double-click a schema name to rename it.
10. Click *OK*.

The Field ID tab allows you to create rules for indentifying which records represent which schemas.

Related Information

Reference Guide: Import or Edit COBOL copybook format options [page 850]

2.6.7.3 To create rules to identify which records represent which schemas

1. In the local object library, click the *Formats* tab, right-click *COBOL copybooks*, and click *Edit*.

   The Edit COBOL Copybook window opens.
2. In the top pane, select a field to represent the schema.
3. Click the *Field ID* tab.
4. On the Field ID tab, select the check box *Use field <schema name.field name> as ID*.
5. Click *Insert below* to add an editable value to the Values list.
6. Type a value for the field.
7. Continue (adding) inserting values as necessary.
8. Select additional fields and insert values as necessary.

9. Click *OK*.

2.6.7.4 To identify the field that contains the length of the schema's record

1. In the local object library, click the *Formats* tab, right-click *COBOL copybooks*, and click *Edit*.

   The Edit COBOL Copybook window opens.
2. Click the *Record Length Field* tab.
3. For the schema to edit, click in its Record Length Field column to enable a drop-down menu.
4. Select the field (one per schema) that contains the record's length.

   The offset value automatically changes to the default of 4; however, you can change it to any other numeric value. The offset is the value that results in the total record length when added to the value in the Record length field.
5. Click *OK*.

2.6.8 Creating Microsoft Excel workbook file formats on UNIX platforms

This section describes how to use a Microsoft Excel workbook as a source with a Job Server on a UNIX platform.

To create Microsoft Excel workbook file formats on Windows, refer to the *Reference Guide*.

To access the workbook, you must create and configure an adapter instance in the Administrator. The following procedure provides an overview of the configuration process. For details about creating adapters, refer to the *Management Console Guide*.

Also consider the following requirements:

- To import the workbook, it must be available on a Windows file system. You can later change the location of the actual file to use for processing in the Excel workbook file format source editor. See the *Reference Guide*.
- To reimport or view data in the Designer, the file must be available on Windows.
- Entries in the error log file might be represented numerically for the date and time fields.
  Additionally, Data Services writes the records with errors to the output (in Windows, these records are ignored).

Related Information

Reference Guide: Excel workbook format [page 914]

Management Console Guide: Adapters [page 1938]

Reference Guide: Excel workbook source options [page 918]

2.6.8.1 To create a Microsoft Excel workbook file format on UNIX

1. Using the Server Manager (**<LINK_DIR>**`/bin/svrcfg`), ensure the UNIX Job Server can support adapters. See the *Installation Guide for UNIX*.
2. Ensure a repository associated with the Job Server is registered in the Central Management Console (CMC). To register a repository in the CMC, see the *Administrator Guide*.
3. In the Administrator, add an adapter to access Excel workbooks. See the *Management Console Guide*.

   You can only configure one Excel adapter per Job Server. Use the following options:

   - On the Status tab, click the job server adapter at right to configure.
   - On the Adapter Configuration tab of Adapter Instances page, click *Add*.
   - On the Adapter Configuration tab, enter the *Adapter instance name*. Type `BOExcelAdapter` (required and case sensitive).
     You may leave all other options at their default values except when processing files larger than 1 MB. In that case, change the Additional Java Launcher Options value to `-Xms64m -Xmx512` or `-Xms128m -Xmx1024m` (the default is `-Xms64m -Xmx256m`). Note that Java memory management can prevent processing very large files (or many smaller files).
4. From the *Administrator* › *Adapter* › *Adapter Instance Status* tab, start the adapter.
5. In the Designer on the *Formats* tab of the object library, create the file format by importing the Excel workbook. For details, see the *Reference Guide*.

Related Information

Administrator Guide: To register a repository in the CMC [page 52]

Reference Guide: Excel workbook format [page 914]

2.6.9 Creating Web log file formats

Web logs are flat files generated by Web servers and are used for business intelligence. Web logs typically track details of Web site hits such as:

- Client domain names or IP addresses
- User names
- Timestamps
- Requested action (might include search string)
- Bytes transferred
- Referred address
- Cookie ID

Web logs use a common file format and an extended common file format.

Common Web log format:

```
151.99.190.27 - - [01/Jan/1997:13:06:51 -0600]
"GET /~bacuslab HTTP/1.0" 301 -4
```

Extended common Web log format:

```
saturn5.cun.com - - [25/JUN/1998:11:19:58 -0500]
"GET /wew/js/mouseover.html HTTP/1.0" 200 1936
"http://av.yahoo.com/bin/query?p=mouse+over+javascript+source+code&hc=0"
"Mozilla/4.02 [en] (x11; U; SunOS 5.6 sun4m)"
```

The software supports both common and extended common Web log formats as sources. The file format editor also supports the following:

- Dash as NULL indicator
- Time zone in date-time, e.g. 01/Jan/1997:13:06:51 –0600

The software includes several functions for processing Web log data:

- Word_ext function
- Concat_data_time function
- WL_GetKeyValue function

Related Information

Word_ext function [page 278]
Concat_date_time function [page 279]
WL_GetKeyValue function [page 279]

2.6.9.1 Word_ext function

The `word_ext` is a string function that extends the word function by returning the word identified by its position in a delimited string. This function is useful for parsing URLs or file names.

Format

```
word_ext(string, word_number, separator(s))
```

A negative word number means count from right to left

Examples

`word_ext('www.bodi.com', 2, '.')` returns '`bodi`'.

`word_ext('www.cs.wisc.edu', -2, '.')` returns '`wisc`'.

`word_ext('www.cs.wisc.edu', 5, '.')` returns `NULL`.

`word_ext('aaa+=bbb+=ccc+zz=dd', 4, '+=')` returns '`zz`'. If 2 separators are specified (+=), the function looks for either one.

`word_ext(',,,,,aaa,,,,bb,,,c ', 2, '.')` returns '`bb`'. This function skips consecutive delimiters.

2.6.9.2 Concat_date_time function

`The concat_date_time` is a date function that returns a datetime from separate date and time inputs.

Format

```
concat_date_time(date, time)
```

Example

```
concat_date_time(MS40."date",MS40."time")
```

2.6.9.3 WL_GetKeyValue function

`The WL_GetKeyValue` is a custom function (written in the Scripting Language) that returns the value of a given keyword. It is useful for parsing search strings.

Format

```
WL_GetKeyValue(string, keyword)
```

Example

`A search in Google for bodi B2B` is recorded in a Web log as:

```
GET "http://www.google.com/search?hl=en&lr=&safe=off&q=bodi+B2B&btnG=Google+Search"
WL_GetKeyValue('http://www.google.com/search?hl=en&lr=&safe=off&q=bodi
+B2B&btnG=Google+Search','q') returns 'bodi+B2B'.
```

2.6.10 Unstructured file formats

Unstructured file formats are a type of flat file format.

To read files that contain unstructured content, create a file format as a source that reads one or more files from a directory. At runtime, the source object in the data flow produces one row per file and contains a reference to each file to access its content. In the data flow, you can use a Text Data Processing transform such as Entity Extraction to process unstructured text or employ another transform to manipulate the data.

The unstructured file format types include:

- *Unstructured text*: Use this format to process a directory of text-based files including
  - text
  - HTML
  - XML

  Data Services stores each file's content using the long data type.
- *Unstructured binary*: Use this format to read binary documents. Data Services stores each file's content using the blob data type.
  - You can process a variety of document formats by obtaining your input from a variety of binary-format files, then passing that blob to the Text Data Processing transform. In this manner, the following formats can be accepted:
    - Microsoft Word: 2003, 2007, and 2010 (Office Open XML)
    - Microsoft PowerPoint: 2003, 2007, and 2010
    - Microsoft Excel: 2003, 2007, and 2010
    - Adobe PDF: 1.3 – 1.7
    - Microsoft RTF: 1.8 and 1.9.1
    - Microsoft Outlook E-mail Message: 2003, 2007, 2010
    - Generic E-mail Message: "`.eml`" files
    - Open Document Text, Spreadsheet, and Presentation: 1.0, 1.1, 1.2
    - Corel WordPerfect: 6.0 (1993) – X5 (2010)
  - You could also use the unstructured binary file format to move a directory of graphic files on disk into a database table. Suppose you want to associate employee photos with the corresponding employee data that is stored in a database. The data flow would include the unstructured binary file format source, a Query transform that associates the employee photo with the employee data using the employee's ID number for example, and the database target table.

Creating file formats [page 257]

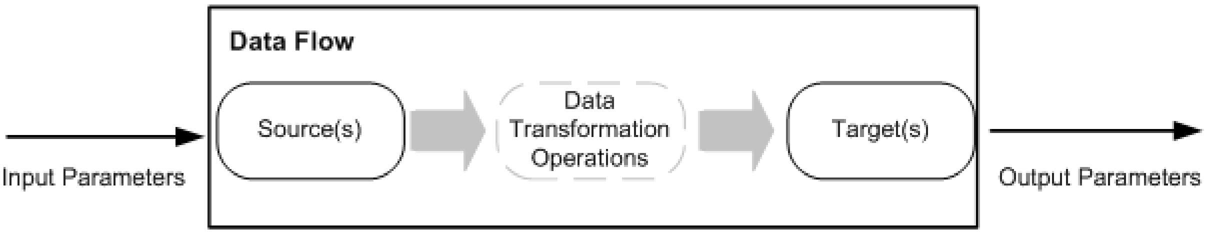
2.7 Data Flows

This section describes the fundamantals of data flows including data flow objects, using lookups, data flow execution, and auditing.

2.7.1 What is a data flow?

Data flows extract, transform, and load data. Everything having to do with data, including reading sources, transforming data, and loading targets, occurs inside a data flow. The lines connecting objects in a data flow represent the flow of data through data transformation steps.

After you define a data flow, you can add it to a job or work flow. From inside a work flow, a data flow can send and receive information to and from other objects through input and output parameters.



2.7.1.1 Naming data flows

Data flow names can include alphanumeric characters and underscores (_). They cannot contain blank spaces.

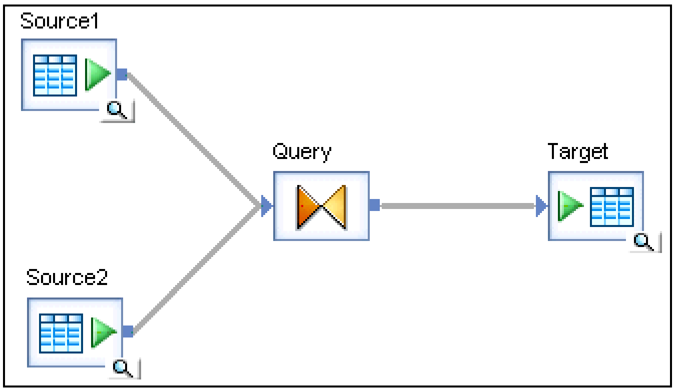
2.7.1.2 Data flow example

Suppose you want to populate the fact table in your data warehouse with new data from two tables in your source transaction database.

Your data flow consists of the following:

- Two source tables
- A join between these tables, defined in a query transform
- A target table where the new rows are placed

You indicate the flow of data through these components by connecting them in the order that data moves through them. The resulting data flow looks like the following:



2.7.1.3 Steps in a data flow

Each icon you place in the data flow diagram becomes a step in the data flow. You can use the following objects as steps in a data flow:

- source
- target
- transforms

The connections you make between the icons determine the order in which the software completes the steps.

Related Information

Source and target objects [page 286]
Transforms [page 303]

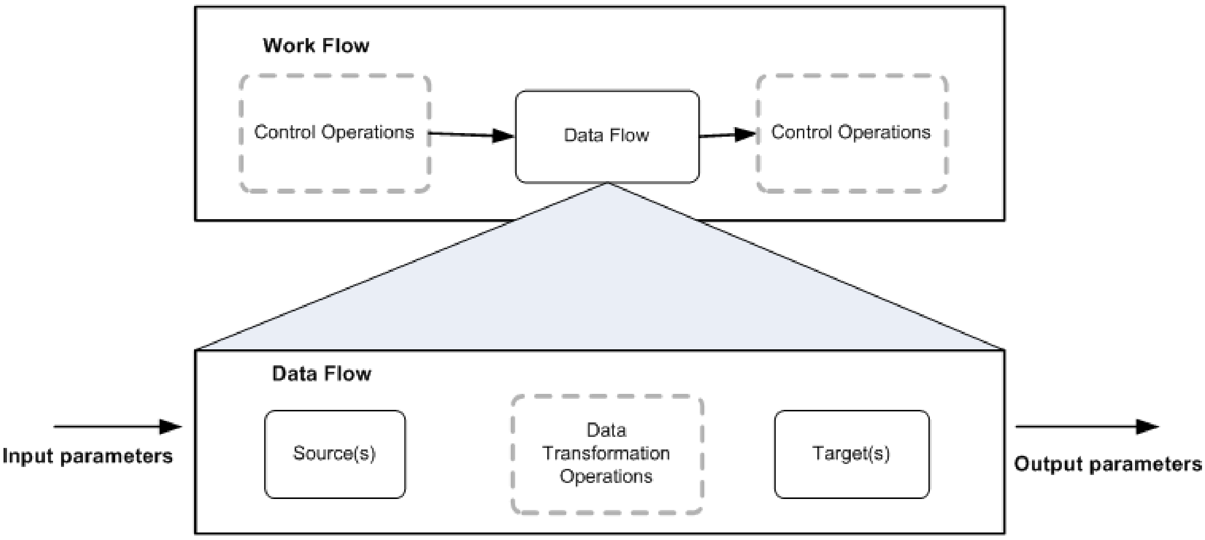
2.7.1.4 Data flows as steps in work flows

Data flows are closed operations, even when they are steps in a work flow. Data sets created within a data flow are not available to other steps in the work flow.

A work flow does not operate on data sets and cannot provide more data to a data flow; however, a work flow can do the following:

- Call data flows to perform data movement operations

- Define the conditions appropriate to run data flows
- Pass parameters to and from data flows



2.7.1.5 Intermediate data sets in a data flow

Each step in a data flow—up to the target definition—produces an intermediate result (for example, the results of a SQL statement containing a WHERE clause), which flows to the next step in the data flow. The intermediate result consists of a set of rows from the previous operation and the schema in which the rows are arranged. This result is called a data set. This data set may, in turn, be further "filtered" and directed into yet another data set.

2.7.1.6 Operation codes

Each row in a data set is flagged with an operation code that identifies the status of the row. The operation codes are as follows:

Operation code	Description
NORMAL	Creates a new row in the target. All rows in a data set are flagged as NORMAL when they are extracted from a source. If a row is flagged as NORMAL when loaded into a target, it is inserted as a new row in the target.
INSERT	Creates a new row in the target. Rows can be flagged as INSERT by transforms in the data flow to indicate that a change occurred in a data set as compared with an earlier image of the same data set. The change is recorded in the target separately from the existing data.

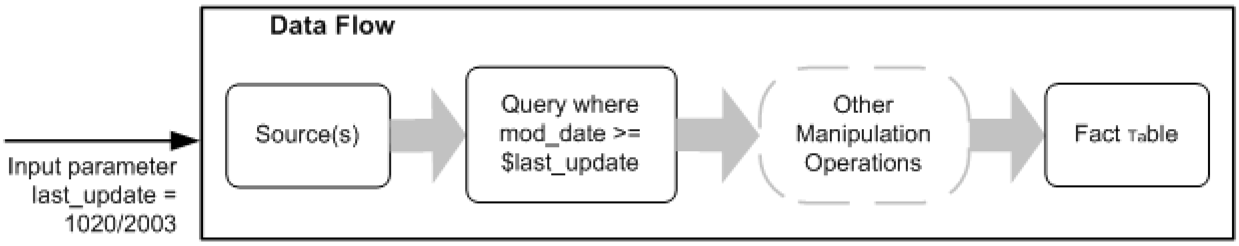
Operation code	Description
DELETE	Is ignored by the target. Rows flagged as DELETE are not loaded. Rows can be flagged as DELETE only by the Map_Operation transform.
UPDATE	Overwrites an existing row in the target. Rows can be flagged as UPDATE by transforms in the data flow to indicate that a change occurred in a data set as compared with an earlier image of the same data set. The change is recorded in the target in the same row as the existing data.

2.7.1.7 Passing parameters to data flows

Data does not flow outside a data flow, not even when you add a data flow to a work flow. You can, however, pass parameters into and out of a data flow. Parameters evaluate single values rather than sets of values.

When a data flow receives parameters, the steps inside the data flow can reference those parameters as variables.

Parameters make data flow definitions more flexible. For example, a parameter can indicate the last time a fact table was updated. You can use this value in a data flow to extract only rows modified since the last update. The following figure shows the parameter `last_update` used in a query to determine the data set used to load the fact table.



Data Flow
Input parameter last_update = 1020/2003
Source(s)
Query where mod_date >= $last_update
Other Manipulation Operations
Fact Table

Variables and Parameters [page 398]

2.7.2 Creating and defining data flows

You can create data flows using objects from

- the object library
- the tool palette

After creating a data flow, you can change its properties.

Related Information

To change properties of a data flow [page 285]

2.7.2.1 To define a new data flow using the object library

1. In the object library, go to the *Data Flows* tab.
2. Select the data flow category, right-click and select *New*.
3. Select the new data flow.
4. Drag the data flow into the workspace for a job or a work flow.
5. Add the sources, transforms, and targets you need.

2.7.2.2 To define a new data flow using the tool palette

1. Select the data flow icon in the tool palette.
2. Click the workspace for a job or work flow to place the data flow.

   You can add data flows to batch and real-time jobs. When you drag a data flow icon into a job, you are telling the software to validate these objects according the requirements of the job type (either batch or real-time).
3. Add the sources, transforms, and targets you need.

2.7.2.3 To change properties of a data flow

1. Right-click the data flow and select *Properties*.

   The Properties window opens for the data flow.
2. Change desired properties of a data flow.
3. Click *OK*.

   This table describes the various properties you can set for the data flow.

Table 5:

Option	Description
Execute only once	When you specify that a data flow should only execute once, a batch job will never re-execute that data flow after the data flow completes successfully, except if the data flow is contained in a work flow that is a recovery unit that re-executes and has not completed successfully elsewhere outside the re-

Option	Description
	covery unit. It is recommended that you do not mark a data flow as Execute only once if a parent work flow is a recovery unit.
Use database links	Database links are communication paths between one database server and another. Database links allow local users to access data on a remote database, which can be on the local or a remote computer of the same or different database type.
Degree of parallelism	Degree Of Parallelism (DOP) is a property of a data flow that defines how many times each transform within a data flow replicates to process a parallel subset of data.
Cache type	You can cache data to improve performance of operations such as joins, groups, sorts, filtering, lookups, and table comparisons. You can select one of the following values for the Cache type option on your data flow Properties window: ○ *In-Memory*: Choose this value if your data flow processes a small amount of data that can fit in the available memory. ○ *Pageable*: This value is the default.

Reference Guide: Objects, Data flow [page 857]

2.7.3 Source and target objects

A data flow directly reads and loads data using two types of objects:

Source objects—Define sources from which you read data.

Target objects—Define targets to which you write (or load) data.

Related Information

Source objects [page 287]
Target objects [page 287]

2.7.3.1 Source objects

Source objects represent data sources read from data flows.

Source object	Description	Software access
Table	A file formatted with columns and rows as used in relational databases.	Direct or through adapter
Template table	A template table that has been created and saved in another data flow (used in development).	Direct
File	A delimited or fixed-width flat file.	Direct
Document	A file with an application- specific format (not readable by SQL or XML parser).	Through adapter
XML file	A file formatted with XML tags.	Direct
XML message	Used as a source in real-time jobs.	Direct

You can also use IDoc messages as real-time sources for SAP applications.

Related Information

Template tables [page 289]
Real-time source and target objects [page 381]
Supplement for SAP: IDoc sources in real-time jobs [page 2496]

2.7.3.2 Target objects

Target objects represent data targets that can be written to in data flows.

Target object	Description	Software access
Table	A file formatted with columns and rows as used in relational databases.	Direct or through adapter
Template table	A table whose format is based on the output of the preceding transform (used in development).	Direct
File	A delimited or fixed-width flat file.	Direct
Document	A file with an application-specific format (not readable by SQL or XML parser).	Through adapter
XML file	A file formatted with XML tags.	Direct
XML template file	An XML file whose format is based on the preceding transform output (used in development, primarily for debugging data flows).	Direct

Target object	Description	Software access
XML message	See *Real-time source and target objects* [page 381].	
Outbound message	See *Real-time source and target objects* [page 381].	

You can also use IDoc messages as real-time sources for SAP applications.

Related Information

Supplement for SAP: IDoc targets in real-time jobs [page 2499]

2.7.3.3 Adding source or target objects to data flows

Fulfill the following prerequisites before using a source or target object in a data flow:

For	Prerequisite
Tables accessed directly from a database	Define a database datastore and import table metadata.
Template tables	Define a database datastore.
Files	Define a file format and import the file.
XML files and messages	Import an XML file format.
Objects accessed through an adapter	Define an adapter datastore and import object metadata.

Related Information

Database datastores [page 210]
Template tables [page 289]
File Formats [page 254]
To import a DTD or XML Schema format [page 354]
Adapter datastores [page 233]

2.7.3.3.1 To add a source or target object to a data flow

1. Open the data flow in which you want to place the object.
2. If the object library is not already open, select *Tools* › *Object Library* to open it.
3. Select the appropriate object library tab: Choose the Formats tab for flat files, DTDs, or XML Schemas, or choose the Datastores tab for database and adapter objects.
4. Select the object you want to add as a source or target. (Expand collapsed lists by clicking the plus sign next to a container icon.)

   For a new template table, select the Template Table icon from the tool palette.

   For a new XML template file, select the Template XML icon from the tool palette.
5. Drop the object in the workspace.
6. For objects that can be either sources or targets, when you release the cursor, a popup menu appears. Select the kind of object to make.

   For new template tables and XML template files, when you release the cursor, a secondary window appears. Enter the requested information for the new template object. Names can include alphanumeric characters and underscores (_). Template tables cannot have the same name as an existing table within a datastore.
7. The source or target object appears in the workspace.
8. Click the object name in the workspace

   The software opens the editor for the object. Set the options you require for the object.

> i Note
>
> Ensure that any files that reference flat file, DTD, or XML Schema formats are accessible from the Job Server where the job will be run and specify the file location relative to this computer.

2.7.3.4 Template tables

During the initial design of an application, you might find it convenient to use template tables to represent database tables. With template tables, you do not have to initially create a new table in your DBMS and import the metadata into the software. Instead, the software automatically creates the table in the database with the schema defined by the data flow when you execute a job.

After creating a template table as a target in one data flow, you can use it as a source in other data flows. Though a template table can be used as a source table in multiple data flows, it can only be used as a target in one data flow.

Template tables are particularly useful in early application development when you are designing and testing a project. If you modify and save the data transformation operation in the data flow where the template table is a target, the schema of the template table automatically changes. Any updates to the schema are automatically made to any other instances of the template table. During the validation process, the software warns you of any errors such as those resulting from changing the schema.

2.7.3.4.1 To create a target template table

1. Use one of the following methods to open the *Create Template* window:
    - From the tool palette:
        - Click the template table icon.
        - Click inside a data flow to place the template table in the workspace.
        - On the Create Template window, select a datastore.
    - From the object library:
        - Expand a datastore.
        - Click the template table icon and drag it to the workspace.
    - From the object library:
        - Expand a datastore.
        - Click the template table icon and drag it to the workspace.
2. On the Create Template window, enter a table name.
3. Click *OK*.

    The table appears in the workspace as a template table icon.
4. Connect the template table to the data flow as a target (usually a Query transform).
5. In the Query transform, map the Schema In columns that you want to include in the target table.
6. From the *Project* menu select *Save*.

    In the workspace, the template table's icon changes to a target table icon and the table appears in the object library under the datastore's list of tables.

After you are satisfied with the design of your data flow, save it. When the job is executed, software uses the template table to create a new table in the database you specified when you created the template table. Once a template table is created in the database, you can convert the template table in the repository to a regular table.

2.7.3.5 Converting template tables to regular tables

You must convert template tables to regular tables to take advantage of some features such as bulk loading. Other features, such as exporting an object, are available for template tables.

> **i Note**
>
> Once a template table is converted, you can no longer alter the schema.

2.7.3.5.1 To convert a template table into a regular table from the object library

1. Open the object library and go to the *Datastores* tab.

2. Click the plus sign (+) next to the datastore that contains the template table you want to convert.

   A list of objects appears.
3. Click the plus sign (+) next to *Template Tables*.

   The list of template tables appears.
4. Right-click a template table you want to convert and select *Import Table*.

   The software converts the template table in the repository into a regular table by importing it from the database. To update the icon in all data flows, choose *View* > *Refresh* . In the datastore object library, the table is now listed under Tables rather than Template Tables.

2.7.3.5.2 To convert a template table into a regular table from a data flow

1. Open the data flow containing the template table.
2. Right-click on the template table you want to convert and select *Import Table*.

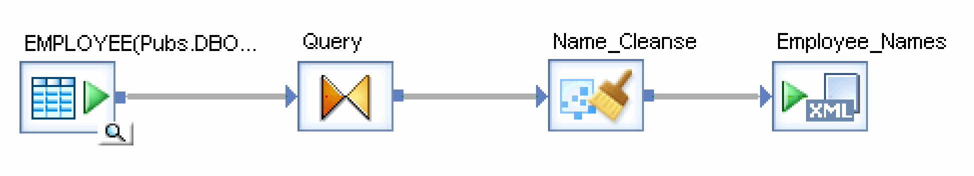
After a template table is converted into a regular table, you can no longer change the table's schema.

2.7.4 Adding columns within a data flow

Within a data flow, the *Propagate Column From* command adds an existing column from an upstream source or transform through intermediate objects to the selected endpoint. Columns are added in each object with no change to the data type or other attributes. When there is more than one possible path between the starting point and ending point, you can specify the route for the added columns.

Column propagation is a pull-through operation. The *Propagate Column From* command is issued from the object where the column is needed. The column is pulled from the selected upstream source or transform and added to each of the intermediate objects as well as the selected endpoint object.

For example, in the data flow below, the `Employee` source table contains employee name information as well as employee ID, job information, and hire dates. The `Name_Cleanse` transform is used to standardize the employee names. Lastly, the data is output to an XML file called `Employee_Names`.



After viewing the output in the `Employee_Names` table, you realize that the middle initial (`minit` column) should be included in the output. You right-click the top-level schema of the `Employee_Names` table and select *Propagate Column From*. The *Propagate Column to Employee_Names* window appears.

In the left pane of the *Propagate Column to Employee_Names* window, select the *Employee* source table from the list of objects. The list of output columns displayed in the right pane changes to display the columns in the schema of the selected object. Select the *MINIT* column as the column you want to pull through from the source, and then click *Propagate*.

The `minit` column schema is carried through the `Query` and `Name_Cleanse` transforms to the `Employee_Names` table.

Characteristics of propagated columns are as follows:

- The *Propagate Column From* command can be issued from the top-level schema of either a transform or a target.
- Columns are added in each object with no change to the data type or other attributes. Once a column is added to the schema of an object, the column functions in exactly the same way as if it had been created manually.
- The propagated column is added at the end of the schema list in each object.
- The output column name is auto-generated to avoid naming conflicts with existing columns. You can edit the column name, if desired.
- Only columns included in top-level schemas can be propagated. Columns in nested schemas cannot be propagated.
- A column can be propagated more than once. Any existing columns are shown in the right pane of the *Propagate Column to* window in the *Already Exists In* field. Each additional column will have a unique name.
- Multiple columns can be selected and propagated in the same operation.

> Note
>
> You cannot propagate a column through a Hierarchy_Flattening transform or a Table_Comparison transform.

2.7.4.1 To add columns within a data flow

Within a data flow, the *Propagate Column From* command adds an existing column from an upstream source or transform through intermediate objects to a selected endpoint. Columns are added in each object with no change to the data type or other attributes.

To add columns within a data flow:

1. In the downstream object where you want to add the column (the endpoint), right-click the top-level schema and click *Propagate Column From*.

   The *Propagate Column From* can be issued from the top-level schema in a transform or target object.
2. In the left pane of the *Propagate Column to* window, select the upstream object that contains the column you want to map.

   The available columns in that object are displayed in the right pane along with a list of any existing mappings from that column.
3. In the right pane, select the column you wish to add and click either *Propagate* or *Propagate and Close*.
   One of the following occurs:

   - If there is a single possible route, the selected column is added through the intermediate transforms to the downstream object.
   - If there is more than one possible path through intermediate objects, the *Choose Route to* dialog displays. This may occur when your data flow contains a Query transform with multiple input objects. Select the path you prefer and click *OK*.

2.7.4.2 Propagating columns in a data flow containing a Merge transform

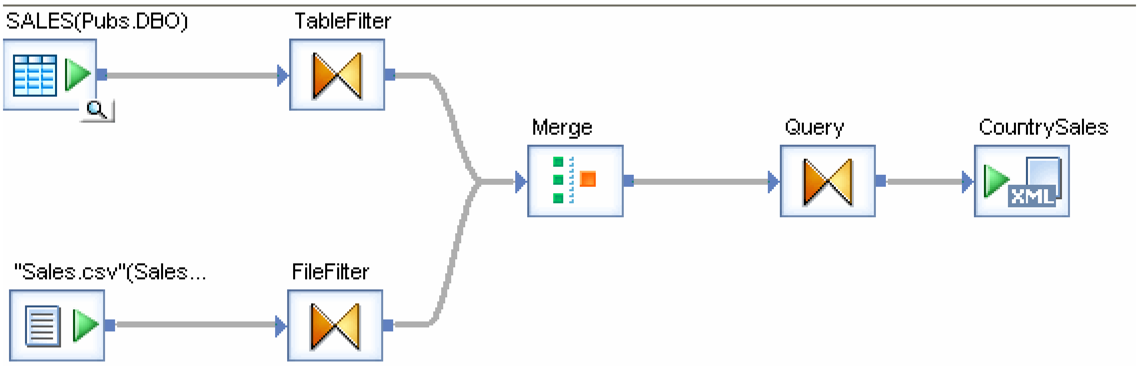
In valid data flows that contain two or more sources which are merged using a Merge transform, the schema of the inputs into the Merge transform must be identical. All sources must have the same schema, including:

- the same number of columns
- the same column names
- like columns must have the same data type

In order to maintain a valid data flow when propagating a column through a Merge transform, you must make sure to meet this restriction.

When you propagate a column and a Merge transform falls between the starting point and ending point, a message warns you that after the propagate operation completes the data flow will be invalid because the input schemas in the Merge transform will not be identical. If you choose to continue with the column propagation operation, you must later add columns to the input schemas in the Merge transform so that the data flow is valid.

For example, in the data flow shown below, the data from each source table is filtered and then the results are merged in the Merge transform.



If you choose to propagate a column from the `SALES(Pubs.DBO)` source to the `CountrySales` target, the column would be added to the `TableFilter` schema but not to the `FileFilter` schema, resulting in differing input schemas in the Merge transform and an invalid data flow.

In order to maintain a valid data flow, when propagating a column through a Merge transform you may want to follow a multi-step process:

1. Ensure that the column you want to propagate is available in the schemas of all the objects that lead into the Merge transform on the upstream side. This ensures that all inputs to the Merge transform are identical and the data flow is valid.
2. Propagate the column on the downstream side of the Merge transform to the desired endpoint.

2.7.5 Lookup tables and the lookup_ext function

Lookup tables contain data that other tables reference. Typically, lookup tables can have the following kinds of columns:

- Lookup column—Use to match a row(s) based on the input values. You apply operators such as =, >, <, ~ to identify a match in a row. A lookup table can contain more than one lookup column.
- Output column—The column returned from the row that matches the lookup condition defined for the lookup column. A lookup table can contain more than one output column.
- Return policy column—Use to specify the data to return in the case where multiple rows match the lookup condition(s).

Use the lookup_ext function to retrieve data from a lookup table based on user-defined lookup conditions that match input data to the lookup table data. Not only can the lookup_ext function retrieve a value in a table or file based on the values in a different source table or file, but it also provides extended functionality that lets you do the following:

- Return multiple columns from a single lookup
- Choose from more operators, including pattern matching, to specify a lookup condition
- Specify a return policy for your lookup
- Call lookup_ext in scripts and custom functions (which also lets you reuse the lookup(s) packaged inside scripts)
- Define custom SQL using the SQL_override parameter to populate the lookup cache, which is useful for narrowing large quantities of data to only the sections relevant for your lookup(s)
- Call lookup_ext using the function wizard in the query output mapping to return multiple columns in a Query transform
- Choose a caching strategy, for example decide to cache the whole lookup table in memory or dynamically generate SQL for each input record
- Use lookup_ext with memory datastore tables or persistent cache tables. The benefits of using persistent cache over memory tables for lookup tables are:
  - Multiple data flows can use the same lookup table that exists on persistent cache.
  - The software does not need to construct the lookup table each time a data flow uses it.
  - Persistent cache has no memory constraints because it is stored on disk and the software quickly pages it into memory.
- Use pageable cache (which is not available for the lookup and lookup_seq functions)
- Use expressions in lookup tables and return the resulting values

For a description of the related functions lookup and lookup_seq, see the *Reference Guide*.

Related Information

Reference Guide: Functions and Procedures, lookup_ext [page 1605]
Performance Optimization Guide: Using Caches, Caching data [page 2129]

2.7.5.1 Accessing the lookup_ext editor

Lookup_ext has its own graphic editor. You can invoke the editor in two ways:

- Add a new function call inside a Query transform—Use this option if you want the lookup table to return more than one column.

- From the Mapping tab in a query or script function.

2.7.5.1.1 To add a new function call

1. In the Query transform *Schema out* pane, without selecting a specific output column right-click in the pane and select *New Function Call*.
2. Select the Function category *Lookup Functions* and the Function name *lookup_ext*.
3. Click *Next* to invoke the editor.

In the Output section, you can add multiple columns to the output schema.

An advantage of using the new function call is that after you close the lookup_ext function window, you can reopen the graphical editor to make modifications (right-click the function name in the schema and select *Modify Function Call*).

2.7.5.1.2 To invoke the lookup_ext editor from the Mapping tab

1. Select the output column name.
2. On the *Mapping* tab, click *Functions*.
3. Select the *Function category Lookup Functions* and the *Function name lookup_ext*.
4. Click *Next* to invoke the editor.

In the Output section, *Variable* replaces *Output column name*. You can define one output column that will populate the selected column in the output schema. When lookup_ext returns more than one output column, use variables to store the output values, or use lookup_ext as a new function call as previously described in this section.

With functions used in mappings, the graphical editor isn't available, but you can edit the text on the *Mapping* tab manually.

2.7.5.2 Example: Defining a simple lookup_ext function

This procedure describes the process for defining a simple lookup_ext function using a new function call. The associated example illustrates how to use a lookup table to retrieve department names for employees.

For details on all the available options for the lookup_ext function, see the *Reference Guide*.

1. In a data flow, open the Query editor.
2. From the *Schema in* pane, drag the ID column to the *Schema out* pane.
3. Select the ID column in the *Schema out* pane, right-click, and click *New Function Call*. Click *Insert Below*.
4. Select the *Function category Lookup Functions* and the *Function name lookup_ext* and click *Next*.
   The lookup_ext editor opens.
5. In the *Lookup_ext - Select Parameters* window, select a lookup table:

a) Next to the *Lookup table* text box, click the drop-down arrow and double-click the datastore, file format, or current schema that includes the table.

b) Select the lookup table and click *OK*.

In the example, the lookup table is a file format called ID_lookup.txt that is in D:\Data.

6. For the *Cache spec*, the default of PRE_LOAD_CACHE is useful when the number of rows in the table is small or you expect to access a high percentage of the table values.
   NO_CACHE reads values from the lookup table for every row without caching values. Select DEMAND_LOAD_CACHE when the number of rows in the table is large and you expect to frequently access a low percentage of table values or when you use the table in multiple lookups and the compare conditions are highly selective, resulting in a small subset of data.
7. To provide more resources to execute the lookup_ext function, select *Run as a separate process*. This option creates a separate child data flow process for the lookup_ext function when the software executes the data flow.
8. Define one or more conditions. For each, add a lookup table column name (select from the drop-down list or drag from the *Parameter* pane), select the appropriate operator, and enter an expression by typing, dragging, pasting, or using the Smart Editor (click the icon in the right column).
   In the example, the condition is `ID_DEPT = Employees.ID_DEPT`.
9. Define the output. For each output column:

   a) Add a lookup table column name.

   b) Optionally change the default value from NULL.

   c) Specify the *Output column name* by typing, dragging, pasting, or using the Smart Editor (click the icon in the right column).

   In the example, the output column is ID_DEPT_NAME.
10. If multiple matches are possible, specify the ordering and set a return policy (default is *MAX*) to select one match. To order the output, enter the column name(s) in the *Order by* list.

Example

The following example illustrates how to use the lookup table ID_lookup.txt to retrieve department names for employees.

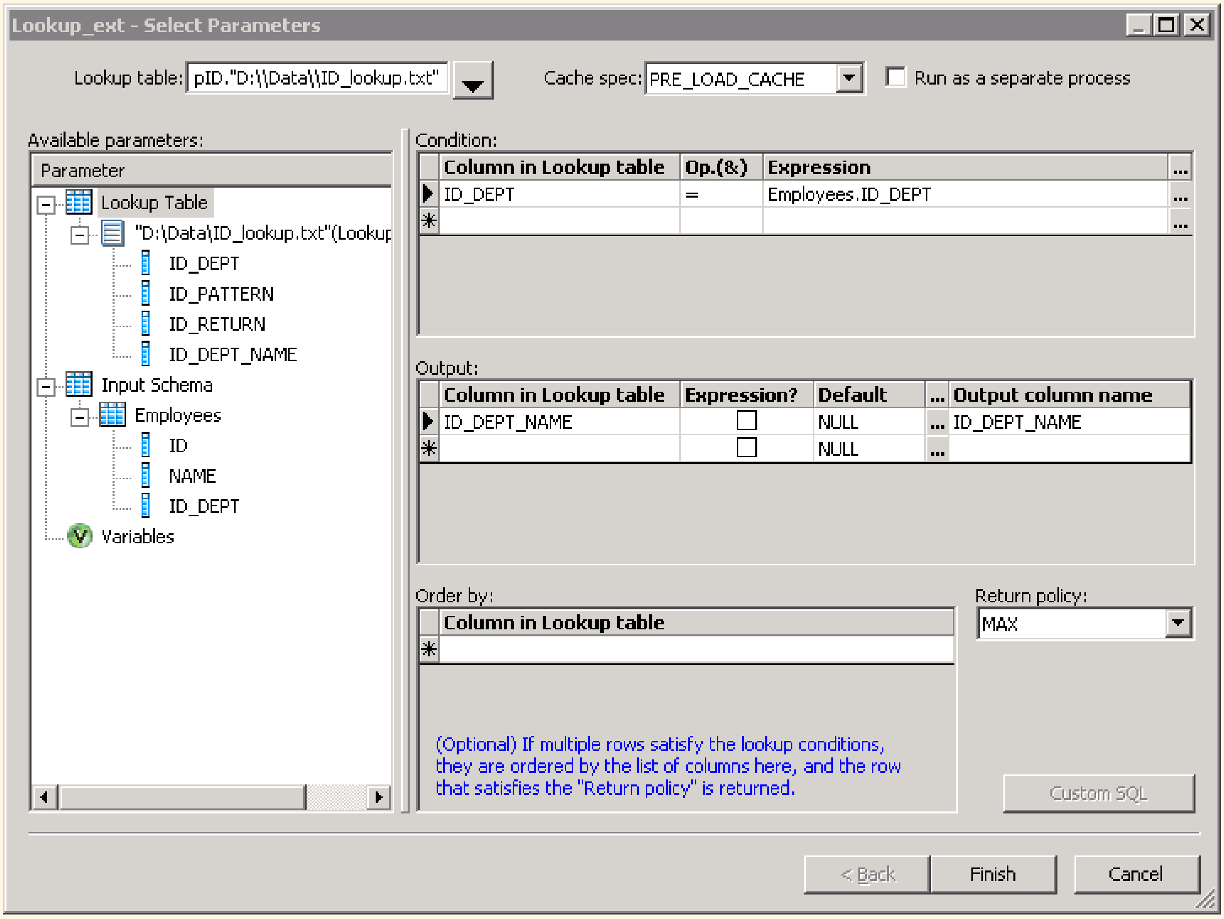
The Employees table is as follows:

ID	NAME	ID_DEPT
SSN111111111	Employee1	10
SSN222222222	Employee2	10
TAXID333333333	Employee3	20

The lookup table ID_lookup.txt is as follows:

ID_DEPT	ID_PATTERN	ID_RETURN	ID_DEPT_NAME
10	ms(SSN*)	=substr(ID_Pattern,4,20)	Payroll
20	ms(TAXID*)	=substr(ID_Pattern,6,30)	Accounting

The lookup_ext editor would be configured as follows.



Lookup table: pID."D:\\Data\\ID_lookup.txt"

Cache spec: PRE_LOAD_CACHE

☐ Run as a separate process

Parameter
- Lookup Table
  - "D:\Data\ID_lookup.txt"(Lookup
    - ID_DEPT
    - ID_PATTERN
    - ID_RETURN
    - ID_DEPT_NAME
- Input Schema
  - Employees
    - ID
    - NAME
    - ID_DEPT
- Variables

Condition:

Column in Lookup table	Op.(&)	Expression
ID_DEPT	=	Employees.ID_DEPT

Output:

Column in Lookup table	Expression?	Default	Output column name
ID_DEPT_NAME	☐	NULL	ID_DEPT_NAME
	☐	NULL	

Order by:

Column in Lookup table

(Optional) If multiple rows satisfy the lookup conditions, they are ordered by the list of columns here, and the row that satisfies the "Return policy" is returned.

Return policy: MAX

Related Information

Example: Defining a complex lookup_ext function [page 297]

2.7.5.3 Example: Defining a complex lookup_ext function

This procedure describes the process for defining a complex lookup_ext function using a new function call. The associated example uses the same lookup and input tables as in the *Example: Defining a simple lookup_ext function* [page 295] This example illustrates how to extract and normalize employee ID numbers.

For details on all the available options for the lookup_ext function, see the *Reference Guide*.

1. In a data flow, open the Query editor.
2. From the *Schema in* pane, drag the ID column to the *Schema out* pane. Do the same for the Name column.
3. In the *Schema out* pane, right-click the Name column and click *New Function Call*. Click *Insert Below*.
4. Select the *Function category Lookup Functions* and the *Function name lookup_ext* and click *Next*.

5. In the *Lookup_ext - Select Parameters* window, select a lookup table:
   In the example, the lookup table is in the file format ID_lookup.txt that is in D:\Data.
6. Define one or more conditions.
   In the example, the condition is `ID_PATTERN ~ Employees.ID`.
7. Define the output. For each output column:
   a) Add a lookup table column name.
   b) If you want the software to interpret the column in the lookup table as an expression and return the calculated value, select the *Expression* check box.
   c) Optionally change the default value from NULL.
   d) Specify the *Output column name*(s) by typing, dragging, pasting, or using the Smart Editor (click the icon in the right column).

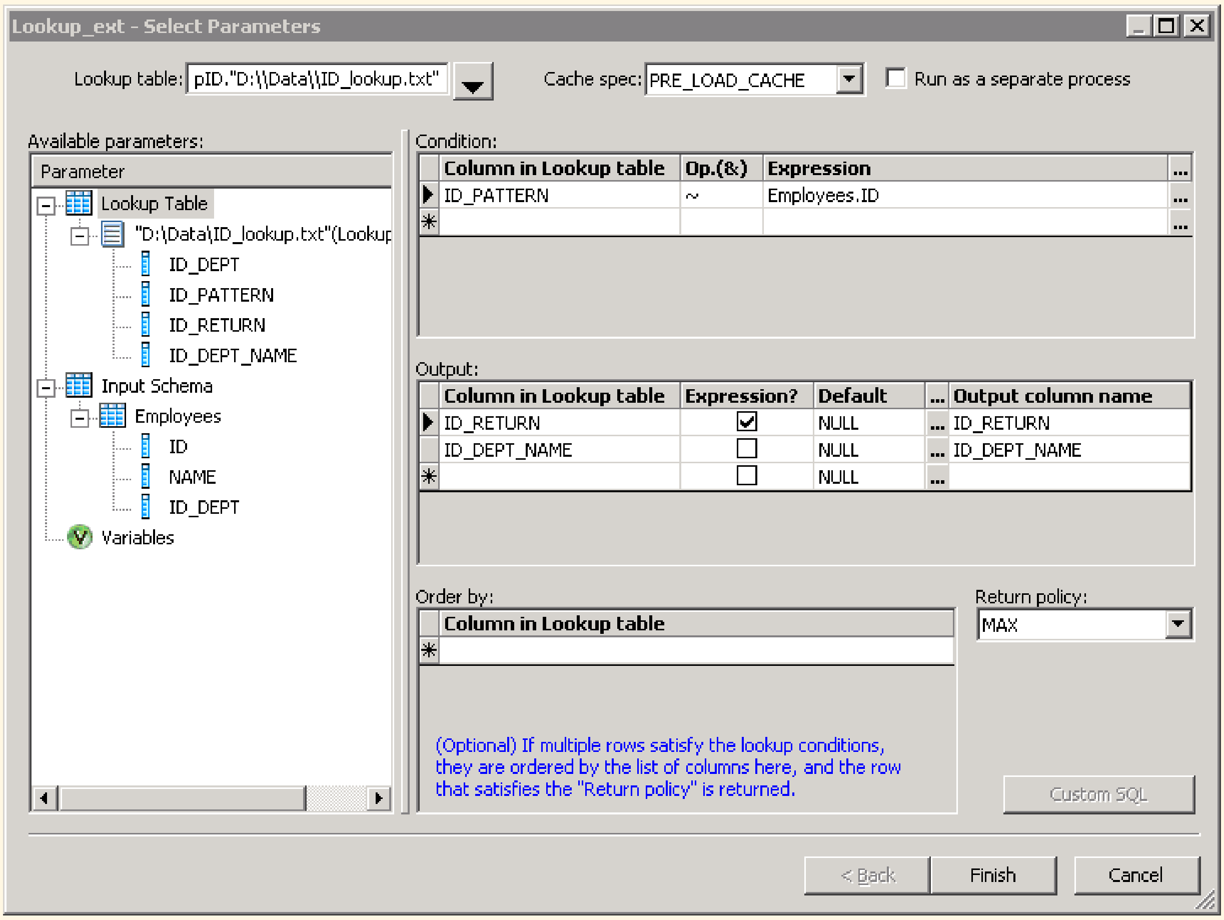
   In the example, the output columns are ID_RETURN and ID_DEPT_NAME.

Example

Extract and normalize employee ID numbers

In this example, you want to extract and normalize employee Social Security numbers and tax identification numbers that have different prefixes. You want to remove the prefixes, thereby normalizing the numbers. You also want to identify the department from where the number came. The data flow has one source table Employees, a query configured with lookup_ext, and a target table.

Configure the lookup_ext editor as in the following graphic.



Lookup_ext - Select Parameters

Lookup table: pID."D:\\Data\\ID_lookup.txt"

Cache spec: PRE_LOAD_CACHE

☐ Run as a separate process

Available parameters:

Condition:

Column in Lookup table	Op.(&)	Expression
ID_PATTERN	~	Employees.ID

Output:

Column in Lookup table	Expression?	Default	Output column name
ID_RETURN	☑	NULL	ID_RETURN
ID_DEPT_NAME	☐	NULL	ID_DEPT_NAME
	☐	NULL	

Order by:

Column in Lookup table

Return policy: MAX

(Optional) If multiple rows satisfy the lookup conditions, they are ordered by the list of columns here, and the row that satisfies the "Return policy" is returned.

The lookup condition is `ID_PATTERN ~ Employees.ID`.

The software reads each row of the source table Employees, then checks the lookup table ID_lookup.txt for all rows that satisfy the lookup condition.

The operator ~ means that the software will apply a pattern comparison to Employees.ID. When it encounters a pattern in ID_lookup.ID_PATTERN that matches Employees.ID, the software applies the expression in ID_lookup.ID_RETURN. In this example, Employee1 and Employee2 both have IDs that match the pattern ms(SSN*) in the lookup table. the software then applies the expression `=substr(ID_PATTERN,4,20)` to the data, which extracts from the matched string (Employees.ID) a substring of up to 20 characters starting from the 4th position. The results for Employee1 and Employee2 are 111111111 and 222222222, respectively.

For the output of the ID_RETURN lookup column, the software evaluates ID_RETURN as an expression because the *Expression* box is checked. In the lookup table, the column ID_RETURN contains the expression `=substr(ID_PATTERN,4,20)`. ID_PATTERN in this expression refers to the lookup table column ID_PATTERN. When the lookup condition `ID_PATTERN ~ Employees.ID` is true, the software evaluates the expression. Here the software substitutes the placeholder ID_PATTERN with the actual Employees.ID value.

The output also includes the ID_DEPT_NAME column, which the software returns as a literal value (because the Expression box is not checked). The resulting target table is as follows:

ID	NAME	ID_RETURN	ID_DEPT_NAME
SSN111111111	Employee1	111111111	Payroll

ID	NAME	ID_RETURN	ID_DEPT_NAME
SSN222222222	Employee2	222222222	Payroll
TAXID333333333	Employee3	333333333	Accounting

2.7.6 Data flow execution

A data flow is a declarative specification from which the software determines the correct data to process. For example in data flows placed in batch jobs, the transaction order is to extract, transform, then load data into a target. Data flows are similar to SQL statements. The specification declares the desired output.

The software executes a data flow each time the data flow occurs in a job. However, you can specify that a batch job execute a particular data flow only one time. In that case, the software only executes the first occurrence of the data flow; the software skips subsequent occurrences in the job.

You might use this feature when developing complex batch jobs with multiple paths, such as jobs with try/catch blocks or conditionals, and you want to ensure that the software only executes a particular data flow one time.

Related Information

Creating and defining data flows [page 284]

2.7.6.1 Push down operations to the database server

From the information in the data flow specification, the software produces output while optimizing performance. For example, for SQL sources and targets, the software creates database-specific SQL statements based on a job's data flow diagrams. To optimize performance, the software pushes down as many transform operations as possible to the source or target database and combines as many operations as possible into one request to the database. For example, the software tries to push down joins and function evaluations. By pushing down operations to the database, the software reduces the number of rows and operations that the engine must process.

Data flow design influences the number of operations that the software can push to the source or target database. Before running a job, you can examine the SQL that the software generates and alter your design to produce the most efficient results.

You can use the Data_Transfer transform to push down resource-intensive operations anywhere within a data flow to the database. Resource-intensive operations include joins, GROUP BY, ORDER BY, and DISTINCT.

Related Information

Performance Optimization Guide: Maximizing push-down operations [page 2116]
Reference Guide: Data_Transfer [page 1071]

2.7.6.2 Distributed data flow execution

The software provides capabilities to distribute CPU-intensive and memory-intensive data processing work (such as join, grouping, table comparison and lookups) across multiple processes and computers. This work distribution provides the following potential benefits:

- Better memory management by taking advantage of more CPU resources and physical memory
- Better job performance and scalability by using concurrent sub data flow execution to take advantage of grid computing

You can create sub data flows so that the software does not need to process the entire data flow in memory at one time. You can also distribute the sub data flows to different job servers within a server group to use additional memory and CPU resources.

Use the following features to split a data flow into multiple sub data flows:

- *Run as a separate process* option on resource-intensive operations that include the following:
  - Hierarchy_Flattening transform
  - Associate transform
  - Country ID transform
  - Global Address Cleanse transform
  - Global Suggestion Lists transform
  - Match Transform
  - United States Regulatory Address Cleanse transform
  - User-Defined transform
  - Query operations that are CPU-intensive and memory-intensive:
    - Join
    - GROUP BY
    - ORDER BY
    - DISTINCT
  - Table_Comparison transform
  - Lookup_ext function
  - Count_distinct function

    - Search_replace function

  If you select the Run as a separate process option for multiple operations in a data flow, the software splits the data flow into smaller sub data flows that use separate resources (memory and computer) from each other. When you specify multiple Run as a separate process options, the sub data flow processes run in parallel.
- Data_Transfer transform
  With this transform, the software does not need to process the entire data flow on the Job Server computer. Instead, the Data_Transfer transform can push down the processing of a resource-intensive operation to the database server. This transform splits the data flow into two sub data flows and transfers the data to a table in the database server to enable the software to push down the operation.

Related Information

Performance Optimization Guide: Splitting a data flow into sub data flows [page 2153]
Performance Optimization Guide: Data_Transfer transform for push-down operations [page 2122]

2.7.6.3 Load balancing

You can distribute the execution of a job or a part of a job across multiple Job Servers within a Server Group to better balance resource-intensive operations. You can specify the following values on the *Distribution level* option when you execute a job:

- Job level—A job can execute on an available Job Server.
- Data flow level—Each data flow within a job can execute on an available Job Server.
- Sub data flow level—An resource-intensive operation (such as a sort, table comparison, or table lookup) within a data flow can execute on an available Job Server.

Related Information

Performance Optimization Guide: Using grid computing to distribute data flows execution [page 2160]

2.7.6.4 Caches

The software provides the option to cache data in memory to improve operations such as the following in your data flows.

- Joins—Because an inner source of a join must be read for each row of an outer source, you might want to cache a source when it is used as an inner source in a join.
- Table comparisons—Because a comparison table must be read for each row of a source, you might want to cache the comparison table.

- Lookups—Because a lookup table might exist on a remote database, you might want to cache it in memory to reduce access times.

The software provides the following types of caches that your data flow can use for all of the operations it contains:

- In-memory—Use in-memory cache when your data flow processes a small amount of data that fits in memory.
- Pageable cache—Use a pageable cache when your data flow processes a very large amount of data that does not fit in memory.

If you split your data flow into sub data flows that each run on a different Job Server, each sub data flow can use its own cache type.

Related Information

Performance Optimization Guide: Using Caches [page 2129]

2.7.7 Audit Data Flow overview

You can audit objects within a data flow to collect run time audit statistics. You can perform the following tasks with this auditing feature:

- Collect audit statistics about data read into a job, processed by various transforms, and loaded into targets.
- Define rules about the audit statistics to determine if the correct data is processed.
- Generate notification of audit failures.
- Query the audit statistics that persist in the repository.

Related Information

Using Auditing [page 452]

2.8 Transforms

Transforms operate on data sets by manipulating input sets and producing one or more output sets. By contrast, functions operate on single values in specific columns in a data set.

Many built-in transforms are available from the object library on the *Transforms* tab.

The transforms that you can use depend on the software package that you have purchased. (If a transform belongs to a package that you have not purchased, it is disabled and cannot be used in a job.)

Transforms are grouped into the following categories:

- Data Integrator: Transforms that allow you to extract, transform, and load data. These transform help ensure data integrity and maximize developer productivity for loading and updating data warehouse environment.
- Data Quality: Transforms that help you improve the quality of your data. These transforms can parse, standardize, correct, enrich, match and consolidate your customer and operational information assets.
- Platform: Transforms that are needed for general data movement operations. These transforms allow you to generate, map and merge rows from two or more sources, create SQL query operations (expressions, lookups, joins, and filters), perform conditional splitting, and so on.
- Text Data Processing: Transforms that help you extract specific information from your text. They can parse large volumes of text, which allows you to identify and extract entities and facts, such as customers, products, locations, and financial information relevant to your organization.

Transform Category	Transform	Description
Data Integrator	Data_Transfer	Allows a data flow to split its processing into two sub data flows and push down resource-consuming operations to the database server.
	Date_Generation	Generates a column filled with date values based on the start and end dates and increment that you provide.
	Effective_Date	Generates an additional "effective to" column based on the primary key's "effective date."
	Hierarchy_Flattening	Flattens hierarchical data into relational tables so that it can participate in a star schema. Hierarchy flattening can be both vertical and horizontal.
	History_Preserving	Converts rows flagged as UPDATE to UPDATE plus INSERT, so that the original values are preserved in the target. You specify in which column to look for updated data.
	Key_Generation	Generates new keys for source data, starting from a value based on existing keys in the table you specify.
	Map_CDC_Operation	Sorts input data, maps output data, and resolves before- and after-images for UPDATE rows. While commonly used to support Oracle changed-data capture, this transform supports any data stream if its input requirements are met.
	Pivot (Columns to Rows)	Rotates the values in specified columns to rows. (Also see Reverse Pivot.)
	Reverse Pivot (Rows to Columns)	Rotates the values in specified rows to columns.
	Table_Comparison	Compares two data sets and produces the difference between them as a data set with rows flagged as INSERT and UPDATE.
	XML_Pipeline	Processes large XML inputs in small batches.
Data Quality	Associate	Combine the results of two or more Match transforms or two or more Associate transforms, or any

Transform Category	Transform	Description
		combination of the two, to find matches across match sets.
	Country ID	Parses input data and then identifies the country of destination for each record.
	Data Cleanse	Identifies and parses name, title, and firm data, phone numbers, Social Security numbers, dates, and e-mail addresses. It can assign gender, add prenames, generate Match standards, and convert input sources to a standard format. It can also parse and manipulate various forms of international data, as well as operational and product data.
	DSF2 Walk Sequencer	Adds delivery sequence information to your data, which you can use with presorting software to qualify for walk-sequence discounts.
	Geocoder	Uses geographic coordinates, addresses, and point-of-interest (POI) data to append address, latitude and longitude, census, and other information to your records.
	Global Address Cleanse	Identifies, parses, validates, and corrects global address data, such as primary number, primary name, primary type, directional, secondary identifier, and secondary number.
	Global Suggestion Lists	Completes and populates addresses with minimal data, and it can offer suggestions for possible matches.
	Match	Identifies matching records based on your business rules. Also performs candidate selection, unique ID, best record, and other operations.
	USA Regulatory Address Cleanse	Identifies, parses, validates, and corrects USA address data according to the U.S. Coding Accuracy Support System (CASS).
	User-Defined	Does just about anything that you can write Python code to do. You can use the User-Defined transform to create new records and data sets, or populate a field with a specific value, just to name a few possibilities.
Platform	Case	Simplifies branch logic in data flows by consolidating case or decision making logic in one transform. Paths are defined in an expression table.
	Map_Operation	Modifies data based on current operation codes and mapping expressions. The operation codes can then

Transform Category	Transform	Description
		be converted between data manipulation operations.
	Merge	Unifies rows from two or more sources into a single target.
	Query	Retrieves a data set that satisfies conditions that you specify. A query transform is similar to a SQL SELECT statement.
	Row_Generation	Generates a column filled with integer values starting at zero and incrementing by one to the end value you specify.
	SQL	Performs the indicated SQL query operation.
	Validation	Ensures that the data at any stage in the data flow meets your criteria. You can filter out or replace data that fails your criteria.
Text Data Processing	Entity_Extraction	Extracts information (entities and facts) from any text, HTML, XML , or binary format content such as PDF.

Related Information

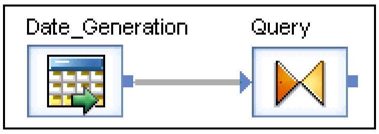
Reference Guide: Transforms [page 1067]

2.8.1 To add a transform to a data flow

You can use the Designer to add transforms to data flows.

1. Open a data flow object.
2. Open the object library if it is not already open and click the *Transforms* tab.
3. Select the transform or transform configuration that you want to add to the data flow.
4. Drag the transform or transform configuration icon into the data flow workspace. If you selected a transform that has available transform configurations, a drop-down menu prompts you to select a transform configuration.
5. Draw the data flow connections.

   To connect a source to a transform, click the square on the right edge of the source and drag the cursor to the arrow on the left edge of the transform.



Continue connecting inputs and outputs as required for the transform.

  ○ The input for the transform might be the output from another transform or the output from a source; or, the transform may not require source data.
  ○ You can connect the output of the transform to the input of another transform or target.

6. Double-click the name of the transform.

   This opens the transform editor, which lets you complete the definition of the transform.
7. Enter option values.

   To specify a data column as a transform option, enter the column name as it appears in the input schema or drag the column name from the input schema into the option box.

Related Information

To add a Data Quality transform to a data flow [page 312]
To add a text data processing transform to a data flow [page 324]

2.8.2 Transform editors

After adding a transform to a data flow, you configure it using the transform's editor. Transform editor layouts vary.

The most commonly used transform is the Query transform, which has two panes:

- An input schema area and/or output schema area
- A options area (or parameters area) that lets you to set all the values the transform requires

Data Quality transforms, such as Match and Data Cleanse, use a transform editor that lets you set options and map input and output fields.

The Entity Extraction transform editor lets you set extraction options and map input and output fields.

Related Information

Query Editor [page 311]
Data Quality transform editors [page 314]
Entity Extraction transform editor [page 325]

2.8.3 Transform configurations

A transform configuration is a transform with preconfigured best practice input fields, best practice output fields, and options that can be used in multiple data flows. These are useful if you repeatedly use a transform with specific options and input and output fields.

Some transforms, such as Data Quality transforms, have read-only transform configurations that are provided when Data Services is installed. You can also create your own transform configuration, either by replicating an existing transform configuration or creating a new one. You cannot perform export or multi-user operations on read-only transform configurations.

In the Transform Configuration Editor window, you set up the default options, best practice input fields, and best practice output fields for your transform configuration. After you place an instance of the transform configuration in a data flow, you can override these preset defaults.

If you edit a transform configuration, that change is inherited by every instance of the transform configuration used in data flows, unless a user has explicitly overridden the same option value in an instance.

Related Information

To create a transform configuration [page 308]
To add a user-defined field [page 309]

2.8.3.1 To create a transform configuration

1. In the *Transforms* tab of the *Local Object Library,* right-click a transform and select *New* to create a new transform configuration, or right-click an existing transform configuration and select *Replicate*.

   If New or Replicate is not available from the menu, then the selected transform type cannot have transform configurations.

   The *Transform Configuration Editor* window opens.
2. In *Transform Configuration Name*, enter the name of the transform configuration.
3. In the *Options* tab, set the option values to determine how the transform will process your data. The available options depend on the type of transform that you are creating a configuration for.

   For the Associate, Match, and User-Defined transforms, options are not editable in the Options tab. You must set the options in the Associate Editor, Match Editor, or User-Defined Editor, which are accessed by clicking the *Edit Options* button.

   If you change an option value from its default value, a green triangle appears next to the option name to indicate that you made an override.
4. To designate an option as "best practice," select the *Best Practice* checkbox next to the option's value. Designating an option as best practice indicates to other users who use the transform configuration which options are typically set for this type of transform.

   Use the filter to display all options or just those options that are designated as best practice options.
5. Click the *Verify* button to check whether the selected option values are valid.

If there are any errors, they are displayed at the bottom of the window.

6. In the *Input Best Practices* tab, select the input fields that you want to designate as the best practice input fields for the transform configuration.

   The transform configurations provided with Data Services do not specify best practice input fields, so that it doesn't appear that one input schema is preferred over other input schemas. For example, you may map the fields in your data flow that contain address data whether the address data resides in discrete fields, multiline fields, or a combination of discrete and multiline fields.

   These input fields will be the only fields displayed when the Best Practice filter is selected in the Input tab of the transform editor when the transform configuration is used within a data flow.
7. For Associate, Match, and User-Defined transform configurations, you can create user-defined input fields. Click the *Create* button and enter the name of the input field.
8. In the *Output Best Practices* tab, select the output fields that you want to designate as the best practice output fields for the transform configuration.
   These output fields will be the only fields displayed when the Best Practice filter is selected in the Output tab of the transform editor when the transform configuration is used within a data flow.
9. Click *OK* to save the transform configuration.
   The transform configuration is displayed in the *Local Object Library* under the base transform of the same type.

You can now use the transform configuration in data flows.

Related Information

Reference Guide: Transforms, Transform configurations [page 1123]

2.8.3.2 To add a user-defined field

For some transforms, such as the Associate, Match, and User-Defined transforms, you can create user-defined input fields rather than fields that are recognized by the transform. These transforms use user-defined fields because they do not have a predefined set of input fields.

You can add a user-defined field either to a single instance of a transform in a data flow or to a transform configuration so that it can be used in all instances.

In the User-Defined transform, you can also add user-defined output fields.

1. In the *Transforms* tab of the *Local Object Library,* right-click an existing Associate, Match, or User-Defined transform configuration and select *Edit*.
   The *Transform Configuration Editor* window opens.
2. In the *Input Best Practices* tab, click the *Create* button and enter the name of the input field.
3. Click *OK* to save the transform configuration.

When you create a user-defined field in the transform configuration, it is displayed as an available field in each instance of the transform used in a data flow. You can also create user-defined fields within each transform instance.

Related Information

Data Quality transform editors [page 314]

2.8.4 The Query transform

The Query transform is by far the most commonly used transform, so this section provides an overview.

The Query transform can perform the following operations:

- Choose (filter) the data to extract from sources
- Join data from multiple sources
- Map columns from input to output schemas
- Perform transformations and functions on the data
- Perform data nesting and unnesting
- Add new columns, nested schemas, and function results to the output schema
- Assign primary keys to output columns

Related Information

Nested Data [page 342]

Reference Guide: Transforms [page 1067]

2.8.4.1 To add a Query transform to a data flow

Because it is so commonly used, the Query transform icon is included in the tool palette, providing an easier way to add a Query transform.

1. Click the Query icon in the tool palette.
2. Click anywhere in a data flow workspace.
3. Connect the Query to inputs and outputs.

> Note
>
> - The inputs for a Query can include the output from another transform or the output from a source.
> - The outputs from a Query can include input to another transform or input to a target.
> - You can change the content type for the columns in your data by selecting a different type from the output content type list.
> - If you connect a target table to a Query with an empty output schema, the software automatically fills the Query's output schema with the columns from the target table, without mappings.

2.8.4.2 Query Editor

The Query Editor is a graphical interface for performing query operations. It contains the following areas: *input schema* area (upper left), *output schema* area (upper right), and a *parameters* area (lower tabbed area). The ⓘ icon indicates that the tab contains user-defined entries or that there is at least one join pair (FROM tab only).

The input and output schema areas can contain: Columns, Nested schemas, and Functions (output only).

The *Schema In* and *Schema Out* lists display the currently selected schema in each area. The currently selected output schema is called the current schema and determines the following items:

- The output elements that can be modified (added, mapped, or deleted)
- The scope of the *Select* through *Order by* tabs in the parameters area

The current schema is highlighted while all other (non-current) output schemas are gray.

2.8.4.2.1 To change the current output schema

You can change the current output schema in the following ways:

- Select a schema from the Output list so that it is highlighted.
- Right-click a schema, column, or function in the Output Schema area and select *Make Current*.
- Double-click one of the non-current (grayed-out) elements in the Output Schema area.

2.8.4.2.2 To modify the output schema contents

You can modify the output schema in several ways:

- Drag and drop (or copy and paste) columns or nested schemas from the input schema area to the output schema area to create simple mappings.
- Use right-click menu options on output elements to:
  - Add new output columns and schemas.
  - Use function calls to generate new output columns.
  - Assign or reverse primary key settings on output columns. Primary key columns are flagged by a key icon.
  - Unnest or re-nest schemas.
- Use the *Mapping* tab to provide complex column mappings. Drag and drop input schemas and columns into the output schema to enable the editor. Use the function wizard and the smart editor to build expressions. When the text editor is enabled, you can access these features using the buttons above the editor.
- Use the *Select* through *Order By* tabs to provide additional parameters for the current schema (similar to SQL SELECT statement clauses). You can drag and drop schemas and columns into these areas.

Tab name	Description
Select	Specifies whether to output only distinct rows (discarding any identical duplicate rows).

Tab name	Description
From	Lists all input schemas. Allows you to specify join pairs and join conditions as well as enter join rank and cache for each input schema. The resulting SQL FROM clause is displayed.

Where	Specifies conditions that determine which rows are output.
	Enter the conditions in SQL syntax, like a WHERE clause in a SQL SELECT statement. For example:
	`<TABLE1.EMPNO> = <TABLE2.EMPNO> AND`
	`<TABLE1.EMPNO> > 1000 OR`
	`<TABLE2.EMPNO> < 9000`
	Use the *Functions*, *Domains*, and *smart editor* buttons for help building expressions.

Group By	Specifies how the output rows are grouped (if required).
Order By	Specifies how the output rows are sequenced (if required).

- Use the *Find* tab to locate input and output elements containing a specific word or term.

2.8.5 Data Quality transforms

Data Quality transforms are a set of transforms that help you improve the quality of your data. The transforms can parse, standardize, correct, and append information to your customer and operational data.

Data Quality transforms include the following transforms:

- Associate
- Country ID
- Data Cleanse
- DSF2 Walk Sequencer
- Global Address Cleanse
- Global Suggestion Lists
- Match
- USA Regulatory Address Cleanse
- User-Defined

Related Information

Reference Guide: Transforms [page 1067]

2.8.5.1 To add a Data Quality transform to a data flow

Data Quality transforms cannot be directly connected to an upstream transform that contains or generates nested tables. This is common in real-time data flows, especially those that perform matching. To connect these transforms, you must insert either a Query transform or an XML Pipeline transform between the transform with the nested table and the Data Quality transform.

1. Open a data flow object.
2. Open the object library if it is not already open.
3. Go to the *Transforms* tab.
4. Expand the Data Quality transform folder and select the transform or transform configuration that you want to add to the data flow.
5. Drag the transform or transform configuration icon into the data flow workspace. If you selected a transform that has available transform configurations, a drop-down menu prompts you to select a transform configuration.
6. Draw the data flow connections.

   To connect a source or a transform to another transform, click the square on the right edge of the source or upstream transform and drag the cursor to the arrow on the left edge of the Data Quality transform.

   - The input for the transform might be the output from another transform or the output from a source; or, the transform may not require source data.
   - You can connect the output of the transform to the input of another transform or target.
7. Double-click the name of the transform.

   This opens the transform editor, which lets you complete the definition of the transform.
8. In the input schema, select the input fields that you want to map and drag them to the appropriate field in the *Input* tab.
   This maps the input field to a field name that is recognized by the transform so that the transform knows how to process it correctly. For example, an input field that is named "Organization" would be mapped to the Firm field. When content types are defined for the input, these columns are automatically mapped to the appropriate input fields. You can change the content type for the columns in your data by selecting a different type from the output content type list.
9. For the Associate, Match, and User-Defined transforms, you can add user-defined fields to the *Input* tab. You can do this in two ways:

   - Click the first empty row at the bottom of the table and press F2 on your keyboard. Enter the name of the field. Select the appropriate input field from the drop-down box to map the field.
   - Drag the appropriate input field to the first empty row at the bottom of the table.

   To rename the user-defined field, click the name, press F2 on your keyboard, and enter the new name.
10. In the *Options* tab, select the appropriate option values to determine how the transform will process your data.

    - Make sure that you map input fields before you set option values, because in some transforms, the available options and option values depend on the mapped input fields.
    - For the Associate, Match, and User-Defined transforms, options are not editable in the Options tab. You must set the options in the Associate Editor, Match Editor, and User-Defined Editor. You can access these editors either by clicking the Edit Options button in the Options tab or by right-clicking the transform in the data flow.

    If you change an option value from its default value, a green triangle appears next to the option name to indicate that you made an override.
11. In the *Output* tab, double-click the fields that you want to output from the transform. Data Quality transforms can generate fields in addition to the input fields that the transform processes, so you can output many fields.

Make sure that you set options before you map output fields.

The selected fields appear in the output schema. The output schema of this transform becomes the input schema of the next transform in the data flow.

12. If you want to pass data through the transform without processing it, drag fields directly from the input schema to the output schema.
13. To rename or resize an output field, double-click the output field and edit the properties in the *Column Properties* window.

Related Information

Reference Guide: Data Quality Fields [page 1130]

Data Quality transform editors [page 314]

2.8.5.2 Data Quality transform editors

The Data Quality editors, graphical interfaces for setting input and output fields and options, contain the following areas: input schema area (upper left), output schema area (upper right), and the parameters area (lower tabbed area).

The parameters area contains three tabs: Input, Options, and Output. Generally, it is considered best practice to complete the tabs in this order, because the parameters available in a tab may depend on parameters selected in the previous tab.

Input schema area

The input schema area displays the input fields that are output from the upstream transform in the data flow.

Output schema area

The output schema area displays the fields that the transform outputs, and which become the input fields for the downstream transform in the data flow.

Input tab

The Input tab displays the available field names that are recognized by the transform. You map these fields to input fields in the input schema area. Mapping input fields to field names that the transform recognizes tells the transform how to process that field.

Options tab

The Options tab contain business rules that determine how the transform processes your data. Each transform has a different set of available options. If you change an option value from its default value, a green triangle appears next to the option name to indicate that you made an override.

In the Associate, Match, and User-Defined transforms, you cannot edit the options directly in the Options tab. Instead you must use the Associate, Match, and User-Defined editors, which you can access from the Edit Options button.

Output tab

The Output tab displays the field names that can be output by the transform. Data Quality transforms can generate fields in addition to the input fields that that transform processes, so that you can output many fields. These mapped output fields are displayed in the output schema area.

Filter and sort

The Input, Options, and Output tabs each contain filters that determine which fields are displayed in the tabs.

Filter	Description
Best Practice	Displays the fields or options that have been designated as a best practice for this type of transform. However, these are merely suggestions; they may not meet your needs for processing or outputting your data. The transform configurations provided with the software do not specify best practice input fields.
In Use	Displays the fields that have been mapped to an input field or output field.
All	Displays all available fields.

The Output tab has additional filter and sort capabilities that you access by clicking the column headers. You can filter each column of data to display one or more values, and also sort the fields in ascending or descending order. Icons in the column header indicate whether the column has a filter or sort applied to it. Because you can filter and sort on multiple columns, they are applied from left to right. The filter and sort menu is not available if there is only one item type in the column.

Embedded help

The embedded help is the place to look when you need more information about Data Services transforms and options. The topic changes to help you with the context you're currently in. When you select a new transform or a new option group, the topic updates to reflect that selection.

You can also navigate to other topics by using hyperlinks within the open topic.

Associate, Match, and User-Defined transform editors

To view option information for the Associate, Match, and User-Defined transforms, you will need to open their respective editors by selecting the transform in the data flow and then choosing *Tools* > `<transform>` *Editor*

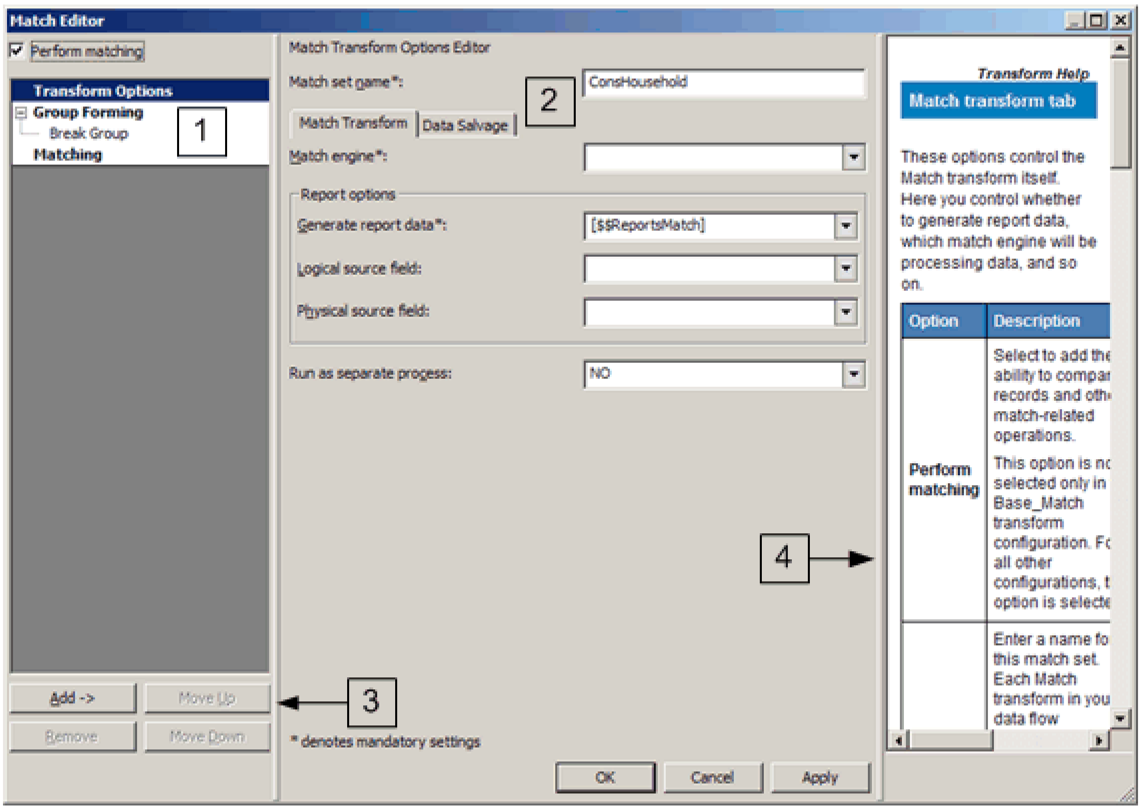
> **Note**
>
> You cannot access the Match editor options while you are reviewing data flows created in Information Steward Data Cleansing Advisor. Match transform options cannot be edited; therefore, controls to access the Match editor are inactive.

Related Information

Associate, Match, and User-Defined transform editors [page 316]

2.8.5.2.1 Associate, Match, and User-Defined transform editors

The Associate, Match, and User-Defined transforms each have their own editor in which you can add option groups and edit options. The editors for these three transforms look and act similarly, and in some cases even share the same option groups.



☑ Perform matching

Match Transform Options Editor

Match set name*: ConsHousehold

Match engine*:

Generate report data*: [$$ReportsMatch]

Logical source field:

Physical source field:

Run as separate process: NO

* denotes mandatory settings

Transform Help

Match transform tab

These options control the Match transform itself. Here you control whether to generate report data, which match engine will be processing data, and so on.

Option	Description
Perform matching	Select to add the ability to compar records and oth match-related operations. This option is nc selected only in Base_Match transform configuration. Fc all other configurations, t option is selecte
	Enter a name fo this match set. Each Match transform in you data flow

The editor window is divided into four areas:

1. *Option Explorer* — In this area, you select the option groups, or operations, that are available for the transform. To display an option group that is hidden, right-click the option group it belongs to and select the name of the option group from the menu.
2. *Option Editor* — In this area, you specify the value of the option.
3. *Buttons* — Use these to add, remove and order option groups.
4. *Embedded help* — The embedded help displays additional information about using the current editor screen.

2.8.5.2.2 Ordered options editor

Some transforms allow you to choose and specify the order of multiple values for a single option. One example is the parser sequence option of the Data Cleanse transform.

To configure an ordered option:

1. Click the *Add* and *Remove* buttons to move option values between the Available and Selected values lists.

   ℹ Note

   Remove all values. To clear the Selected values list and move all option values to the Available values list, click *Remove All*.

2. Select a value in the Available values list, and click the up and down arrow buttons to change the position of the value in the list.
3. Click *OK* to save your changes to the option configuration. The values are listed in the Designer and separated by pipe characters.

2.8.6 Text Data Processing transforms

Text Data Processing transforms help you extract specific information from your text. They can parse large volumes of text, identifying and extracting entities and facts, such as customers, products, locations, and financial information relevant to your organization. The following sections provide an overview of this functionality and the Entity Extraction transform.

2.8.6.1 Text Data Processing overview

Text Data Processing can automatically identify the input text language and select language-specific dictionaries and rules for analysis to extract entities, including people, dates, places, organizations and so on, in the languages. It also looks for patterns, activities, events, and relationships among entities and enables their extraction. Extracting such information from text tells you what the text is about — this information can be used within applications for information management, data integration, and data quality; business intelligence; query, analytics and reporting; search, navigation, document and content management; among other usage scenarios.

Text Data Processing goes beyond conventional character matching tools for information retrieval, which can only seek exact matches for specific strings. It understands semantics of words. In addition to known entity matching, it performs a complementary function of new entity discovery. To customize entity extraction, the software enables you to specify your own list of entities in a custom dictionary. These dictionaries enable you to store entities and manage name variations. Known entity names can be standardized using a dictionary.

Text Data Processing automates extraction of key information from text sources to reduce manual review and tagging. This in turn can reduce cost towards understanding important insights hidden in text. Access to relevant information from unstructured text can help streamline operations and reduce unnecessary costs.

In Data Services, text data processing refers to a set of transforms that extracts information from unstructured data and creates structured data that can be used by various business intelligence tools.

2.8.6.2 Entity Extraction transform overview

Text data processing is accomplished in the software using the following transform:

- Entity Extraction - Extracts entities and facts from unstructured text.

Extraction involves processing and analyzing text identifying languages, finding entities of interest, assigning them to the appropriate type, and presenting this metadata in a standard format. By using dictionaries and rules, you can customize your extraction output to include entities defined in them. Extraction applications are as diverse as your information needs. Some examples of information that can be extracted using this transform include:

- Co-occurrence and associations of brand names, company names, people, supplies, and more.
- Competitive and market intelligence such as competitors' activities, merger and acquisition events, press releases, contact information, and so on.
- A person's associations, activities, or role in a particular event.
- Customer claim information, defect reports, or patient information such as adverse drug effects.
- Various alphanumeric patterns such as ID numbers, contract dates, profits, and so on.

2.8.6.2.1 Entities and facts overview

Entities denote names of people, places, and things that can be extracted. *Entities* are defined as a pairing of a name and its type. *Type* indicates the main category of an entity.

Here are some examples of entities:

- Paris is an entity with name "Paris" and type *LOCALITY*.
- Mr. Joe Smith is an entity with name "Mr. Joe Smith" and type *PERSON*.

Entities can have subtypes. A subtype indicates further classification of an entity; it is a hierarchical specification of an entity type that enables the distinction between different semantic varieties of the same entity type. A subtype can be described as a sub-category of an entity.

Here are some examples of entities and subtypes:

- Boeing 747 is an entity of type *VEHICLE* with a subtype *AIR*.
- Mercedes-Benz SL500 is an entity of type *VEHICLE* with a subtype *LAND*.
- SAP is an entity of type *ORGANIZATION* with a subtype *COMMERCIAL*.

Facts denote a pattern that creates an expression to extract information such as sentiments, events, or relationships. Facts are extracted using custom extraction rules. Fact is an umbrella term covering extractions of more complex patterns including one or more entities, a relationship between one or more entities, or some sort of predicate about an entity. Facts provide context of how different entities are connected in the text. Entities by themselves only show that they are present in a document, but facts provide information on how these entities are related. Fact types identify the category of a fact; for example, sentiments and requests. A *subfact* is a key piece of information embedded within a fact. A subfact type can be described as a category associated with the subfact.

Here are some examples of facts and fact types:

- SAP acquired Business Objects in a friendly takeover. This is an event of type merger and acquisition (*M&A*).
- Mr. Joe Smith is very upset with his airline bookings. This is a fact of type *SENTIMENT*.

How extraction works

The extraction process uses its inherent knowledge of the semantics of words and the linguistic context in which these words occur to find entities and facts. It creates specific patterns to extract entities and facts based on system rules. You can add entries in a dictionary as well as write custom rules to customize extraction output. The following sample text and sample output shows how unstructured content can be transformed into structured information for further processing and analysis.

Example

Sample text and extraction information

"Mr. Jones is very upset with Green Insurance Corp. The offer for his totaled vehicle is too low. He states that Green offered him $1250.00 but his car is worth anywhere from $2500 to $4500. Mr. Jones would like Green's comprehensive coverage to be in line with other competitors."

This sample text when processed with the extraction transform, configured with the sentiment and request custom rules would identify and group the information in a logical way (identifying entities, subtypes, facts, fact types, subfacts, and subfact types) that can be further processed.

The following tables show partial results with information tagged as entities, entity types, subtypes, facts, fact types, subfacts, and subfact types from the sample text:

Entities	Entity type	Subtype
Mr. Jones	*PERSON*	
Green Insurance	*ORGANIZATION*	*COMMERCIAL*
Green	*PROP_MISC*	
$1250.00	*CURRENCY*	

Facts	Fact type	Subfact	Subfact type
Mr. Jones is very upset with Green Insurance Corp.	*SENTIMENT*	*very upset*	*StrongNegativeSentiment*
Jones would like that Green's comprehensive coverage to be in line with other competitors.	*REQUEST*		

2.8.6.2.2 Dictionary overview

An extraction dictionary is a user-defined repository of entities. It is an easy-to-use customization tool that specifies a list of entities that the Entity Extraction transform should always extract while processing text. The information is classified under the *standard form* and the *variant* of an entity. A standard form may have one or more variants embedded under it; variants are other commonly known names of an entity. For example, *United*

Parcel Service of America is the standard form for that company, and *United Parcel Service* and *UPS* are both variants for the same company.

While each standard form must have a type, variants can optionally have their own type; for example, while *United Parcel Service of America* is associated with a standard form type *ORGANIZATION*, you might define a variant type *ABBREV* to include abbreviations. A dictionary structure can help standardize references to an entity.

For more information, see “Using Dictionaries” in the *Text Data Processing Extraction Customization Guide*.

2.8.6.2.3 Rule overview

An extraction rule defines custom patterns to extract entities, relationships, events, and other larger extractions that are together referred to as facts. You write custom extraction rules to perform extraction that is customized to your specific needs.

For more information, see “Using Extraction Rules” in the *Text Data Processing Extraction Customization Guide*.

2.8.6.3 Using the Entity Extraction transform

The Entity Extraction transform can extract information from any text, HTML, XML, or certain binary-format (such as PDF) content and generate structured output. You can use the output in several ways based on your work flow. You can use it as an input to another transform or write to multiple output sources such as a database table or a flat file. The output is generated in `UTF-16` encoding. The following list provides some scenarios on when to use the transform alone or in combination with other Data Services transforms.

- Searching for specific information and relationships from a large amount of text related to a broad domain. For example, a company is interested in analyzing customer feedback received in free form text after a new product launch.
- Linking structured information from unstructured text together with existing structured information to make new connections. For example, a law enforcement department is trying to make connections between various crimes and people involved using their own database and information available in various reports in text format.
- Analyzing and reporting on product quality issues such as excessive repairs and returns for certain products. For example, you may have structured information about products, parts, customers, and suppliers in a database, while important information pertaining to problems may be in notes: fields of maintenance records, repair logs, product escalations, and support center logs. To identify the issues, you need to make connections between various forms of data.

2.8.6.4 Differences between text data processing and data cleanse transforms

The Entity Extraction transform provides functionality similar to the Data Cleanse transform in certain cases, especially with respect to customization capabilities. This section describes the differences between the two and which transform to use to meet your goals. The Text Data Processing Entity Extraction transform is for making sense of unstructured content and the Data Cleanse transform is for standardizing and cleansing structured data. The following table describes some of the main differences. In many cases, using a combination of Entity Extraction and Data Cleanse transforms will generate the data that is best suited for your business intelligence analyses and reports.

Criteria	Text Data Processing	Data Cleanse
Input type	Unstructured text that requires linguistic parsing to generate relevant information.	Structured data represented as fields in records.
Input size	More than 5KB of text.	Less than 5KB of text.
Input scope	Normally broad domain with many variations.	Specific data domain with limited variations.
Matching task	Content discovery, noise reduction, pattern matching, and relationship between different entities.	Dictionary lookup, pattern matching.
Potential usage	Identifies potentially meaningful information from unstructured content and extracts it into a format that can be stored in a repository.	Ensures quality of data for matching and storing into a repository such as Meta Data Management.
Output	Creates annotations about the source text in the form of entities, entity types, facts, and their offset, length, and so on. Input is not altered.	Creates parsed and standardized fields. Input is altered if desired.

2.8.6.5 Using multiple transforms

You can include multiple transforms in the same data flow to perform various analytics on unstructured information.

For example, to extract names and addresses embedded in some text and validate the information before running analytics on the extracted information, you could:

- Use the Entity Extraction transform to process text containing names and addresses and extract different entities.
- Pass the extraction output to the Case transform to identify which rows represent names and which rows represent addresses
- Use the Data Cleanse transform to standardize the extracted names and use the Global Address Cleanse transform to validate and correct the extracted address data.

Note

To generate the correct data, include the `standard_form` and `type` fields in the Entity Extraction transform output schema; map the `type` field in the Case transform based on the entity type such as `PERSON`, `ADDRESS1`, etc. Next, map any `PERSON` entities from the Case transform to the Data Cleanse transform and map any `ADDRESS1` entities to the Global Address Cleanse transform.

2.8.6.6 Examples for using the Entity Extraction transform

This section describes some examples for employing the Entity Extraction transform.

The scenario is that a human resources department wants to analyze résumés received in a variety of formats. The formats include:

- A text file as an attachment to an email
- A text résumé pasted into a field on the company's Web site
- Updates to résumé content that the department wants to process in real time

Example

Text file email attachment

The human resources department frequently receives résumés as attachments to emails from candidates. They store these attachments in a separate directory on a server.

To analyze and process data from these text files:

1. Configure an *Unstructured text* file format that points to the directory of résumés.
2. Build a data flow with the unstructured text file format as the source, an Entity Extraction transform, and a target.
3. Configure the transform to process and analyze the text.

Example

Text résumé pasted into a field on a Web site

The human resources department's online job application form includes a field into which applicants can paste their résumés. This field is captured in a database table column.

To analyze and process data from the database:

1. Configure a connection to the database via a datastore.
2. Build a data flow with the database table as the source, an Entity Extraction transform, and a target.
3. Configure the transform to process and analyze the text.

Example

Updated content to be processed in real time

Suppose the human resources department is seeking a particular qualification in an applicant. When the applicant updates her résumé in the company's Web-based form with the desired qualification, the HR manager wants to be immediately notified. Use a real-time job to enable this functionality.

To analyze and process the data in real time:

1. Add a real-time job including begin and end markers and a data flow. Connect the objects.
2. Build the data flow with a message source, an Entity Extraction transform, and a message target.
3. Configure the transform to process and analyze the text.

Database datastores [page 210]
Real-time Jobs [page 372]

2.8.6.7 To add a text data processing transform to a data flow

1. Open a data flow object.
2. Open the local object library if it is not already open.
3. Go to the *Transforms* tab.
4. Expand the *Text Data Processing* transform folder and select the transform or transform configuration that you want to add to the data flow.
5. Drag the transform or transform configuration icon into the data flow workspace. If you selected a transform that has available transform configurations, a drop-down menu prompts you to select a transform configuration.
6. Draw the data flow connections.

   To connect a source or a transform to another transform, click the square on the right edge of the source or upstream transform and drag the cursor to the arrow on the left edge of the text data processing transform.

   - The input for the transform might be the output from another transform or the output from a source.
   - You can connect the output of the transform to the input of another transform or target.
7. Double-click the name of the transform.

   This opens the transform editor, which lets you complete the definition of the transform.
8. In the input schema, select the input field that you want to map and drag it to the appropriate field in the *Input* tab.
   This maps the input field to a field name that is recognized by the transform so that the transform knows how to process it correctly. For example,

   - an input field that is named *Content* would be mapped to the *TEXT* input field.
   - an input field that can uniquely identify the content would be mapped to the *TEXT_ID* input field.
9. In the *Options* tab, select the appropriate option values to determine how the transform will process your data.

   Make sure that you map input fields before you set option values.

   If you change an option value from its default value, a green triangle appears next to the option name to indicate that you made an override.
10. In the *Output* tab, double-click the fields that you want to output from the transform. The transforms can generate fields in addition to the input fields that the transform processes, so you can output many fields.

    Make sure that you set options before you map output fields.

    The selected fields appear in the output schema. The output schema of this transform becomes the input schema of the next transform in the data flow.

11. If you want to pass data through the transform without processing it, drag fields directly from the input schema to the output schema.
12. To rename or resize an output field, double-click the output field and edit the properties in the *Column Properties* window.

Related Information

Using Extraction Options [page 325]

Reference Guide: Entity Extraction transform, Extraction options [page 1502]

2.8.6.8 Entity Extraction transform editor

The *Entity Extraction* transform options specify various parameters to process content using the transform. Filtering options, under different extraction options, enable you to limit the entities and facts extracted to specific entities from a dictionary, the system files, entities/facts from rules, or a combination of them.

Extraction options are divided into the following categories:

- *Common*
  This option is set to specify that the Entity Extraction transform is to be run as a separate process.
- *Languages*
  Use this option to specify the language for the extraction process.
  - *Language*—The default is 'Auto', directing the transform to attempt to identify the language. You may select another language from a list.
  - *Default Language*—You may select the language that should be assumed if the transform was not able to identify the language.
  - *Filter by Entity Types* is optional and you may select it when you select the language to limit your extraction output.
- *Processing Options*
  Use these options to specify parameters to be used when processing the content.
- *Dictionaries*
  Use this option to specify different dictionaries to be used for processing the content. To use the *Entity Types* filtering option, you must specify the *Dictionary File*.

  > Note
  >
  > Text Data Processing includes the dictionary schema file `extraction-dictionary.xsd`. By default, this file is installed in the `LINK_DIR/bin` folder, where `LINK_DIR` is your Data Services installation directory. Refer to this schema to create your own dictionary files.

- *Rules*
  Use this option to specify different rule files to be used for processing the content. To use the *Rule Names* filtering option, you must specify the *Rule File*.

If you do not specify any filtering options, the extraction output will contain all entities extracted using entity types defined in the selected language, dictionary file(s), and rule name(s) in the selected rule file(s).

> **Note**
>
> Selecting a dictionary file or a rule file in the extraction process is optional. The extraction output will include the entities from them if they are specified.

For more information, see “Using Dictionaries” in the *Text Data Processing Extraction Customization Guide*.

Related Information

Importing XML Schemas [page 346]

Reference Guide: Entity Extraction transform, Extraction options [page 1502]

2.8.6.9 Using filtering options

The filtering options under different extraction options control the output generated by the Entity Extraction transform. Using these options, you can limit the entities extracted to specific entities from a dictionary, the system files, entities/facts from rules, or a combination of them. For example, you are processing customer feedback fields for an automobile company and are interested in looking at the comments related to one specific model. Using the filtering options, you can control your output to extract data only related to that model.

Filtering options are divided into three categories:

- The *Filter By Entity Types* option under the *Languages* option group—Use this option to limit extraction output to include only selected entities for this language.
- The *Filter By Entity Types* option under the *Dictionary* option group—Use this option to limit extraction output to include only entities defined in a dictionary.
- The *Filter By Rules Names* option under the *Rules* option group—Use this option to limit extraction output to include only entities and facts returned by the specific rules.

The following table describes information contained in the extraction output based on the combination of these options:

Languages	Dictionaries	Rules	Extraction output content	Note
Entity Types	Entity Types	Rule Names		
Yes	No	No	Entities (extracted using the entity types) selected in the filter.	
No	Yes	No	Entities (extracted using the entity types) defined in the selected language and entity types selected from the dictionaries filter.	If multiple dictionaries are specified that contain the same entity type but this entity type is selected as a filter for only one of them, entities of this

Languages	Dictionaries	Rules	Extraction output content	Note
				type will also be returned from the other dictionary.
Yes	Yes	No	Entities (extracted using the entity types) defined in the filters for the selected language and any specified dictionaries.	
No	No	Yes	Entities (extracted using the entity types) defined in the selected language and any rule names selected in the filter from any specified rule files.	If multiple rule files are specified that contain the same rule name but it is only selected as a filter for one of them, entities and facts of this type will also be returned from the other rule file.
No	Yes	Yes	Entities (extracted using entity types) defined in the selected language, entity types selected from the dictionaries filter, and any rule names selected in the filter from any specified rule files.	
Yes	No	Yes	Entities (extracted using entity types) defined in the filters for the selected language and any rule names selected in the filter from any specified rule files.	
Yes	Yes	Yes	Entities (extracted using entity types) defined in the filters for the selected language, entity types selected from the dictionaries filter, and any rule names selected in the filter from any specified rule files.	The extraction process filters the output using the union of the extracted entities or facts for the selected language, the dictionaries, and the rule files.

If you change your selection for the language, dictionaries, or rules, any filtering associated with that option will only be cleared by clicking the *Filter by...* option. You must select new filtering choices based on the changed selection.

i Note

If you are using multiple dictionaries (or rules) and have set filtering options for some of the selected dictionaries (or rules), the extraction process combines the dictionaries internally, and output is filtered using the union of the entity types selected for each dictionary and rule names selected for each rule file. The output will identify the source as a dictionary (or rule) file and not the individual name of a dictionary (or rule) file.

i Note

If you select the *Dictionary Only* option under the *Processing Options* group, with a valid dictionary file, the entity types defined for the language are not included in the extraction output, but any extracted rule file entities and facts are included.

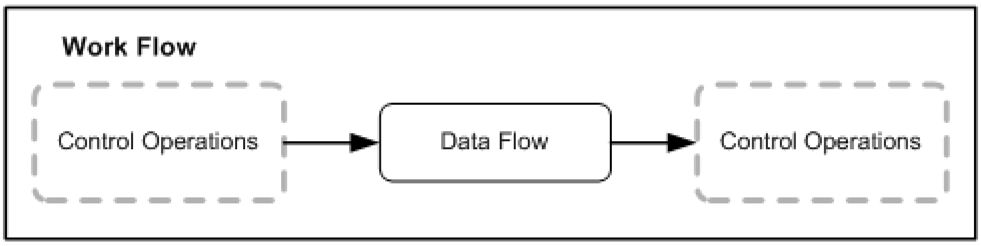
2.9 Work Flows

2.9.1 What is a work flow?

A work flow defines the decision-making process for executing data flows. For example, elements in a work flow can determine the path of execution based on a value set by a previous job or can indicate an alternative path if something goes wrong in the primary path. Ultimately, the purpose of a work flow is to prepare for executing data flows and to set the state of the system after the data flows are complete.



Jobs are special work flows. Jobs are special because you can execute them. Almost all of the features documented for work flows also apply to jobs, with one exception: jobs do not have parameters.

Related Information

Projects [page 205]

2.9.2 Steps in a work flow

Work flow steps take the form of icons that you place in the work space to create a work flow diagram. The following objects can be elements in work flows:

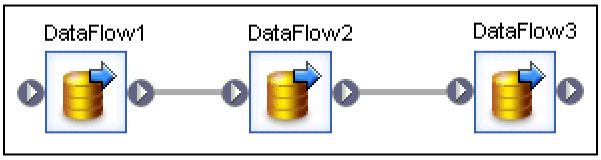
- Work flows
- Data flows
- Scripts
- Conditionals
- While loops
- Try/catch blocks

Work flows can call other work flows, and you can nest calls to any depth. A work flow can also call itself.

The connections you make between the icons in the workspace determine the order in which work flows execute, unless the jobs containing those work flows execute in parallel.

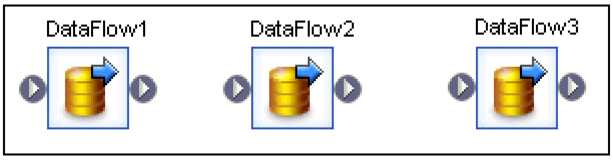
2.9.3 Order of execution in work flows

Steps in a work flow execute in a left-to-right sequence indicated by the lines connecting the steps. Here is the diagram for a work flow that calls three data flows:

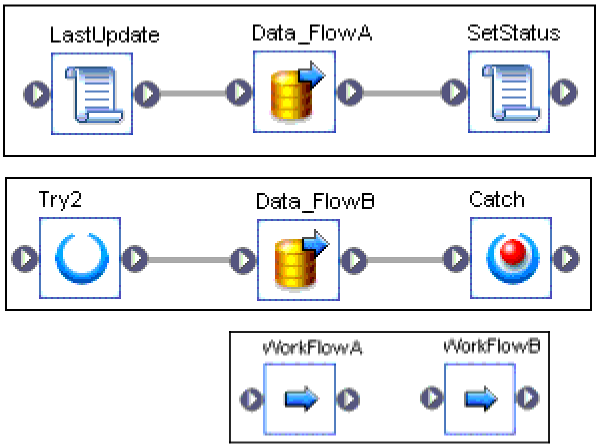


Note that Data_Flow1 has no connection from the left but is connected on the right to the left edge of Data_Flow2 and that Data_Flow2 is connected to Data_Flow3. There is a single thread of control connecting all three steps. Execution begins with Data_Flow1 and continues through the three data flows.

Connect steps in a work flow when there is a dependency between the steps. If there is no dependency, the steps need not be connected. In that case, the software can execute the independent steps in the work flow as separate processes. In the following work flow, the software executes data flows 1 through 3 in parallel:



To execute more complex work flows in parallel, define each sequence as a separate work flow, then call each of the work flows from another work flow as in the following example:



You can specify that a job execute a particular work flow or data flow only one time. In that case, the software only executes the first occurrence of the work flow or data flow; the software skips subsequent occurrences in the job. You might use this feature when developing complex jobs with multiple paths, such as jobs with try/catch blocks or conditionals, and you want to ensure that the software only executes a particular work flow or data flow one time.

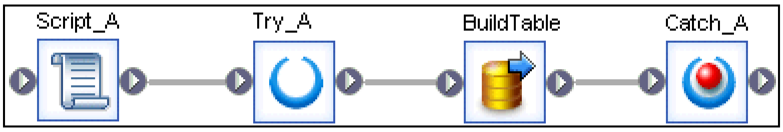
2.9.4 Example of a work flow

Suppose you want to update a fact table. You define a data flow in which the actual data transformation takes place. However, before you move data from the source, you want to determine when the fact table was last updated so that you only extract rows that have been added or changed since that date.

You need to write a script to determine when the last update was made. You can then pass this date to the data flow as a parameter.

In addition, you want to check that the data connections required to build the fact table are active when data is read from them. To do this in the software, you define a try/catch block. If the connections are not active, the catch runs a script you wrote, which automatically sends mail notifying an administrator of the problem.

Scripts and error detection cannot execute in the data flow. Rather, they are steps of a decision-making process that influences the data flow. This decision-making process is defined as a work flow, which looks like the following:



The software executes these steps in the order that you connect them.

2.9.5 Creating work flows

You can create work flows using one of two methods:

- Object library
- Tool palette

After creating a work flow, you can specify that a job only execute the work flow one time, as a single process, or as a continous process even if the work flow appears in the job multiple times.

2.9.5.1 To create a new work flow using the object library

1. Open the object library.
2. Go to the *Work Flows* tab.
3. Right-click and choose *New*.

4. Drag the work flow into the diagram.
5. Add the data flows, work flows, conditionals, try/catch blocks, and scripts that you need.

2.9.5.2 To create a new work flow using the tool palette

1. Select the work flow icon in the tool palette.
2. Click where you want to place the work flow in the diagram.

If more than one instance of a work flow appears in a job, you can improve execution performance by running the work flow only one time.

2.9.5.3 To specify that a job executes the work flow one time

When you specify that a work flow should only execute once, a job will never re-execute that work flow after the work flow completes successfully, except if the work flow is contained in a work flow that is a recovery unit that re-executes and has not completed successfully elsewhere outside the recovery unit.

It is recommended that you not mark a work flow as *Execute only once* if the work flow or a parent work flow is a recovery unit.

1. Right click on the work flow and select *Properties*.

   The Properties window opens for the work flow.
2. Select *Regular* from the *Execution type* dropdown list.
3. Select the *Execute only once* check box.
4. Click *OK*.

Related Information

Reference Guide: Work flow [page 1002]

2.9.5.4 What is a single work flow?

A single work flow runs all of its child data flows in one operating system process. If the data flows are designed to be run in parallel then they are run in different threads instead of different processes. The advantage of single process is that it is possible to share resources such as database connections across multiple data flows.

> Note
>
> Single work flows have the following limitations:
>
> - A single work flow cannot call or contain a continuous work flow.

- A single work flow cannot use sub data flows. Therefore, the Data Transfer transform and "Run as a separate process" options are invalid. The software will generate a runtime validation error.
- A single work flow can be only executed by a continuous work flow. A single work flow cannot call another single work flow.

2.9.5.5 To specify that a job executes as a single work flow

1. Right-click a work flow and select *Properties*
2. Select *Single* from the Execution type dropdown list.
3. Click *OK*.

2.9.5.6 What is a continuous work flow?

A continuous work flow runs all data flows in a loop but keeps them in the memory for the next iteration. This eliminates the need to repeat some of the common steps of execution (for example, connecting to the repository, parsing/optimizing/compiling ATL, opening database connections.

Note

Continuous work flows have the following limitations:

- A continuous work flow cannot call or contain another continuous work flow. If a continuous work flow calls another continous work flow which never terminates, the work flow can never restart the child processes.
- A continuous work flow cannot use sub data flows. Therefore, the Data Transfer transform and "Run as a separate process" options are invalid. The software will generate a runtime validation error.
- A regular or single work flow cannot call or contain a continuous work flow.
- A real-time job cannot call a continuous work flow.
- The platform transform XML_Map cannot be used in a continuous work flow.
- The Data Integrator transforms, Data_Transfer, Table_Comparison, and XML_Pipeline cannot be used in a continuous work flow.

2.9.5.7 To specify that a job executes a continuous work flow

1. Right-click a work flow and select *Properties*
2. Select *Continuous* from the Execution type dropdown list.
3. Access the *Continuous Options* tab.
4. Specify when you want the work flow to release resources:
   - To release resources after a number of runs, select *Number of runs* and enter the number of runs. The default is 100.
   - To release resources after a number of hours, select the *After* checkbox, select *Number of hours*, and enter the number of hours.

- To release resources after a number of days, select the *After* checkbox, select *Number of days*, and enter the number of days.
- To release resources when the result of a function is not equal to zero, select the *After* checkbox, select *Result of the function is not equal to zero*, and enter the function you want to use.

5. To stop the work flow when the result of a custom function is equal to zero, select *When result of the function is equal to zero*, and enter the custom function you want to use.
6. Click *OK.*

2.9.6 Conditionals

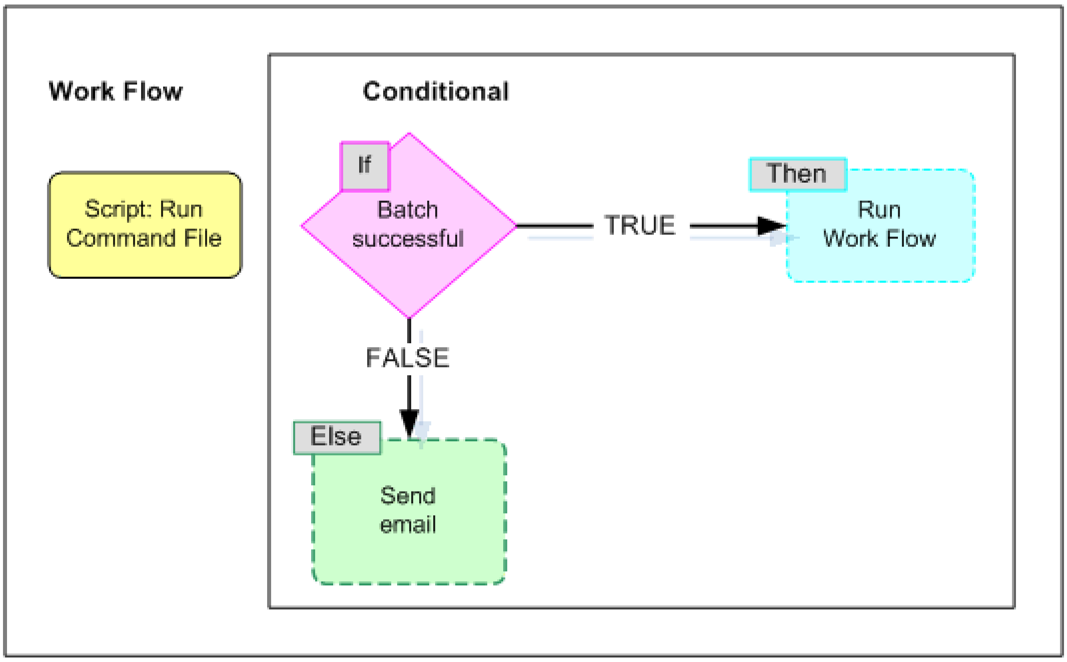
Conditionals are single-use objects used to implement if/then/else logic in a work flow. Conditionals and their components (if expressions, then and else diagrams) are included in the scope of the parent control flow's variables and parameters.

To define a conditional, you specify a condition and two logical branches:

Conditional branch	Description
If	A Boolean expression that evaluates to TRUE or FALSE. You can use functions, variables, and standard operators to construct the expression.
Then	Work flow elements to execute if the *If* expression evaluates to TRUE.
Else	(Optional) Work flow elements to execute if the *If* expression evaluates to FALSE.

Define the *Then* and *Else* branches inside the definition of the conditional.

A conditional can fit in a work flow. Suppose you use a Windows command file to transfer data from a legacy system into the software. You write a script in a work flow to run the command file and return a success flag. You then define a conditional that reads the success flag to determine if the data is available for the rest of the work flow.



To implement this conditional in the software, you define two work flows—one for each branch of the conditional. If the elements in each branch are simple, you can define them in the conditional editor itself.

Both the *Then* and *Else* branches of the conditional can contain any object that you can have in a work flow including other work flows, nested conditionals, try/catch blocks, and so on.

2.9.6.1 To define a conditional

1. Define the work flows that are called by the *Then* and *Else* branches of the conditional.

   It is recommended that you define, test, and save each work flow as a separate object rather than constructing these work flows inside the conditional editor.
2. Open the work flow in which you want to place the conditional.
3. Click the icon for a conditional in the tool palette.
4. Click the location where you want to place the conditional in the diagram.

   The conditional appears in the diagram.
5. Click the name of the conditional to open the conditional editor.
6. Click *if*.
7. Enter the Boolean expression that controls the conditional.

   Continue building your expression. You might want to use the function wizard or smart editor.
8. After you complete the expression, click *OK*.
9. Add your predefined work flow to the *Then* box.

   To add an existing work flow, open the object library to the Work Flows tab, select the desired work flow, then drag it into the Then box.

10. (Optional) Add your predefined work flow to the *Else* box.

    If the If expression evaluates to FALSE and the Else box is blank, the software exits the conditional and continues with the work flow.
11. After you complete the conditional, choose *DebugValidate*.

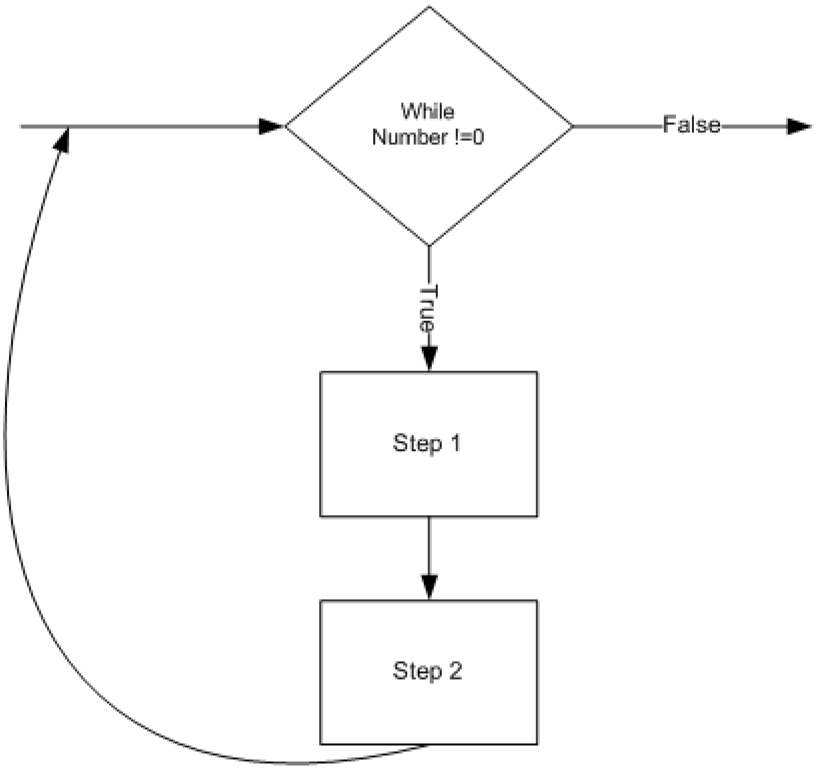
    The software tests your conditional for syntax errors and displays any errors encountered.
12. The conditional is now defined. Click the *Back* button to return to the work flow that calls the conditional.

2.9.7 While loops

Use a while loop to repeat a sequence of steps in a work flow as long as a condition is true.

2.9.7.1 Design considerations

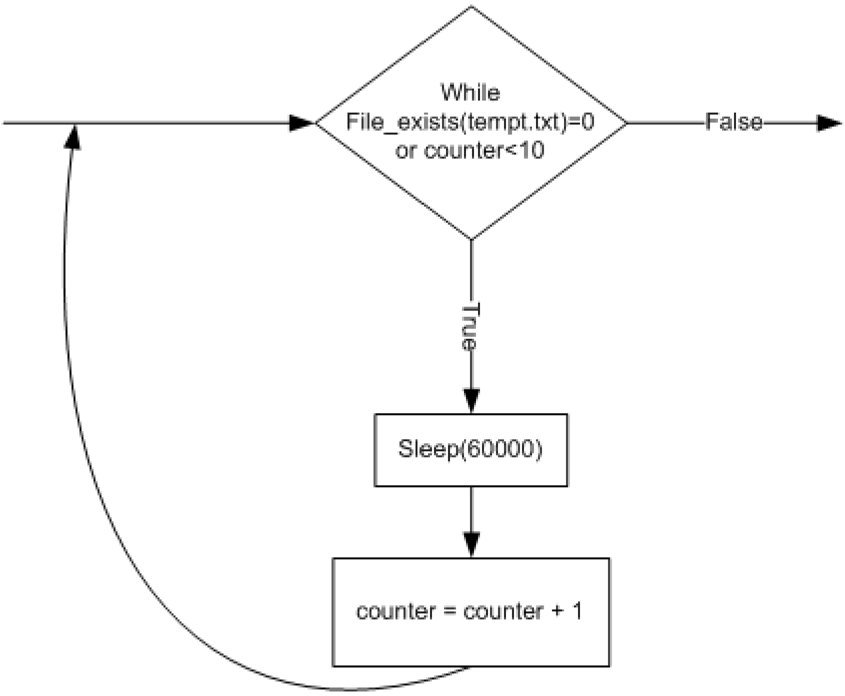
The while loop is a single-use object that you can use in a work flow. The while loop repeats a sequence of steps as long as a condition is true.



Typically, the steps done during the while loop result in a change in the condition so that the condition is eventually no longer satisfied and the work flow exits from the while loop. If the condition does not change, the while loop will not end.

For example, you might want a work flow to wait until the system writes a particular file. You can use a while loop to check for the existence of the file using the `file_exists` function. As long as the file does not exist, you can have the work flow go into sleep mode for a particular length of time, say one minute, before checking again.

Because the system might never write the file, you must add another check to the loop, such as a counter, to ensure that the while loop eventually exits. In other words, change the while loop to check for the existence of the file and the value of the counter. As long as the file does not exist and the counter is less than a particular value, repeat the while loop. In each iteration of the loop, put the work flow in sleep mode and then increment the counter.



2.9.7.2 Defining a while loop

You can define a while loop in any work flow.

2.9.7.2.1 To define a while loop

1. Open the work flow where you want to place the while loop.
2. Click the while loop icon on the tool palette.
3. Click the location where you want to place the while loop in the workspace diagram.

   The while loop appears in the diagram.
4. Click the while loop to open the while loop editor.
5. In the *While* box at the top of the editor, enter the condition that must apply to initiate and repeat the steps in the while loop.

   Alternatively, click to open the expression editor, which gives you more space to enter an expression and access to the function wizard. Click OK after you enter an expression in the editor.

6. Add the steps you want completed during the while loop to the workspace in the while loop editor.

   You can add any objects valid in a work flow including scripts, work flows, and data flows. Connect these objects to represent the order that you want the steps completed.

   > **Note**
   >
   > Although you can include the parent work flow in the while loop, recursive calls can create an infinite loop.

7. After defining the steps in the while loop, choose *Debug* > *Validate*.

   The software tests your definition for syntax errors and displays any errors encountered.
8. Close the while loop editor to return to the calling work flow.

2.9.7.3 Using a while loop with View Data

When using View Data, a job stops when the software has retrieved the specified number of rows for all scannable objects.

Depending on the design of your job, the software might not complete all iterations of a while loop if you run a job in view data mode:

- If the while loop contains scannable objects and there are no scannable objects outside the while loop (for example, if the while loop is the last object in a job), then the job will complete after the scannable objects in the while loop are satisfied, possibly after the first iteration of the while loop.
- If there are scannable objects after the while loop, the while loop will complete normally. Scanned objects in the while loop will show results from the last iteration.
- If there are no scannable objects following the while loop but there are scannable objects completed in parallel to the while loop, the job will complete as soon as all scannable objects are satisfied. The while loop might complete any number of iterations.

2.9.8 Try/catch blocks

A try/catch block is a combination of one try object and one or more catch objects that allow you to specify alternative work flows if errors occur while the software is executing a job. Try/catch blocks:

- "Catch" groups of exceptions "thrown" by the software, the DBMS, or the operating system.
- Apply solutions that you provide for the exceptions groups or for specific errors within a group.
- Continue execution.

Try and catch objects are single-use objects.

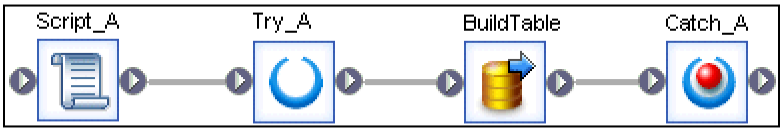
Here's the general method to implement exception handling:

1. Insert a try object before the steps for which you are handling errors.
2. Insert a catch object in the work flow after the steps.
3. In the catch object, do the following:
   - ○ Select one or more groups of errors that you want to catch.

- Define the actions that a thrown exception executes. The actions can be a single script object, a data flow, a work flow, or a combination of these objects.
- Optional. Use catch functions inside the catch block to identify details of the error.

If an exception is thrown during the execution of a try/catch block and if no catch object is looking for that exception, then the exception is handled by normal error logic.

The following work flow shows a try/catch block surrounding a data flow:



In this case, if the data flow BuildTable causes any system-generated exceptions specified in the catch Catch_A, then the actions defined in Catch_A execute.

The action initiated by the catch object can be simple or complex. Here are some examples of possible exception actions:

- Send the error message to an online reporting database or to your support group.
- Rerun a failed work flow or data flow.
- Run a scaled-down version of a failed work flow or data flow.

Related Information

Defining a Try/Catch block [page 338]

Categories of available exceptions [page 340]

Example: Catching details of an error [page 340]

Reference Guide: Objects, Catch [page 846]

2.9.8.1 Defining a try/catch block

To define a try/catch block:

1. Open the work flow that will include the try/catch block.
2. Click the try icon in the tool palette.
3. Click the location where you want to place the try in the diagram.

   The try icon appears in the diagram.

   > Note
   >
   > There is no editor for a try; the try merely initiates the try/catch block.

4. Click the catch icon in the tool palette.

5. Click the location where you want to place the catch object in the work space.

   The catch object appears in the work space.
6. Connect the try and catch objects to the objects they enclose.
7. Click the name of the catch object to open the catch editor.
8. Select one or more groups from the list of *Exceptions*.

   To select all exception groups, click the check box at the top.
9. Define the actions to take for each exception group and add the actions to the catch work flow box. The actions can be an individual script, a data flow, a work flow, or any combination of these objects.
   a) It is recommended that you define, test, and save the actions as a separate object rather than constructing them inside the catch editor.
   b) If you want to define actions for specific errors, use the following catch functions in a script that the work flow executes:
      - error_context()
      - error_message()
      - error_number()
      - error_timestamp()
   c) To add an existing work flow to the catch work flow box, open the object library to the Work Flows tab, select the desired work flow, and drag it into the box.
10. After you have completed the catch, choose *Validation* > *Validate* > *All Objects in View*.

    The software tests your definition for syntax errors and displays any errors encountered.
11. Click the *Back* button to return to the work flow that calls the catch.
12. If you want to catch multiple exception groups and assign different actions to each exception group, repeat steps 4 through 11 for each catch in the work flow.

    > Note
    >
    > In a sequence of catch blocks, if one catch block catches an exception, the subsequent catch blocks will not be executed. For example, if your work flow has the following sequence and Catch1 catches an exception, then Catch2 and CatchAll will not execute.
    >
    > ```
    > Try > DataFlow1 > Catch1 > Catch2 > CatchAll
    > ```

If any error in the exception group listed in the catch occurs during the execution of this try/catch block, the software executes the catch work flow.

Related Information

Categories of available exceptions [page 340]
Example: Catching details of an error [page 340]
Reference Guide: Objects, Catch [page 846]

2.9.8.2 Categories of available exceptions

Categories of available exceptions include:

- Execution errors (1001)
- Database access errors (1002)
- Database connection errors (1003)
- Flat file processing errors (1004)
- File access errors (1005)
- Repository access errors (1006)
- SAP system errors (1007)
- System resource exception (1008)
- SAP BW execution errors (1009)
- XML processing errors (1010)
- COBOL copybook errors (1011)
- Excel book errors (1012)
- Data Quality transform errors (1013)

2.9.8.3 Example: Catching details of an error

This example illustrates how to use the error functions in a catch script. Suppose you want to catch database access errors and send the error details to your support group.

1. In the catch editor, select the exception group that you want to catch. In this example, select the checkbox in front of *Database access errors (1002)*.
2. In the work flow area of the catch editor, create a script object with the following script:

```
mail_to('support@my.com',
  'Data Service error number' || error_number(),
  'Error message: ' || error_message(),20,20);
print('DBMS Error: ' || error_message());
```

3. This sample catch script includes the mail_to function to do the following:
   - Specify the email address of your support group.
   - Send the error number that the error_number() function returns for the exception caught.
   - Send the error message that the error_message() function returns for the exception caught.
4. The sample catch script includes a print command to print the error message for the database error.

Related Information

Reference Guide: Objects, Catch error functions [page 846]

Reference Guide: Objects, Catch scripts [page 846]

2.9.9 Scripts

Scripts are single-use objects used to call functions and assign values to variables in a work flow.

For example, you can use the SQL function in a script to determine the most recent update time for a table and then assign that value to a variable. You can then assign the variable to a parameter that passes into a data flow and identifies the rows to extract from a source.

A script can contain the following statements:

- Function calls
- If statements
- While statements
- Assignment statements
- Operators

The basic rules for the syntax of the script are as follows:

- Each line ends with a semicolon (;).
- Variable names start with a dollar sign ($).
- String values are enclosed in single quotation marks (').
- Comments start with a pound sign (#).
- Function calls always specify parameters even if the function uses no parameters.

For example, the following script statement determines today's date and assigns the value to the variable `$`**`<TODAY>`**:

```
$<TODAY> = sysdate();
```

You cannot use variables unless you declare them in the work flow that calls the script.

Related Information

Reference Guide: Data Services Scripting Language [page 1709]

2.9.9.1 To create a script

1. Open the work flow.
2. Click the script icon in the tool palette.
3. Click the location where you want to place the script in the diagram.

   The script icon appears in the diagram.
4. Click the name of the script to open the script editor.
5. Enter the script statements, each followed by a semicolon.

   The following example shows a script that determines the start time from the output of a custom function.

   ```
   AW_StartJob ('NORMAL','DELTA', $G_STIME,$GETIME);
   $GETIME =to_date(
   ```

```
sql('ODS_DS','SELECT to_char(MAX(LAST_UPDATE) ,
\'YYYY-MM-DDD HH24:MI:SS\')
FROM EMPLOYEE'),
'YYYY_MMM_DDD_HH24:MI:SS');
```

Click the function button to include functions in your script.

6. After you complete the script, select *Validation* > *Validate*.

   The software tests your script for syntax errors and displays any errors encountered.
7. Click the *...* button and then *save* to name and save your script.
   The script is saved by default in **<LINK_DIR>**/Data Services/ DataQuality/Samples.

2.9.9.2 Debugging scripts using the print function

The software has a debugging feature that allows you to print:

- The values of variables and parameters during execution
- The execution path followed within a script

You can use the print function to write the values of parameters and variables in a work flow to the trace log. For example, this line in a script:

```
print('The value of parameter $<x>: [$<x>]');
```

produces the following output in the trace log:

```
The following output is being printed via the Print function in <Session <job_name>.
The value of parameter $<x>: <value>
```

Reference Guide: Functions and Procedures, print [page 1639]

2.10 Nested Data

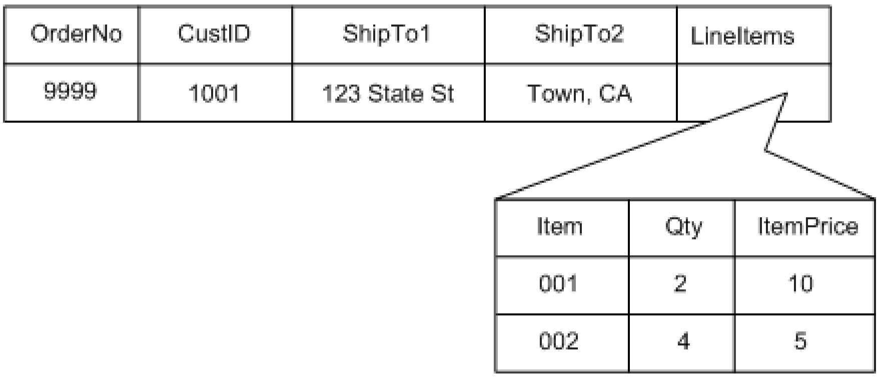
This section discusses nested data and how to use it in the software.

2.10.1 What is nested data?

Real-world data often has hierarchical relationships that are represented in a relational database with master-detail schemas using foreign keys to create the mapping. However, some data sets, such as XML documents and SAP ERP IDocs, handle hierarchical relationships through nested data.

The software maps nested data to a separate schema implicitly related to a single row and column of the parent schema. This mechanism is called Nested Relational Data Modelling (NRDM). NRDM provides a way to view and manipulate hierarchical relationships within data flow sources, targets, and transforms.

Sales orders are often presented using nesting: the line items in a sales order are related to a single header and are represented using a nested schema. Each row of the sales order data set contains a nested line item schema.



OrderNo	CustID	ShipTo1	ShipTo2	LineItems
9999	1001	123 State St	Town, CA	

Item	Qty	ItemPrice
001	2	10
002	4	5

2.10.2 Representing hierarchical data

You can represent the same hierarchical data in several ways. Examples include:

- Multiple rows in a single data set
  Order data set

OrderNo	CustID	ShipTo1	ShipTo2	Item	Qty	ItemPrice
9999	1001	123 State St	Town, CA	001	2	10
9999	1001	123 State St	Town, CA	002	4	5

- Multiple data sets related by a join
  Order header data set

OrderNo	CustID	ShipTo1	ShipTo2
9999	1001	123 State St	Town, CA

Line-item data set

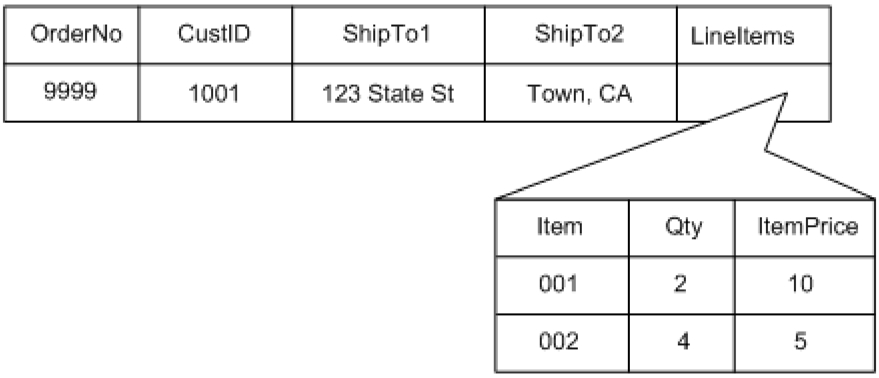
OrderNo	Item	Qty	ItemPrice
9999	001	2	10
9999	002	4	5

WHERE Header.OrderNo=LineItem.OrderNo

- Nested data

Using the nested data method can be more concise (no repeated information), and can scale to present a deeper level of hierarchical complexity. For example, columns inside a nested schema can also contain columns. There is a unique instance of each nested schema for each row at each level of the relationship.

Order data set

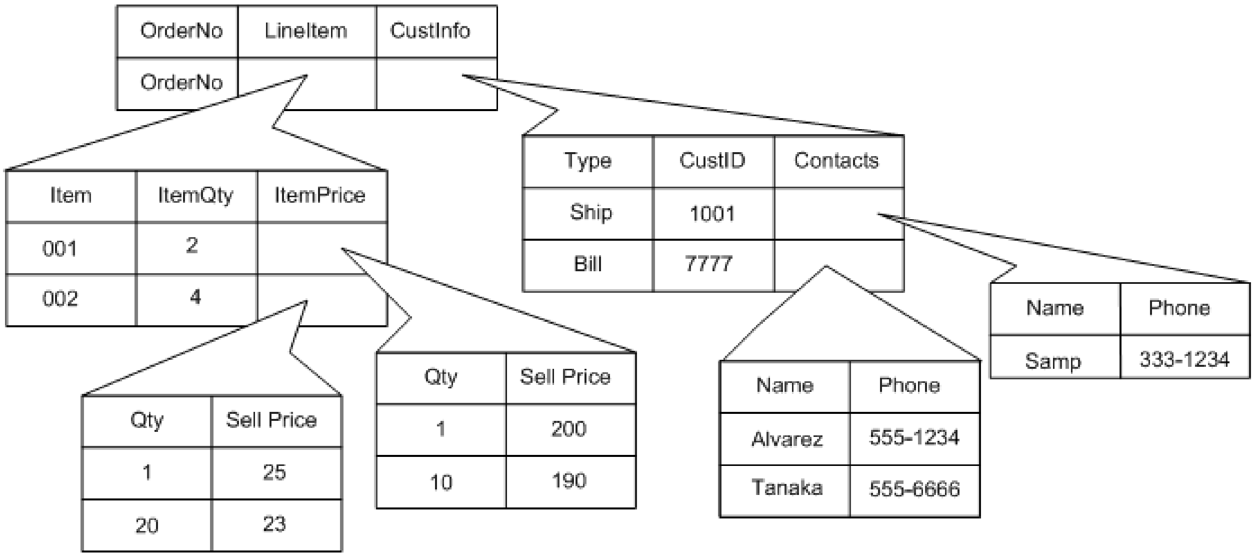


OrderNo	CustID	ShipTo1	ShipTo2	LineItems
9999	1001	123 State St	Town, CA	

Item	Qty	ItemPrice
001	2	10
002	4	5

Generalizing further with nested data, each row at each level can have any number of columns containing nested schemas.

Order data set



OrderNo	LineItem	CustInfo
OrderNo		

Item	ItemQty	ItemPrice
001	2	
002	4	

Qty	Sell Price
1	25
20	23

Qty	Sell Price
1	200
10	190

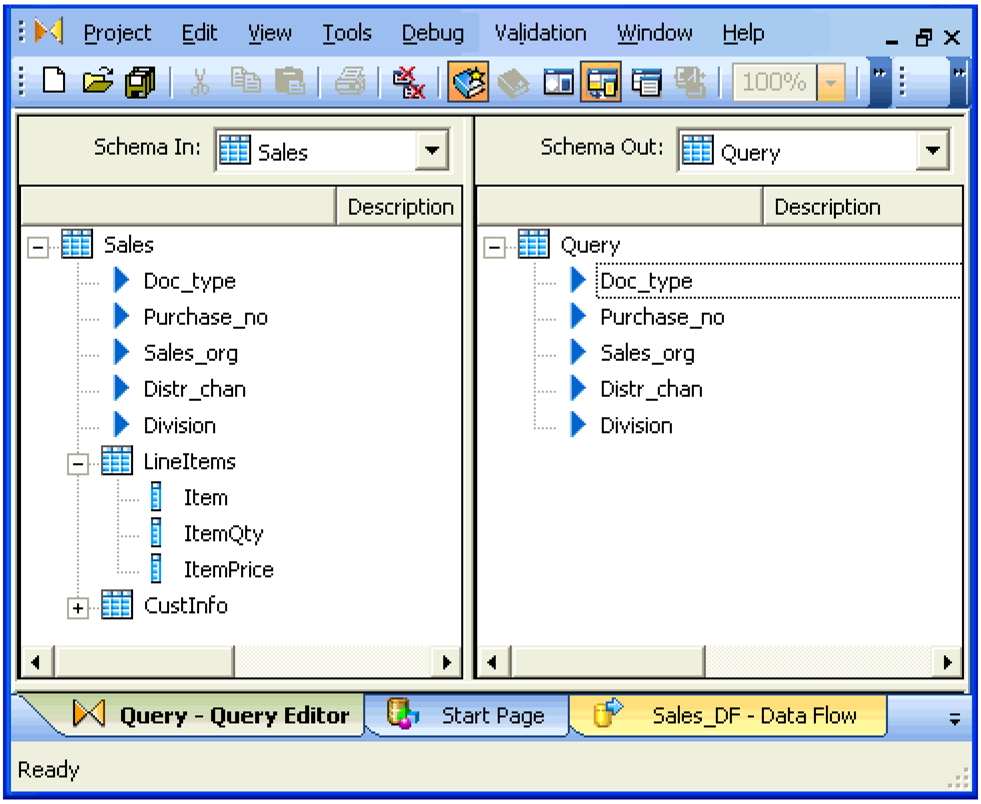
Type	CustID	Contacts
Ship	1001	
Bill	7777	

Name	Phone
Alvarez	555-1234
Tanaka	555-6666

Name	Phone
Samp	333-1234

You can see the structure of nested data in the input and output schemas of sources, targets, and transforms in data flows. Nested schemas appear with a schema icon paired with a plus sign, which indicates that the object contains columns. The structure of the schema shows how the data is ordered.

- Sales is the top-level schema.
- LineItems is a nested schema. The minus sign in front of the schema icon indicates that the column list is open.
- CustInfo is a nested schema with the column list closed.



2.10.3 Formatting XML documents

The software allows you to import and export metadata for XML documents (files or messages), which you can use as sources or targets in jobs. XML documents are hierarchical. Their valid structure is stored in separate format documents.

The format of an XML file or message (.xml) can be specified using either an XML Schema (for example, .xsd) or a document type definition (.dtd).

When you import a format document's metadata, it is structured into the software's internal schema for hierarchical documents which uses the nested relational data model (NRDM).

Related Information

Importing XML Schemas [page 346]
Specifying source options for XML files [page 350]
Mapping optional schemas [page 352]
Using Document Type Definitions (DTDs) [page 353]
Generating DTDs and XML Schemas from an NRDM schema [page 355]

2.10.3.1 Importing XML Schemas

The software supports WC3 XML Schema Specification 1.0.

For an XML document that contains information to place a sales order—order header, customer, and line items—the corresponding XML Schema includes the order structure and the relationship between data.

Message with data

OrderNo	CustID	ShipTo1	ShipTo2	LineItems		
				Item	ItemQty	ItemPrice
9999	1001	123 State St	Town, CA	001	2	10
				002	4	5

Each column in the XML document corresponds to an ELEMENT or attribute definition in the XML schema.

Corresponding XML schema

```
<?xml version="1.0"?>

<xs:schema xmlns:xs="http://www.w3.org/2001/XMLSchema">
  <xs:element name="Order">
    <xs:complexType>
      <xs:sequence>
        <xs:element name="OrderNo" type="xs:string" />
        <xs:element name="CustID" type="xs:string" />
        <xs:element name="ShipTo1" type="xs:string" />
        <xs:element name="ShipTo2" type="xs:string" />
        <xs:element maxOccurs="unbounded" name="LineItems">
          <xs:complexType>
            <xs:sequence>
              <xs:element name="Item" type="xs:string" />
              <xs:element name="ItemQty" type="xs:string" />
              <xs:element name="ItemPrice" type="xs:string" />
            </xs:sequence>
          </xs:complexType>
        </xs:element>
      </xs:sequence>
    </xs:complexType>
  </xs:element>
</xs:schema>
```

Related Information

Reference Guide: XML schema [page 1008]

2.10.3.1.1 Importing XML schemas

Import the metadata for each XML Schema you use. The object library lists imported XML Schemas in the *Formats* tab.

When importing an XML Schema, the software reads the defined elements and attributes, and then imports the following:

- Document structure
- Namespace
- Table and column names
- Data type of each column
- Content type of each column
- Nested table and column attributes
  While XML Schemas make a distinction between elements and attributes, the software imports and converts them all to nested table and column attributes.

Related Information

Reference Guide: XML schema [page 1008]

2.10.3.1.1.1 To import an XML Schema

1. From the object library, click the *Format* tab.
2. Right-click the *XML Schemas* icon and select *New*.
3. Enter the settings for the XML schemas that you import.

   When importing an XML Schema:

   - Enter the name you want to use for the format in the software.
   - Enter the file name of the XML Schema or its URL address.

     > i Note
     >
     > If your Job Server is on a different computer than the Designer, you cannot use Browse to specify the file path. You must type the path. You can type an absolute path or a relative path, but the Job Server must be able to access it.

   - If the root element name is not unique within the XML Schema, select a name in the *Namespace* drop-down list to identify the imported XML Schema.

     > i Note
     >
     > When you import an XML schema for a real-time web service job, you should use a unique target namespace for the schema. When Data Services generates the WSDL file for a real-time job with a source or target schema that has no target namespace, it adds an automatically generated target namespace to the types section of the XML schema. This can reduce performance because Data

> Services must suppress the namespace information from the web service request during processing, and then reattach the proper namespace information before returning the response to the client.

- In the *Root element name* drop-down list, select the name of the primary node that you want to import. The software only imports elements of the XML Schema that belong to this node or any subnodes.
- If the XML Schema contains recursive elements (element A contains B, element B contains A), specify the number of levels it has by entering a value in the *Circular level* box. This value must match the number of recursive levels in the XML Schema's content. Otherwise, the job that uses this XML Schema will fail.
- You can set the software to import strings as a varchar of any size. Varchar 1024 is the default.

4. Click *OK*.

After you import an XML Schema, you can edit its column properties such as data type using the *General* tab of the Column Properties window. You can also view and edit nested table and column attributes from the Column Properties window.

2.10.3.1.1.2 To view and edit nested table and column attributes for XML Schema

1. From the object library, select the *Formats* tab.
2. Expand the *XML Schema* category.
3. Double-click an XML Schema name.

   The XML Schema Format window appears in the workspace.

   The Type column displays the data types that the software uses when it imports the XML document metadata.
4. Double-click a nested table or column and select *Attributes* to view or edit XML Schema attributes.

Related Information

Reference Guide: XML schema [page 1008]

2.10.3.1.2 Importing abstract types

An XML schema uses abstract types to force substitution for a particular element or type.

- When an element is defined as abstract, a member of the element's substitution group must appear in the instance document.
- When a type is defined as abstract, the instance document must use a type derived from it (identified by the xsi:type attribute).

For example, an abstract element PublicationType can have a substitution group that consists of complex types such as MagazineType, BookType, and NewspaperType.

The default is to select all complex types in the substitution group or all derived types for the abstract type, but you can choose to select a subset.

2.10.3.1.2.1 To limit the number of derived types to import for an abstract type

1. On the Import XML Schema Format window, when you enter the file name or URL address of an XML Schema that contains an abstract type, the *Abstract type* button is enabled.

   For example, the following excerpt from an xsd defines the PublicationType element as abstract with derived types BookType and MagazineType:

   ```
   <xsd:complexType name="PublicationType" abstract="true">
       <xsd:sequence>
           <xsd:element name="Title" type="xsd:string"/>
           <xsd:element name="Author" type="xsd:string" minOccurs="0"
   maxOccurs="unbounded"/>
           <xsd:element name="Date" type="xsd:gYear"/>
       </xsd:sequence>
   </xsd:complexType>
   <xsd:complexType name="BookType">
       <xsd:complexContent>
           <xsd:extension base="PublicationType">
           <xsd:sequence>
               <xsd:element name="ISBN" type="xsd:string"/>
               <xsd:element name="Publisher" type="xsd:string"/>
           </xsd:sequence>
           </xsd:extension>
       /xsd:complexContent>
   </xsd:complexType>
   <xsd:complexType name="MagazineType">
           <xsd:complexContent>
               <xsd:restriction base="PublicationType">
                   <xsd:sequence>
                       <xsd:element name="Title" type="xsd:string"/>
                       <xsd:element name="Author" type="xsd:string" minOccurs="0"
   maxOccurs="1"/>
                       <xsd:element name="Date" type="xsd:gYear"/>
                   </xsd:sequence>
               </xsd:restriction>
           </xsd:complexContent>
       </xsd:complexType>
   ```

2. To select a subset of derived types for an abstract type, click the *Abstract type* button and take the following actions:

   a) From the drop-down list on the *Abstract type* box, select the name of the abstract type.

   b) Select the check boxes in front of each derived type name that you want to import.

   c) Click *OK*.

   > i Note
   >
   > When you edit your XML schema format, the software selects all derived types for the abstract type by default. In other words, the subset that you previously selected is not preserved.

2.10.3.1.3 Importing substitution groups

An XML schema uses substitution groups to assign elements to a special group of elements that can be substituted for a particular named element called the head element. The list of substitution groups can have hundreds or even thousands of members, but an application typically only uses a limited number of them. The default is to select all substitution groups, but you can choose to select a subset.

2.10.3.1.3.1 To limit the number of substitution groups to import

1. On the Import XML Schema Format window, when you enter the file name or URL address of an XML Schema that contains substitution groups, the *Substitution Group* button is enabled.

   For example, the following excerpt from an xsd defines the PublicationType element with substitution groups MagazineType, BookType, AdsType, and NewspaperType:

   ```
   <xsd:element name="Publication" type="PublicationType"/>
       <xsd:element name="BookStore">
           <xsd:complexType>
               <xsd:sequence>
                   <xsd:element ref="Publication" maxOccurs="unbounded"/>
               </xsd:sequence>
           </xsd:complexType>
       </xsd:element>
   <xsd:element name="Magazine" type="MagazineType"
   substitutionGroup="Publication"/>
   <xsd:element name="Book" type="BookType" substitutionGroup="Publication"/>
   <xsd:element name="Ads" type="AdsType" substitutionGroup="Publication"/>
   <xsd:element name="Newspaper" type="NewspaperType"
   substitutionGroup="Publication"/>
   ```

2. Click the *Substitution Group* button.
   a) From the drop-down list on the *Substitution group* box, select the name of the substitution group.
   b) Select the check boxes in front of each substitution group name that you want to import.
   c) Click *OK*.

> Note
>
> When you edit your XML schema format, the software selects all elements for the substitution group by default. In other words, the subset that you previously selected is not preserved.

2.10.3.2 Specifying source options for XML files

After you import metadata for XML documents (files or messages), you create a data flow to use the XML documents as sources or targets in jobs.

2.10.3.2.1 Creating a data flow with a source XML file

2.10.3.2.1.1 To create a data flow with a source XML file

1. From the object library, click the *Format* tab.
2. Expand the XML Schema and drag the XML Schema that defines your source XML file into your data flow.
3. Place a query in the data flow and connect the XML source to the input of the query.
4. Double-click the XML source in the work space to open the XML Source File Editor.
5. You must specify the name of the source XML file in the *XML file* text box.

Related Information

Reading multiple XML files at one time [page 351]
Identifying source file names [page 263]
Reference Guide: XML file source [page 954]

2.10.3.2.2 Reading multiple XML files at one time

The software can read multiple files with the same format from a single directory using a single source object.

2.10.3.2.2.1 To read multiple XML files at one time

1. Open the editor for your source XML file.
2. In *XML File* on the Source tab, enter a file name containing a wild card character (* or ?).

   For example:

   `D:\orders\1999????.xml` might read files from the year 1999.

   `D:\orders\*.xml` reads all files with the xml extension from the specified directory.

Related Information

Reference Guide: XML file source [page 954]

2.10.3.2.3 Identifying source file names

You might want to identify the source XML file for each row in your source output in the following situations:

- You specified a wildcard character to read multiple source files at one time.
- You load from a different source file on different days.

2.10.3.2.3.1 To identify the source XML file for each row in the target

1. In the XML Source File Editor, select *Include file name column*, which generates a column DI_FILENAME to contain the name of the source XML file.
2. In the Query editor, map the DI_FILENAME column from Schema In to Schema Out.
3. When you run the job, the target DI_FILENAME column will contain the source XML file name for each row in the target.

2.10.3.3 Mapping optional schemas

You can quickly specify default mapping for optional schemas without having to manually construct an empty nested table for each optional schema in the Query transform. Also, when you import XML schemas (either through DTDs or XSD files), the software automatically marks nested tables as optional if the corresponding option was set in the DTD or XSD file. The software retains this option when you copy and paste schemas into your Query transforms.

This feature is especially helpful when you have very large XML schemas with many nested levels in your jobs. When you make a schema column optional and do not provide mapping for it, the software instantiates the empty nested table when you run the job.

While a schema element is marked as optional, you can still provide a mapping for the schema by appropriately programming the corresponding sub-query block with application logic that specifies how the software should produce the output. However, if you modify any part of the sub-query block, the resulting query block must be complete and conform to normal validation rules required for a nested query block. You must map any output schema not marked as optional to a valid nested query block. The software generates a NULL in the corresponding PROJECT list slot of the ATL for any optional schema without an associated, defined sub-query block.

2.10.3.3.1 To make a nested table "optional"

1. Right-click a nested table and select *Optional* to toggle it on. To toggle it off, right-click the nested table again and select *Optional* again.
2. You can also right-click a nested table and select *Properties*, and then open the Attributes tab and set the *Optional Table* attribute value to *yes* or *no*. Click *Apply* and *OK* to set.

Note

If the Optional Table value is something other than yes or no, the nested table cannot be marked as optional.

When you run a job with a nested table set to optional and you have nothing defined for any columns and nested tables beneath that table, the software generates special ATL and does not perform user interface validation for this nested table.

Example:

```
CREATE NEW Query ( EMPNO int KEY ,

ENAME varchar(10),
JOB varchar (9)
NT1 al_nested_table ( DEPTNO int KEY ,
DNAME varchar (14),
NT2 al_nested_table (C1 int) ) SET("Optional
Table" = 'yes') )
AS SELECT EMP.EMPNO, EMP.ENAME, EMP.JOB,

NULL FROM EMP, DEPT;
```

Note

You cannot mark top-level schemas, unnested tables, or nested tables containing function calls optional.

2.10.3.4 Using Document Type Definitions (DTDs)

The format of an XML document (file or message) can be specified by a document type definition (DTD). The DTD describes the data contained in the XML document and the relationships among the elements in the data.

For an XML document that contains information to place a sales order—order header, customer, and line items—the corresponding DTD includes the order structure and the relationship between data.

Message with data

OrderNo	CustID	ShipTo1	ShipTo2	LineItems		
9999	1001	123 State St	Town, CA	Item	ItemQty	ItemPrice
				001	2	10
				002	4	5

Each column in the XML document corresponds to an ELEMENT definition.

Corresponding DTD Definition

```
<?xml encoding="UTF-8"?>
<!ELEMENT Order (OrderNo, CustID, ShipTo1, ShipTo2, LineItems+)>
<!ELEMENT OrderNo (#PCDATA)>
<!ELEMENT CustID (#PCDATA)>
<!ELEMENT ShipTo1 (#PCDATA)>
<!ELEMENT ShipTo2 (#PCDATA)>
<!ELEMENT LineItems (Item, ItemQty, ItemPrice)>
<!ELEMENT Item (#PCDATA)>
<!ELEMENT ItemQty (#PCDATA)>
<!ELEMENT ItemPrice (#PCDATA)>
```

Import the metadata for each DTD you use. The object library lists imported DTDs in the *Formats* tab.

You can import metadata from either an existing XML file (with a reference to a DTD) or DTD file. If you import the metadata from an XML file, the software automatically retrieves the DTD for that XML file.

When importing a DTD, the software reads the defined elements and attributes. The software ignores other parts of the definition, such as text and comments. This allows you to modify imported XML data and edit the data type as needed.

Related Information

Reference Guide: DTD [page 906]

2.10.3.4.1 To import a DTD or XML Schema format

1. From the object library, click the *Format* tab.
2. Right-click the *DTDs* icon and select *New*.
3. Enter settings into the Import DTD Format window:
    - In the *DTD definition name* box, enter the name that you want to give the imported DTD format in the software.
    - Enter the file that specifies the DTD you want to import.

      Note

      If your Job Server is on a different computer than the Designer, you cannot use Browse to specify the file path. You must type the path. You can type an absolute path or a relative path, but the Job Server must be able to access it.

    - If importing an XML file, select *XML* for the *File type* option. If importing a DTD file, select the *DTD* option.
    - In the *Root element name* box, select the name of the primary node that you want to import. The software only imports elements of the DTD that belong to this node or any subnodes.
    - If the DTD contains recursive elements (element A contains B, element B contains A), specify the number of levels it has by entering a value in the *Circular level* box. This value must match the number of recursive levels in the DTD's content. Otherwise, the job that uses this DTD will fail.

- ○ You can set the software to import strings as a varchar of any size. Varchar 1024 is the default.

4. Click *OK*.

After you import a DTD, you can edit its column properties, such as data type, using the *General* tab of the Column Properties window. You can also view and edit DTD nested table and column attributes from the Column Properties window.

2.10.3.4.2 To view and edit nested table and column attributes for DTDs

1. From the object library, select the *Formats* tab.
2. Expand the *DTDs* category.
3. Double-click a DTD name.

   The DTD Format window appears in the workspace.
4. Double-click a nested table or column.

   The Column Properties window opens.
5. Select the *Attributes* tab to view or edit DTD attributes.

2.10.3.5 Generating DTDs and XML Schemas from an NRDM schema

You can right-click any schema from within a query editor in the Designer and generate a DTD or an XML Schema that corresponds to the structure of the selected schema (either NRDM or relational).

This feature is useful if you want to stage data to an XML file and subsequently read it into another data flow.

1. Generate a DTD/XML Schema.
2. Use the DTD/XML Schema to setup an XML format.
3. Use the XML format to set up an XML source for the staged file.

The DTD/XML Schema generated will be based on the following information:

- Columns become either elements or attributes based on whether the XML Type attribute is set to ATTRIBUTE or ELEMENT.
- If the Required attribute is set to NO, the corresponding element or attribute is marked optional.
- Nested tables become intermediate elements.
- The Native Type attribute is used to set the type of the element or attribute.
- While generating XML Schemas, the MinOccurs and MaxOccurs values are set based on the Minimum Occurrence and Maximum Occurrence attributes of the corresponding nested table.

No other information is considered while generating the DTD or XML Schema.

2.10.4 Operations on nested data

This section discusses the operations that you can perform on nested data.

2.10.4.1 Overview of nested data and the Query transform

With relational data, a Query transform allows you to execute a SELECT statement. The mapping between input and output schemas defines the project list for the statement. When working with nested data, the Query transform provides an interface to perform SELECT statements at each level of the relationship that you define in the output schema.

You use the Query transform to manipulate nested data. If you want to extract only part of the nested data, you can use the XML_Pipeline transform.

Without nested schemas, the Query transform assumes that the FROM clause in the SELECT statement contains the data sets that are connected as inputs to the query object. When working with nested data, you must explicitly define the FROM clause in a query. The software assists by setting the top-level inputs as the default FROM clause values for the top-level output schema.

The other SELECT statement elements defined by the query work the same with nested data as they do with flat data. However, because a SELECT statement can only include references to relational data sets, a query that includes nested data includes a SELECT statement to define operations for each parent and child schema in the output.

The Query Editor contains a tab for each clause of the query:

- SELECT provides an option to specify distinct rows to output (discarding any identical duplicate rows).
- FROM lists all input schemas and allows you to specify join pairs and conditions.

The parameters you enter for the following tabs apply only to the current schema (displayed in the Schema Out text box at the top right of the Query Editor):

- WHERE
- GROUP BY
- ORDER BY

Related Information

Query Editor [page 311]
Reference Guide: XML_Pipeline [page 1119]

2.10.4.2 FROM clause construction

The FROM clause is located at the bottom of the FROM tab. It automatically populates with the information included in the Input Schema(s) section at the top, and the Join Pairs section in the middle of the tab. You can change the FROM clause by changing the selected schema in the Input Schema(s) area and the Join Pairs section.

Schemas selected in the Input Schema(s) section (and reflected in the FROM clause), including columns containing nested schemas, are available to be included in the output.

When you include more than one schema in the Input Schema(s) section (by selecting the *From* check box), you can specify join pairs and join conditions as well as enter join rank and cache for each input schema.

FROM clause descriptions and the behavior of the query are exactly the same with nested data as with relational data. The current schema allows you to distinguish multiple SELECT statements from each other within a single query. However, because the SELECT statements are dependent upon each other, and because the user interface makes it easy to construct arbitrary data sets, determining the appropriate FROM clauses for multiple levels of nesting can be complex.

A FROM clause can contain:

- Any top-level schema from the input
- Any schema that is a column of a schema in the FROM clause of the parent schema
- Any join conditions from the join pairs

The FROM clause forms a path that can start at any level of the output. The first schema in the path must always be a top-level schema from the input.

The data that a SELECT statement from a lower schema produces differs depending on whether or not a schema is included in the FROM clause at the top-level.

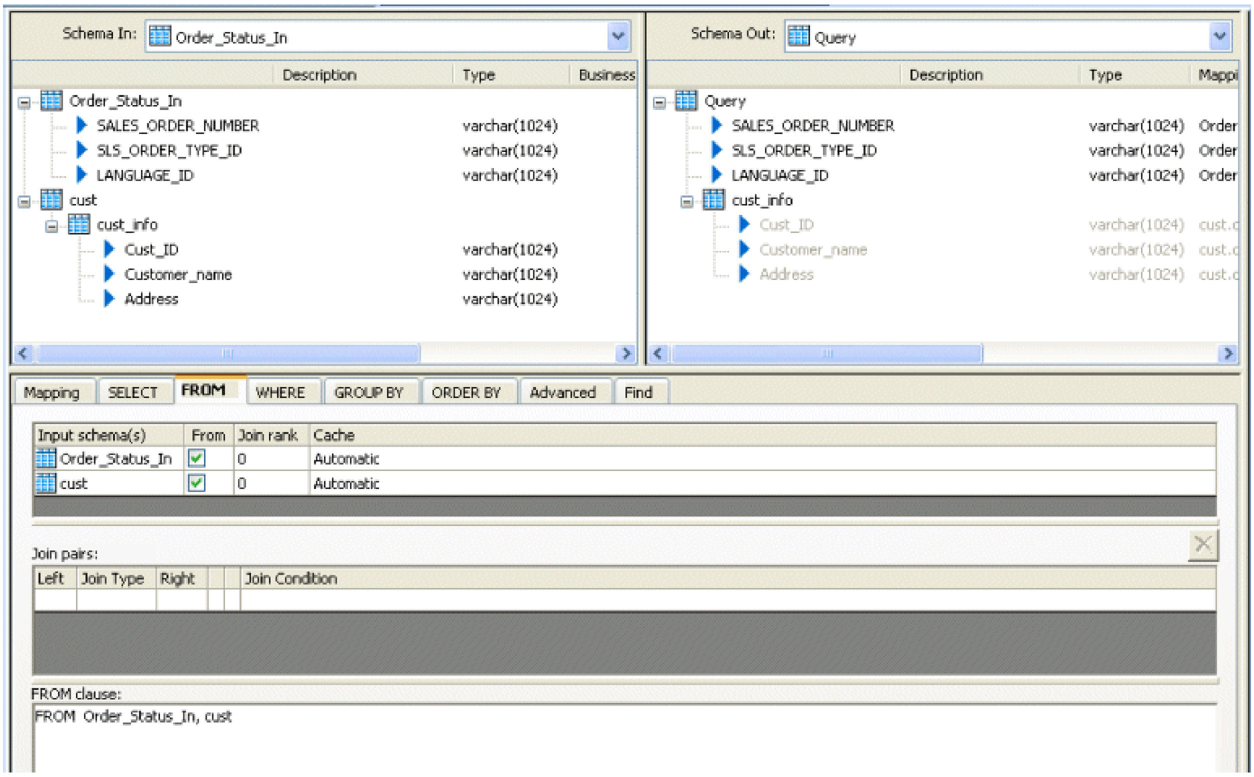
The next two examples use the sales order data set to illustrate scenarios where FROM clause values change the data resulting from the query.

Related Information

To modify the output schema contents [page 311]

2.10.4.2.1 Example: FROM clause includes all top-level inputs

To include detailed customer information for all of the orders in the output, join the Order_Status_In schema at the top level with the Cust schema. Include both input schemas at the top level in the FROM clause to produce the appropriate data. When you select both input schemas in the Input schema(s) area of the FROM tab, they automatically appear in the FROM clause.



Schema In: Order_Status_In

	Description	Type	Business
Order_Status_In			
SALES_ORDER_NUMBER		varchar(1024)	
SLS_ORDER_TYPE_ID		varchar(1024)	
LANGUAGE_ID		varchar(1024)	
cust			
cust_info			
Cust_ID		varchar(1024)	
Customer_name		varchar(1024)	
Address		varchar(1024)	

Schema Out: Query

	Description	Type	Mappi
Query			
SALES_ORDER_NUMBER		varchar(1024)	Order
SLS_ORDER_TYPE_ID		varchar(1024)	Order
LANGUAGE_ID		varchar(1024)	Order
cust_info			
Cust_ID		varchar(1024)	cust.c
Customer_name		varchar(1024)	cust.c
Address		varchar(1024)	cust.c

Input schema(s)	From	Join rank	Cache
Order_Status_In	☑	0	Automatic
cust	☑	0	Automatic

Join pairs:

Left	Join Type	Right			Join Condition

FROM clause:

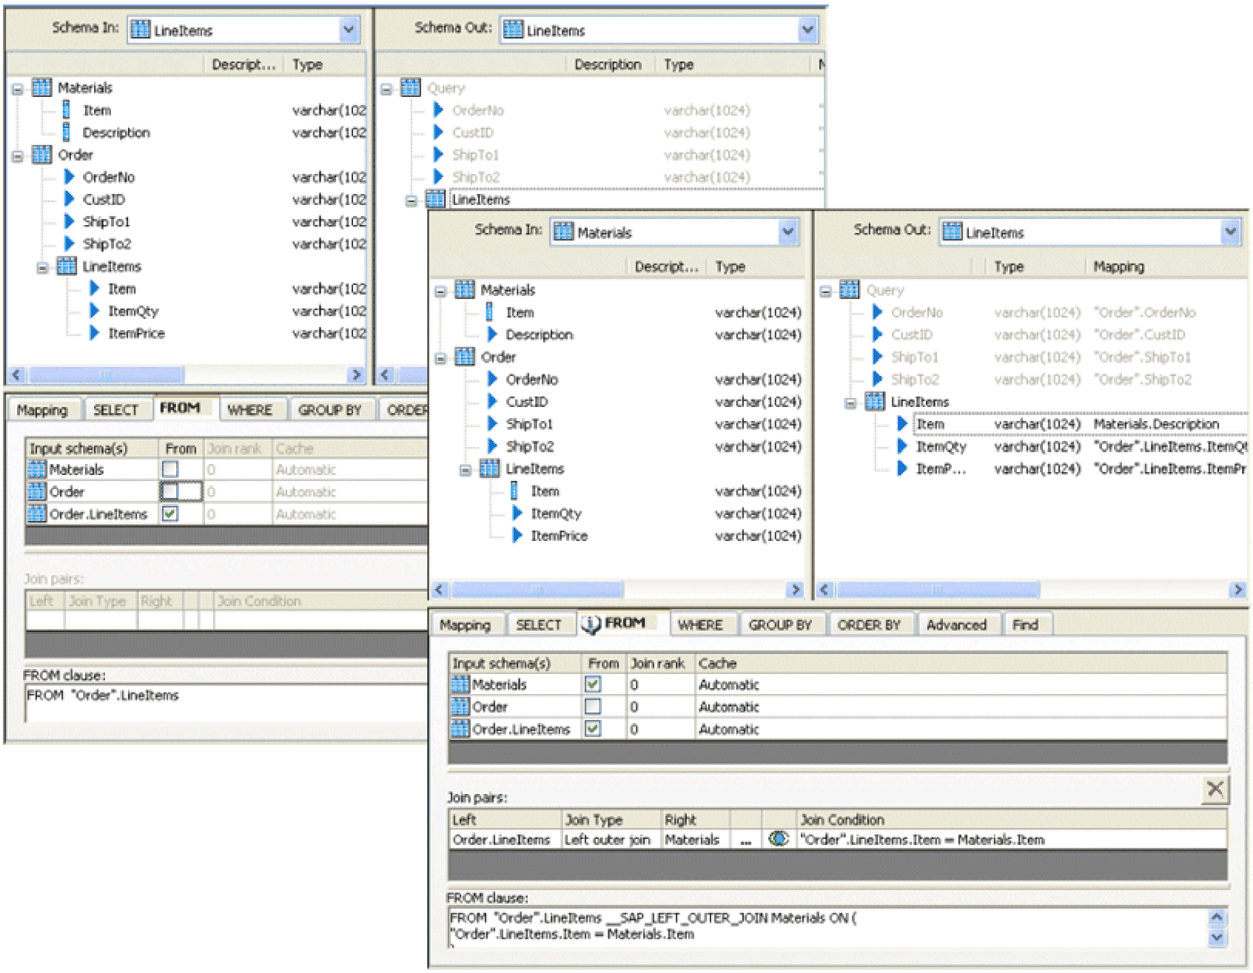
```
FROM Order_Status_In, cust
```

Observe the following points:

- The Input schema(s) table in the FROM tab includes the two top-level schemas Order_Status_In and Cust (this is also reflected in the FROM clause).
- The Schema Out pane shows the nested schema, cust_info, and the columns Cust_ID, Customer_name, and Address.

2.10.4.2.2 Example: Lower level FROM clause contains top-level input

Suppose you want the detailed information from one schema to appear for each row in a lower level of another schema. For example, the input includes a top-level Materials schema and a nested LineItems schema, and you want the output to include detailed material information for each line item. The graphic below illustrates how to set this up in the Designer.



Schema In: LineItems

	Descript...	Type
Materials		
Item		varchar(102
Description		varchar(102
Order		
OrderNo		varchar(102
CustID		varchar(102
ShipTo1		varchar(102
ShipTo2		varchar(102
LineItems		
Item		varchar(102
ItemQty		varchar(102
ItemPrice		varchar(102

Schema Out: LineItems

	Description	Type
Query		
OrderNo		varchar(1024)
CustID		varchar(1024)
ShipTo1		varchar(1024)
ShipTo2		varchar(1024)
LineItems		

Input schema(s)	From	Join rank	Cache
Materials	☐	0	Automatic
Order	☐	0	Automatic
Order.LineItems	☑	0	Automatic

Join pairs:

Left	Join Type	Right		Join Condition

FROM clause:
FROM "Order".LineItems

Schema In: Materials

	Descript...	Type
Materials		
Item		varchar(1024)
Description		varchar(1024)
Order		
OrderNo		varchar(1024)
CustID		varchar(1024)
ShipTo1		varchar(1024)
ShipTo2		varchar(1024)
LineItems		
Item		varchar(1024)
ItemQty		varchar(1024)
ItemPrice		varchar(1024)

Schema Out: LineItems

	Type	Mapping
Query		
OrderNo	varchar(1024)	"Order".OrderNo
CustID	varchar(1024)	"Order".CustID
ShipTo1	varchar(1024)	"Order".ShipTo1
ShipTo2	varchar(1024)	"Order".ShipTo2
LineItems		
Item	varchar(1024)	Materials.Description
ItemQty	varchar(1024)	"Order".LineItems.ItemQt
ItemP...	varchar(1024)	"Order".LineItems.ItemPr

Input schema(s)	From	Join rank	Cache
Materials	☑	0	Automatic
Order	☐	0	Automatic
Order.LineItems	☑	0	Automatic

Join pairs:

Left	Join Type	Right		Join Condition
Order.LineItems	Left outer join	Materials	...	"Order".LineItems.Item = Materials.Item

FROM clause:
FROM "Order".LineItems __SAP_LEFT_OUTER_JOIN Materials ON (
"Order".LineItems.Item = Materials.Item

The example on the left shows the following setup:

- The Input Schema area in the FROM tab shows the nested schema LineItems selected.
- The FROM tab shows the FROM clause "FROM "Order".LineItems".

The example on the right shows the following setup:

- The Materials.Description schema is mapped to LineItems.Item output schema.
- The Input schema(s) Materials and Order.LineItems are selected in the Input Schema area in the FROM tab (the From column has a check mark).
- A Join Pair is created joining the nested Order.LineItems schema with the top-level Materials schema using a left outer join type.
- A Join Condition is added where the Item field under the nested schema LineItems is equal to the Item field in the top-level Materials schema.

The resulting FROM clause:

```
"Order".LineItems.Item = Materials.Item
```

2.10.4.3 Nesting columns

When you nest rows of one schema inside another, the data set produced in the nested schema is the result of a query against the first one using the related values from the second one.

For example, if you have sales-order information in a header schema and a line-item schema, you can nest the line items under the header schema. The line items for a single row of the header schema are equal to the results of a query including the order number:

```
SELECT * FROM LineItems

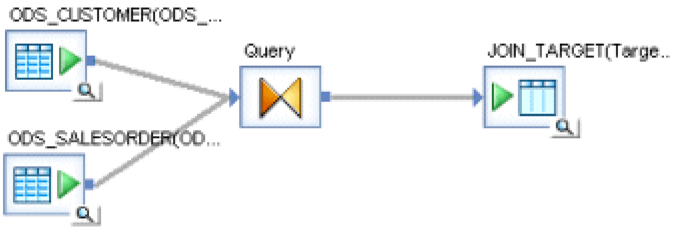
WHERE Header.OrderNo = LineItems.OrderNo
```

You can use a query transform to construct a nested data set from relational data. When you indicate the columns included in the nested schema, specify the query used to define the nested data set for each row of the parent schema.

2.10.4.3.1 To construct a nested data set

Follow the steps below to set up a nested data set.

1. Create a data flow with the input sources that you want to include in the nested data set.
2. Place a Query transform and a target table in the data flow. Connect the sources to the input of the query.



3. Open the Query transform and set up the select list, FROM clause, and WHERE clause to describe the SELECT statement that the query executes to determine the top-level data set.
   - *Select list*: Map the input schema items to the output schema by dragging the columns from the input schema to the output schema. You can also include new columns or include mapping expressions for the columns.
   - *FROM clause*: Include the input sources in the list on the *FROM* tab, and include any joins and join conditions required to define the data.
   - *WHERE clause*: Include any filtering required to define the data set for the top-level output.
4. Create a new schema in the output.

   Right-click in the Schema Out area of the Query Editor, choose *New Output Schema*, and name the new schema. A new schema icon appears in the output, nested under the top-level schema.

   You can also drag an entire schema from the input to the output.
5. Change the current output schema to the nested schema by right-clicking the nested schema and selecting *Make Current*.

The Query Editor changes to display the new current schema.

6. Indicate the FROM clause, select list, and WHERE clause to describe the SELECT statement that the query executes to determine the top-level data set.
   - *FROM clause*: If you created a new output schema, you need to drag schemas from the input to populate the FROM clause. If you dragged an existing schema from the input to the top-level output, that schema is automatically mapped and listed in the From tab.
   - *Select list*: Only columns are available that meet the requirements for the FROM clause.
   - *WHERE clause*: Only columns are available that meet the requirements for the FROM clause.
7. If the output requires it, nest another schema at this level.

   Repeat steps 4 through 6 in this current schema for as many nested schemas that you want to set up.
8. If the output requires it, nest another schema under the top level.

   Make the top-level schema the current schema.

Related Information

Query Editor [page 311]
FROM clause construction [page 357]
To modify the output schema contents [page 311]

2.10.4.4 Using correlated columns in nested data

Correlation allows you to use columns from a higher-level schema to construct a nested schema. In a nested-relational model, the columns in a nested schema are implicitly related to the columns in the parent row. To take advantage of this relationship, you can use columns from the parent schema in the construction of the nested schema. The higher-level column is a correlated column.

Including a correlated column in a nested schema can serve two purposes:

- The correlated column is a key in the parent schema. Including the key in the nested schema allows you to maintain a relationship between the two schemas after converting them from the nested data model to a relational model.
- The correlated column is an attribute in the parent schema. Including the attribute in the nested schema allows you to use the attribute to simplify correlated queries against the nested data.

To include a correlated column in a nested schema, you do not need to include the schema that includes the column in the FROM clause of the nested schema.

2.10.4.4.1 To used a correlated column in a nested schema

1. Create a data flow with a source that includes a parent schema with a nested schema.

For example, the source could be an order header schema that has a LineItems column that contains a nested schema.

2. Connect a query to the output of the source.
3. In the query editor, copy all columns of the parent schema to the output.

   In addition to the top-level columns, the software creates a column called LineItems that contains a nested schema that corresponds to the LineItems nested schema in the input.
4. Change the current schema to the LineItems schema.
5. Include a correlated column in the nested schema.

   Correlated columns can include columns from the parent schema and any other schemas in the FROM clause of the parent schema.

   For example, drag the OrderNo column from the Header schema into the LineItems schema. Including the correlated column creates a new output column in the LineItems schema called OrderNo and maps it to the Order.OrderNo column. The data set created for LineItems includes all of the LineItems columns and the OrderNo.

   If the correlated column comes from a schema other than the immediate parent, the data in the nested schema includes only the rows that match both the related values in the current row of the parent schema and the value of the correlated column.

You can always remove the correlated column from the lower-level schema in a subsequent query transform.

Related Information

Query Editor [page 311]

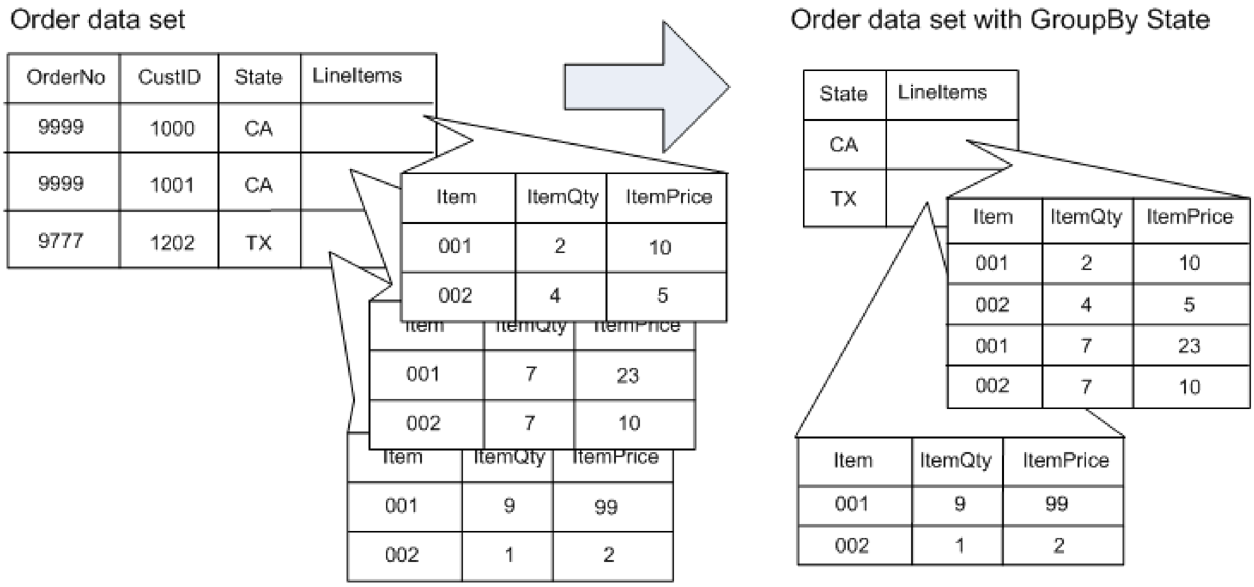
2.10.4.5 Distinct rows and nested data

The *Distinct rows* option in Query transforms removes any duplicate rows at the top level of a join. This is particularly useful to avoid cross products in joins that produce nested output.

2.10.4.6 Grouping values across nested schemas

When you specify a Group By clause for a schema with a nested schema, the grouping operation combines the nested schemas for each group.

For example, to assemble all the line items included in all the orders for each state from a set of orders, you can set the Group By clause in the top level of the data set to the state column (Order.State) and create an output schema that includes State column (set to Order.State) and LineItems nested schema.



Order data set

OrderNo	CustID	State	LineItems
9999	1000	CA	
9999	1001	CA	
9777	1202	TX	

Item	ItemQty	ItemPrice
001	2	10
002	4	5

Item	ItemQty	ItemPrice
001	7	23
002	7	10

Item	ItemQty	ItemPrice
001	9	99
002	1	2

Order data set with GroupBy State

State	LineItems
CA	
TX	

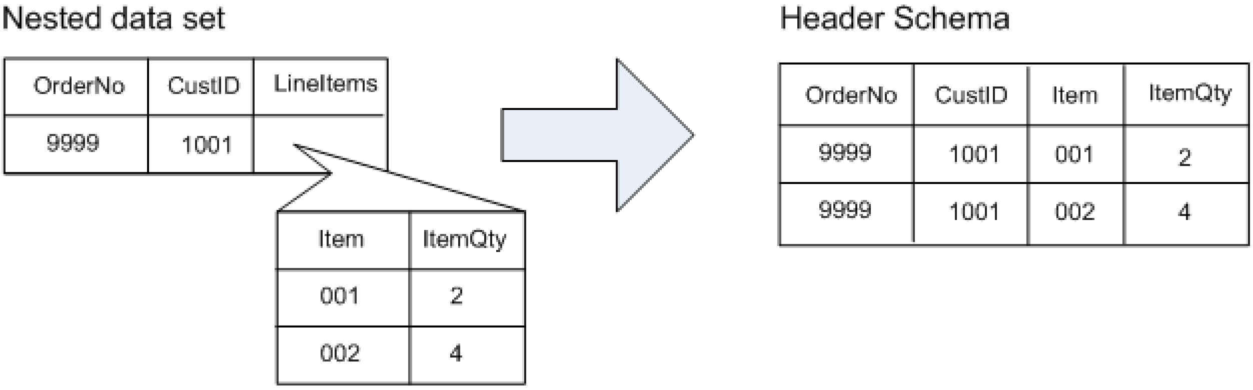
Item	ItemQty	ItemPrice
001	2	10
002	4	5
001	7	23
002	7	10

Item	ItemQty	ItemPrice
001	9	99
002	1	2

The result is a set of rows (one for each state) that has the State column and the LineItems nested schema that contains all the LineItems for all the orders for that state.

2.10.4.7 Unnesting nested data

Loading a data set that contains nested schemas into a relational (non-nested) target requires that the nested rows be unnested. For example, a sales order may use a nested schema to define the relationship between the order header and the order line items. To load the data into relational schemas, the multi-level must be unnested. Unnesting a schema produces a cross-product of the top-level schema (parent) and the nested schema (child).



Nested data set

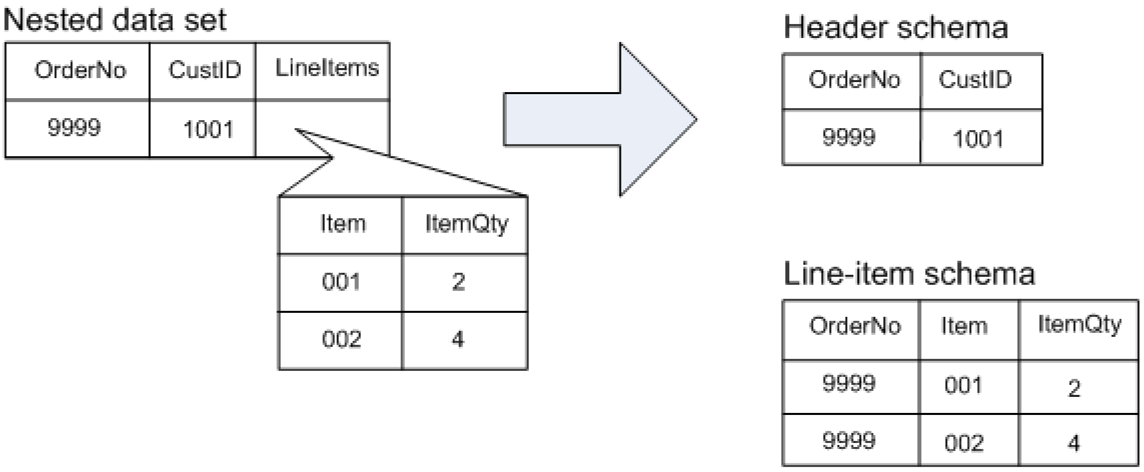
OrderNo	CustID	LineItems
9999	1001	

Item	ItemQty
001	2
002	4

Header Schema

OrderNo	CustID	Item	ItemQty
9999	1001	001	2
9999	1001	002	4

It is also possible that you would load different columns from different nesting levels into different schemas. A sales order, for example, may be flattened so that the order number is maintained separately with each line item and the header and line item information loaded into separate schemas.



Nested data set

OrderNo	CustID	LineItems
9999	1001	

Item	ItemQty
001	2
002	4

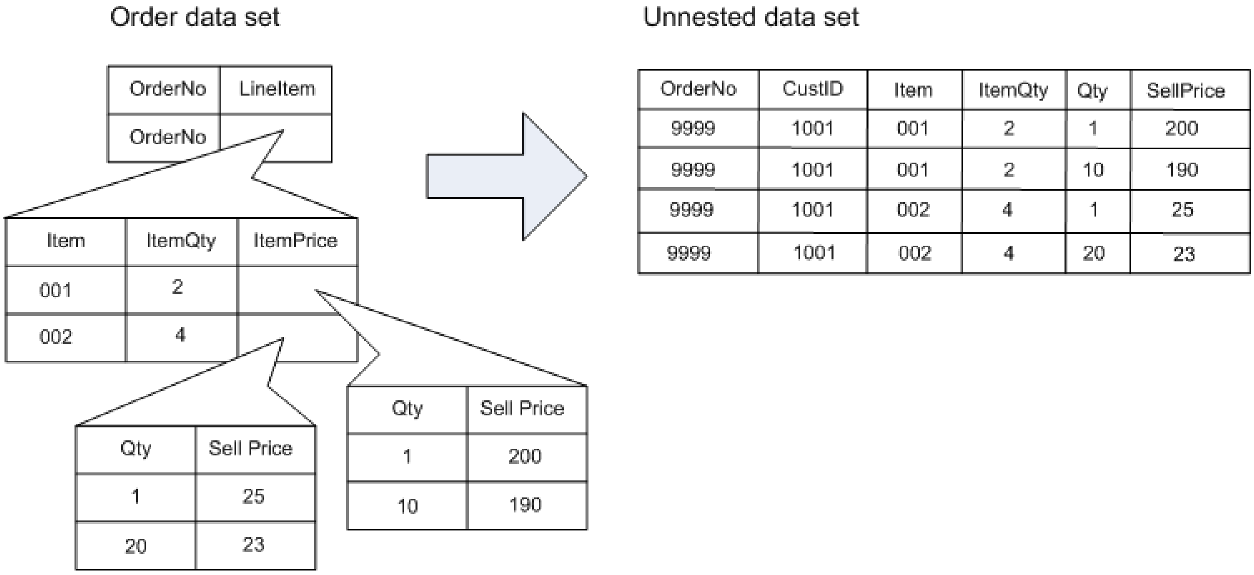
Header schema

OrderNo	CustID
9999	1001

Line-item schema

OrderNo	Item	ItemQty
9999	001	2
9999	002	4

The software allows you to unnest any number of nested schemas at any depth. No matter how many levels are involved, the result of unnesting schemas is a cross product of the parent and child schemas. When more than one level of unnesting occurs, the inner-most child is unnested first, then the result—the cross product of the parent and the inner-most child—is then unnested from its parent, and so on to the top-level schema.



Order data set

OrderNo	LineItem
OrderNo	

Item	ItemQty	ItemPrice
001	2	
002	4	

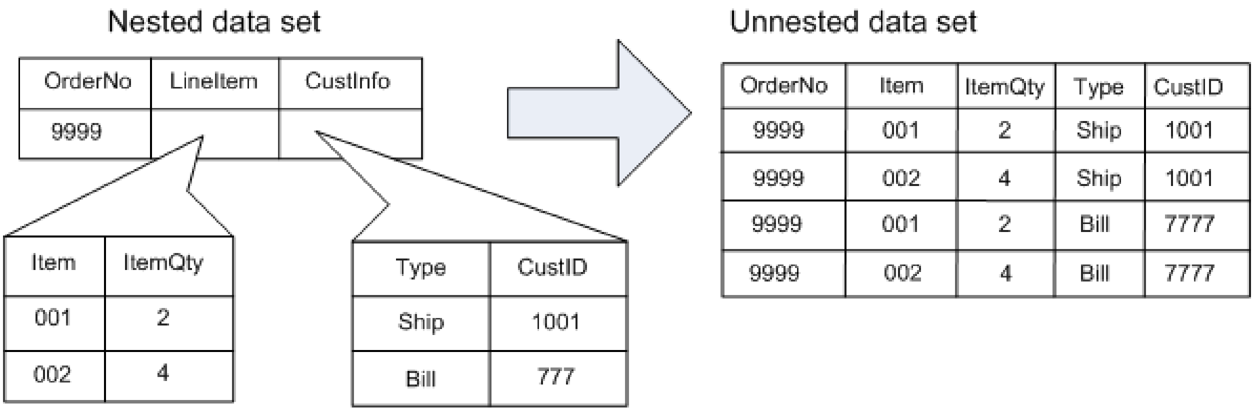
Qty	Sell Price
1	25
20	23

Qty	Sell Price
1	200
10	190

Unnested data set

OrderNo	CustID	Item	ItemQty	Qty	SellPrice
9999	1001	001	2	1	200
9999	1001	001	2	10	190
9999	1001	002	4	1	25
9999	1001	002	4	20	23

Unnesting all schemas (cross product of all data) might not produce the results that you intend. For example, if an order includes multiple customer values such as ship-to and bill-to addresses, flattening a sales order by unnesting customer and line-item schemas produces rows of data that might not be useful for processing the order.



Nested data set

OrderNo	LineItem	CustInfo
9999		

Item	ItemQty
001	2
002	4

Type	CustID
Ship	1001
Bill	777

Unnested data set

OrderNo	Item	ItemQty	Type	CustID
9999	001	2	Ship	1001
9999	002	4	Ship	1001
9999	001	2	Bill	7777
9999	002	4	Bill	7777

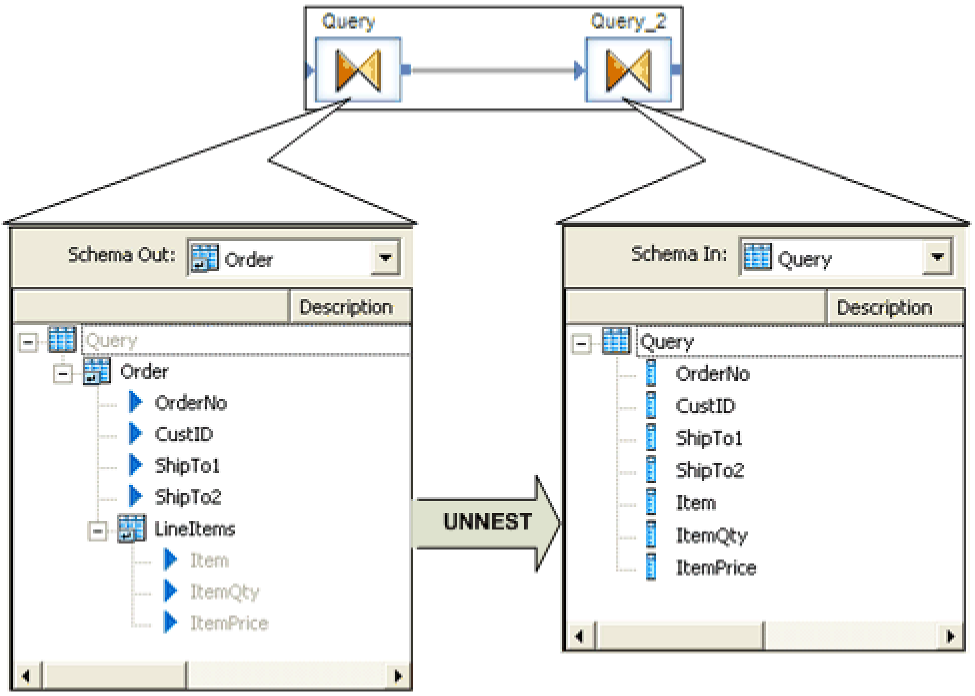
2.10.4.7.1 To unnest nested data

1. Create the output that you want to unnest in the output schema of a query.

   Data for unneeded columns or schemas might be more difficult to filter out after the unnesting operation. You can use the Cut command to remove columns or schemas from the top level; to remove nested schemas or columns inside nested schemas, make the nested schema the current schema, and then cut the unneeded columns or nested columns.

2. For each of the nested schemas that you want to unnest, right-click the schema name and choose *Unnest*.

   The output of the query (the input to the next step in the data flow) includes the data in the new relationship, as the following diagram shows.



2.10.4.8 Transforming lower levels of nested data

Nested data included in the input to transforms (with the exception of a Query or XML_Pipeline transform) passes through the transform without being included in the transform's operation. Only the columns at the first level of the input data set are available for subsequent transforms.

2.10.4.8.1 To transform values in lower levels of nested schemas

1. Take one of the following actions to obtain the nested data:
   - Use a Query transform to unnest the data.
   - Use an XML_Pipeline transform to select portions of the nested data.
   - Perform the transformation.
2. Nest the data again to reconstruct the nested relationships.

Related Information

Unnesting nested data [page 363]

Reference Guide: XML_Pipeline [page 1119]

2.10.5 XML extraction and parsing for columns

In addition to extracting XML message and file data, representing it as NRDM data during transformation, and then loading it to an XML message or file, you can also use the software to extract XML data stored in a source table or flat file column, transform it as NRDM data, and then load it to a target or flat file column.

More and more database vendors allow you to store XML in one column. The field is usually a varchar, long, or clob. The software's XML handling capability also supports reading from and writing to such fields. The software provides four functions to support extracting from and loading to columns:

- extract_from_xml
- load_to_xml
- long_to_varchar
- varchar_to_long

The extract_from_xml function gets the XML content stored in a single column and builds the corresponding NRDM structure so that the software can transform it. This function takes varchar data only.

To enable extracting and parsing for columns, data from long and clob columns must be converted to varchar before it can be transformed by the software.

- The software converts a clob data type input to varchar if you select the *Import unsupported data types as VARCHAR of size* option when you create a database datastore connection in the Datastore Editor.

- If your source uses a long data type, use the long_to_varchar function to convert data to varchar.

> **Note**
>
> The software limits the size of the XML supported with these methods to 100K due to the current limitation of its varchar data type. There are plans to lift this restriction in the future.

The function load_to_xml generates XML from a given NRDM structure in the software, then loads the generated XML to a varchar column. If you want a job to convert the output to a long column, use the varchar_to_long function, which takes the output of the load_to_xml function as input.

2.10.5.1 Sample scenarios

The following scenarios describe how to use functions to extract XML data from a source column and load it into a target column.

Related Information

Extracting XML data from a column into the software [page 367]
Loading XML data into a column of the data type long [page 369]
Extracting data quality XML strings using extract_from_xml function [page 370]

2.10.5.1.1 Extracting XML data from a column into the software

This scenario uses long_to_varchar and extract_from_xml functions to extract XML data from a column with data of the type long.

1. First, assume you have previously performed the following steps:
   a) Imported an Oracle table that contains a column named *Content* with the data type long, which contains XML data for a purchase order.
   b) Imported the XML Schema PO.xsd, which provides the format for the XML data, into the repository.
   c) Created a Project, a job, and a data flow for your design.
   d) Opened the data flow and dropped the source table with the column named *content* in the data flow.
2. From this point:
   a) Create a query with an output column of data type varchar, and make sure that its size is big enough to hold the XML data.
   b) Name this output column *content*.
   c) In the Map section of the query editor, open the Function Wizard, select the *Conversion* function type, then select the *long_to_varchar* function and configure it by entering its parameters.

```
long_to_varchar(content, 4000)
```

The second parameter in this function (4000 in this case) is the maximum size of the XML data stored in the table column. Use this parameter with caution. If the size is not big enough to hold the maximum XML data for the column, the software will truncate the data and cause a runtime error. Conversely, do not enter a number that is too big, which would waste computer memory at runtime.

d) In the query editor, map the source table column to a new output column.

e) Create a second query that uses the function extract_from_xml to extract the XML data.

To invoke the function extract_from_xml, right-click the current context in the query, choose *New Function Call*.

When the Function Wizard opens, select Conversion and extract_from_xml.

> ℹ Note
>
> You can only use the extract_from_xml function in a new function call. Otherwise, this function is not displayed in the function wizard.

f) Enter values for the input parameters.

- The first is the XML column name. Enter *content*, which is the output column in the previous query that holds the XML data
- The second parameter is the DTD or XML Schema name. Enter the name of the purchase order schema (in this case *PO*)
- The third parameter is Enable validation. Enter `1` if you want the software to validate the XML with the specified Schema. Enter `0` if you do not.

g) Click *Next*.

h) For the function, select a column or columns that you want to use on output.

Imagine that this purchase order schema has five top-level elements: orderDate, shipTo, billTo, comment, and items. You can select any number of the top-level columns from an XML schema, which include either scalar or NRDM column data. The return type of the column is defined in the schema. If the function fails due to an error when trying to produce the XML output, the software returns NULL for scalar columns and empty nested tables for NRDM columns.

The extract_from_xml function also adds two columns:

- AL_ERROR_NUM — returns error codes: `0` for success and a non-zero integer for failures
- AL_ERROR_MSG — returns an error message if AL_ERROR_NUM is not `0`. Returns NULL if AL_ERROR_NUM is `0`

Choose one or more of these columns as the appropriate output for the extract_from_xml function.

i) Click *Finish*.

The software generates the function call in the current context and populates the output schema of the query with the output columns you specified.

With the data converted into the NRDM structure, you are ready to do appropriate transformation operations on it.

For example, if you want to load the NRDM structure to a target XML file, create an XML file target and connect the second query to it.

ℹ Note

If you find that you want to modify the function call, right-click the function call in the second query and choose *Modify Function Call*.

In this example, to extract XML data from a column of data type long, we created two queries: the first query to convert the data using the long_to_varchar function and the second query to add the extract_from_xml function.

Alternatively, you can use just one query by entering the function expression long_to_varchar directly into the first parameter of the function extract_from_xml. The first parameter of the function extract_from_xml can take a column of data type varchar or an expression that returns data of type varchar.

If the data type of the source column is not long but varchar, do not include the function long_to_varchar in your data flow.

2.10.5.1.2 Loading XML data into a column of the data type long

This scenario uses the load_to_xml function and the varchar_to_long function to convert an NRDM structure to scalar data of the varchar type in an XML format and load it to a column of the data type long.

In this example, you want to convert an NRDM structure for a purchase order to XML data using the function load_to_xml, and then load the data to an Oracle table column called *content*, which is of the long data type. Because the function load_to_xml returns a value of varchar data type, you use the function varchar_to_long to convert the value of varchar data type to a value of the data type long.

1. Create a query and connect a previous query or source (that has the NRDM structure of a purchase order) to it. In this query, create an output column of the data type varchar called *content*. Make sure the size of the column is big enough to hold the XML data.
2. From the *Mapping* area open the function wizard, click the category *Conversion Functions*, and then select the function *load_to_xml*.
3. Click *Next*.
4. Enter values for the input parameters.

   The function load_to_xml has seven parameters.
5. Click *Finish*.

   In the mapping area of the Query window, notice the function expression:

   ```
   load_to_xml(PO, 'PO', 1, '<?xml version="1.0" encoding = "UTF-8" ?>', NULL, 1,
   4000)
   ```

   In this example, this function converts the NRDM structure of purchase order PO to XML data and assigns the value to output column content.
6. Create another query with output columns matching the columns of the target table.
   a) Assume the column is called *content* and it is of the data type long.
   b) Open the function wizard from the mapping section of the query and select the *Conversion Functions* category
   c) Use the function varchar_to_long to map the input column *content* to the output column *content*.

The function varchar_to_long takes only one input parameter.

d) Enter a value for the input parameter.

```
varchar_to_long(content)
```

7. Connect this query to a database target.

Like the example using the extract_from_xml function, in this example, you used two queries. You used the first query to convert an NRDM structure to XML data and to assign the value to a column of varchar data type. You used the second query to convert the varchar data type to long.

You can use just one query if you use the two functions in one expression:

```
varchar_to_long( load_to_xml(PO, 'PO', 1, '<?xml version="1.0" encoding = "UTF-8" ?
>', NULL, 1, 4000) )
```

If the data type of the column in the target database table that stores the XML data is varchar, there is no need for varchar_to_long in the transformation.

Reference Guide: Functions and Procedure [page 1511]

2.10.5.1.3 Extracting data quality XML strings using extract_from_xml function

This scenario uses the extract_from_xml function to extract XML data from the Geocoder, Global Suggestion Lists, Global Address Cleanse, and USA Regulatory Address Cleanse transforms.

The Geocoder transform, Global Suggestion Lists transform, and the suggestion list functionality in the Global Address Cleanse and USA Regulatory Address Cleanse transforms can output a field that contains an XML string. The transforms output the following fields that can contain XML.

Transform	XML output field	Output field description
Geocoder	Result_List	Contains an XML output string when multiple records are returned for a search. The content depends on the available data.
Global Address Cleanse Global Suggestion List USA Regulatory Address Cleanse	Suggestion_List	Contains an XML output string that includes all of the suggestion list component field values specified in the transform options.

Transform	XML output field	Output field description
		To output these fields as XML, you must choose XML as the output style in the transform options.

To use the data contained within the XML strings (for example, in a web application that uses the job published as a web service), you must extract the data. There are two methods that you can use to extract the data:

1. Insert a Query transform using the extract_from_xml function.
   With this method, you insert a Query transform into the data flow after the Geocoder, Global Suggestion Lists, Global Address Cleanse, or USA Regulatory Address Cleanse transform. Then you use the extract_from_xml function to parse the nested output data.
   This method is considered a best practice, because it provides parsed output data that is easily accessible to an integrator.
2. Develop a simple data flow that does not unnest the nested data.
   With this method, you simply output the output field that contains the XML string without unnesting the nested data.
   This method allows the application developer, or integrator, to dynamically select the output components in the final output schema before exposing it as a web service. The application developer must work closely with the data flow designer to understand the data flow behind a real-time web service. The application developer must understand the transform options and specify what to return from the return address suggestion list, and then unnest the XML output string to generate discrete address elements.

2.10.5.1.3.1 To extract data quality XML strings using extract_from_xml function

1. Create an XSD file for the output.
2. In the Format tab of the Local Object Library, create an XML Schema for your output XSD.
3. In the Format tab of the Local Object Library, create an XML Schema for the `gac_suggestion_list.xsd`, `global_suggestion_list.xsd`,`urac_suggestion_list.xsd`, or `result_list.xsd`.
4. In the data flow, include the following field in the Schema Out of the transform:
   - For the Global Address Cleanse, Global Suggestion Lists, and USA Regulatory Address Cleanse transforms, include the Suggestion_List field.
   - For the Geocoder transform, include the Result_List field
5. Add a Query transform after the Global Address Cleanse, Global Suggestion Lists,USA Regulatory Address Cleanse, or Geocoder transform. Complete it as follows.
6. Pass through all fields except the Suggestion_List or Result_List field from the Schema In to the Schema Out. To do this, drag fields directly from the input schema to the output schema.
7. In the Schema Out, right-click the Query node and select New Output Schema. Enter Suggestion_List or Result_List as the schema name (or whatever the field name is in your output XSD).
8. In the Schema Out, right-click the Suggestion_List or Result_List field and select Make Current.
9. In the Schema Out, right-click the Suggestion_List or Result_List list field and select New Function Call.
10. Select extract_from_xml from the Conversion Functions category and click Next. In the Define Input Parameter(s) window, enter the following information and click Next.

- ○ XML field name—Select the Suggestion_List or Result_List field from the upstream transform.
- ○ DTD or Schema name—Select the XML Schema that you created for the gac_suggestion_list.xsd, urac_suggestion_list.xsd, or result_list.xsd.
- ○ Enable validation—Enter 1 to enable validation.

11. Select LIST or RECORD from the left parameter list and click the right arrow button to add it to the Selected output parameters list.
12. Click Finish.
    The Schema Out includes the suggestion list/result list fields within the Suggestion_List or Result_List field.
13. Include the XML Schema for your output XML following the Query. Open the XML Schema to validate that the fields are the same in both the Schema In and the Schema Out.
14. If you are extracting data from a Global Address Cleanse, Global Suggestion Lists, or USA Regulatory Address Cleanse transform, and have chosen to output only a subset of the available suggestion list output fields in the Options tab, insert a second Query transform to specify the fields that you want to output. This allows you to select the output components in the final output schema before it is exposed as a web service.

2.11 Real-time Jobs

The software supports real-time data transformation. Real-time means that the software can receive requests from ERP systems and Web applications and send replies immediately after getting the requested data from a data cache or a second application. You define operations for processing on-demand messages by building real-time jobs in the Designer.

2.11.1 Request-response message processing

The message passed through a real-time system includes the information required to perform a business transaction. The content of the message can vary:

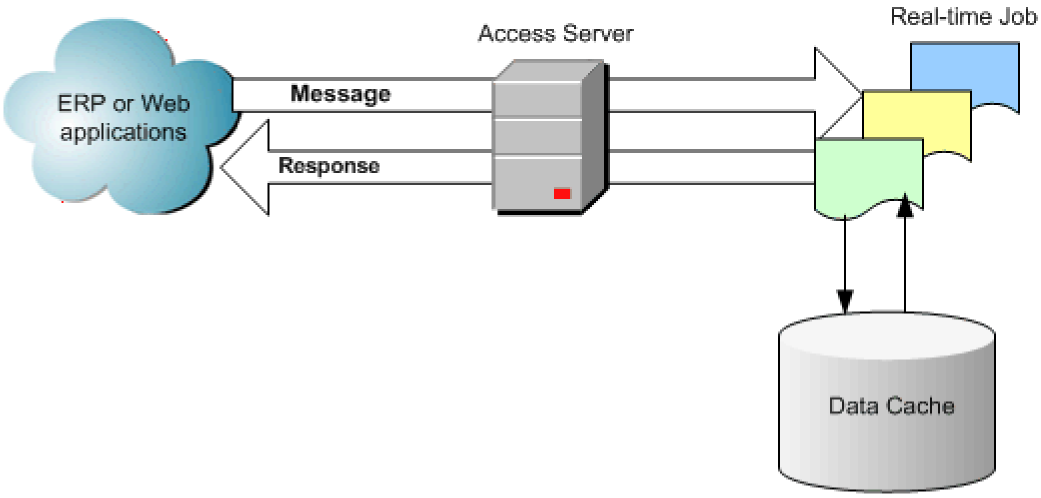
- It could be a sales order or an invoice processed by an ERP system destined for a data cache.
- It could be an order status request produced by a Web application that requires an answer from a data cache or back-office system.

The Access Server constantly listens for incoming messages. When a message is received, the Access Server routes the message to a waiting process that performs a predefined set of operations for the message type. The Access Server then receives a response for the message and replies to the originating application.

Two components support request-response message processing:

- *Access Server* — Listens for messages and routes each message based on message type.
- *Real-time job* — Performs a predefined set of operations for that message type and creates a response.

Processing might require that additional data be added to the message from a data cache or that the message data be loaded to a data cache. The Access Server returns the response to the originating application.



2.11.2 What is a real-time job?

The Designer allows you to define the processing of real-time messages using a real-time job. You create a different real-time job for each type of message your system can produce.

2.11.2.1 Real-time versus batch

Like a batch job, a real-time job extracts, transforms, and loads data. Real-time jobs "extract" data from the body of the message received and from any secondary sources used in the job. Each real-time job can extract data from a single message type. It can also extract data from other sources such as tables or files.

The same powerful transformations you can define in batch jobs are available in real-time jobs. However, you might use transforms differently in real-time jobs. For example, you might use branches and logic controls more often than you would in batch jobs. If a customer wants to know when they can pick up their order at your distribution center, you might want to create a CheckOrderStatus job using a look-up function to count order items and then a case transform to provide status in the form of strings: "No items are ready for pickup" or "X items in your order are ready for pickup" or "Your order is ready for pickup".

Also in real-time jobs, the software writes data to message targets and secondary targets in parallel. This ensures that each message receives a reply as soon as possible.

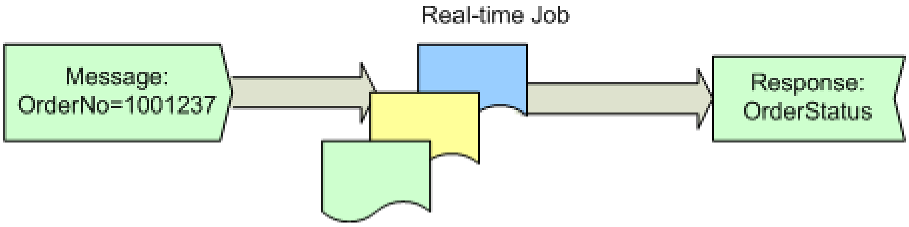
Unlike batch jobs, real-time jobs do not execute in response to a schedule or internal trigger; instead, real-time jobs execute as real-time services started through the Administrator. Real-time services then wait for messages from the Access Server. When the Access Server receives a message, it passes the message to a running real-time service designed to process this message type. The real-time service processes the message and returns a response. The real-time service continues to listen and process messages on demand until it receives an instruction to shut down.

2.11.2.2 Messages

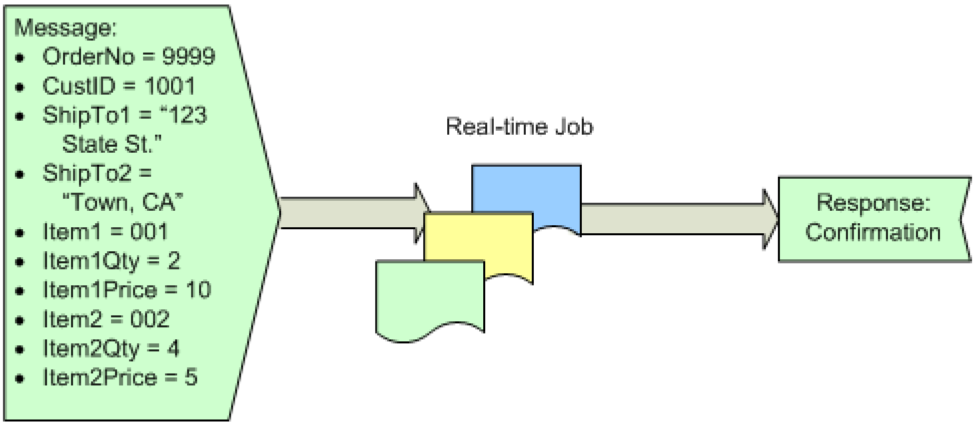
How you design a real-time job depends on what message you want it to process. Typical messages include information required to implement a particular business operation and to produce an appropriate response.

For example, suppose a message includes information required to determine order status for a particular order. The message contents might be as simple as the sales order number. The corresponding real-time job might use the input to query the right sources and return the appropriate product information.

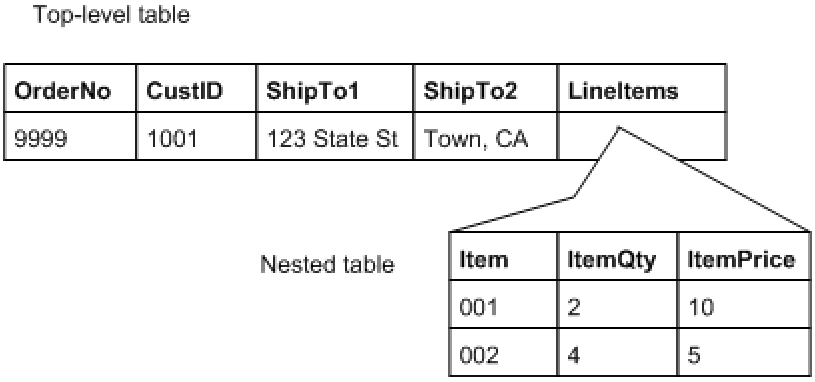
In this case, the message contains data that can be represented as a single column in a single-row table.



In a second case, a message could be a sales order to be entered into an ERP system. The message might include the order number, customer information, and the line-item details for the order. The message processing could return confirmation that the order was submitted successfully.



In this case, the message contains data that cannot be represented in a single table; the order header information can be represented by a table and the line items for the order can be represented by a second table. The software represents the header and line item data in the message in a nested relationship.



Top-level table

OrderNo	CustID	ShipTo1	ShipTo2	LineItems
9999	1001	123 State St	Town, CA	

Nested table

Item	ItemQty	ItemPrice
001	2	10
002	4	5

When processing the message, the real-time job processes all of the rows of the nested table for each row of the top-level table. In this sales order, both of the line items are processed for the single row of header information.

Real-time jobs can send only one row of data in a reply message (message target). However, you can structure message targets so that all data is contained in a single row by nesting tables within columns of a single, top-level table.

The software data flows support the nesting of tables within other tables.

Related Information

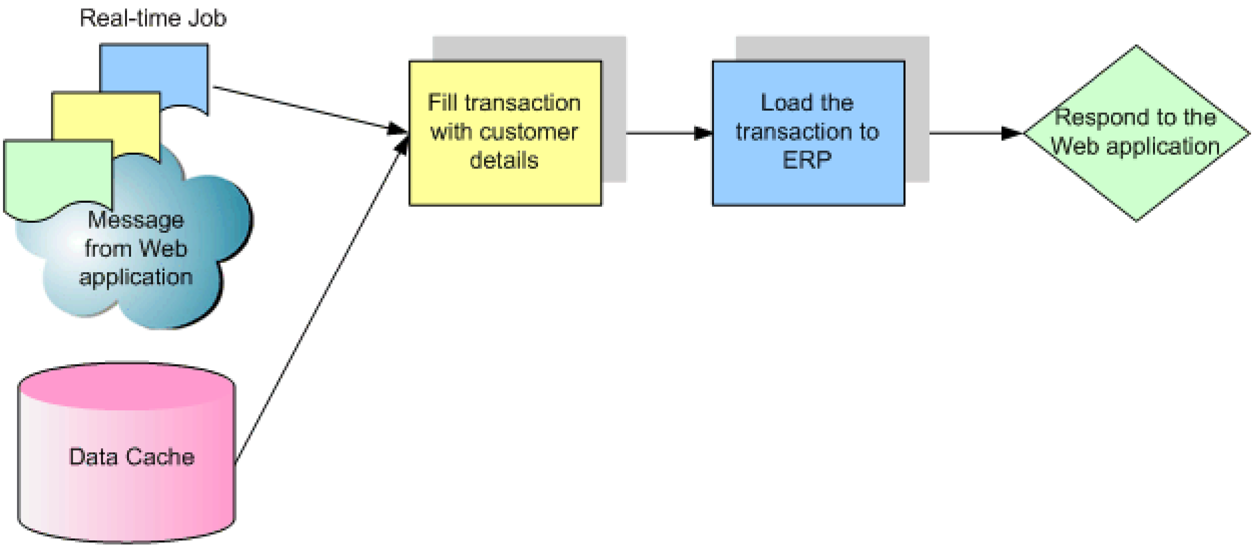
Nested Data [page 342]

2.11.2.3 Real-time job examples

These examples provide a high-level description of how real-time jobs address typical real-time scenarios. Later sections describe the actual objects that you would use to construct the logic in the Designer.

2.11.2.3.1 Loading transactions into a back-office application

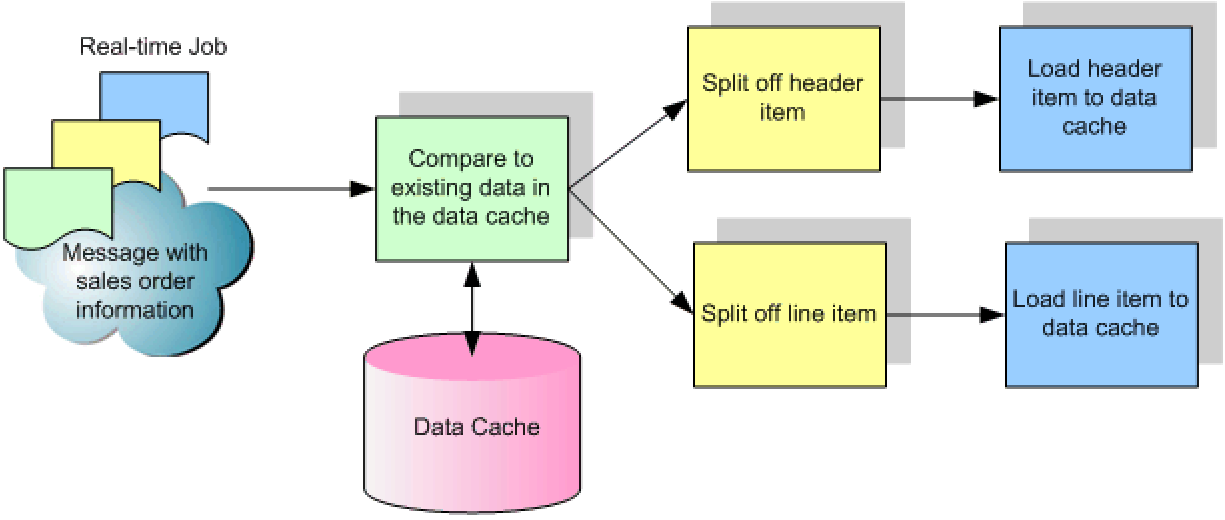
A real-time job can receive a transaction from a Web application and load it to a back-office application (ERP, SCM, legacy). Using a query transform, you can include values from a data cache to supplement the transaction before applying it against the back-office application (such as an ERP system).



Real-time Job
Message from Web application
Data Cache
Fill transaction with customer details
Load the transaction to ERP
Respond to the Web application

2.11.2.3.2 Collecting back-office data into a data cache

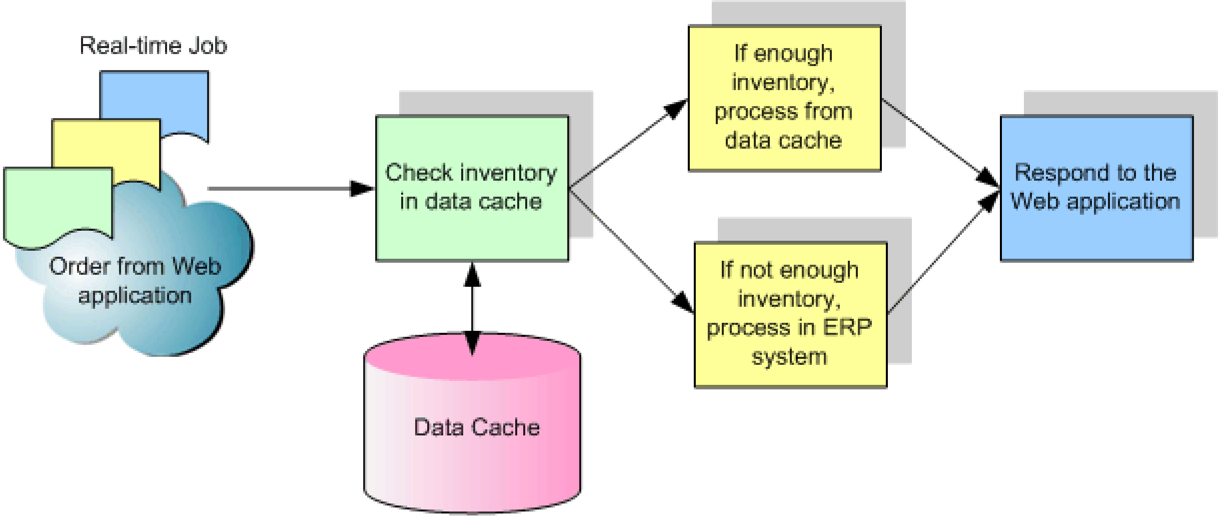
You can use messages to keep the data cache current. Real-time jobs can receive messages from a back-office application and load them into a data cache or data warehouse.



Real-time Job
Message with sales order information
Compare to existing data in the data cache
Data Cache
Split off header item
Load header item to data cache
Split off line item
Load line item to data cache

2.11.2.3.3 Retrieving values, data cache, back-office applications

You can create real-time jobs that use values from a data cache to determine whether or not to query the back-office application (such as an ERP system) directly.



Real-time Job
Order from Web application
Check inventory in data cache
Data Cache
If enough inventory, process from data cache
If not enough inventory, process in ERP system
Respond to the Web application

2.11.3 Creating real-time jobs

You can create real-time jobs using the same objects as batch jobs (data flows, work flows, conditionals, scripts, while loops, etc.). However, object usage must adhere to a valid real-time job model.

2.11.3.1 Real-time job models

In contrast to batch jobs, which typically move large amounts of data at scheduled times, a real-time job, once started as a real-time service, listens for a request. When a real-time job receives a request (typically to access small number of records), the software processes the request, returns a reply, and continues listening. This listen-process-listen logic forms a processing loop.

A real-time job is divided into three processing components: initialization, a real-time processing loop, and clean-up.

- The initialization component (optional) can be a script, work flow, data flow, or a combination of objects. It runs only when a real-time service starts.
- The real-time processing loop is a container for the job's single process logic. You can specify any number of work flows and data flows inside it.
- The clean-up component (optional) can be a script, work flow, data flow, or a combination of objects. It runs only when a real-time service is shut down.

In a real-time processing loop, a single message source must be included in the first step and a single message target must be included in the last step.

The following models support this rule:

- Single data flow model
- Multiple data flow model
- Request/Acknowledge data flow model

Related Information

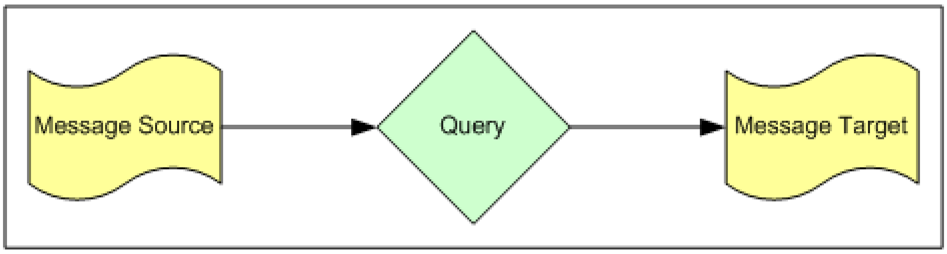
Single data flow model [page 377]

Multiple data flow model [page 378]

Supplement for SAP: SAP ERP and R/3 and Real-Time Jobs, IDoc sources in real-time jobs [page 2496]

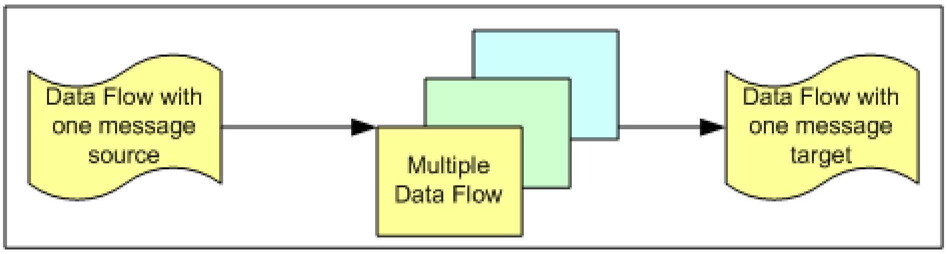
2.11.3.1.1 Single data flow model

With the single data flow model, you create a real-time job using a single data flow in its real-time processing loop. This single data flow must include a single message source and a single message target.



2.11.3.1.2 Multiple data flow model

The multiple data flow model allows you to create a real-time job using multiple data flows in its real-time processing loop.



Data Flow with one message source
Multiple Data Flow
Data Flow with one message target

By using multiple data flows, you can ensure that data in each message is completely processed in an initial data flow before processing for the next data flows starts. For example, if the data represents 40 items, all 40 must pass though the first data flow to a staging or memory table before passing to a second data flow. This allows you to control and collect all the data in a message at any point in a real-time job for design and troubleshooting purposes.

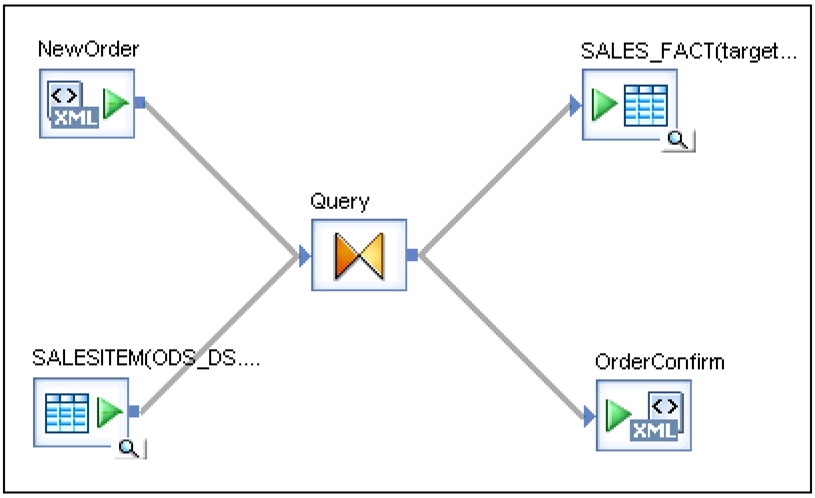
If you use multiple data flows in a real-time processing loop:

- The first object in the loop must be a data flow. This data flow must have one and only one message source.
- The last object in the loop must be a data flow. This data flow must have a message target.
- Additional data flows cannot have message sources or targets.
- You can add any number of additional data flows to the loop, and you can add them inside any number of work flows.
- All data flows can use input and/or output memory tables to pass data sets on to the next data flow. Memory tables store data in memory while a loop runs. They improve the performance of real-time jobs with multiple data flows.

2.11.3.2 Using real-time job models

2.11.3.2.1 Single data flow model

When you use a single data flow within a real-time processing loop your data flow diagram might look like this:



Notice that the data flow has one message source and one message target.

2.11.3.2.2 Multiple data flow model

When you use multiple data flows within a real-time processing loop your data flow diagrams might look like those in the following example scenario in which Data Services writes data to several targets according to your multiple data flow design.

Example scenario requirements:

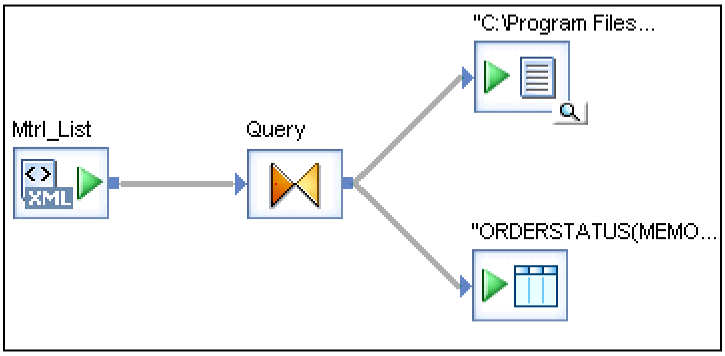
Your job must do the following tasks, completing each one before moving on to the next:

- Receive requests about the status of individual orders from a web portal and record each message to a backup flat file
- Perform a query join to find the status of the order and write to a customer database table.
- Reply to each message with the query join results

Solution:

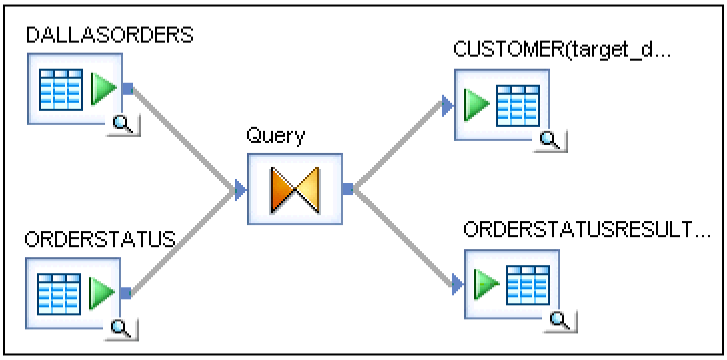
First, create a real-time job and add a data flow, a work flow, and another data flow to the real-time processing loop. Second, add a data flow to the work flow. Next, set up the tasks in each data flow:

- The first data flow receives the XML message (using an XML message source) and records the message to the flat file (flat file format target). Meanwhile, this same data flow writes the data into a memory table (table target).

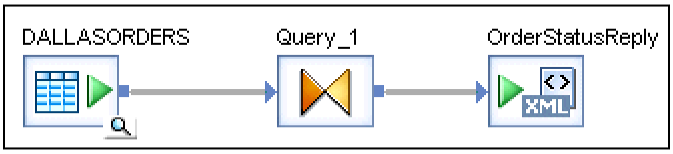


> Note
>
> You might want to create a memory table to move data to sequential data flows.

- The second data flow reads the message data from the memory table (table source), performs a join with stored data (table source), and writes the results to a database table (table target) and a new memory table (table target).
  Notice that this data flow has neither a message source nor a message target.



- The last data flow sends the reply. It reads the result of the join in the memory table (table source) and loads the reply (XML message target).



Related Information

Designing real-time applications [page 390]
Memory datastores [page 224]

2.11.3.3 To create a real-time job with a single data flow

1. In the Designer, create or open an existing project.

2. From the project area, right-click the white space and select *New Real-time job* from the shortcut menu.

   New_RTJob1 appears in the project area. The workspace displays the job's structure, which consists of two markers:

   ○ RT_Process_begins
   ○ Step_ends

   These markers represent the beginning and end of a real-time processing loop.
3. In the project area, rename *New_RTJob1*.

   Always add a prefix to job names with their job type. In this case, use the naming convention: RTJOB_JobName.

   Although saved real-time jobs are grouped together under the Job tab of the object library, job names may also appear in text editors used to create adapter or Web Services calls. In these cases, a prefix saved with the job name will help you identify it.
4. If you want to create a job with a single data flow:
   a) Click the data flow icon in the tool palette.

      You can add data flows to either a batch or real-time job. When you place a data flow icon into a job, you are telling Data Services to validate the data flow according the requirements of the job type (batch or real-time).
   b) Click inside the loop.

      The boundaries of a loop are indicated by begin and end markers. One message source and one message target are allowed in a real-time processing loop.
   c) Connect the begin and end markers to the data flow.
   d) Build the data flow including a message source and message target.
   e) Add, configure, and connect initialization object(s) and clean-up object(s) as needed.

2.11.4 Real-time source and target objects

Real-time jobs must contain a real-time source and/or target object. Those normally available are:

Object	Description	Used as a:	Software access
XML message	An XML message structured in a DTD or XML Schema format	Source or target	Directly or through adapters
Outbound message	A real-time message with an application-specific format (not readable by XML parser)	Target	Through an adapter

You can also use IDoc messages as real-time sources for SAP applications. For more information, see the *Supplement for SAP*.

Adding sources and targets to real-time jobs is similar to adding them to batch jobs, with the following additions:

For	Prerequisite	Object library location
XML messages	Import a DTD or XML Schema to define a format	*Formats* tab

For	Prerequisite	Object library location
Outbound message	Define an adapter datastore and import object metadata.	*Datastores* tab, under adapter datastore

Related Information

To import a DTD or XML Schema format [page 354]

Adapter datastores [page 233]

2.11.4.1 To view an XML message source or target schema

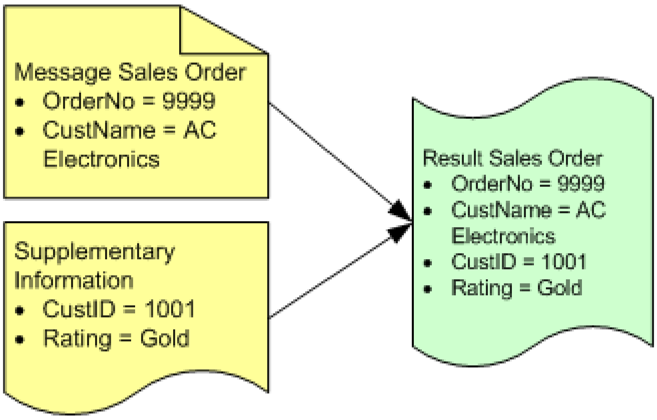
In the workspace of a real-time job, click the name of an XML message source or XML message target to open its editor.

If the XML message source or target contains nested data, the schema displays nested tables to represent the relationships among the data.

2.11.4.2 Secondary sources and targets

Real-time jobs can also have secondary sources or targets. For example, suppose you are processing a message that contains a sales order from a Web application. The order contains the customer name, but when you apply the order against your ERP system, you need to supply more detailed customer information.

Inside a data flow of a real-time job, you can supplement the message with the customer information to produce the complete document to send to the ERP system. The supplementary information might come from the ERP system itself or from a data cache containing the same information.



Tables and files (including XML files) as sources can provide this supplementary information.

The software reads data from secondary sources according to the way you design the data flow. The software loads data to secondary targets in parallel with a target message.

Add secondary sources and targets to data flows in real-time jobs as you would to data flows in batch jobs.

Related Information

Source and target objects [page 286]
Adding source or target objects to data flows [page 288]

2.11.4.3 Transactional loading of tables

Target tables in real-time jobs support transactional loading, in which the data resulting from the processing of a single data flow can be loaded into multiple tables as a single transaction. No part of the transaction applies if any part fails.

> Note
>
> Target tables in batch jobs also support transactional loading. However, use caution when you consider enabling this option for a batch job because it requires the use of memory, which can reduce performance when moving large amounts of data.

You can specify the order in which tables in the transaction are included using the target table editor. This feature supports a scenario in which you have a set of tables with foreign keys that depend on one with primary keys.

You can use transactional loading only when all the targets in a data flow are in the same datastore. If the data flow loads tables in more than one datastore, targets in each datastore load independently. While multiple targets in one datastore may be included in one transaction, the targets in another datastores must be included in another transaction.

You can specify the same transaction order or distinct transaction orders for all targets to be included in the same transaction. If you specify the same transaction order for all targets in the same datastore, the tables are still included in the same transaction but are loaded together. Loading is committed after all tables in the transaction finish loading.

If you specify distinct transaction orders for all targets in the same datastore, the transaction orders indicate the loading orders of the tables. The table with the smallest transaction order is loaded first, and so on, until the table with the largest transaction order is loaded last. No two tables are loaded at the same time. Loading is committed when the last table finishes loading.

2.11.4.4 Design tips for data flows in real-time jobs

Keep in mind the following when you are designing data flows:

- If you include a table in a join with a real-time source, the software includes the data set from the real-time source as the outer loop of the join. If more than one supplementary source is included in the join, you can control which table is included in the next outer-most loop of the join using the join ranks for the tables.

- In real-time jobs, do not cache data from secondary sources unless the data is static. The data will be read when the real-time job starts and will not be updated while the job is running.
- If no rows are passed to the XML target, the real-time job returns an empty response to the Access Server. For example, if a request comes in for a product number that does not exist, your job might be designed in such a way that no data passes to the reply message. You might want to provide appropriate instructions to your user (exception handling in your job) to account for this type of scenario.
- If more than one row passes to the XML target, the target reads the first row and discards the other rows. To avoid this issue, use your knowledge of the software's Nested Relational Data Model (NRDM) and structure your message source and target formats so that one "row" equals one message. With NRDM, you can structure any amount of data into a single "row" because columns in tables can contain other tables.
- Recovery mechanisms are not supported in real-time jobs.

Nested Data [page 342]

2.11.5 Testing real-time jobs

2.11.5.1 Executing a real-time job in test mode

You can test real-time job designs without configuring the job as a service associated with an Access Server. In test mode, you can execute a real-time job using a sample source message from a file to determine if the software produces the expected target message.

2.11.5.1.1 To specify a sample XML message and target test file

1. In the XML message source and target editors, enter a file name in the *XML test file* box.

   Enter the full path name for the source file that contains your sample data. Use paths for both test files relative to the computer that runs the Job Server for the current repository.
2. Execute the job.

   Test mode is always enabled for real-time jobs. The software reads data from the source test file and loads it into the target test file.

2.11.5.2 Using View Data

To ensure that your design returns the results you expect, execute your job using View Data. With View Data, you can capture a sample of your output data to ensure that your design is working.

Related Information

Design and Debug [page 685]

2.11.5.3 Using an XML file target

You can use an "XML file target" to capture the message produced by a data flow while allowing the message to be returned to the Access Server.

Just like an XML message, you define an XML file by importing a DTD or XML Schema for the file, then dragging the format into the data flow definition. Unlike XML messages, you can include XML files as sources or targets in batch and real-time jobs.

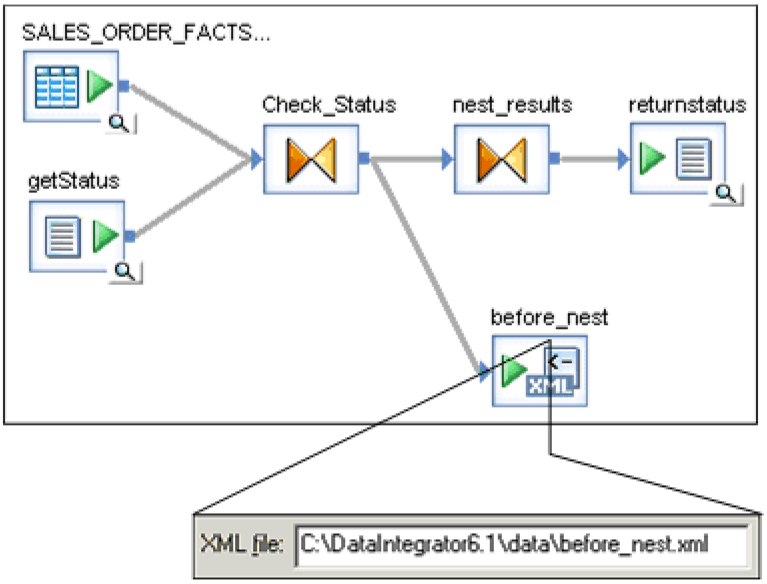
2.11.5.3.1 To use a file to capture output from steps in a real-time job

1. In the *Formats* tab of the object library, drag the DTD or XML Schema into a data flow of a real-time job.

   A menu prompts you for the function of the file.
2. Choose *Make XML File Target*.

   The XML file target appears in the workspace.
3. In the file editor, specify the location to which the software writes data.

   Enter a file name relative to the computer running the Job Server.
4. Connect the output of the step in the data flow that you want to capture to the input of the file.



XML file: C:\DataIntegrator6.1\data\before_nest.xml

2.11.6 Building blocks for real-time jobs

2.11.6.1 Supplementing message data

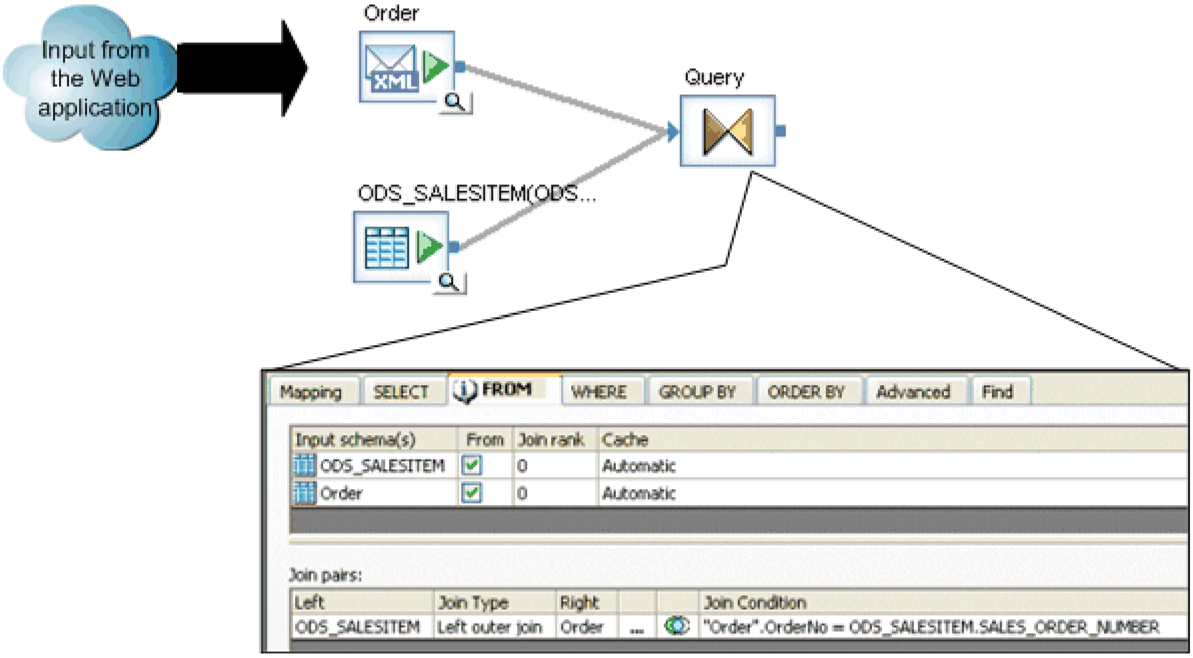
The data included in messages from real-time sources might not map exactly to your requirements for processing or storing the information. If not, you can define steps in the real-time job to supplement the message information.

One technique for supplementing the data in a real-time source includes these steps:

1. Include a table or file as a source.

   In addition to the real-time source, include the files or tables from which you require supplementary information.
2. Use a query to extract the necessary data from the table or file.
3. Use the data in the real-time source to find the necessary supplementary data.

   You can include a join expression in the query to extract the specific values required from the supplementary source.



Input schema(s)	From	Join rank	Cache
ODS_SALESITEM	☑	0	Automatic
Order	☑	0	Automatic

Join pairs:

Left	Join Type	Right			Join Condition
ODS_SALESITEM	Left outer join	Order	...		"Order".OrderNo = ODS_SALESITEM.SALES_ORDER_NUMBER

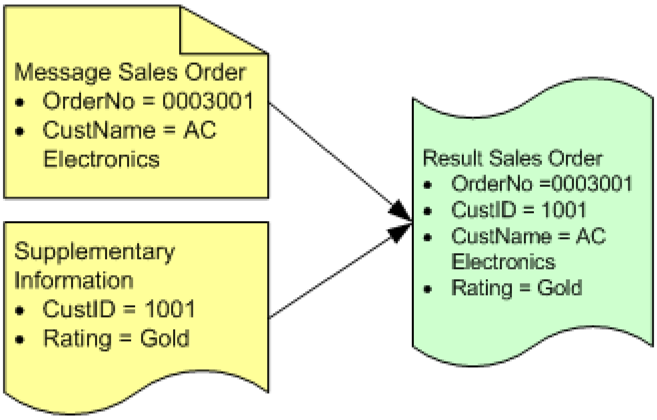
The Join Condition joins the two input schemas resulting in output for only the sales item document and line items included in the input from the application.

Be careful to use data in the join that is guaranteed to return a value. If no value returns from the join, the query produces no rows and the message returns to the Access Server empty. If you cannot guarantee that a value returns, consider these alternatives:

- *Lookup function call*—Returns a default value if no match is found.
- *Outer join*—Always returns a value, even if no match is found.

2.11.6.1.1 To supplement message data

In this example, a request message includes sales order information and its reply message returns order status. The business logic uses the customer number and priority rating to determine the level of status to return. The message includes only the customer name and the order number. A real-time job is then defined to retrieve the customer number and rating from other sources before determining the order status.



1. Include the real-time source in the real-time job.
2. Include the supplementary source in the real-time job.

   This source could be a table or file. In this example, the supplementary information required doesn't change very often, so it is reasonable to extract the data from a data cache rather than going to an ERP system directly.
3. Join the sources.

   In a query transform, construct a join on the customer name:

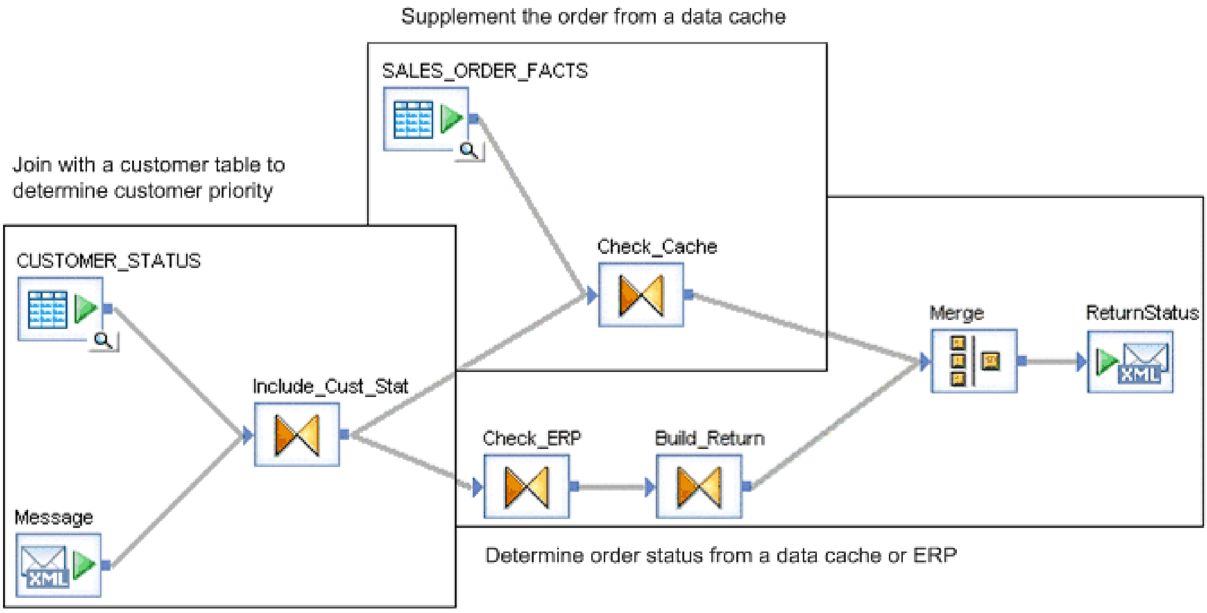
   ```
   Message.CustName = Cust_Status.CustName
   ```

   You can construct the output to include only the columns that the real-time job needs to determine order status.
4. Complete the real-time job to determine order status.

   The example shown here determines order status in one of two methods based on the customer status value. Order status for the highest ranked customers is determined directly from the ERP. Order status for other customers is determined from a data cache of sales order information.

   The logic can be arranged in a single or multiple data flows. The illustration below shows a single data flow model.

   Both branches return order status for each line item in the order. The data flow merges the results and constructs the response. The next section describes how to design branch paths in a data flow.



Supplement the order from a data cache
SALES_ORDER_FACTS
Join with a customer table to determine customer priority
Check_Cache
CUSTOMER_STATUS
Merge
ReturnStatus
XML
Include_Cust_Stat
Check_ERP
Build_Return
Message
XML
Determine order status from a data cache or ERP

2.11.6.2 Branching data flow based on a data cache value

One of the most powerful things you can do with a real-time job is to design logic that determines whether responses should be generated from a data cache or if they must be generated from data in a back-office application (ERP, SCM, CRM).

Here is one technique for constructing this logic:

1. Determine the rule for when to access the data cache and when to access the back-office application.
2. Compare data from the real-time source with the rule.
3. Define each path that could result from the outcome.

   You might need to consider the case where the rule indicates back-office application access, but the system is not currently available.
4. Merge the results from each path into a single data set.
5. Route the single result to the real-time target.

   You might need to consider error-checking and exception-handling to make sure that a value passes to the target. If the target receives an empty set, the real-time job returns an empty response (begin and end XML tags only) to the Access Server.

This example describes a section of a real-time job that processes a new sales order. The section is responsible for checking the inventory available of the ordered products—it answers the question, "is there enough inventory on hand to fill this order?"

The rule controlling access to the back-office application indicates that the inventory (Inv) must be more than a pre-determined value (IMargin) greater than the ordered quantity (Qty) to consider the data cached inventory value acceptable.

The software makes a comparison for each line item in the order they are mapped.

Table 6: Incoming sales order

OrderNo	CustID	LineItem		
		Item	Material	Qty
9999	1001	001	7333	300
		002	2288	1400

Table 7: Inventory data cache

Material	Inv	IMargin
7333	600	100
2288	1500	200

Note

The quantity of items in the sales order is compared to inventory values in the data cache.

2.11.6.3 Calling application functions

A real-time job can use application functions to operate on data. You can include tables as input or output parameters to the function.

Application functions require input values for some parameters and some can be left unspecified. You must determine the requirements of the function to prepare the appropriate inputs.

To make up the input, you can specify the top-level table, top-level columns, and any tables nested one-level down relative to the tables listed in the FROM clause of the context calling the function. If the application function includes a structure as an input parameter, you must specify the individual columns that make up the structure.

A data flow may contain several steps that call a function, retrieve results, then shape the results into the columns and tables required for a response.

2.11.7 Designing real-time applications

The software provides a reliable and low-impact connection between a Web application and back-office applications such as an enterprise resource planning (ERP) system. Because each implementation of an ERP system is different and because the software includes versatile decision support logic, you have many opportunities to design a system that meets your internal and external information and resource needs.

2.11.7.1 Reducing queries requiring back-office application access

This section provides a collection of recommendations and considerations that can help reduce the time you spend experimenting in your development cycles.

The information you allow your customers to access through your Web application can impact the performance that your customers see on the Web. You can maximize performance through your Web application design decisions. In particular, you can structure your application to reduce the number of queries that require direct back-office (ERP, SCM, Legacy) application access.

For example, if your ERP system supports a complicated pricing structure that includes dependencies such as customer priority, product availability, or order quantity, you might not be able to depend on values from a data cache for pricing information. The alternative might be to request pricing information directly from the ERP system. ERP system access is likely to be much slower than direct database access, reducing the performance your customer experiences with your Web application.

To reduce the impact of queries requiring direct ERP system access, modify your Web application. Using the pricing example, design the application to avoid displaying price information along with standard product information and instead show pricing only after the customer has chosen a specific product and quantity. These techniques are evident in the way airline reservations systems provide pricing information—a quote for a specific flight—contrasted with other retail Web sites that show pricing for every item displayed as part of product catalogs.

2.11.7.2 Messages from real-time jobs to adapter instances

If a real-time job will send a message to an adapter instance, refer to the adapter documentation to decide if you need to create a message function call or an outbound message.

- Message function calls allow the adapter instance to collect requests and send replies.
- Outbound message objects can only send outbound messages. They cannot be used to receive messages.

Related Information

Importing metadata through an adapter datastore [page 236]

2.11.7.3 Real-time service invoked by an adapter instance

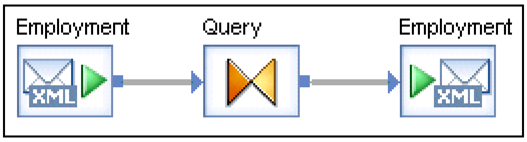
This section uses terms consistent with Java programming. (Please see your adapter SDK documentation for more information about terms such as operation instance and information resource.)

When an operation instance (in an adapter) gets a message from an information resource, it translates it to XML (if necessary), then sends the XML message to a real-time service.

In the real-time service, the message from the adapter is represented by a DTD or XML Schema object (stored in the *Formats* tab of the object library). The DTD or XML Schema represents the data schema for the information resource.

The real-time service processes the message from the information resource (relayed by the adapter) and returns a response.

In the example data flow below, the Query processes a message (here represented by "Employment") received from a source (an adapter instance), and returns the response to a target (again, an adapter instance).



2.12 Embedded Data Flows

The software provides an easy-to-use option to create embedded data flows.

2.12.1 Overview of embedded data flows

An embedded data flow is a data flow that is called from inside another data flow. Data passes into or out of the embedded data flow from the parent flow through a single source or target. The embedded data flow can contain any number of sources or targets, but only one input or one output can pass data to or from the parent data flow.

You can create the following types of embedded data flows:

Type	Use when you want to...
One input	Add an embedded data flow at the end of a data flow.
One output	Add an embedded data flow at the beginning of a data flow.
No input or output	Replicate an existing data flow.

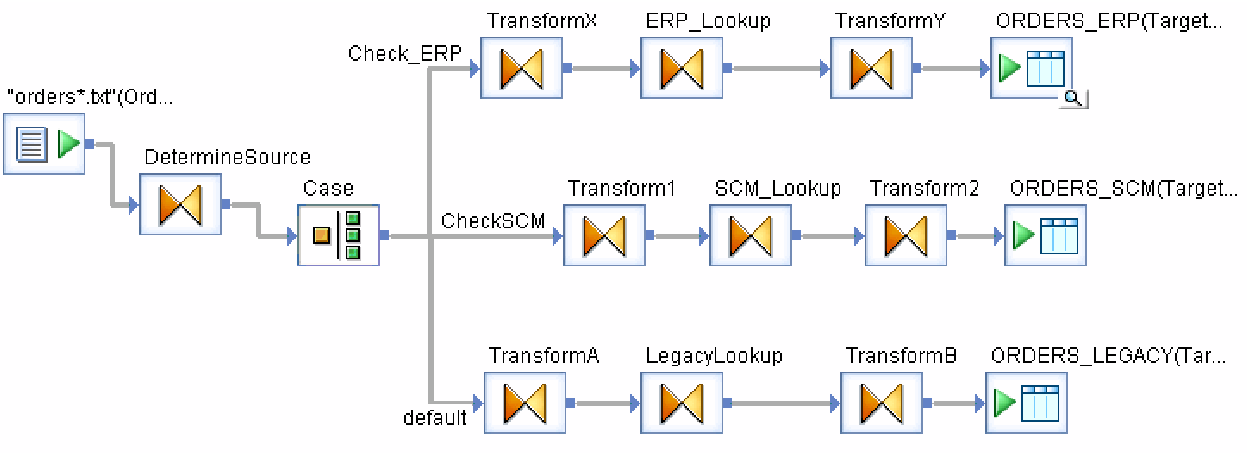
An embedded data flow is a design aid that has no effect on job execution. When the software executes the parent data flow, it expands any embedded data flows, optimizes the parent data flow, and then executes it.

Use embedded data flows to:

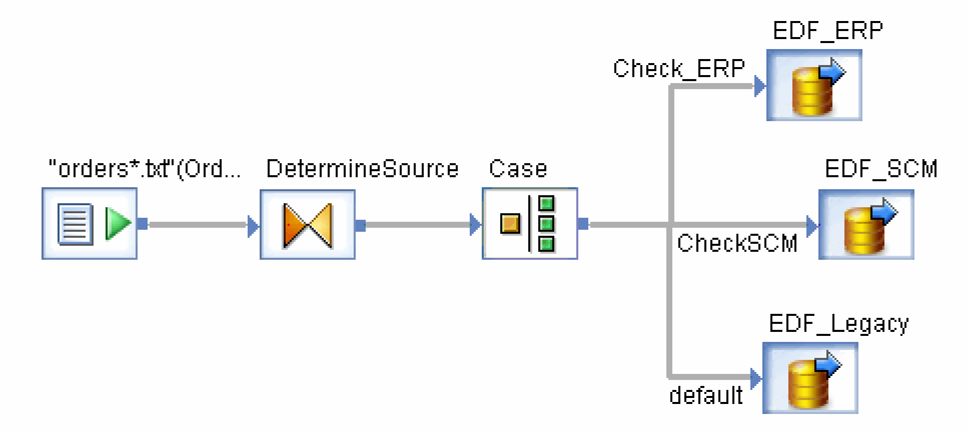
- Simplify data flow display. Group sections of a data flow in embedded data flows to allow clearer layout and documentation.
- Reuse data flow logic. Save logical sections of a data flow so you can use the exact logic in other data flows, or provide an easy way to replicate the logic and modify it for other flows.
- Debug data flow logic. Replicate sections of a data flow as embedded data flows so you can execute them independently.

2.12.2 Example of when to use embedded data flows

In this example, a data flow uses a single source to load three different target systems. The Case transform sends each row from the source to different transforms that process it to get a unique target output.



You can simplify the parent data flow by using embedded data flows for the three different cases.



2.12.3 Creating embedded data flows

There are two ways to create embedded data flows.

- Select objects within a data flow, right-click, and select *Make Embedded Data Flow*.
- Drag a complete and fully validated data flow from the object library into an open data flow in the workspace. Then:
  - Open the data flow you just added.
  - Right-click one object you want to use as an input or as an output port and select *Make Port* for that object.
    The software marks the object you select as the connection point for this embedded data flow.

> **Note**
>
> You can specify only one port, which means that the embedded data flow can appear only at the beginning or at the end of the parent data flow.
>
> Data Services ignores some physical files that are required for sources and targets with assigned ports.
>
> - When you use an embedded data flow, data will flow directly from the caller to the transform(s) next to the port source.
> - When you use a data flow directly, Data Services uses the physical files in sources and targets, but ignores the ports.

2.12.3.1 Using the Make Embedded Data Flow option

2.12.3.1.1 To create an embedded data flow

1. Select objects from an open data flow using one of the following methods:
   - Click the white space and drag the rectangle around the objects.
   - CTRL-click each object.

   Ensure that the set of objects you select are:
   - All connected to each other.
   - Connected to other objects according to the type of embedded data flow you want to create such as one input, one output, or no input or output.
2. Right-click and select *Make Embedded Data Flow*.

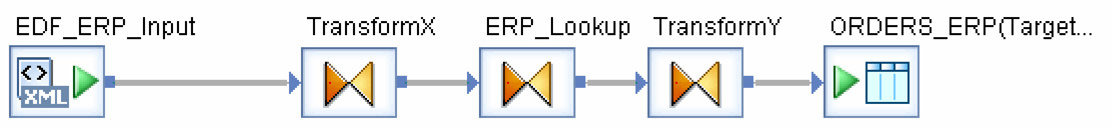
   The Create Embedded Data Flow window opens, with the embedded data flow connected to the parent by one input object.
3. Name the embedded data flow using the convention `EDF_` **`<EDFName>`** for example `EDF_ERP`.

   If you deselect the Replace objects in original data flow box, the software will not make a change in the original data flow. The software saves the new embedded data flow object to the repository and displays it in the object library under the Data Flows tab.

   You can use an embedded data flow created without replacement as a stand-alone data flow for troubleshooting.

   If Replace objects in original data flow is selected, the original data flow becomes a parent data flow, which has a call to the new embedded data flow.
4. Click *OK*.

   The embedded data flow appears in the new parent data flow.
5. Click the name of the embedded data flow to open it.



6. Notice that the software created a new object, `EDF_ERP_Input`, which is the input port that connects this embedded data flow to the parent data flow.

When you use the *Make Embedded Data flow* option, the software automatically creates an input or output object based on the object that is connected to the embedded data flow when it is created.

For example, if an embedded data flow has an output connection, the embedded data flow will include a target XML file object labeled **`<EDFName>`**`_Output`.

The naming conventions for each embedded data flow type are:

Type	Naming conventions
One input	**`<EDFName>`**`_Input`
One output	**`<EDFName>`**`_Output`
No input or output	The software creates an embedded data flow without an input or output object.

2.12.3.2 Creating embedded data flows from existing flows

To call an existing data flow from inside another data flow, put the data flow inside the parent data flow, then mark which source or target to use to pass data between the parent and the embedded data flows.

2.12.3.2.1 To create an embedded data flow out of an existing data flow

1. Drag an existing valid data flow from the object library into a data flow that is open in the workspace.
2. Consider renaming the flow using the `EDF_`**`<EDFName>`** naming convention.

   The embedded data flow appears without any arrowheads (ports) in the workspace.
3. Open the embedded data flow.
4. Right-click a source or target object (file or table) and select *Make Port*.

   > i Note
   >
   > Ensure that you specify only one input or output port.

Like a normal data flow, different types of embedded data flow ports are indicated by directional markings on the embedded data flow icon.

2.12.3.3 Using embedded data flows

When you create and configure an embedded data flow using the *Make Embedded Data Flow* option, the software creates new input or output XML file and saves the schema in the repository as an XML Schema. You can reuse an embedded data flow by dragging it from the *Data Flow* tab of the object library into other data flows. To save mapping time, you might want to use the Update Schema option or the Match Schema option.

The following example scenario uses both options:

- Create data flow 1.
- Select objects in data flow 1, and create embedded data flow 1 so that parent data flow 1 calls embedded data flow 1.
- Create data flow 2 and data flow 3 and add embedded data flow 1 to both of them.
- Go back to data flow 1. Change the schema of the object preceding embedded data flow 1 and use the Update Schema option with embedded data flow 1. It updates the schema of embedded data flow 1 in the repository.
- Now the schemas in data flow 2 and data flow 3 that are feeding into embedded data flow 1 will be different from the schema the embedded data flow expects.
- Use the Match Schema option for embedded data flow 1 in both data flow 2 and data flow 3 to resolve the mismatches at runtime. The Match Schema option only affects settings in the current data flow.

The following sections describe the use of the Update Schema and Match Schema options in more detail.

2.12.3.3.1 Updating Schemas

The software provides an option to update an input schema of an embedded data flow. This option updates the schema of an embedded data flow's input object with the schema of the preceding object in the parent data flow. All occurrences of the embedded data flow update when you use this option.

2.12.3.3.1.1 To update a schema

1. Open the embedded data flow's parent data flow.
2. Right-click the embedded data flow object and select *Update Schema*.

2.12.3.3.2 Matching data between parent and embedded data flow

The schema of an embedded data flow's input object can match the schema of the preceding object in the parent data flow by name or position. A match by position is the default.

2.12.3.3.2.1 To specify how schemas should be matched

1. Open the embedded data flow's parent data flow.
2. Right-click the embedded data flow object and select *Match SchemaBy Name* or *Match SchemaBy Position*.

   The Match Schema option only affects settings for the current data flow.

Data Services also allows the schema of the preceding object in the parent data flow to have more or fewer columns than the embedded data flow. The embedded data flow ignores additional columns and reads missing columns as NULL.

Columns in both schemas must have identical or convertible data types. See the section on "Type conversion" in the *Reference Guide* for more information.

2.12.3.3.3 Deleting embedded data flow objects

You can delete embedded data flow ports, or remove entire embedded data flows.

2.12.3.3.3.1 To remove a port

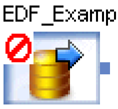
Right-click the input or output object within the embedded data flow and deselect *Make Port*. Data Services removes the connection to the parent object.

> Note
>
> You cannot remove a port simply by deleting the connection in the parent flow.

2.12.3.3.3.2 To remove an embedded data flow

Select it from the open parent data flow and choose *Delete* from the right-click menu or edit menu.

If you delete embedded data flows from the object library, the embedded data flow icon appears with a red circle-slash flag in the parent data flow.



Delete these defunct embedded data flow objects from the parent data flows.

2.12.3.4 Separately testing an embedded data flow

Embedded data flows can be tested by running them separately as regular data flows.

1. Specify an XML file for the input port or output port.

   When you use the Make Embedded Data Flow option, an input or output XML file object is created and then (optional) connected to the preceding or succeeding object in the parent data flow. To test the XML file without a parent data flow, click the name of the XML file to open its source or target editor to specify a file name.

2. Put the embedded data flow into a job.
3. Run the job.

You can also use the following features to test embedded data flows:

- View Data to sample data passed into an embedded data flow.
- Auditing statistics about the data read from sources, transformed, and loaded into targets, and rules about the audit statistics to verify the expected data is processed.

Related Information

Reference Guide: XML file [page 1004]
Design and Debug [page 685]

2.12.3.5 Troubleshooting embedded data flows

The following situations produce errors:

- Both an input port and output port are specified in an embedded data flow.
- Trapped defunct data flows.
- Deleted connection to the parent data flow while the *Make Port* option, in the embedded data flow, remains selected.
- Transforms with splitters (such as the Case transform) specified as the output port object because a splitter produces multiple outputs, and embedded data flows can only have one.
- Variables and parameters declared in the embedded data flow that are not also declared in the parent data flow.
- Embedding the same data flow at any level within itself.
  You can however have unlimited embedding levels. For example, DF1 data flow calls EDF1 embedded data flow which calls EDF2.

To remove an embedded data flow [page 397]
To remove a port [page 397]

2.13 Variables and Parameters

This section contains information about the following:

- Adding and defining local and global variables for jobs

- Using environment variables
- Using substitution parameters and configurations

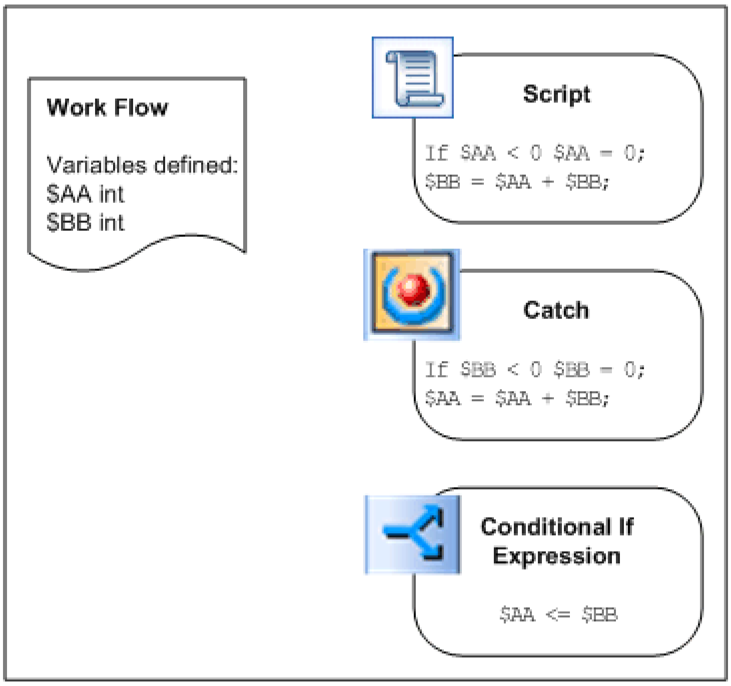
2.13.1 Overview of variables and parameters

You can increase the flexibility and reusability of work flows and data flows by using local and global variables when you design your jobs. Variables are symbolic placeholders for values. The data type of a variable can be any supported by the software such as an integer, decimal, date, or text string.

You can use variables in expressions to facilitate decision-making or data manipulation (using arithmetic or character substitution). For example, a variable can be used in a `LOOP` or `IF` statement to check a variable's value to decide which step to perform:

```
If $<amount_owed> > 0 print('$<invoice.doc>');
```

If you define variables in a job or work flow, the software typically uses them in a script, catch, or conditional process.



```
If $AA < 0 $AA = 0;
$BB = $AA + $BB;
```

```
If $BB < 0 $BB = 0;
$AA = $AA + $BB;
```

```
$AA <= $BB
```

You can use variables inside data flows. For example, use them in a custom function or in the `WHERE` clause of a query transform.

In the software, local variables are restricted to the object in which they are created (job or work flow). You must use parameters to pass local variables to child objects (work flows and data flows).

Global variables are restricted to the job in which they are created; however, they do not require parameters to be passed to work flows and data flows.

ℹ Note

If you have work flows that are running in parallel, the global variables are not assigned.

Parameters are expressions that pass to a work flow or data flow when they are called in a job.

You create local variables, parameters, and global variables using the Variables and Parameters window in the Designer.

You can set values for local or global variables in script objects. You can also set global variable values using external job, execution, or schedule properties.

Using global variables provides you with maximum flexibility. For example, during production you can change values for default global variables at runtime from a job's schedule or *SOAP* call without having to open a job in the Designer.

Variables can be used as file names for:

- Flat file sources and targets
- XML file sources and targets
- XML message targets (executed in the Designer in test mode)
- IDoc file sources and targets (in an SAP application environment)
- IDoc message sources and targets (SAP application environment)

Related Information

Management Console Guide: Administrator, Support for Web Services [page 1945]

2.13.2 The Variables and Parameters window

The software displays the variables and parameters defined for an object in the *Variables and Parameters* window.

2.13.2.1 To view the variables and parameters in each job, work flow, or data flow

1. In the *Tools* menu, select *Variables*.

   The *Variables and Parameters* window opens.
2. From the object library, double-click an object, or from the project area click an object to open it in the workspace.

   The Context box in the window changes to show the object you are viewing. If there is no object selected, the window does not indicate a context.

The Variables and Parameters window contains two tabs.

The *Definitions* tab allows you to create and view variables (name and data type) and parameters (name, data type, and parameter type) for an object type. Local variable and parameters can only be set at the work flow and data flow level. Global variables can only be set at the job level.

The following table lists what type of variables and parameters you can create using the Variables and Parameters window when you select different objects.

Object type	What you can create for the object	Used by
Job	Local variables Global variables	A script or conditional in the job. Any object in the job.
Work flow	Local variables Parameters	This work flow or passed down to other work flows or data flows using a parameter. Parent objects to pass local variables. Work flows may also return variables or parameters to parent objects.
Data flow	Parameters	A WHERE clause, column mapping, or a function in the data flow. Data flows cannot return output values.

The *Calls* tab allows you to view the name of each parameter defined for all objects in a parent object's definition. You can also enter values for each parameter.

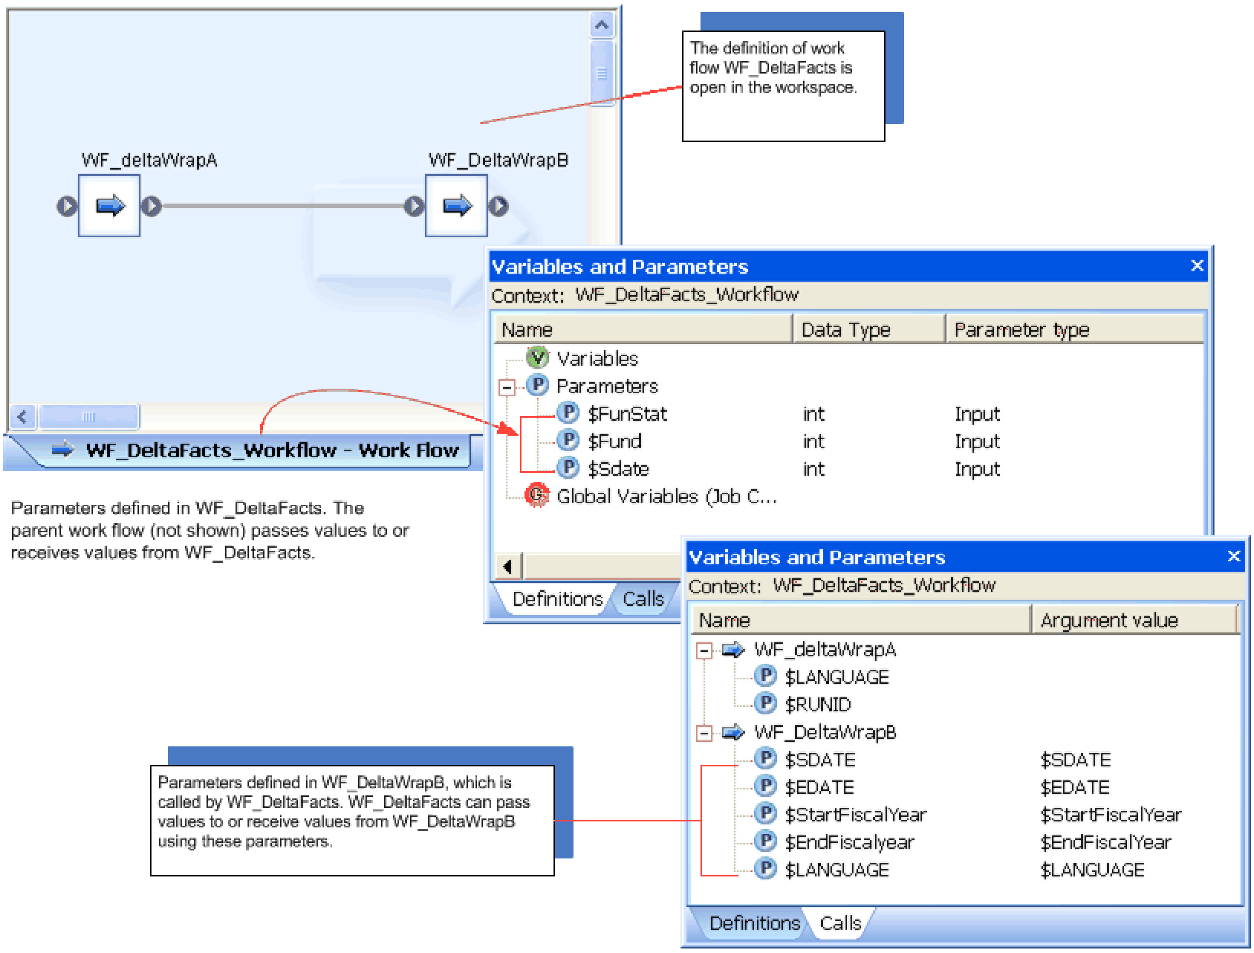
For the input parameter type, values in the *Calls* tab can be constants, variables, or another parameter.

For the output or input/output parameter type, values in the *Calls* tab can be variables or parameters.

Values in the *Calls* tab must also use:

- The same data type as the variable if they are placed inside an input or input/output parameter type, and a compatible data type if they are placed inside an output parameter type.
- Scripting language rules and syntax.

The following illustration shows the relationship between an open work flow called DeltaFacts, the *Context* box in the Variables and Parameters window, and the content in the *Definition* and *Calls* tabs.



The definition of work flow WF_DeltaFacts is open in the workspace.

Parameters defined in WF_DeltaFacts. The parent work flow (not shown) passes values to or receives values from WF_DeltaFacts.

Variables and Parameters

Context: WF_DeltaFacts_Workflow

Name	Data Type	Parameter type
Variables		
Parameters		
$FunStat	int	Input
$Fund	int	Input
$Sdate	int	Input
Global Variables (Job C...		

Variables and Parameters

Context: WF_DeltaFacts_Workflow

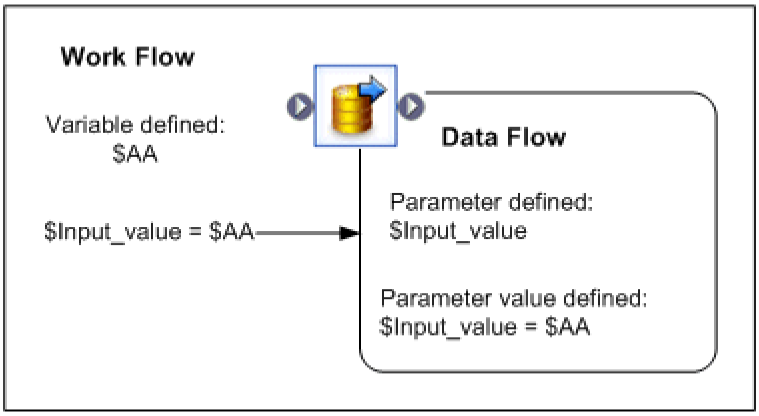
Name	Argument value
WF_deltaWrapA	
$LANGUAGE	
$RUNID	
WF_DeltaWrapB	
$SDATE	$SDATE
$EDATE	$EDATE
$StartFiscalYear	$StartFiscalYear
$EndFiscalyear	$EndFiscalYear
$LANGUAGE	$LANGUAGE

Parameters defined in WF_DeltaWrapB, which is called by WF_DeltaFacts. WF_DeltaFacts can pass values to or receive values from WF_DeltaWrapB using these parameters.

2.13.3 Using local variables and parameters

To pass a local variable to another object, define the local variable, then from the calling object, create a parameter and map the parameter to the local variable by entering a parameter value.

For example, to use a local variable inside a data flow, define the variable in a parent work flow and then pass the value of the variable as a parameter of the data flow.



Work Flow
Variable defined: $AA
$Input_value = $AA
Data Flow
Parameter defined: $Input_value
Parameter value defined: $Input_value = $AA

2.13.3.1 Parameters

Parameters can be defined to:

- Pass their values into and out of work flows
- Pass their values into data flows

Each parameter is assigned a type: input, output, or input/output. The value passed by the parameter can be used by any object called by the work flow or data flow.

> Note
>
> You can also create local variables and parameters for use in custom functions.

Related Information

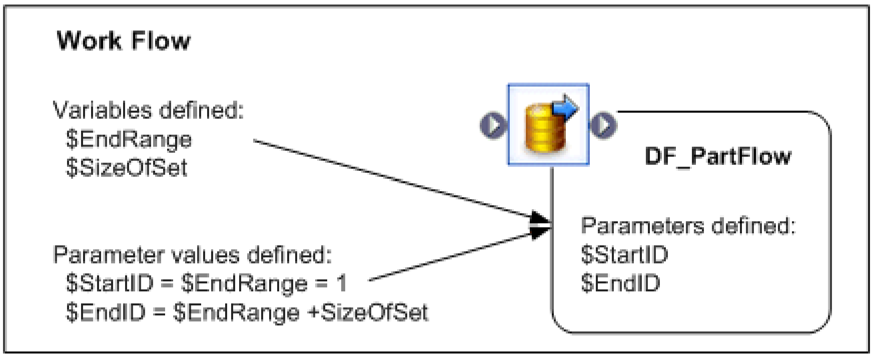
Reference Guide: Custom functions [page 1694]

2.13.3.2 Passing values into data flows

You can use a value passed as a parameter into a data flow to control the data transformed in the data flow. For example, the data flow DF_PartFlow processes daily inventory values. It can process all of the part numbers in use or a range of part numbers based on external requirements such as the range of numbers processed most recently.

If the work flow that calls DF_PartFlow records the range of numbers processed, it can pass the end value of the range `$EndRange` as a parameter to the data flow to indicate the start value of the range to process next.

The software can calculate a new end value based on a stored number of parts to process each time, such as `$SizeOfSet`, and pass that value to the data flow as the end value. A query transform in the data flow uses the parameters passed in to filter the part numbers extracted from the source.



The data flow could be used by multiple calls contained in one or more work flows to perform the same task on different part number ranges by specifying different parameters for the particular calls.

2.13.3.3 To define a local variable

1. Click the name of the job or work flow in the project area or workspace, or double-click one from the object library.
2. Click *Tools* > *Variables* .

   The *Variables and Parameters* window appears.
3. From the *Definitions* tab, select *Variables*.
4. Right-click and select *Insert*. Or, to insert a variable in a specific position in the list, select an existing variable, right-click, and select *Insert Before* or *Insert After*.

   A new variable appears (for example, `$NewVariable0`). A focus box appears around the name cell and the cursor shape changes to an arrow with a yellow pencil.
5. To edit the name of the new variable, click the name cell.

   The name can include alphanumeric characters or underscores (_), but cannot contain blank spaces. Always begin the name with a dollar sign ($).
6. Click the data type cell for the new variable and select the appropriate data type from the drop-down list.
7. To specify the order of the variable in the list, select the variable, right-click, and select *Move Up* or *Move Down*.
8. Close the *Variables and Parameters* window.

2.13.3.4 To replicate a local variable

1. Click the name of the job or work flow in the project area or workspace, or double-click one from the object library.
2. Click *Tools* > *Variables* .

   The *Variables and Parameters* window appears.
3. From the *Definitions* tab, select *Variables*.
4. Select an existing variable, right-click, and select *Replicate*.

A properties window opens and displays a new variable with the same properties as the replicated variable (for example, `$Copy_1_NewVariable1`).

5. Edit the name of the new variable.

   The name can include alphanumeric characters or underscores (_), but cannot contain blank spaces. Always begin the name with a dollar sign ($).
6. Select the appropriate data type from the drop-down list.
7. Click *OK*.
8. To specify the order of the variable in the list, select the variable, right-click, and select *Move Up* or *Move Down*.
9. Close the *Variables and Parameters* window.

2.13.3.5 Defining parameters

There are two steps for setting up a parameter for a work flow or data flow:

- Add the parameter definition to the flow.
- Set the value of the parameter in the flow call.

2.13.3.5.1 To add a parameter to a work flow or data flow

1. Click the name of the work flow or data flow.
2. Click ▶ *Tools* › *Variables* ◀.

   The *Variables and Parameters* window appears.
3. Go to the *Definition* tab.
4. Select *Parameters*.
5. Right-click and select *Insert*. Or, to insert a parameter in a specific position in the list, select an existing parameter, right-click, and select *Insert Before* or *Insert After*.

   A new parameter appears (for example, `$NewParameter0`). A focus box appears and the cursor shape changes to an arrow with a yellow pencil.
6. To edit the name of the new variable, click the name cell.

   The name can include alphanumeric characters or underscores (_), but cannot contain blank spaces. Always begin the name with a dollar sign ($).
7. Click the data type cell for the new parameter and select the appropriate data type from the drop-down list.

   If the parameter is an input or input/output parameter, it must have the same data type as the variable; if the parameter is an output parameter type, it must have a compatible data type.
8. Click the parameter type cell and select the parameter type (input, output, or input/output).
9. To specify the order of the parameter in the list, select the parameter, right-click, and select *Move Up* or *Move Down*.
10. Close the *Variables and Parameters* window.

2.13.3.5.2 To set the value of the parameter in the flow call

1. Open the calling job, work flow, or data flow.
2. Click ▸ *Tools* ▸ *Variables* ◢ to open the *Variables and Parameters* window.
3. Select the *Calls* tab.

   The Calls tab shows all the objects that are called from the open job, work flow, or data flow.
4. Click the *Argument Value* cell.
   A focus box appears and the cursor shape changes to an arrow with a yellow pencil.
5. Enter the expression the parameter will pass in the cell.

   If the parameter type is input, then its value can be an expression that contains a constant (for example, 0, 3, or 'string1'), a variable, or another parameter (for example, `$startID` or `$parm1`).

   If the parameter type is output or input/output, then the value must be a variable or parameter. The value cannot be a constant because, by definition, the value of an output or input/output parameter can be modified by any object within the flow.

   To indicate special values, use the following syntax:

Value type	Special syntax
Variable	**`<$variable_name>`**
String	**`<'string>`**'

2.13.4 Using global variables

Global variables are global within a job. Setting parameters is not necessary when you use global variables. However, once you use a name for a global variable in a job, that name becomes reserved for the job. Global variables are exclusive within the context of the job in which they are created.

2.13.4.1 Creating global variables

Define variables in the Variables and Parameter window.

2.13.4.1.1 To create a global variable

1. Click the name of a job in the project area or double-click a job from the object library.
2. Click ▸ *Tools* ▸ *Variables* ◢.
   The *Variables and Parameters* window appears.

3. From the *Definitions* tab, select *Global Variables*.
4. Right-click *Global Variables* and select *Insert*. Or, to insert a variable in a specific position in the list, select an existing variable, right-click, and select *Insert Before* or *Insert After*.

   A new global variable appears (for example, `$NewJobGlobalVariable0`). A focus box appears and the cursor shape changes to an arrow with a yellow pencil.
5. To edit the name of the new variable, click the name cell.

   The name can include alphanumeric characters or underscores (_), but cannot contain blank spaces. Always begin the name with a dollar sign ($).
6. Click the data type cell for the new variable and select the appropriate data type from the drop-down list.
7. To specify the order of the variable in the list, select the variable, right-click, and select *Move Up* or *Move Down*.
8. Close the *Variables and Parameters* window.

2.13.4.1.2 To replicate a global variable

1. Click the name of a job in the project area or double-click a job from the object library.
2. Click ▸ *Tools* ▸ *Variables* ◂.

   The *Variables and Parameters* window appears.
3. From the *Definitions* tab, select *Global Variables*.
4. Select an existing variable, right-click, and select *Replicate*.

   A properties window opens and displays a new variable with the same properties as the replicated variable (for example, `$Copy_1_NewJobGlobalVariable1`).
5. Edit the name of the new global variable.

   The name can include alphanumeric characters or underscores (_), but cannot contain blank spaces. Always begin the name with a dollar sign ($).
6. Select the appropriate data type from the drop-down list.
7. Click *OK*.
8. To specify the order of the variable in the list, select the variable, right-click, and select *Move Up* or *Move Down*.
9. Close the *Variables and Parameters* window.

2.13.4.2 Viewing global variables

Global variables, defined in a job, are visible to those objects relative to that job. A global variable defined in one job is not available for modification or viewing from another job.

You can view global variables from the Variables and Parameters window (with an open job in the work space) or from the Properties dialog of a selected job.

2.13.4.2.1 To view global variables in a job from the Properties dialog

1. In the object library, select the *Jobs* tab.
2. Right-click the job whose global variables you want to view and select *Properties*.
3. Click the *Global Variable* tab.

   Global variables appear on this tab.

2.13.4.3 Setting global variable values

In addition to setting a variable inside a job using an initialization script, you can set and maintain global variable values outside a job. Values set outside a job are processed the same way as those set in an initialization script. However, if you set a value for the same variable both inside and outside a job, the internal value will override the external job value.

Values for global variables can be set outside a job:

- As a job property
- As an execution or schedule property

Global variables without defined values are also allowed. They are read as NULL.

All values defined as job properties are shown in the Properties and the Execution Properties dialogs of the Designer and in the Execution Options and Schedule pages of the Administrator. By setting values outside a job, you can rely on these dialogs for viewing values set for global variables and easily edit values when testing or scheduling a job.

> Note
>
> You cannot pass global variables as command line arguments for real-time jobs.

2.13.4.3.1 To set a global variable value as a job property

1. Right-click a job in the object library or project area.
2. Click *Properties*.
3. Click the *Global Variable* tab.

   All global variables created in the job appear.
4. To filter the displayed global variables by name, enter part of the name in the *Filter* box.
5. Enter values for the global variables in this job.

   You can use any statement used in a script with this option.
6. To set multiple global variable values, use the Control button to select the variables, right-click, and select *Update Value*. Enter the value in the Smart Editor and click *OK*.

7. Click *OK*.

   The software saves values in the repository as job properties.

   You can also view and edit these default values in the Execution Properties dialog of the Designer and in the Execution Options and Schedule pages of the Administrator. This allows you to override job property values at run-time.

Related Information

Reference Guide: Scripting Language [page 1709]

2.13.4.3.2 To set a global variable value as an execution property

1. Execute a job from the Designer, or execute or schedule a batch job from the Administrator.

   > Note
   >
   > For testing purposes, you can execute real-time jobs from the Designer in test mode. Make sure to set the execution properties for a real-time job.

2. View the global variables in the job and their default values (if available).
3. Edit values for global variables as desired.
4. If you are using the Designer, click *OK*. If you are using the Administrator, click *Execute* or *Schedule*.

   The job runs using the values you enter. Values entered as execution properties are not saved. Values entered as schedule properties are saved but can only be accessed from within the Administrator.

2.13.4.3.3 Automatic ranking of global variable values in a job

Using the methods described in the previous section, if you enter different values for a single global variable, the software selects the highest ranking value for use in the job. A value entered as a job property has the lowest rank. A value defined inside a job has the highest rank.

- If you set a global variable value as both a job and an execution property, the execution property value overrides the job property value and becomes the default value for the current job run. You cannot save execution property global variable values.
  For example, assume that a job, JOB_Test1, has three global variables declared: $YEAR, $MONTH, and $DAY. Variable $YEAR is set as a job property with a value of 2003.
  For the job run, you set variables $MONTH and $DAY as execution properties to values 'JANUARY' and 31 respectively. The software executes a list of statements which includes default values for JOB_Test1:

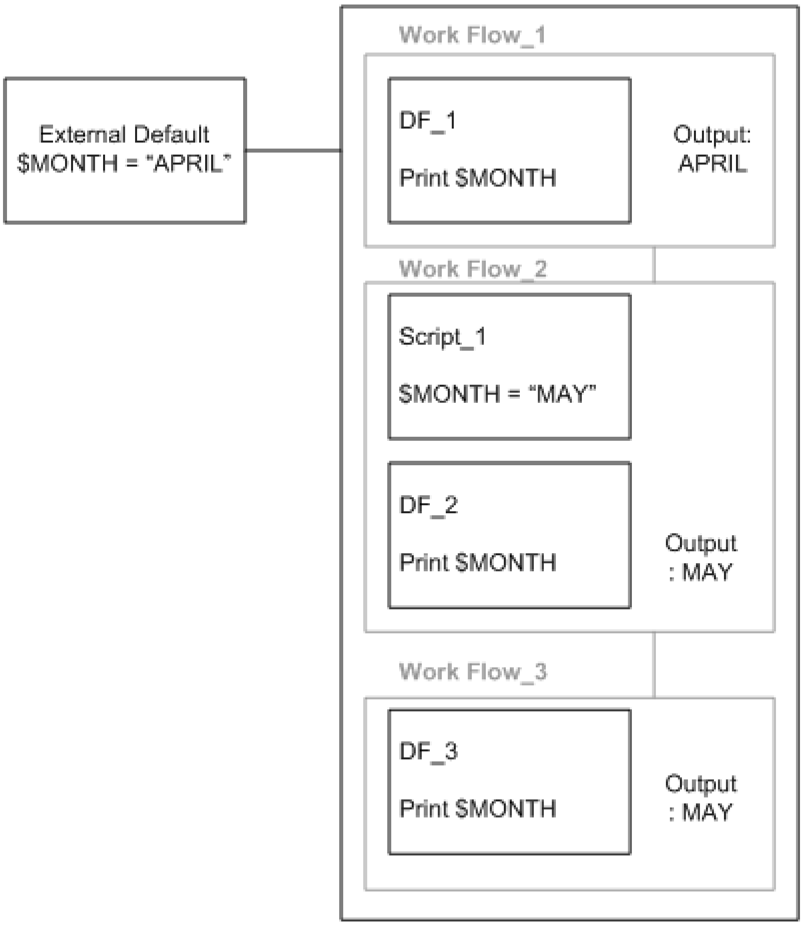
  ```
  $YEAR=2003;
  $MONTH='JANUARY';
  $DAY=31;
  ```

For the second job run, if you set variables $YEAR and $MONTH as execution properties to values 2002 and 'JANUARY' respectively, then the statement $YEAR=2002 will replace $YEAR=2003. The software executes the following list of statements:

```
$YEAR=2002;
$MONTH='JANUARY';
```

> **Note**
>
> In this scenario, $DAY is not defined and the software reads it as NULL. You set $DAY to 31 during the first job run; however, execution properties for global variable values are not saved.

- If you set a global variable value for both a job property and a schedule property, the schedule property value overrides the job property value and becomes the external, default value for the current job run.
  The software saves schedule property values in the repository. However, these values are only associated with a job schedule, not the job itself. Consequently, these values are viewed and edited from within the Administrator.
- A global variable value defined inside a job always overrides any external values. However, the override does not occur until the software attempts to apply the external values to the job being processed with the internal value. Up until that point, the software processes execution, schedule, or job property values as default values.
  For example, suppose you have a job called JOB_Test2 that has three work flows, each containing a data flow. The second data flow is inside a work flow that is preceded by a script in which $MONTH is defined as 'MAY'. The first and third data flows have the same global variable with no value defined. The execution property $MONTH = 'APRIL' is the global variable value.
  In this scenario, 'APRIL' becomes the default value for the job. 'APRIL' remains the value for the global variable until it encounters the other value for the same variable in the second work flow. Since the value in the script is inside the job, 'MAY' overrides 'APRIL' for the variable $MONTH. The software continues the processing the job with this new value.



2.13.4.3.4 Advantages to setting values outside a job

While you can set values inside jobs, there are advantages to defining values for global variables outside a job.

For example, values defined as job properties are shown in the Properties and the Execution Properties dialogs of the Designer and in the Execution Options and Schedule pages of the Administrator. By setting values outside a job, you can rely on these dialogs for viewing all global variables and their values. You can also easily edit them for testing and scheduling.

In the Administrator, you can set global variable values when creating or editing a schedule without opening the Designer. For example, use global variables as file names and start and end dates.

2.13.5 Local and global variable rules

When defining local or global variables, consider rules for:

- Naming
- Replicating jobs and work flows

- Importing and exporting

2.13.5.1 Naming

- Local and global variables must have unique names within their job context.
- Any name modification to a global variable can only be performed at the job level.

2.13.5.2 Replicating jobs and work flows

- When you replicate all objects, the local and global variables defined in that job context are also replicated.
- When you replicate a data flow or work flow, all parameters and local and global variables are also replicated. However, you must validate these local and global variables within the job context in which they were created. If you attempt to validate a data flow or work flow containing global variables without a job, Data Services reports an error.

2.13.5.3 Importing and exporting

- When you export a job object, you also export all local and global variables defined for that job.
- When you export a lower-level object (such as a data flow) without the parent job, the global variable is not exported. Only the call to that global variable is exported. If you use this object in another job without defining the global variable in the new job, a validation error will occur.

2.13.6 Environment variables

You can use system-environment variables inside jobs, work flows, or data flows. The get_env, set_env, and is_set_env functions provide access to underlying operating system variables that behave as the operating system allows.

You can temporarily set the value of an environment variable inside a job, work flow or data flow. Once set, the value is visible to all objects in that job.

Use the get_env, set_env, and is_set_env functions to set, retrieve, and test the values of environment variables.

Related Information

Reference Guide: Functions and Procedures [page 1511]

2.13.7 Setting file names at run-time using variables

You can set file names at runtime by specifying a variable as the file name.

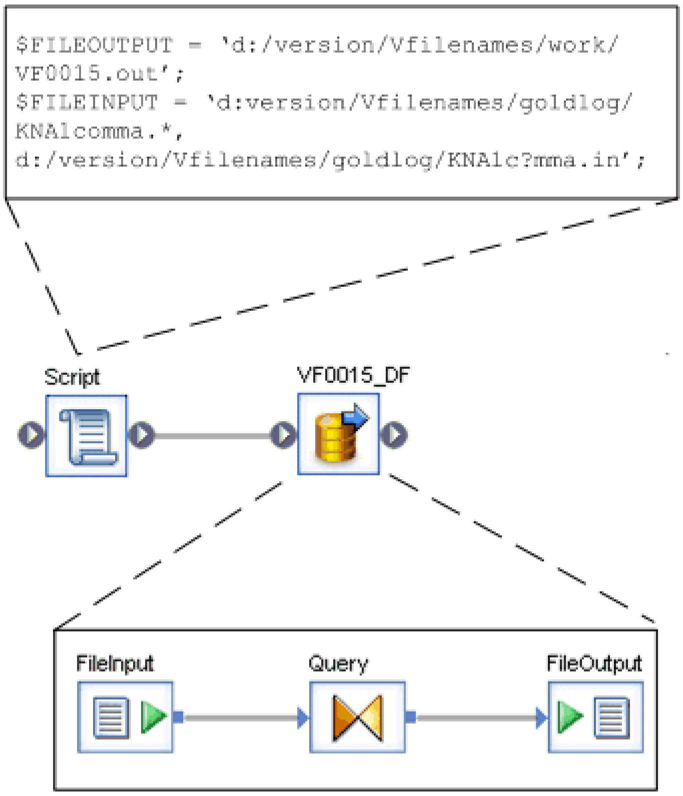
Variables can be used as file names for:

- The following sources and targets:
  - Flat files
  - XML files and messages
  - IDoc files and messages (in an SAP environment)
- The `lookup_ext` function (for a flat file used as a lookup table parameter)

2.13.7.1 To use a variable in a flat file name

1. Create a local or global variable using the Variables and Parameters window.
2. Create a script to set the value of a local or global variable, or call a system environment variable.
3. Declare the variable in the file format editor or in the Function editor as a `lookup_ext` parameter.
   - When you set a variable value for a flat file, specify both the file name and the directory name. Enter the variable in the *File(s)* property under *Data File(s)* in the File Format Editor. You cannot enter a variable in the *Root directory* property.
   - For lookups, substitute the path and file name in the *Lookup table* box in the `lookup_ext` function editor with the variable name.

The following figure shows how you can set values for variables in flat file sources and targets in a script.



```
$FILEOUTPUT = 'd:/version/Vfilenames/work/
VF0015.out';
$FILEINPUT = 'd:version/Vfilenames/goldlog/
KNA1comma.*,
d:/version/Vfilenames/goldlog/KNA1c?mma.in';
```

When you use variables as sources and targets, you can also use multiple file names and wild cards. Neither is supported when using variables in the `lookup_ext` function.

The figure above provides an example of how to use multiple variable names and wild cards. Notice that the `$FILEINPUT` variable includes two file names (separated by a comma). The two names (`KNA1comma.*` and `KNA1c?mma.in`) also make use of the wild cards (`*` and `?`) supported by the software.

2.13.8 Substitution parameters

2.13.8.1 Overview of substitution parameters

Substitution parameters are useful when you want to export and run a job containing constant values in a specific environment. For example, if you create a job that references a unique directory on your local computer and you export that job to another computer, the job will look for the unique directory in the new environment. If that directory doesn't exist, the job won't run.

Instead, by using a substitution parameter, you can easily assign a value for the original, constant value in order to run the job in the new environment. After creating a substitution parameter value for the directory in your environment, you can run the job in a different environment and all the objects that reference the original directory will automatically use the value. This means that you only need to change the constant value (the original directory name) in one place (the substitution parameter) and its value will automatically propagate to all objects in the job when it runs in the new environment.

You can configure a group of substitution parameters for a particular run-time environment by associating their constant values under a substitution parameter configuration.

2.13.8.1.1 Substitution parameters versus global variables

Substitution parameters differ from global variables in that they apply at the repository level. Global variables apply only to the job in which they are defined. You would use a global variable when you do not know the value prior to execution and it needs to be calculated in the job. You would use a substitution parameter for constants that do not change during execution. A substitution parameter defined in a given local repository is available to all the jobs in that repository. Therefore, using a substitution parameter means you do not need to define a global variable in each job to parameterize a constant value.

The following table describes the main differences between global variables and substitution parameters.

Global variables	Substitution parameters
Defined at the job level	Defined at the repository level
Cannot be shared across jobs	Available to all jobs in a repository
Data-type specific	No data type (all strings)
Value can change during job execution	Fixed value set prior to execution of job (constants)

However, you can use substitution parameters in all places where global variables are supported, for example:

- Query transform WHERE clauses
- Mappings
- SQL transform SQL statement identifiers
- Flat-file options
- User-defined transforms
- Address cleanse transform options
- Matching thresholds

2.13.8.1.2 Using substitution parameters

You can use substitution parameters in expressions, SQL statements, option fields, and constant strings. For example, many options and expression editors include a drop-down menu that displays a list of all the available substitution parameters.

The software installs some default substitution parameters that are used by some Data Quality transforms. For example, the USA Regulatory Address Cleanse transform uses the following built-in substitution parameters:

- $$RefFilesAddressCleanse defines the location of the address cleanse directories.
- $$ReportsAddressCleanse (set to Yes or No) enables data collection for creating reports with address cleanse statistics. This substitution parameter provides one location where you can enable or disable that option for all jobs in the repository.

Other examples of where you can use substitution parameters include:

- In a script, for example:

  ```
  Print('Data read in : [$$FilePath]'); or Print('[$$FilePath]');
  ```
- In a file format, for example with `[$$FilePath]/file.txt` as the file name

2.13.8.2 Using the Substitution Parameter Editor

Open the *Substitution Parameter Editor* from the Designer by selecting *Tools* › *Substitution Parameter Configurations*. Use the Substitution Parameter editor to do the following tasks:

- Add and define a substitution parameter by adding a new row in the editor.
- For each substitution parameter, use right-click menus and keyboard shortcuts to Cut, Copy, Paste, Delete, and Insert parameters.
- Change the order of substitution parameters by dragging rows or using the Cut, Copy, Paste, and Insert commands.
- Add a substitution parameter configuration by clicking the *Create New Substitution Parameter Configuration* icon in the toolbar.
- Duplicate an existing substitution parameter configuration by clicking the *Create Duplicate Substitution Parameter Configuration* icon.
- Rename a substitution parameter configuration by clicking the *Rename Substitution Parameter Configuration* icon.
- Delete a substitution parameter configuration by clicking the *Delete Substitution Parameter Configuration* icon.
- Reorder the display of configurations by clicking the *Sort Configuration Names in Ascending Order* and *Sort Configuration Names in Descending Order* icons.
- Move the default configuration so it displays next to the list of substitution parameters by clicking the *Move Default Configuration To Front* icon.
- Change the default configuration.

Related Information

Adding and defining substitution parameters [page 417]

2.13.8.2.1 Naming substitution parameters

When you name and define substitution parameters, use the following rules:

- The name prefix is two dollar signs $$ (global variables are prefixed with one dollar sign). When adding new substitution parameters in the Substitution Parameter Editor, the editor automatically adds the prefix.
- When typing names in the Substitution Parameter Editor, do not use punctuation (including quotes or brackets) except underscores. The following characters are not allowed:

  ```
  ,: / ' \ " = < > + | - * % ; \t [ ] ( ) \r \n $ ] +
  ```

- You can type names directly into fields, column mappings, transform options, and so on. However, you must enclose them in square brackets, for example [$$SamplesInstall].
- Names can include any alpha or numeric character or underscores but cannot contain spaces.
- Names are not case sensitive.
- The maximum length for most repository types is 256 (MySQL is 64 and MS SQL server is 128).
- Names must be unique within the repository.

2.13.8.2.2 Adding and defining substitution parameters

1. In the Designer, open the Substitution Parameter Editor by selecting ▶ *Tools* ▶ *Substitution Parameter Configurations* ◀.
2. The first column lists the substitution parameters available in the repository. To create a new one, double-click in a blank cell (a pencil icon will appear in the left) and type a name. The software automatically adds a double dollar-sign prefix ($$) to the name when you navigate away from the cell.
3. The second column identifies the name of the first configuration, by default *Configuration1* (you can change configuration names by double-clicking in the cell and retyping the name). Double-click in the blank cell next to the substitution parameter name and type the constant value that the parameter represents in that configuration. The software applies that value when you run the job.
4. To add another configuration to define a second value for the substitution parameter, click the *Create New Substitution Parameter Configuration* icon on the toolbar.
5. Type a unique name for the new substitution parameter configuration.
6. Enter the value the substitution parameter will use for that configuration.

You can now select from one of the two substitution parameter configurations you just created.

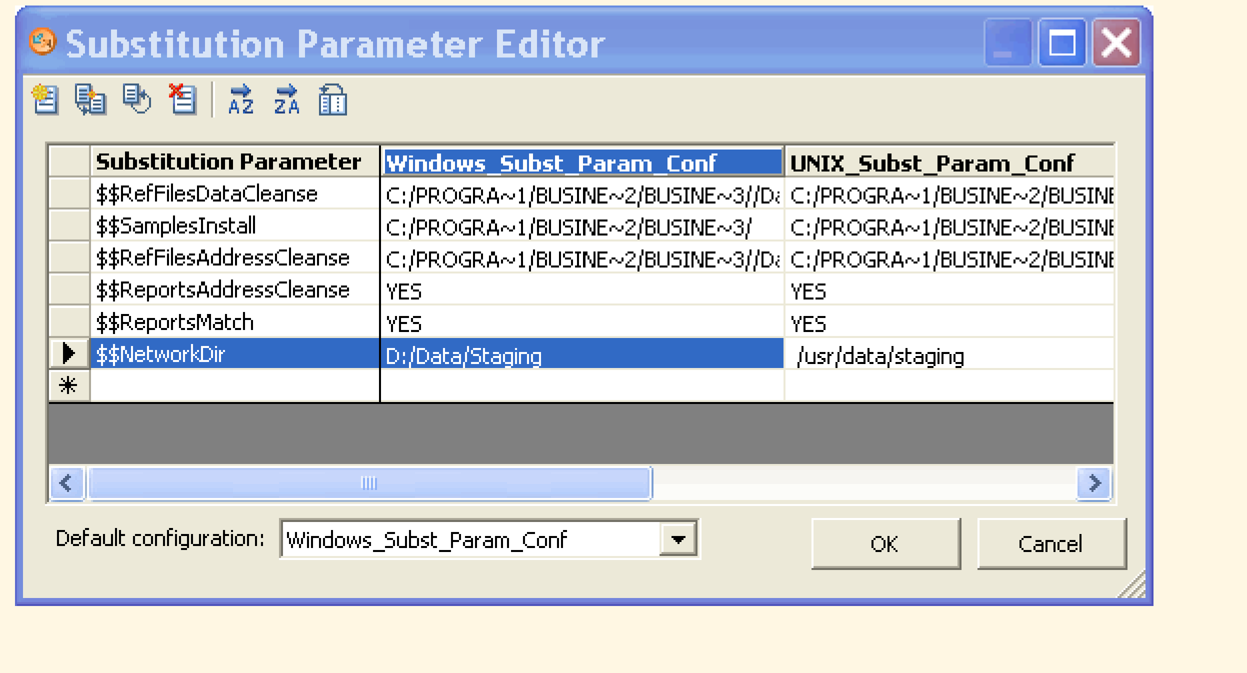
To change the default configuration that will apply when you run jobs, select it from the drop-down list box at the bottom of the window.

You can also export these substitution parameter configurations for use in other environments.

Example

In the following example, the substitution parameter $$NetworkDir has the value D:/Data/Staging in the configuration named Windows_Subst_Param_Conf and the value /usr/data/staging in the UNIX_Subst_Param_Conf configuration.

Notice that each configuration can contain multiple substitution parameters.



Substitution Parameter	Windows_Subst_Param_Conf	UNIX_Subst_Param_Conf
$$RefFilesDataCleanse	C:/PROGRA~1/BUSINE~2/BUSINE~3//Da	C:/PROGRA~1/BUSINE~2/BUSINE
$$SamplesInstall	C:/PROGRA~1/BUSINE~2/BUSINE~3/	C:/PROGRA~1/BUSINE~2/BUSINE
$$RefFilesAddressCleanse	C:/PROGRA~1/BUSINE~2/BUSINE~3//Da	C:/PROGRA~1/BUSINE~2/BUSINE
$$ReportsAddressCleanse	YES	YES
$$ReportsMatch	YES	YES
$$NetworkDir	D:/Data/Staging	/usr/data/staging

Default configuration: Windows_Subst_Param_Conf

Naming substitution parameters [page 416]
Exporting and importing substitution parameters [page 421]

2.13.8.3 Associating a substitution parameter configuration with a system configuration

A system configuration groups together a set of datastore configurations and a substitution parameter configuration. A substitution parameter configuration can be associated with one or more system configurations. For example, you might create one system configuration for your local system and a different system configuration for another system. Depending on your environment, both system configurations might point to the same substitution parameter configuration or each system configuration might require a different substitution parameter configuration.

At job execution time, you can set the system configuration and the job will execute with the values for the associated substitution parameter configuration.

To associate a substitution parameter configuration with a new or existing system configuration:

1. In the Designer, open the System Configuration Editor by selecting *Tools* > *System Configurations*.
2. Optionally create a new system configuration.
3. Under the desired system configuration name, select a substitution parameter configuration to associate with the system configuration.
4. Click *OK*.

Example

The following example shows two system configurations, Americas and Europe. In this case, there are substitution parameter configurations for each region (Europe_Subst_Parm_Conf and Americas_Subst_Parm_Conf). Each substitution parameter configuration defines where the data source files are located for that region, for example D:/Data/Americas and D:/Data/Europe. Select the appropriate substitution parameter configuration and datastore configurations for each system configuration.

	SC_Americas	SC_Europe
Substitution parameter	Americas_Subst_Parm_Conf	Europe_Subst_Parm_Conf
DataQualityBlueprints	<Default configuration>	<Default configuration>
ODS_DS	DSConf_Americas	DSConf_Europe
Pubs	<Default configuration>	<Default configuration>
Target_DS	<Default configuration>	<Default configuration>

Related Information

Defining a system configuration [page 252]

2.13.8.4 Overriding a substitution parameter in the Administrator

In the Administrator, you can override the substitution parameters, or select a system configuration to specify a substitution parameter configuration, on four pages:

- Execute Batch Job
- Schedule Batch Job

- Export Execution Command
- Real-Time Service Configuration

For example, the Execute Batch Job page displays the name of the selected system configuration, the substitution parameter configuration, and the name of each substitution parameter and its value.

To override a substitution parameter:

1. Select the appropriate system configuration.
2. Under *Substitution Parameters*, click *Add Overridden Parameter*, which displays the available substitution parameters.
3. From the drop-down list, select the substitution parameter to override.
4. In the second column, type the override value. Enter the value as a string without quotes (in contrast with Global Variables).
5. Execute the job.

2.13.8.5 Executing a job with substitution parameters

To see the details of how substitution parameters are being used in the job during execution in the Designer trace log:

1. Right-click the job name and click *Properties*.
2. Click the *Trace* tab.
3. For the *Trace Assemblers* option, set the value to *Yes.*
4. Click *OK.*

When you execute a job from the Designer, the Execution Properties window displays. You have the following options:

- On the *Execution Options* tab from the *System configuration* drop-down menu, optionally select the system configuration with which you want to run the job. If you do not select a system configuration, the software applies the default substitution parameter configuration as defined in the Substitution Parameter Editor.
  You can click *Browse* to view the *Select System Configuration* window in order to see the substitution parameter configuration associated with each system configuration. The *Select System Configuration* is read-only. If you want to change a system configuration, click ▸ *Tools* ▸ *System Configurations* ◂.
- You can override the value of specific substitution parameters at run time. Click the *Substitution Parameter* tab, select a substitution parameter from the Name column, and enter a value by double-clicking in the Value cell.
  To override substitution parameter values when you start a job via a Web service, see the *Integrator Guide*.

Related Information

Associating a substitution parameter configuration with a system configuration [page 418]
Overriding a substitution parameter in the Administrator [page 419]

2.13.8.6 Exporting and importing substitution parameters

Substitution parameters are stored in a local repository along with their configured values. The software does not include substitution parameters as part of a regular export.You can, however, export substitution parameters and configurations to other repositories by exporting them to a file and then importing the file to another repository.

2.13.8.6.1 Exporting substitution parameters

1. Right-click in the local object library and select *Repository* ▸ *Export Substitution Parameter Configurations*.
2. Select the check box in the *Export* column for the substitution parameter configurations to export.
3. *Save* the file.
   The software saves it as a text file with an .atl extension.

2.13.8.6.2 Importing substitution parameters

The substitution parameters must have first been exported to an ATL file.

Be aware of the following behaviors when importing substitution parameters:

- The software adds any new substitution parameters and configurations to the destination local repository.
- If the repository has a substitution parameter with the same name as in the exported file, importing will overwrite the parameter's value. Similarly, if the repository has a substitution parameter configuration with the same name as the exported configuration, importing will overwrite all the parameter values for that configuration.

1. In the Designer, right-click in the object library and select *Repository* ▸ *Import from file*.
2. Browse to the file to import.
3. Click *OK*.

Related Information

Exporting substitution parameters [page 421]

2.14 Executing Jobs

This section contains an overview of the software job execution, steps to execute jobs, debug errors, and change job server options.

2.14.1 Overview of job execution

You can run jobs in three different ways. Depending on your needs, you can configure:

- *Immediate jobs*
  The software initiates both batch and real-time jobs and runs them immediately from within the Designer. For these jobs, both the Designer and designated Job Server (where the job executes, usually many times on the same machine) must be running. You will most likely run immediate jobs only during the development cycle.
- *Scheduled jobs*
  Batch jobs are scheduled. To schedule a job, use the Administrator or use a third-party scheduler.
  When jobs are scheduled by third-party software:
  - The job initiates outside of the software.
  - The job operates on a batch job (or shell script for UNIX) that has been exported from the software.

  When a job is invoked by a third-party scheduler:
  - The corresponding Job Server must be running.
  - The Designer does not need to be running.
- *Services*
  Real-time jobs are set up as services that continuously listen for requests from an Access Server and process requests on-demand as they are received. Use the Administrator to create a service from a real-time job.

2.14.2 Preparing for job execution

2.14.2.1 Validating jobs and job components

You can also explicitly validate jobs and their components as you create them by:

	Clicking the *Validate All* button from the toolbar (or choosing *Validate* > *All Objects in View* from the *Debug* menu). This command checks the syntax of the object definition for the active workspace and for all objects that are called from the active workspace view recursively.
	Clicking the *Validate Current View* button from the toolbar (or choosing *Validate* > *Current View* from the *Debug* menu). This command checks the syntax of the object definition for the active workspace.

You can set the Designer options (*Tools* > *Options* > *Designer* > *General*) to validate jobs started in Designer before job execution. The default is not to validate.

The software also validates jobs before exporting them.

If during validation the software discovers an error in an object definition, it opens a dialog box indicating that an error exists, then opens the Output window to display the error.

If there are errors, double-click the error in the Output window to open the editor of the object containing the error.

If you are unable to read the complete error text in the window, you can access additional information by right-clicking the error listing and selecting *View* from the context menu.

Error messages have these levels of severity:

Severity	Description
Information ⓘ	Informative message only—does not prevent the job from running. No action is required.
Warning ⚠	The error is not severe enough to stop job execution, but you might get unexpected results. For example, if the data type of a source column in a transform within a data flow does not match the data type of the target column in the transform, the software alerts you with a warning message.
Error ✖	The error is severe enough to stop job execution. You must fix the error before the job will execute.

2.14.2.2 Ensuring that the Job Server is running

Before you execute a job (either as an immediate or scheduled task), ensure that the Job Server is associated with the repository where the client is running.

When the Designer starts, it displays the status of the Job Server for the repository to which you are connected.

Icon	Description
	Job Server is running
	Job Server is inactive

The name of the active Job Server and port number appears in the status bar when the cursor is over the icon.

2.14.2.3 Setting job execution options

Options for jobs include Debug and Trace. Although these are object options—they affect the function of the object—they are located in either the Property or the Execution window associated with the job.

Execution options for jobs can either be set for a single instance or as a default value.

- The right-click *Execute* menu sets the options for a single execution only and overrides the default settings.
- The right-click *Properties* menu sets the default settings.

2.14.2.3.1 To set execution options for every execution of the job

1. From the *Project* area, right-click the job name and choose *Properties*.
2. Select options on the Properties window.

Related Information

Viewing and changing object properties [page 190]
Reference Guide: Parameters [page 840]
Reference Guide: Trace properties [page 843]
Setting global variable values [page 408]

2.14.3 Executing jobs as immediate tasks

Immediate or "on demand" tasks are initiated from the Designer. Both the Designer and Job Server must be running for the job to execute.

2.14.3.1 To execute a job as an immediate task

1. In the project area, select the job name.
2. Right-click and choose *Execute*.

   The software prompts you to save any objects that have changes that have not been saved.
3. The next step depends on whether you selected the *Perform complete validation before job execution* check box in the Designer Options:
   - If you have not selected this check box, a window opens showing execution properties (debug and trace) for the job. Proceed to the next step.
   - If you have selected this check box, the software validates the job before it runs. You must correct any serious errors before the job will run. There might also be warning messages—for example, messages indicating that date values will be converted to datetime values. Correct them if you want (they will not prevent job execution) or click *OK* to continue. After the job validates, a window opens showing the execution properties (debug and trace) for the job.
4. Set the execution properties.

   You can choose the Job Server that you want to process this job, datastore profiles for sources and targets if applicable, enable automatic recovery, override the default trace properties, or select global variables at runtime.

   For more information, see:

> Note
>
> Setting execution properties here affects a temporary change for the current execution only.

5. Click *OK*.

   As the software begins execution, the execution window opens with the trace log button active.

   Use the buttons at the top of the log window to display the trace log, monitor log, and error log (if there are any errors).

   After the job is complete, use an RDBMS query tool to check the contents of the target table or file.

Related Information

Reference Guide: Parameters [page 840]
Reference Guide: Trace properties [page 843]
Setting global variable values [page 408]
Debugging execution errors [page 426]
Examining target data [page 428]

2.14.3.2 Monitor tab

The *Monitor* tab lists the trace logs of all current or most recent executions of a job.

The traffic-light icons in the *Monitor* tab have the following meanings:

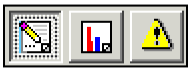
- A green light indicates that the job is running
  You can right-click and select Kill Job to stop a job that is still running.
- A red light indicates that the job has stopped
  You can right-click and select Properties to add a description for a specific trace log. This description is saved with the log which can be accessed later from the Log tab.
- A red cross indicates that the job encountered an error

2.14.3.3 Log tab

You can also select the *Log* tab to view a job's trace log history.

Click a trace log to open it in the workspace.

Use the trace, monitor, and error log icons (left to right at the top of the job execution window in the workspace) to view each type of available log for the date and time that the job was run.



2.14.4 Debugging execution errors

The following tables lists tools that can help you understand execution errors:

Tool	Definition
Trace log	Itemizes the steps executed in the job and the time execution began and ended.
Monitor log	Displays each step of each data flow in the job, the number of rows streamed through each step, and the duration of each step.
Error log	Displays the name of the object being executed when an error occurred and the text of the resulting error message. If the job ran against SAP data, some of the ABAP errors are also available in the error log.
Target data	Always examine your target data to see if your job produced the results you expected.

Related Information

Using logs [page 426]
Examining trace logs [page 428]
Examining monitor logs [page 428]
Examining error logs [page 428]
Examining target data [page 428]

2.14.4.1 Using logs

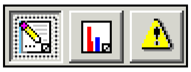
This section describes how to use logs in the Designer.

- To open the trace log on job execution, select ▶ *Tools* › *Options* › *Designer* › *General* › *Open monitor on job execution* ◀.
- To copy log content from an open log, select one or multiple lines and use the key commands [Ctrl+C].

2.14.4.1.1 To access a log during job execution

If your Designer is running when job execution begins, the execution window opens automatically, displaying the trace log information.

Use the monitor and error log icons (middle and right icons at the top of the execution window) to view these logs.



The execution window stays open until you close it.

2.14.4.1.2 To access a log after the execution window has been closed

1. In the project area, click the *Log* tab.
2. Click a job name to view all trace, monitor, and error log files in the workspace. Or expand the job you are interested in to view the list of trace log files and click one.

   Log indicators signify the following:

Job Log Indicator	Description
✓ N_	Indicates that the job executed successfully on this explicitly selected Job Server.
🖧	Indicates that the was job executed successfully by a server group. The Job Server listed executed the job.
☒	Indicates that the job encountered an error on this explicitly selected Job Server.
🖧✗	Indicates that the job encountered an error while being executed by a server group. The Job Server listed executed the job.

3. Click the log icon for the execution of the job you are interested in. (Identify the execution from the position in sequence or datetime stamp.)
4. Use the list box to switch between log types or to view *No logs* or *All logs*.

2.14.4.1.3 To delete a log

You can set how long to keep logs in Administrator.

If want to delete logs from the Designer manually:

1. In the project area, click the *Log* tab.
2. Right-click the log you want to delete and select *Delete Log*.

Related Information

Administrator Guide: Setting the log retention period [page 57]

2.14.4.1.4 Examining trace logs

Use the trace logs to determine where an execution failed, whether the execution steps occur in the order you expect, and which parts of the execution are the most time consuming.

2.14.4.1.5 Examining monitor logs

The monitor log quantifies the activities of the components of the job. It lists the time spent in a given component of a job and the number of data rows that streamed through the component.

2.14.4.1.6 Examining error logs

The software produces an error log for every job execution. Use the error logs to determine how an execution failed. If the execution completed without error, the error log is blank.

2.14.4.2 Examining target data

The best measure of the success of a job is the state of the target data. Always examine your data to make sure the data movement operation produced the results you expect. Be sure that:

- Data was not converted to incompatible types or truncated.
- Data was not duplicated in the target.
- Data was not lost between updates of the target.
- Generated keys have been properly incremented.
- Updated values were handled properly.

2.14.5 Changing Job Server options

Familiarize yourself with the more technical aspects of how the software handles data (using the *Reference Guide*) and some of its interfaces like those for adapters and SAP application.

There are many options available in the software for troubleshooting and tuning a job.

Option	Option description	Default value
Adapter Data Exchange Time-out	(For adapters) Defines the time a function call or outbound message will wait for the response from the adapter operation.	10800000 (3 hours)

Option	Option description	Default value
Adapter Start Time-out	(For adapters) Defines the time that the Administrator or Designer will wait for a response from the Job Server that manages adapters (start/stop/status).	90000 (90 seconds)
AL_JobServerLoadBalanceDebug	Enables a Job Server to log server group information if the value is set to `TRUE`. Information is saved in: **`<$LINK_DIR>`** `/log/`**`<JobServerName>`**`/server_eventlog.txt`.	FALSE
AL_JobServerLoadOSPolling	Sets the polling interval (in seconds) that the software uses to get status information used to calculate the load balancing index. This index is used by server groups.	60
Display DI Internal Jobs	Displays the software's internal datastore CD_DS_d0cafae2 and its related jobs in the object library. The CD_DS_d0cafae2 datastore supports two internal jobs. The first calculates usage dependencies on repository tables and the second updates server group configurations. If you change your repository password, user name, or other connection information, change the default value of this option to TRUE, close and reopen the Designer, then update the CD_DS_d0cafae2 datastore configuration to match your new repository configuration. This enables the calculate usage dependency job (CD_JOBd0cafae2) and the server group job (di_job_al_mach_info) to run without a connection error.	FALSE
FTP Number of Retry	Sets the number of retries for an FTP connection that initially fails.	0
FTP Retry Interval	Sets the FTP connection retry interval in milliseconds.	1000
Global_DOP	Sets the Degree of Parallelism for all data flows run by a given Job Server. You can also set the *Degree of parallelism* for individual data flows from each data flow's Properties window. If a data flow's *Degree of parallelism* value is `0`, then the Job Server will use the Global_DOP value. The Job Server will use the data flow's *Degree of parallelism* value if it is set to any value except zero because it overrides the Global_DOP value.	2
Ignore Reduced Msg Type	(For SAP applications) Disables IDoc reduced message type processing for all message types if the value is set to `TRUE`.	FALSE

Option	Option description	Default value
Ignore Reduced Msg Type_foo	(For SAP application) Disables IDoc reduced message type processing for a specific message type (such as `<foo>`) if the value is set to `TRUE`.	FALSE
OCI Server Attach Retry	The engine calls the Oracle `OCIServerAttach` function each time it makes a connection to Oracle. If the engine calls this function too fast (processing parallel data flows for example), the function may fail. To correct this, increase the retry value to `5`.	3
Splitter Optimization	The software might hang if you create a job in which a file source feeds into two queries. If this option is set to TRUE, the engine internally creates two source files that feed the two queries instead of a splitter that feeds the two queries.	FALSE
Use Explicit Database Links	Jobs with imported database links normally will show improved performance because the software uses these links to push down processing to a database. If you set this option to FALSE, all data flows will not use linked datastores. The use of linked datastores can also be disabled from any data flow properties dialog. The data flow level option takes precedence over this Job Server level option.	TRUE
Use Domain Name	Adds a domain name to a Job Server name in the repository. This creates a fully qualified server name and allows the Designer to locate a Job Server on a different domain. If the fully qualified host name (including domain) is not stored properly, the connection between the Designer or Job Server and the repository may fail. If this problem occurs, change this option to FALSE before adding repositories.	TRUE

Performance Optimization Guide: Maximizing Push-Down Operations, Database link support for push-down operations across datastores [page 2124]

2.14.5.1 To change option values for an individual Job Server

1. Select the Job Server you want to work with by making it your default Job Server.
   a) Select *Tools* > *Options* > *Designer* > *Environment* .
   b) Select a Job Server from the *Default Job Server* section.
   c) Click *OK*.
2. Select *Tools* > *Options* > *Job Server* > *General* .
3. Enter the section and key you want to use from the following list of value pairs:

Section	Key
`int`	`AdapterDataExchangeTimeout`
`int`	`AdapterStartTimeout`
`AL_JobServer`	`AL_JobServerLoadBalanceDebug`
`AL_JobServer`	`AL_JobServerLoadOSPolling`
`string`	`DisplayDIInternalJobs`
`AL_Engine`	`FTPNumberOfRetry`
`AL_Engine`	`FTPRetryInterval`
`AL_Engine`	`Global_DOP`
`AL_Engine`	`IgnoreReducedMsgType`
`AL_Engine`	`IgnoreReducedMsgType_foo`
`AL_Engine`	`OCIServerAttach_Retry`
`AL_Engine`	`SPLITTER_OPTIMIZATION`
`AL_Engine`	`UseExplicitDatabaseLinks`
`Repository`	`UseDomainName`

4. Enter a value.

   For example, enter the following to change the default value for the number of times a Job Server will retry to make an FTP connection if it initially fails:

Option	Sample value
Section	AL_Engine
Key	FTPNumberOfRetry
Value	2

These settings will change the default value for the FTPNumberOfRetry option from zero to two.

5. To save the settings and close the Options window, click *OK*.
6. Re-select a default Job Server by repeating step 1, as needed.

2.14.5.2 To use mapped drive names in a path

The software supports only UNC (Universal Naming Convention) paths to directories. If you set up a path to a mapped drive, the software will convert that mapped drive to its UNC equivalent.

To make sure that your mapped drive is not converted back to the UNC path, you need to add your drive names in the *Options* window in the Designer.

1. Choose *Tools* > *Options* .
2. In the *Options* window, expand *Job Server* and then select *General*.
3. In the *Section* edit box, enter **`MappedNetworkDrives`**.
4. In the *Key* edit box, enter **`LocalDrive1`** to map to a local drive or **`RemoteDrive1`** to map to a remote drive.
5. In the *Value* edit box, enter a drive letter, such as **`M:\`** for a local drive or **`\\<machine_name>\<share_name>`** for a remote drive.
6. Click OK to close the window.

If you want to add another mapped drive, you need to close the *Options* window and re-enter. Be sure that each entry in the *Key* edit box is a unique name.

2.15 Data Assessment

With operational systems frequently changing, data quality control becomes critical in your extract, transform and load (ETL) jobs. The Designer provides data quality controls that act as a firewall to identify and fix errors in your data. These features can help ensure that you have trusted information.

The Designer provides the following features that you can use to determine and improve the quality and structure of your source data:

- Use the Data Profiler to determine:
  - The quality of your source data before you extract it. The Data Profiler can identify anomalies in your source data to help you better define corrective actions in the Validation transform, data quality, or other transforms.
  - The distribution, relationship, and structure of your source data to better design your jobs and data flows, as well as your target data warehouse.

  - The content of your source and target data so that you can verify that your data extraction job returns the results you expect.
- Use the View Data feature to:
  - View your source data before you execute a job to help you create higher quality job designs.
  - Compare sample data from different steps of your job to verify that your data extraction job returns the results you expect.
- Use the Design-Time Data Viewer feature to view and analyze the input and output for a data set in real time as you design a transform even before data flow is complete or valid.
- Use the Validation transform to:
  - Verify that your source data meets your business rules.
  - Take appropriate actions when the data does not meet your business rules.
- Use the auditing data flow feature to:
  - Define rules that determine if a source, transform, or target object processes correct data.
  - Define the actions to take when an audit rule fails.
- Use data quality transforms to improve the quality of your data.
- Use Data Validation dashboards in the Metadata Reporting tool to evaluate the reliability of your target data based on the validation rules you created in your batch jobs. This feedback allows business users to quickly review, assess, and identify potential inconsistencies or errors in source data.

Related Information

Management Console Guide: Data Validation Dashboard Reports [page 1981]

2.15.1 Using the Data Profiler

The Data Profiler executes on a profiler server to provide the following data profiler information that multiple users can view:

- Column analysis—The Data Profiler provides two types of column profiles:
  - Basic profiling—This information includes minimum value, maximum value, average value, minimum string length, and maximum string length.
  - Detailed profiling—Detailed column analysis includes distinct count, distinct percent, median, median string length, pattern count, and pattern percent.
- Relationship analysis—This information identifies data mismatches between any two columns for which you define a relationship, including columns that have an existing primary key and foreign key relationship. You can save two levels of data:

- Save the data only in the columns that you select for the relationship.
- Save the values in all columns in each row.

2.15.1.1 Data sources that you can profile

You can execute the Data Profiler on data contained in the following sources. See the *Release Notes* for the complete list of sources that the Data Profiler supports.

- Databases, which include:
  - Attunity Connector for mainframe databases
  - DB2
  - Oracle
  - SQL Server
  - SAP Sybase IQ
  - SAP Sybase SQL Anywhere
  - Teradata
- Applications, which include:
  - JDE One World
  - JDE World
  - Oracle Applications
  - PeopleSoft
  - SAP Applications
  - SAP Master Data Services
  - SAP NetWeaver Business Warehouse
  - Siebel
- Flat files

2.15.1.2 Connecting to the profiler server

You must install and configure the profiler server before you can use the Data Profiler.

The Designer must connect to the profiler server to run the Data Profiler and view the profiler results. You provide this connection information on the Profiler Server Login window.

1. Use one of the following methods to invoke the Profiler Server Login window:
   - From the tool bar menu, select *Tools* > *Profiler Server Login* .
   - On the bottom status bar, double-click the Profiler Server icon which is to the right of the Job Server icon.
2. Enter your user credentials for the CMS.
   - *System*—Specify the server name and optionally the port for the CMS.
   - *User name*—Specify the user name to use to log into CMS.
   - *Password*—Specify the password to use to log into the CMS.
   - *Authentication*—Specify the authentication type used by the CMS.

3. Click *Log on*.
   The software attempts to connect to the CMS using the specified information. When you log in successfully, the list of profiler repositories that are available to you is displayed.
4. Select the repository you want to use.
5. Click *OK* to connect using the selected repository.

   When you successfully connect to the profiler server, the Profiler Server icon on the bottom status bar no longer has the red X on it. In addition, when you move the pointer over this icon, the status bar displays the location of the profiler server.

Related Information

Management Console Guide: Profile Server Management [page 1929]
Administrator Guide: User and rights management [page 46]

2.15.1.3 Profiler statistics

2.15.1.3.1 Column profile

You can generate statistics for one or more columns. The columns can all belong to one data source or from multiple data sources. If you generate statistics for multiple sources in one profile task, all sources must be in the same datastore.

Basic profiling

By default, the Data Profiler generates the following basic profiler attributes for each column that you select.

Basic attribute	Description
Min	Of all values, the lowest value in this column.
Min count	Number of rows that contain this lowest value in this column.
Max	Of all values, the highest value in this column.
Max count	Number of rows that contain this highest value in this column.
Average	For numeric columns, the average value in this column.
Min string length	For character columns, the length of the shortest string value in this column.
Max string length	For character columns, the length of the longest string value in this column.
Average string length	For character columns, the average length of the string values in this column.
Nulls	Number of `NULL` values in this column.

Basic attribute	Description
Nulls %	Percentage of rows that contain a `NULL` value in this column.
Zeros	Number of `0` values in this column.
Zeros %	Percentage of rows that contain a `0` value in this column.
Blanks	For character columns, the number of rows that contain a blank in this column.
Blanks %	Percentage of rows that contain a blank in this column.

Detailed profiling

You can generate more detailed attributes in addition to the above attributes, but detailed attributes generation consumes more time and computer resources. Therefore, it is recommended that you do not select the detailed profile unless you need the following attributes:

Detailed attribute	Description
Median	The value that is in the middle row of the source table.
Median string length	For character columns, the value that is in the middle row of the source table.
Distincts	Number of distinct values in this column.
Distinct %	Percentage of rows that contain each distinct value in this column.
Patterns	Number of different patterns in this column.
Pattern %	Percentage of rows that contain each pattern in this column.

Examples of using column profile statistics to improve data quality

You can use the column profile attributes to assist you in different tasks, including the following tasks:

- Obtain basic statistics, frequencies, ranges, and outliers. For example, these profile statistics might show that a column value is markedly higher than the other values in a data source. You might then decide to define a validation transform to set a flag in a different table when you load this outlier into the target table.
- Identify variations of the same content. For example, part number might be an integer data type in one data source and a varchar data type in another data source. You might then decide which data type you want to use in your target data warehouse.
- Discover data patterns and formats. For example, the profile statistics might show that phone number has several different formats. With this profile information, you might decide to define a validation transform to convert them all to use the same target format.
- Analyze the numeric range. For example, customer number might have one range of numbers in one source, and a different range in another source. Your target will need to have a data type that can accommodate the maximum range.
- Identify missing information, nulls, and blanks in the source system. For example, the profile statistics might show that nulls occur for fax number. You might then decide to define a validation transform to replace the null value with a phrase such as "Unknown" in the target table.

Related Information

To view the column attributes generated by the Data Profiler [page 444]
Submitting column profiler tasks [page 438]

2.15.1.3.2 Relationship profile

A relationship profile shows the percentage of non matching values in columns of two sources. The sources can be:

- Tables
- Flat files
- A combination of a table and a flat file

The key columns can have a primary key and foreign key relationship defined or they can be unrelated (as when one comes from a datastore and the other from a file format).

You can choose between two levels of relationship profiles to save:

- *Save key columns data only*—By default, the Data Profiler saves the data only in the columns that you select for the relationship.

  > Note
  >
  > The Save key columns data only level is not available when using Oracle datastores.

- *Save all columns data*—You can save the values in the other columns in each row, but this processing will take longer and consume more computer resources to complete.

When you view the relationship profile results, you can drill down to see the actual data that does not match.

You can use the relationship profile to assist you in different tasks, including the following tasks:

- Identify missing data in the source system. For example, one data source might include region, but another source might not.
- Identify redundant data across data sources. For example, duplicate names and addresses might exist between two sources or no name might exist for an address in one source.
- Validate relationships across data sources. For example, two different problem tracking systems might include a subset of common customer-reported problems, but some problems only exist in one system or the other.

Related Information

Submitting relationship profiler tasks [page 440]
Viewing the profiler results [page 443]

2.15.1.4 Executing a profiler task

The Data Profiler allows you to calculate profiler statistics for any set of columns you choose.

> **Note**
>
> This optional feature is not available for columns with nested schemas, LONG or TEXT data type.

You cannot execute a column profile task with a relationship profile task.

2.15.1.4.1 Submitting column profiler tasks

1. In the Object Library of the Designer, you can select either a table or flat file.

   For a table, go to the *Datastores* tab and select a table. If you want to profile all tables within a datastore, select the datastore name. To select a subset of tables in the *Ddatastore* tab, hold down the Ctrl key as you select each table.

   For a flat file, go to the *Formats* tab and select a file.
2. After you select your data source, you can generate column profile statistics in one of the following ways:
   - Right-click and select *Submit Column Profile Request*.
     Some of the profile statistics can take a long time to calculate. Select this method so the profile task runs asynchronously and you can perform other Designer tasks while the profile task executes.
     This method also allows you to profile multiple sources in one profile task.
   - Right-click, select *View Data*, click the *Profile* tab, and click *Update*. This option submits a synchronous profile task, and you must wait for the task to complete before you can perform other tasks in the Designer .
     You might want to use this option if you are already in the *View Data* window and you notice that either the profile statistics have not yet been generated, or the date that the profile statistics were generated is older than you want.
3. (Optional) Edit the profiler task name.

   The Data Profiler generates a default name for each profiler task. You can edit the task name to create a more meaningful name, a unique name, or to remove dashes which are allowed in column names but not in task names.

   If you select a single source, the default name has the following format:

   `<username_t_sourcename>`

   If you select multiple sources, the default name has the following format:

   `<username_t_firstsourcename_lastsourcename>`

Column	Description
username	Name of the user that the software uses to access system services.
t	Type of profile. The value is `C` for column profile that obtains attributes (such as low value and high value) for each selected column.

Column	Description
firstsourcename	Name of first source in alphabetic order.
lastsourcename	Name of last source in alphabetic order if you select multiple sources.

4. If you select one source, the *Submit Column Profile Request* window lists the columns and data types.

   Keep the check in front of each column that you want to profile and remove the check in front of each column that you do not want to profile.

   Alternatively, you can click the check box at the top in front of *Name* to deselect all columns and then select the check boxes.
5. If you selected multiple sources, the *Submit Column Profiler Request* window lists the sources on the left.
   a) Select a data source to display its columns on the right side.
   b) On the right side of the *Submit Column Profile Request* window, keep the check in front of each column that you want to profile, and remove the check in front of each column that you do not want to profile.

      Alternatively, you can click the check box at the top in front of Name to deselect all columns and then select the individual check box for the columns you want to profile.
   c) Repeat steps 1 and 2 for each data source.
6. (Optional) Select *Detailed profiling* for a column.

   > i Note
   >
   > The Data Profiler consumes a large amount of resources when it generates detailed profile statistics. Choose Detailed profiling only if you want these attributes: distinct count, distinct percent, median value, median string length, pattern, pattern count. If you choose Detailed profiling, ensure that you specify a pageable cache directory that contains enough disk space for the amount of data you profile.

   If you want detailed attributes for all columns in all sources listed, click *Detailed profiling* and select *Apply* to all columns of all sources.

   If you want to remove Detailed profiling for all columns, click *Detailed profiling* and select *Remove* from all columns of all sources.
7. Click *Submit* to execute the profile task.

   > i Note
   >
   > If the table metadata changed since you imported it (for example, a new column was added), you must re-import the source table before you execute the profile task.

   If you clicked the *Submit Column Profile Request* option to reach this *Submit Column Profiler Request* window, the Profiler monitor pane appears automatically when you click *Submit*.

   If you clicked *Update* on the *Profile* tab of the *View Data* window, the *Profiler* monitor window does not appear when you click *Submit*. Instead, a profile task is submitted asynchronously and you must wait for it to complete before you can do other tasks in the Designer .

   You can also monitor your profiler task by name in the Administrator.
8. When the profiler task has completed, you can view the profile results in the *View Data* option.

Related Information

Administrator Guide: To configure run-time resources [page 87]
Management Console Guide: Monitoring profiler tasks using the Administrator [page 1933]

2.15.1.4.2 Submitting relationship profiler tasks

A relationship profile shows the percentage of non matching values in columns of two sources. The sources can be any of the following:

- Tables
- Flat files
- A combination of a table and a flat file

The columns can have a primary key and foreign key relationship defined or they can be unrelated (as when one comes from a datastore and the other from a file format).

The two columns do not need to be the same data type, but they must be convertible. For example, if you run a relationship profiler task on an integer column and a varchar column, the Data Profiler converts the integer value to a varchar value to make the comparison.

> i Note
>
> The Data Profiler consumes a large amount of resources when it generates relationship values. If you plan to use Relationship profiling, ensure that you specify a pageable cache directory that contains enough disk space for the amount of data you profile.

Related Information

Data sources that you can profile [page 434]
Administrator Guide: To configure run-time resources [page 87]

2.15.1.4.2.1 To generate a relationship profile for columns in two sources

1. In the Object Library of the Designer, select two sources.

   To select two sources in the same datastore or file format:

   a) Go to the *Datastore* or *Format* tab in the Object Library.

b) Hold the Ctrl key down as you select the second table.
c) Right-click and select *Submit Relationship Profile Request*.

To select two sources from different datastores or files:

a) Go to the *Datastore* or *Format* tab in the Object Library.
b) Right-click on the first source, select *Submit Relationship Profile Request* > *Relationship with* .
c) Change to a different Datastore or Format in the Object Library
d) Click on the second source.

The *Submit Relationship Profile Request* window appears.

> **Note**
>
> You cannot create a relationship profile for columns with a LONG or TEXT data type.

2. (Optional) Edit the profiler task name.

   You can edit the task name to create a more meaningful name, a unique name, or to remove dashes, which are allowed in column names but not in task names. The default name that the Data Profiler generates for multiple sources has the following format:

   ```
   <username>_<t>_<firstsourcename>_<lastsourcename>
   ```

Column	Description
username	Name of the user that the software uses to access system services.
t	Type of profile. The value is `R` for Relationship profile that obtains non matching values in the two selected columns.
firstsourcename	Name first selected source.
lastsourcename	Name last selected source.

3. By default, the upper pane of the *Submit Relationship Profile Request* window shows a line between the primary key column and foreign key column of the two sources, if the relationship exists. You can change the columns to profile.

   The bottom half of the *Submit Relationship Profile Request* window shows that the profile task will use the equal (=) operation to compare the two columns. The Data Profiler will determine which values are not equal and calculate the percentage of non matching values.
4. To delete an existing relationship between two columns, select the line, right-click, and select *Delete Selected Relation*.

   To delete all existing relationships between the two sources, do one of the following actions:

   ○ Right-click in the upper pane and click *Delete All Relations*.
   ○ Click *Delete All Relations* near the bottom of the *Submit Relationship Profile Request* window.
5. If a primary key and foreign key relationship does not exist between the two data sources, specify the columns to profile. You can resize each data source to show all columns.

   To specify or change the columns for which you want to see relationship values:

   a) Move the cursor to the first column to select. Hold down the cursor and draw a line to the other column that you want to select.

b) If you deleted all relations and you want the Data Profiler to select an existing primary-key and foreign-key relationship, either right-click in the upper pane and click *Propose Relation*, or click *Propose Relation* near the bottom of the *Submit Relationship Profile Request* window.

6. By default, the *Save key columns data only* option is selected. This option indicates that the Data Profiler saves the data only in the columns that you select for the relationship, and you will not see any sample data in the other columns when you view the relationship profile.

   If you want to see values in the other columns in the relationship profile, select the *Save all columns data* option.
7. Click *Submit* to execute the profiler task.

   > i Note
   >
   > If the table metadata changed since you imported it (for example, a new column was added), you must re-import the source table before you execute the profile task.
8. The Profiler monitor pane appears automatically when you click *Submit*.

   You can also monitor your profiler task by name in the Administrator.
9. When the profiler task has completed, you can view the profile results in the *View Data* option when you right click on a table in the Object Library.

Related Information

2.15.1.5 Monitoring profiler tasks using the Designer

The *Profiler* monitor window appears automatically when you submit a profiler task if you clicked the menu bar to view the *Profiler* monitor window. You can dock this profiler monitor pane in the Designer or keep it separate.

The Profiler monitor pane displays the currently running task and all of the profiler tasks that have executed within a configured number of days.

The icons in the upper-left corner of the Profiler monitor display the following information:

- Click the *Refresh* icon to refresh the Profiler monitor pane and display the latest status of profiler tasks.
- Click the *Information* icon to view the sources that the selected task is profiling. If the task failed, the Information window also displays an error message.

The Profiler monitor shows the following columns:

Column	Description

Name	Name of the profiler task that was submitted from the Designer.
	If the profiler task is for a single source, the default name has the following format:
	`<username_t_sourcename>`
	If the profiler task is for multiple sources, the default name has the following format:
	`<username_t_firstsourcename_lastsourcename>`

Type	The type of profiler task can be: ● Column ● Relationship
Status	The status of a profiler task can be: ● Done—The task completed successfully. ● Pending—The task is on the wait queue because the maximum number of concurrent tasks has been reached or another task is profiling the same table. ● Running—The task is currently executing. ● Error—The task terminated with an error. Double-click on the value in this Status column to display the error message.
Timestamp	Date and time that the profiler task executed.
Sources	Names of the tables for which the profiler task executes.

Related Information

Executing a profiler task [page 438]
Management Console Guide: Configuring profiler task parameters [page 1930]

2.15.1.6 Viewing the profiler results

The Data Profiler calculates and saves the profiler attributes into a profiler repository that multiple users can view.

Related Information

To view the column attributes generated by the Data Profiler [page 444]
To view the relationship profile data generated by the Data Profiler [page 446]

2.15.1.6.1 To view the column attributes generated by the Data Profiler

1. In the Object Library, select the table for which you want to view profiler attributes.
2. Right-click and select *View Data*.
3. Click the *Profile* tab (second) to view the column profile attributes.
   a) The *Profile* tab shows the number of physical records that the Data Profiler processed to generate the values in the profile grid.
   b) The profile grid contains the column names in the current source and profile attributes for each column. To populate the profile grid, execute a profiler task or select names from this column and click *Update*.
   c) You can sort the values in each attribute column by clicking the column heading. The value `n/a` in the profile grid indicates an attribute does not apply to a data type,

Basic profile attribute	Description	Relevant data type		
		Character	Numeric	Datetime
Min	Of all values, the lowest value in this column.	Yes	Yes	Yes
Min count	Number of rows that contain this lowest value in this column.	Yes	Yes	Yes
Max	Of all values, the highest value in this column.	Yes	Yes	Yes
Max count	Number of rows that contain this highest value in this column.	Yes	Yes	Yes
Average	For numeric columns, the average value in this column.	n/a	Yes	n/a
Min string length	For character columns, the length of the shortest string value in this column.	Yes	No	No
Max string length	For character columns, the length of the longest string value in this column.	Yes	No	No
Average string length	For character columns, the average length of the string values in this column.	Yes	No	No
Nulls	Number of `NULL` values in this column.	Yes	Yes	Yes
Nulls %	Percentage of rows that contain a `NULL` value in this column.	Yes	Yes	Yes
Zeros	Number of `0` values in this column.	No	Yes	No
Zeros %	Percentage of rows that contain a `0` value in this column.	No	Yes	No
Blanks	For character columns, the number of rows that contain a blank in this column.	Yes	No	No
Blanks %	Percentage of rows that contain a blank in this column.	Yes	No	No

   d) If you selected the *Detailed profiling* option on the *Submit Column Profile Request* window, the *Profile* tab also displays the following detailed attribute columns.

Detailed profile attribute	Description	Relevant data type		
		Character	Numeric	Datetime
Distincts	Number of distinct values in this column.	Yes	Yes	Yes
Distinct %	Percentage of rows that contain each distinct value in this column.	Yes	Yes	Yes
Median	The value that is in the middle row of the source table.	Yes	Yes	Yes
Median string length	For character columns, the value that is in the middle row of the source table.	Yes	No	No
Pattern %	Percentage of rows that contain each distinct value in this column. The format of each unique pattern in this column.	Yes	No	No
Patterns	Number of different patterns in this column.	Yes	No	No

4. Click an attribute value to view the entire row in the source table. The bottom half of the *View Data* window displays the rows that contain the attribute value that you clicked. You can hide columns that you do not want to view by clicking the Show/Hide Columns icon.

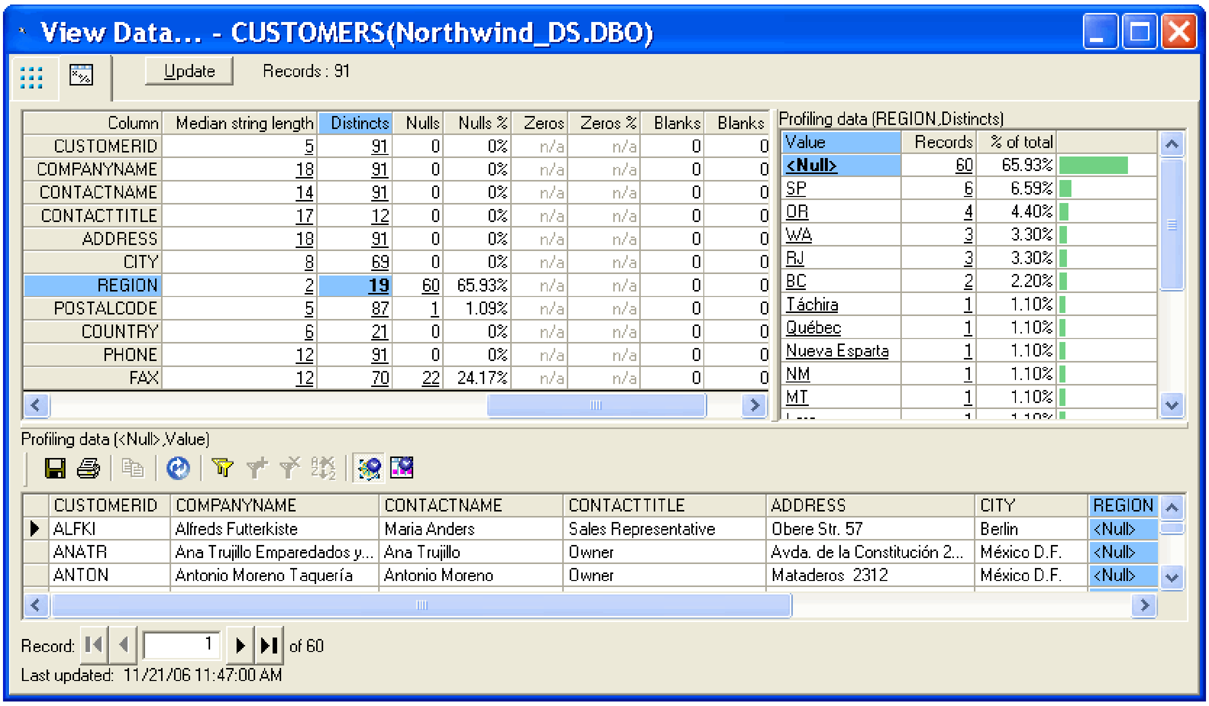
   For example, your target ADDRESS column might only be 45 characters, but the Profiling data for this Customer source table shows that the maximum string length is 46. Click the value 46 to view the actual data. You can resize the width of the column to display the entire string.
5. (Optional) Click *Update* if you want to update the profile attributes. Reasons to update at this point include:
   - The profile attributes have not yet been generated.
   - The date that the profile attributes were generated is older than you want. The Last updated value in the bottom left corner of the *Profile* tab is the timestamp when the profile attributes were last generated.

   > Note
   >
   > The Update option submits a synchronous profiler task, and you must wait for the task to complete before you can perform other tasks in the Designer.

   The *Submit column Profile Request* window appears.

   Select only the column names you need for this profiling operation because Update calculations impact performance. You can also click the check box at the top in front of Name to deselect all columns and then select each check box in front of each column you want to profile.
6. Click a statistic in either Distincts or Patterns to display the percentage of each distinct value or pattern value in a column. The pattern values, number of records for each pattern value, and percentages appear on the right side of the *Profile* tab.

   For example, the following *Profile* tab for table CUSTOMERS shows the profile attributes for column REGION. The Distincts attribute for the REGION column shows the statistic 19 which means 19 distinct values for REGION exist.



View Data... - CUSTOMERS(Northwind_DS.DBO)

7. Click the statistic in the Distincts column to display each of the 19 values and the percentage of rows in table CUSTOMERS that have that value for column REGION. In addition, the bars in the right-most column show the relative size of each percentage.
8. The Profiling data on the right side shows that a very large percentage of values for REGION is Null. Click either `Null` under Value or `60` under Records to display the other columns in the rows that have a Null value in the REGION column.
9. Your business rules might dictate that REGION should not contain Null values in your target data warehouse. Therefore, decide what value you want to substitute for Null values when you define a validation transform.

Related Information

Executing a profiler task [page 438]

Defining a validation rule based on a column profile [page 451]

2.15.1.6.2 To view the relationship profile data generated by the Data Profiler

Relationship profile data shows the percentage of non matching values in columns of two sources. The sources can be tables, flat files, or a combination of a table and a flat file. The columns can have a primary key and foreign key relationship defined or they can be unrelated (as when one comes from a datastore and the other from a file format).

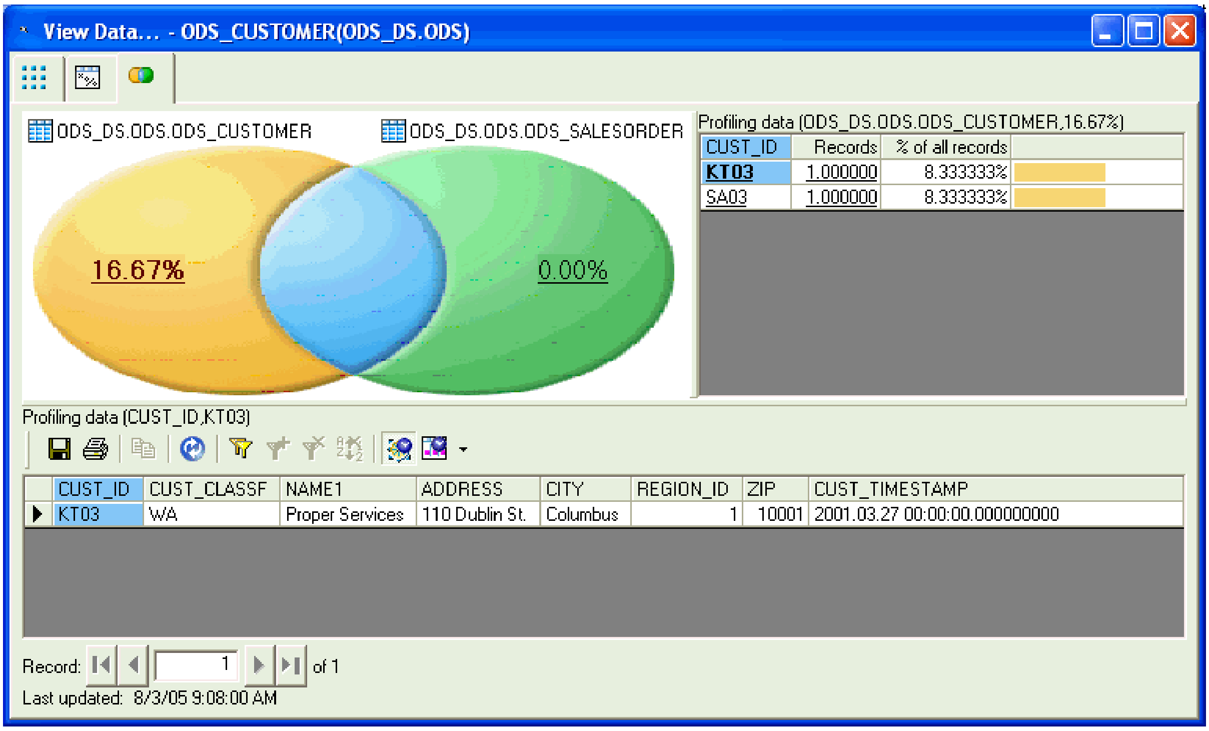
1. In the Object Library, select the table or file for which you want to view relationship profile data.

2. Right-click and select *View Data*.
3. Click the *Relationship* tab (third) to view the relationship profile results.

> i Note
>
> The *Relationship* tab is visible only if you executed a relationship profiler task.

4. Click the nonzero percentage in the diagram to view the key values that are not contained within the other table.

   For example, the following View Data Relationship tab shows the percentage (16.67) of customers that do not have a sales order. The relationship profile was defined on the CUST_ID column in table ODS_CUSTOMER and CUST_ID column in table ODS_SALESORDER. The value in the left oval indicates that 16.67% of rows in table ODS_CUSTOMER have CUST_ID values that do not exist in table ODS_SALESORDER.



View Data... - ODS_CUSTOMER(ODS_DS.ODS)

ODS_DS.ODS.ODS_SALESORDER
16.67%
0.00%

Profiling data (ODS_DS.ODS.ODS_CUSTOMER,16.67%)

CUST_ID	Records	% of all records
KT03	1.000000	8.333333%
SA03	1.000000	8.333333%

Profiling data (CUST_ID,KT03)

CUST_ID	CUST_CLASSF	NAME1	ADDRESS	CITY	REGION_ID	ZIP	CUST_TIMESTAMP
KT03	WA	Proper Services	110 Dublin St.	Columbus	1	10001	2001.03.27 00:00:00.000000000

Record: 1 of 1

Last updated: 8/3/05 9:08:00 AM

   Click the 16.67 percentage in the ODS_CUSTOMER oval to display the CUST_ID values that do not exist in the ODS_SALESORDER table. The non matching values KT03 and SA03 display on the right side of the Relationship tab. Each row displays a non matching CUST_ID value, the number of records with that CUST_ID value, and the percentage of total customers with this CUST_ID value.

5. Click one of the values on the right side to display the other columns in the rows that contain that value.

   The bottom half of the *Relationship Profile* tab displays the values in the other columns of the row that has the value KT03 in the column CUST_ID.

> i Note
>
> If you did not select Save all column data on the *Submit Relationship Profile Request* window, you cannot view the data in the other columns.

Related Information

Submitting relationship profiler tasks [page 440]

2.15.2 Using View Data to determine data quality

Use View Data to help you determine the quality of your source and target data. View Data provides the capability to:

- View sample source data before you execute a job to create higher quality job designs.
- Compare sample data from different steps of your job to verify that your data extraction job returns the results you expect.

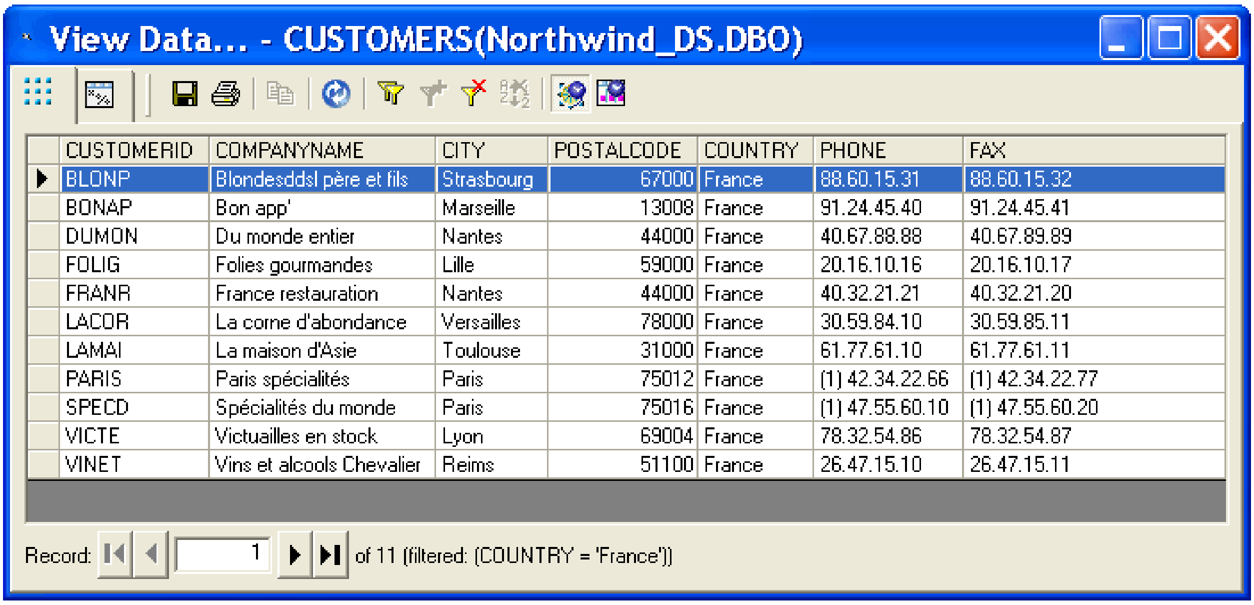
Related Information

Defining a validation rule based on a column profile [page 451]
Using View Data [page 688]

2.15.2.1 Data tab

The *Data* tab is always available and displays the data contents of sample rows. You can display a subset of columns in each row and define filters to display a subset of rows.

For example, your business rules might dictate that all phone and fax numbers be in one format for each country. The following *Data* tab shows a subset of rows for the customers that are in France.



CUSTOMERID	COMPANYNAME	CITY	POSTALCODE	COUNTRY	PHONE	FAX
BLONP	Blondesddsl père et fils	Strasbourg	67000	France	88.60.15.31	88.60.15.32
BONAP	Bon app'	Marseille	13008	France	91.24.45.40	91.24.45.41
DUMON	Du monde entier	Nantes	44000	France	40.67.88.88	40.67.89.89
FOLIG	Folies gourmandes	Lille	59000	France	20.16.10.16	20.16.10.17
FRANR	France restauration	Nantes	44000	France	40.32.21.21	40.32.21.20
LACOR	La corne d'abondance	Versailles	78000	France	30.59.84.10	30.59.85.11
LAMAI	La maison d'Asie	Toulouse	31000	France	61.77.61.10	61.77.61.11
PARIS	Paris spécialités	Paris	75012	France	(1) 42.34.22.66	(1) 42.34.22.77
SPECD	Spécialités du monde	Paris	75016	France	(1) 47.55.60.10	(1) 47.55.60.20
VICTE	Victuailles en stock	Lyon	69004	France	78.32.54.86	78.32.54.87
VINET	Vins et alcools Chevalier	Reims	51100	France	26.47.15.10	26.47.15.11

Record: 1 of 11 (filtered: (COUNTRY = 'France'))

Notice that the PHONE and FAX columns displays values with two different formats. You can now decide which format you want to use in your target data warehouse and define a validation transform accordingly.

Related Information

View Data Properties [page 692]
Defining a validation rule based on a column profile [page 451]
Data tab [page 696]

2.15.2.2 Profile tab

Two displays are available on the *Profile* tab:

- Without the Data Profiler, the *Profile* tab displays the following column attributes: distinct values, NULLs, minimum value, and maximum value.
- If you configured and use the Data Profiler, the *Profile* tab displays the same above column attributes plus many more calculated statistics, such as average value, minimum string length, and maximum string length, distinct count, distinct percent, median, median string length, pattern count, and pattern percent.

Related Information

Profile tab [page 697]
To view the column attributes generated by the Data Profiler [page 444]

2.15.2.3 Relationship Profile or Column Profile tab

The third tab that displays depends on whether or not you configured and use the Data Profiler.

- If you do not use the Data Profiler, the *Column Profile* tab allows you to calculate statistical information for a single column.
- If you use the Data Profiler, the *Relationship* tab displays the data mismatches between two columns from which you can determine the integrity of your data between two sources.

Related Information

Column Profile tab [page 698]
To view the relationship profile data generated by the Data Profiler [page 446]

2.15.3 Using the Validation transform

The Data Profiler and View Data features can identify anomalies in incoming data. You can then use a Validation transform to define the rules that sort good data from bad. You can write the bad data to a table or file for subsequent review.

For details on the Validation transform including how to implement reusable validation functions, see the *SAP Data Services Reference Guide*.

Related Information

Reference Guide: Transforms, Validation [page 1472]

2.15.3.1 Analyzing the column profile

You can obtain column profile information by submitting column profiler tasks.

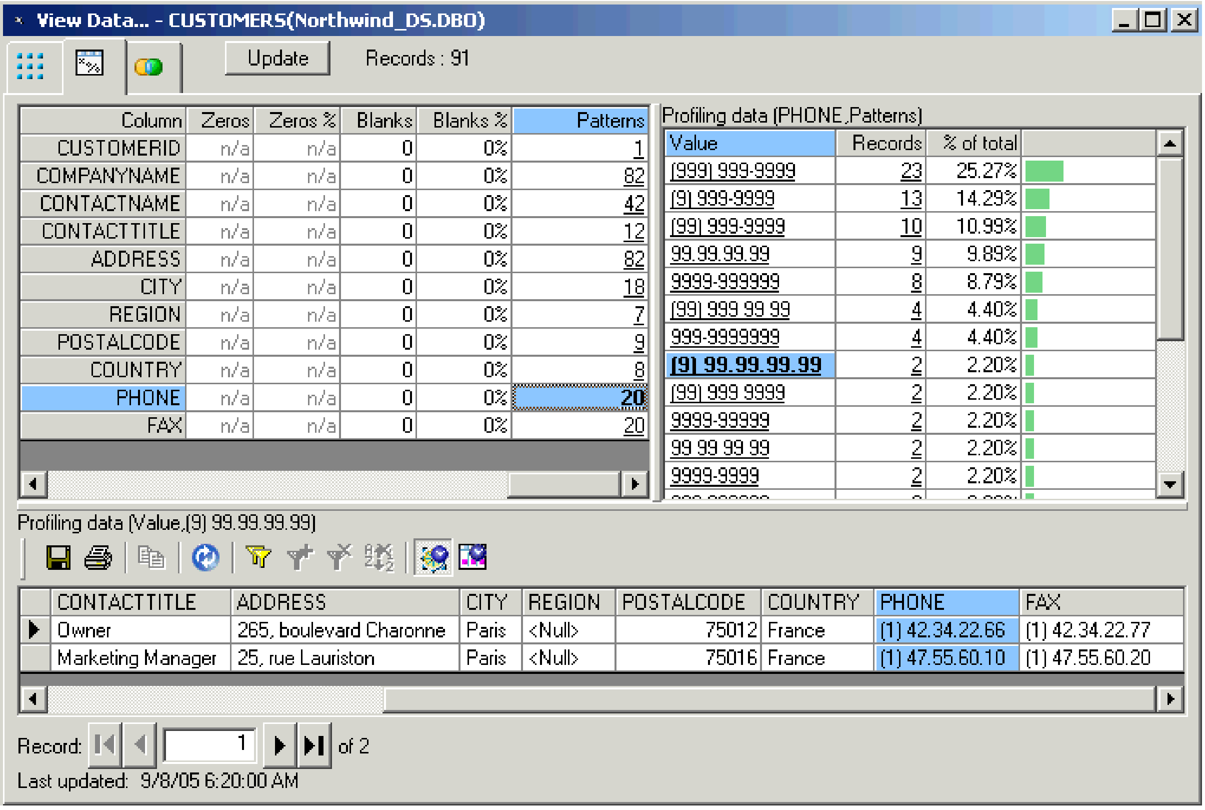
For example, suppose you want to analyze the data in the Customers table in the Microsoft SQL Server Northwinds sample database.

Related Information

Submitting column profiler tasks [page 438]

2.15.3.1.1 To analyze column profile attributes

1. In the object library, right-click the profiled Customers table and select *View Data*.
2. Select the *Profile* tab in the *View Data* window. The Profile tab displays the column-profile attributes shown in the following graphic.



View Data... - CUSTOMERS(Northwind_DS.DBO)

Record: 1 of 2

Last updated: 9/8/05 6:20:00 AM

The Patterns attribute for the PHONE column shows the value 20, which means 20 different patterns exist.

3. Click the value 20 in the *Patterns* attribute column. The *Profiling data* pane displays the individual patterns for the column PHONE and the percentage of rows for each pattern.
4. Suppose that your business rules dictate that all phone numbers in France should have the format 99.99.99.99. However, the profiling data shows that two records have the format (9) 99.99.99.99. To display the columns for these two records in the bottom pane, click either `(9) 99.99.99.99` under Value or click `2` under Records. You can see that some phone numbers in France have a prefix of (1).

You can use a Validation transform to identify rows containing the unwanted prefix. Then you can correct the data to conform to your busness rules then reload it.

The next section describes how to configure the Validation transform to identify the errant rows.

Related Information

Defining a validation rule based on a column profile [page 451]

2.15.3.2 Defining a validation rule based on a column profile

This section takes the Data Profiler results and defines the Validation transform according to the sample business rules. Based on the preceding example of the phone prefix (1) for phone numbers in France, the following procedure describes how to define a data flow and validation rule that identifies that pattern. You can then review the failed data, make corrections, and reload the data.

2.15.3.2.1 To define the validation rule that identifies a pattern

This procedure describes how to define a data flow and validation rule that identifies rows containing the (1) prefix described in the previous section.

1. Create a data flow with the Customers table as a source, add a Validation transform and a target, and connect the objects.
2. Open the Validation transform by clicking its name.
3. In the transform editor, click *Add*.
   The Rule Editor dialog box displays.
4. Type a *Name* and optionally a *Description* for the rule.
5. Verify the *Enabled* check box is selected.
6. For *Action on Fail*, select *Send to Fail*.
7. Select the *Column Validation* radio button.
   a) Select the *Column* CUSTOMERS.PHONE from the drop-down list.
   b) For *Condition*, from the drop-down list select *Match pattern*.
   c) For the value, type the expression `'99.99.99.99'`.
8. Click *OK*.
   The rule appears in the Rules list.

After running the job, the incorrectly formatted rows appear in the Fail output. You can now review the failed data, make corrections as necessary upstream, and reload the data.

Related Information

Analyzing the column profile [page 450]

2.15.4 Using Auditing

Auditing provides a way to ensure that a data flow loads correct data into the warehouse. Use auditing to perform the following tasks:

- Define audit points to collect run time statistics about the data that flows out of objects. Auditing stores these statistics in the repository.
- Define rules with these audit statistics to ensure that the data at the following points in a data flow is what you expect:
  - Extracted from sources

- Processed by transforms
- Loaded into targets

- Generate a run time notification that includes the audit rule that failed and the values of the audit statistics at the time of failure.
- Display the audit statistics after the job execution to help identify the object in the data flow that might have produced incorrect data.

Note

If you add an audit point prior to an operation that is usually pushed down to the database server, performance might degrade because push-down operations cannot occur after an audit point.

2.15.4.1 Auditing objects in a data flow

You can collect audit statistics on the data that flows out of any object, such as a source, transform, or target. If a transform has multiple distinct or different outputs (such as Validation or Case), you can audit each output independently.

To use auditing, you define the following objects in the *Audit* window:

<table>
<tr><th>Object name</th><th>Description</th></tr>
<tr><td>Audit point</td><td>The object in a data flow where you collect audit statistics. You can audit a source, a transform, or a target. You identify the object to audit when you define an audit function on it.</td></tr>
<tr><td>Audit function</td><td>The audit statistic that the software collects for a table, output schema, or column. The following table shows the audit functions that you can define.
<table>
<tr><th>Data object</th><th>Audit function</th><th>Description</th></tr>
<tr><td>Table or output schema</td><td>Count</td><td>This function collects two statistics:
• Good count for rows that were successfully processed.
• Error count for rows that generated some type of error if you enabled error handling.</td></tr>
<tr><td>Column</td><td>Sum</td><td>Sum of the numeric values in the column. Applicable data types include decimal, double, integer, and real. This function only includes the Good rows.</td></tr>
<tr><td>Column</td><td>Average</td><td>Average of the numeric values in the column. Applicable data types include decimal, double, integer, and real. This function only includes the Good rows.</td></tr>
</table></td></tr>
</table>

<table>
<tr><th>Object name</th><th>Description</th></tr>
<tr><td></td><td><table><tr><th>Data object</th><th>Audit function</th><th>Description</th></tr><tr><td>Column</td><td>Checksum</td><td>Checksum of the values in the column.</td></tr></table></td></tr>
<tr><td>Audit label</td><td>The unique name in the data flow that the software generates for the audit statistics collected for each audit function that you define. You use these labels to define audit rules for the data flow.</td></tr>
<tr><td>Audit rule</td><td>A Boolean expression in which you use audit labels to verify the job. If you define multiple rules in a data flow, all rules must succeed or the audit fails.</td></tr>
<tr><td>Actions on audit failure</td><td>One or more of three ways to generate notification of an audit rule (or rules) failure: email, custom script, raise exception.</td></tr>
</table>

2.15.4.1.1 Audit function

This section describes the data types for the audit functions and the error count statistics.

Data types

The following table shows the default data type for each audit function and the permissible data types. You can change the data type in the *Properties* window for each audit function in the Designer.

Audit functions	Default data type	Allowed data types
Count	Integer	Integer
Sum	Type of audited column	Integer, Decimal, Double, Real
Average	Type of audited column	Integer, Decimal, Double, Real
Checksum	Varchar(128)	Varchar(128)

Error count statistic

When you enable a Count audit function, the software collects two types of statistics:

- *Good* row count for rows processed without any error.
- *Error* row count for rows that the job could not process but ignores those rows to continue processing. One way that error rows can result is when you specify the *Use overflow file* option in the Source Editor or Target Editor.

2.15.4.1.2 Audit label

The software generates a unique name for each audit function that you define on an audit point. You can edit the label names. You might want to edit a label name to create a shorter meaningful name or to remove dashes, which are allowed in column names but not in label names.

Generating label names

If the audit point is on a table or output schema, the software generates the following two labels for the audit function Count:

```
$Count<_objectname>
$CountError<_objectname>
```

If the audit point is on a column, the software generates an audit label with the following format:

```
$ <auditfunction_objectname>
```

If the audit point is in an embedded data flow, the labels have the following formats:

```
$Count<_objectname_embeddedDFname>
$CountError<_objectname_embeddedDFname>
$<auditfunction_objectname_embeddedDFname>
```

Editing label names

You can edit the audit label name when you create the audit function and before you create an audit rule that uses the label.

If you edit the label name after you use it in an audit rule, the audit rule does not automatically use the new name. You must redefine the rule with the new name.

2.15.4.1.3 Audit rule

An audit rule is a Boolean expression which consists of a Left-Hand-Side (LHS), a Boolean operator, and a Right-Hand-Side (RHS).

- The LHS can be a single audit label, multiple audit labels that form an expression with one or more mathematical operators, or a function with audit labels as parameters.
- The RHS can be a single audit label, multiple audit labels that form an expression with one or more mathematical operators, a function with audit labels as parameters, or a constant.

The following Boolean expressions are examples of audit rules:

```
$Count_CUSTOMER = $Count_CUSTDW
$Sum_ORDER_US + $Sum_ORDER_EUROPE = $Sum_ORDER_DW
round($Avg_ORDER_TOTAL) >= 10000
```

2.15.4.1.4 Audit notification

You can choose any combination of the following actions for notification of an audit failure. If you choose all three actions, the software executes them in this order:

- Email to list — the software sends a notification of which audit rule failed to the email addresses that you list in this option. Use a comma to separate the list of email addresses.
  You can specify a variable for the email list.
  This option uses the smtp_to function to send email. Therefore, you must define the server and sender for the Simple Mail Transfer Protocol (SMTP) in the Server Manager.
- Script — the software executes the custom script that you create in this option.
- Raise exception — The job fails if an audit rule fails, and the error log shows which audit rule failed. The job stops at the first audit rule that fails. This action is the default.
  You can use this audit exception in a try/catch block. You can continue the job execution in a try/catch block.
  If you clear this action and an audit rule fails, the job completes successfully and the audit does not write messages to the job log. You can view which rule failed in the Auditing Details report in the Metadata Reporting tool.

Related Information

Viewing audit results [page 463]

2.15.4.2 Accessing the Audit window

Access the *Audit* window from one of the following places in the Designer:

- From the Data Flows tab of the object library, right-click on a data flow name and select the *Auditing* option.
- In the workspace, right-click on a data flow icon and select the *Auditing* option.
- When a data flow is open in the workspace, click the *Audit* icon in the toolbar.

When you first access the *Audit* window, the Label tab displays the sources and targets in the data flow. If your data flow contains multiple consecutive query transforms, the *Audit* window shows the first query.

Click the icons on the upper left corner of the Label tab to change the display.

Icon	Tool tip	Description
⊟	Collapse All	Collapses the expansion of the source, transform, and target objects.

Icon	Tool tip	Description
	Show All Objects	Displays all the objects within the data flow.
	Show Source, Target and first-level Query	Default display which shows the source, target, and first-level query objects in the data flow. If the data flow contains multiple consecutive query transforms, only the first-level query displays.
Σ	Show Labelled Objects	Displays the objects that have audit labels defined.

2.15.4.3 Defining audit points, rules, and action on failure

1. Access the *Audit* window.
2. Define audit points.

   On the Label tab, right-click on an object that you want to audit and choose an audit function or Properties.

   When you define an audit point, the software generates the following:

   ○ An audit icon on the object in the data flow in the workspace
   ○ An audit label that you use to define audit rules.

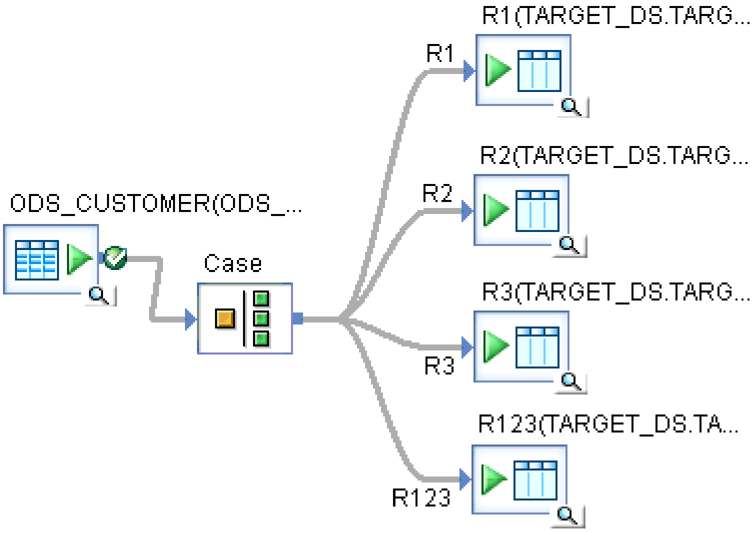
   In addition to choosing an audit function, the Properties window allows you to edit the audit label and change the data type of the audit function.

   For example, the data flow Case_DF has the following objects and you want to verify that all of the source rows are processed by the Case transform.

   ○ Source table ODS_CUSTOMER
   ○ Four target tables:
     R1 contains rows where ODS_CUSTOMER.REGION_ID = 1
     R2 contains rows where ODS_CUSTOMER.REGION_ID = 2
     R3 contains rows where ODS_CUSTOMER.REGION_ID = 3
     R123 contains rows where ODS_CUSTOMER.REGION_ID IN (1, 2 or 3)

   a) Right-click on source table ODS_CUSTOMER and choose *Count*.

      The software creates the audit labels $Count_ODS_CUSTOMER and $CountError_ODS_CUSTOMER, and an audit icon appears on the source object in the workspace.



b) Similarly, right-click on each of the target tables and choose *Count*. The Audit window shows the following audit labels.

Target table	Audit function	Audit label
ODS_CUSTOMER	Count	$Count_ODS_CUSTOMER
R1	Count	$Count_ R1
R2	Count	$Count_ R2
R3	Count	$Count_ R3
R123	Count	$Count_ R123

c) If you want to remove an audit label, right-click on the label, and the audit function that you previously defined displays with a check mark in front of it. Click the function to remove the check mark and delete the associated audit label.

When you right-click on the label, you can also select Properties, and select the value (No Audit) in the *Audit function* drop-down list.

3. Define audit rules. On the Rule tab in the *Audit* window, click *Add* which activates the expression editor of the Auditing Rules section.

If you want to compare audit statistics for one object against one other object, use the expression editor, which consists of three text boxes with drop-down lists:

a) Select the label of the first audit point in the first drop-down list.

b) Choose a Boolean operator from the second drop-down list. The options in the editor provide common Boolean operators. If you require a Boolean operator that is not in this list, use the Custom expression box with its function and smart editors to type in the operator.

c) Select the label for the second audit point from the third drop-down list. If you want to compare the first audit value to a constant instead of a second audit value, use the Customer expression box.

For example, to verify that the count of rows from the source table is equal to the rows in the target table, select audit labels and the Boolean operation in the expression editor as follows:

● $Count_ODS_CUSTOMER = $Count_R123

If you want to compare audit statistics for one or more objects against statistics for multiple other objects or a constant, select the Custom expression box.

a) Click the ellipsis button to open the full-size smart editor window.
b) Click the *Variables* tab on the left and expand the *Labels* node.
c) Drag the first audit label of the object to the editor pane.
d) Type a Boolean operator
e) Drag the audit labels of the other objects to which you want to compare the audit statistics of the first object and place appropriate mathematical operators between them.
f) Click *OK* to close the smart editor.
g) The audit rule displays in the Custom editor. To update the rule in the top Auditing Rule box, click on the title "Auditing Rule" or on another option.
h) Click *Close* in the Audit window.

For example, to verify that the count of rows from the source table is equal to the sum of rows in the first three target tables, drag the audit labels, type in the Boolean operation and plus signs in the smart editor as follows:

```
Count_ODS_CUSTOMER = $Count_R1 + $Count_R2 + $Count_R3
```

4. Define the action to take if the audit fails.

   You can choose one or more of the following actions:

   - Raise exception: The job fails if an audit rule fails and the error log shows which audit rule failed. This action is the default.
     If you clear this option and an audit rule fails, the job completes successfully and the audit does not write messages to the job log. You can view which rule failed in the Auditing Details report in the Metadata Reporting tool.
   - Email to list: The software sends a notification of which audit rule failed to the email addresses that you list in this option. Use a comma to separate the list of email addresses.
     You can specify a variable for the email list.
   - Script: The software executes the script that you create in this option.

5. Execute the job.

   The *Execution Properties* window has the *Enable auditing* option checked by default. Clear this box if you do not want to collect audit statistics for this specific job execution.

6. Look at the audit results.

   You can view passed and failed audit rules in the metadata reports. If you turn on the audit trace on the Trace tab in the *Execution Properties* window, you can view all audit results on the Job Monitor Log.

Related Information

Viewing audit results [page 463]

2.15.4.4 Guidelines to choose audit points

The following are guidelines to choose audit points:

- When you audit the output data of an object, the optimizer cannot push down operations after the audit point. Therefore, if the performance of a query that is pushed to the database server is more important than gathering audit statistics from the source, define the first audit point on the query or later in the data flow. For example, suppose your data flow has a source, query, and target objects, and the query has a WHERE clause that is pushed to the database server that significantly reduces the amount of data that returns to the software. Define the first audit point on the query, rather than on the source, to obtain audit statistics on the query results.
- If a pushdown_sql function is after an audit point, the software cannot execute it.
- You can only audit a bulkload that uses the Oracle API method. For the other bulk loading methods, the number of rows loaded is not available to the software.
- Auditing is disabled when you run a job with the debugger.
- You cannot audit NRDM schemas or real-time jobs.
- You cannot audit within an ABAP data flow, but you can audit the output of an ABAP data flow.
- If you use the CHECKSUM audit function in a job that normally executes in parallel, the software disables the DOP for the whole data flow. The order of rows is important for the result of CHECKSUM, and DOP processes the rows in a different order than in the source.

2.15.4.5 Auditing embedded data flows

You can define audit labels and audit rules in an embedded data flow. This section describes the following considerations when you audit embedded data flows:

- Enabling auditing in an embedded data flow
- Audit points not visible outside of the embedded data flow

2.15.4.5.1 Enabling auditing in an embedded data flow

If you want to collect audit statistics on an embedded data flow when you execute the parent data flow, you must enable the audit label of the embedded data flow.

2.15.4.5.1.1 To enable auditing in an embedded data flow

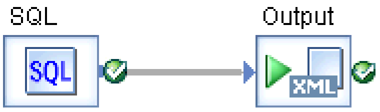
1. Open the parent data flow in the Designer workspace.
2. Click on the Audit icon in the toolbar to open the Audit window
3. On the Label tab, expand the objects to display any audit functions defined within the embedded data flow. If a data flow is embedded at the beginning or at the end of the parent data flow, an audit function might exist on the output port or on the input port.

4. Right-click the Audit function name and choose *Enable*. You can also choose *Properties* to change the label name and enable the label.
5. You can also define audit rules with the enabled label.

2.15.4.5.2 Audit points not visible outside of the embedded data flow

When you embed a data flow at the beginning of another data flow, data passes from the embedded data flow to the parent data flow through a single source. When you embed a data flow at the end of another data flow, data passes into the embedded data flow from the parent through a single target. In either case, some of the objects are not visible in the parent data flow.

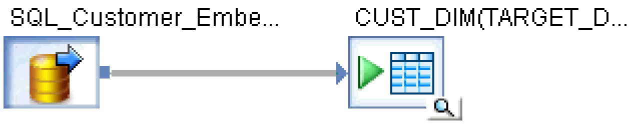
Because some of the objects are not visible in the parent data flow, the audit points on these objects are also not visible in the parent data flow. For example, the following embedded data flow has an audit function defined on the source SQL transform and an audit function defined on the target table.



The following Audit window shows these two audit points.

	Audit Function	Audit Label
SQL	Count	$Count_SQL
Output	Count	$Count_Output

When you embed this data flow, the target Output becomes a source for the parent data flow and the SQL transform is no longer visible.



An audit point still exists for the entire embedded data flow, but the label is no longer applicable. The following Audit window for the parent data flow shows the audit function defined in the embedded data flow, but does not show an Audit Label.

	Audit Function	Audit Label
SQL_Customer_Embed_DF		
SQL	Count	
CUST_DIM		

If you want to audit the embedded data flow, right-click on the audit function in the Audit window and select *Enable*.

2.15.4.6 Resolving invalid audit labels

An audit label can become invalid in the following situations:

- If you delete the audit label in an embedded data flow that the parent data flow has enabled.
- If you delete or rename an object that had an audit point defined on it

2.15.4.6.1 To resolve invalid audit labels

1. Open the Audit window.
2. Expand the Invalid Labels node to display the individual labels.
3. Note any labels that you would like to define on any new objects in the data flow.
4. After you define a corresponding audit label on a new object, right-click on the invalid label and choose *Delete*.
5. If you want to delete all of the invalid labels at once, right click on the Invalid Labels node and click on *Delete All*.

2.15.4.7 Viewing audit results

You can see the audit status in one of the following places:

- Job Monitor Log
- If the audit rule fails, the places that display audit information depends on the *Action on failure* option that you chose:

Action on failure	Places where you can view audit information
Raise exception	Job Error Log, Metadata Reports
Email to list	Email message, Metadata Reports
Script	Wherever the custom script sends the audit messages, Metadata Reports

Related Information

Job Monitor Log [page 463]
Job Error Log [page 464]
Metadata Reports [page 464]

2.15.4.7.1 Job Monitor Log

If you set *Audit Trace* to `Yes` on the Trace tab in the Execution Properties window, audit messages appear in the Job Monitor Log. You can see messages for audit rules that passed and failed.

The following sample audit success messages appear in the Job Monitor Log when *Audit Trace* is set to `Yes`:

```
Audit Label $Count_R2 = 4. Data flow <Case_DF>.
Audit Label $CountError_R2 = 0. Data flow <Case_DF>.
Audit Label $Count_R3 = 3. Data flow <Case_DF>.
Audit Label $CountError_R3 = 0. Data flow <Case_DF>.
Audit Label $Count_R123 = 12. Data flow <Case_DF>.
Audit Label $CountError_R123 = 0. Data flow <Case_DF>.
Audit Label $Count_R1 = 5. Data flow <Case_DF>.
Audit Label $CountError_R1 = 0. Data flow <Case_DF>.
Audit Label $Count_ODS_CUSTOMER = 12. Data flow <Case_DF>.
Audit Label $CountError_ODS_CUSTOMER = 0. Data flow <Case_DF>.
Audit Rule passed ($Count_ODS_CUSTOMER = (($CountR1 + $CountR2 + $Count_R3)):
LHS=12, RHS=12. Data flow <Case_DF>.
Audit Rule passed ($Count_ODS_CUSTOMER = $CountR123): LHS=12, RHS=12. Data flow
<Case_DF>.
```

2.15.4.7.2 Job Error Log

When you choose the *Raise exception* option and an audit rule fails, the Job Error Log shows the rule that failed. The following sample message appears in the Job Error Log:

```
Audit rule failed <($Count_ODS_CUSTOMER = $CountR1)> for <Data flow Case_DF>.
```

2.15.4.7.3 Metadata Reports

You can look at the Audit Status column in the Data Flow Execution Statistics reports of the Metadata Report tool. This Audit Status column has the following values:

- Not Audited
- Passed—All audit rules succeeded. This value is a link to the Auditing Details report which shows the audit rules and values of the audit labels.
- Information Collected—This status occurs when you define audit labels to collect statistics but do not define audit rules. This value is a link to the Auditing Details report which shows the values of the audit labels.
- Failed—Audit rule failed. This value is a link to the Auditing Details report which shows the rule that failed and values of the audit labels.

Management Console Guide: Operational Dashboard Reports [page 1975]

2.16 Data Quality

2.16.1 Overview of data quality

Data quality is a term that refers to the set of transforms that work together to improve the quality of your data by cleansing, enhancing, matching and consolidating data elements.

Data quality is primarily accomplished in the software using four transforms:

- Address Cleanse: Parses, standardizes, corrects, and enhances address data.
- Data Cleanse: Parses, standardizes, corrects, and enhances customer and operational data.
- Geocoding: Uses geographic coordinates, addresses, and point-of-interest (POI) data to append address, latitude and longitude, census, and other information to your records.
- Match: Identifies duplicate records at multiple levels within a single pass for individuals, households, or corporations within multiple tables or databases and consolidates them into a single source.

Related Information

Address Cleanse [page 585]
About cleansing data [page 465]
Geocoding [page 489]
Match [page 510]

2.16.2 Data Cleanse

2.16.2.1 About cleansing data

Data cleansing is the process of parsing and standardizing data.

The parsing rules and other information that define how to parse and standardize are stored in a cleansing package. The Cleansing Package Builder in SAP Information Steward provides a graphical user interface to create and refine cleansing packages. You can create a cleansing package from scratch based on sample data or adapt an existing cleansing package or SAP-supplied cleansing package to meet your specific data cleansing requirements and standards.

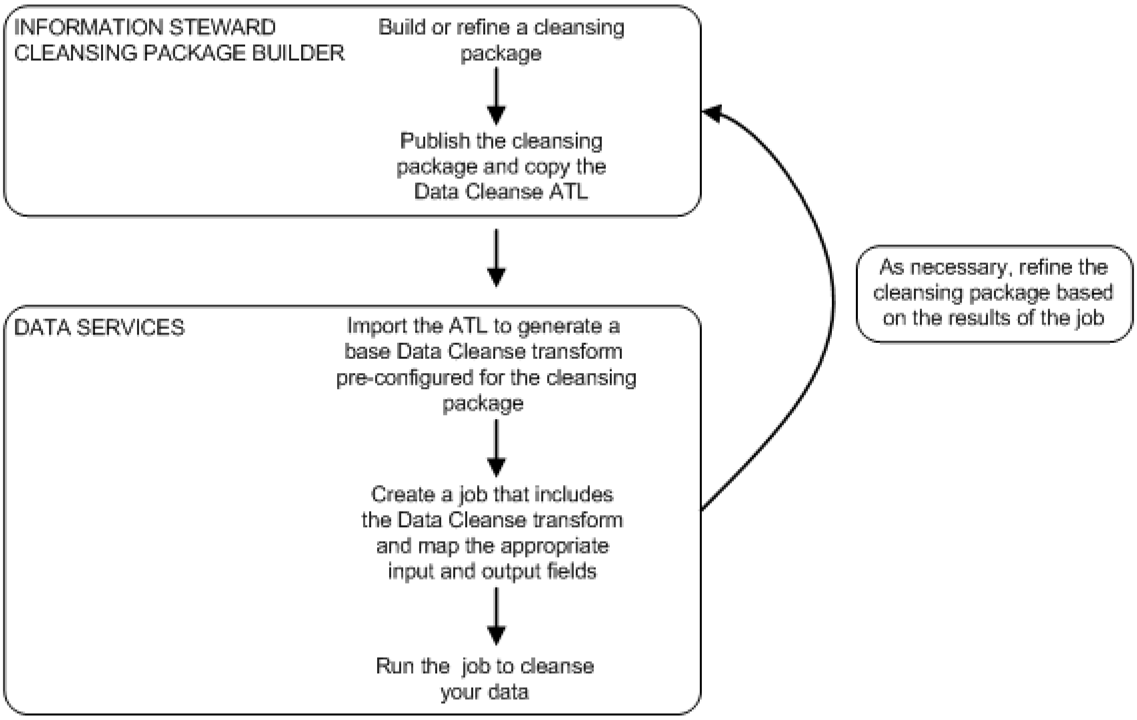
> Note
>
> The Data Cleansing Advisor feature uses the SAP-supplied Person_Firm cleansing package when processing data. Do not delete or rename the SAP-supplied cleansing package. If you modify the SAP-supplied cleansing package, it may alter the results in Data Cleansing Advisor.

> Note
>
> After creating one or more custom content types in Data Insight, you will see a cleansing package named CTID_CUSTOM_TYPE in Cleansing Package Builder. Do not open or modify CTID_CUSTOM_TYPE in Cleansing Package Builder because it will impact the custom content types.

A cleansing package is created and published within Cleansing Package Builder and then referenced by the Data Cleanse transform within Data Services for testing and production deployment.

Within a Data Services work flow, the Data Cleanse transform identifies and isolates specific parts of mixed data, and then parses and formats the data based on the referenced cleansing package as well as options set directly in the transform.

The following diagram shows how Data Services and Information Steward work together to allow you to develop a cleansing package specific to your data requirements and then apply it when you cleanse your data.



INFORMATION STEWARD CLEANSING PACKAGE BUILDER
Build or refine a cleansing package
Publish the cleansing package and copy the Data Cleanse ATL
DATA SERVICES
Import the ATL to generate a base Data Cleanse transform pre-configured for the cleansing package
Create a job that includes the Data Cleanse transform and map the appropriate input and output fields
Run the job to cleanse your data
As necessary, refine the cleansing package based on the results of the job

2.16.2.2 Cleansing package lifecycle: develop, deploy and maintain

The process of developing, deploying, and maintaining a cleansing package is the result of action and communication between the Data Services administrator, Data Services tester, and Cleansing Package Builder data steward. The exact roles, responsibilities, and titles vary by organization, but often include the following:

Role	Responsibility
Cleansing Package Builder data steward	Uses Cleansing Package Builder and has domain knowledge to develop and refine a cleansing package for a specific data domain.
Data Services tester	In a Data Services test environment, uses the Data Services transform to cleanse data and verify the results. Works with the Cleansing Package Builder data steward to refine a cleansing package.
Data Services administrator	In a Data Services production environment, uses the Data Cleanse transform to cleanse data based on the rules and standards defined in the selected cleansing package.

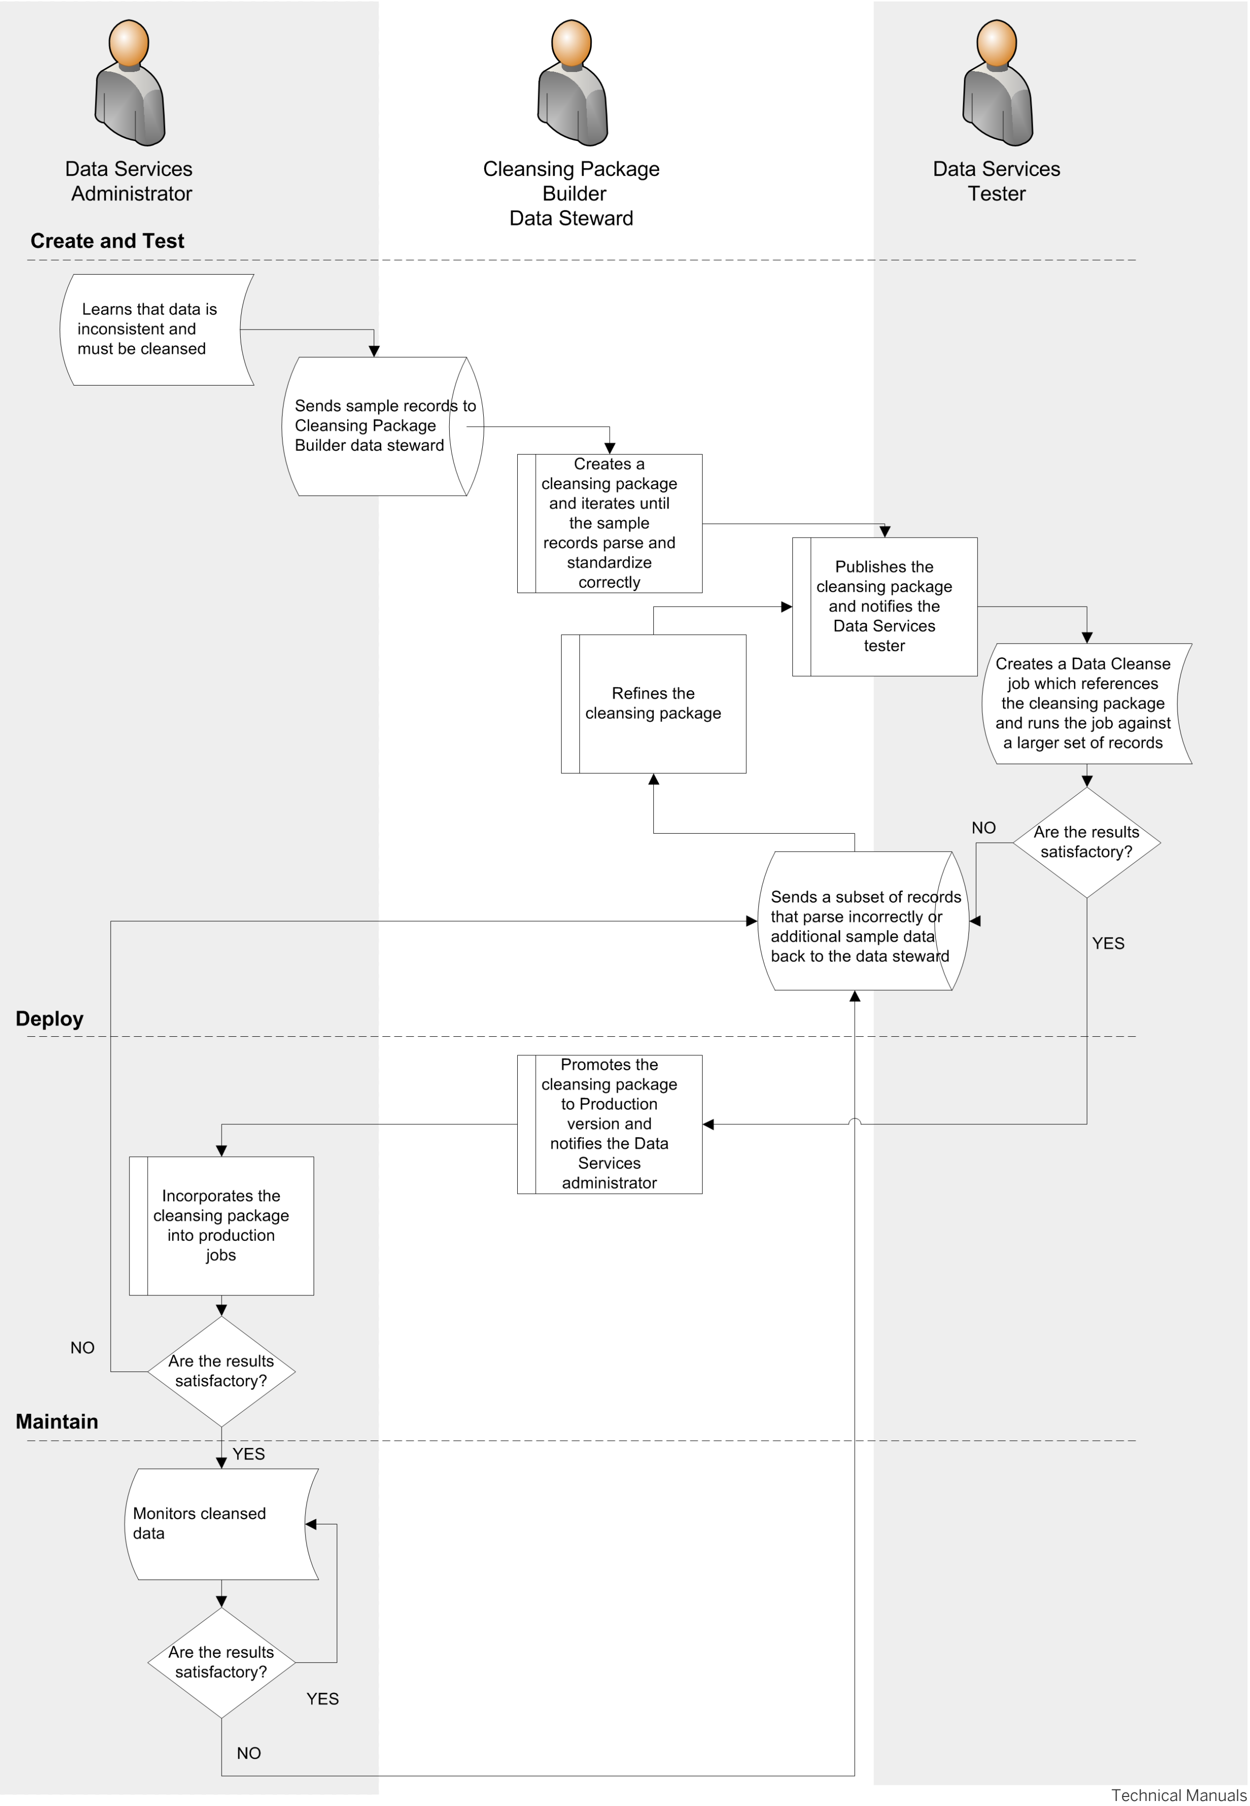
There are typically three iterative phases in a cleansing package workflow: develop (create and test), deploy, and maintain.

In the create and test phase, the data steward creates a custom cleansing package based on sample data provided by the Data Services administrator and then works with the Data Services tester to refine the cleansing package. When everyone is satisfied with the results, the cleansing package is deployed to production.

In the deployment phase the Data Services administrator, tester, and data steward work together to further refine the cleansing package so that production data is cleansed within the established acceptable range.

Finally, the cleansing package is moved to the maintenance phase and updated only when the results of regularly scheduled jobs fall out of range or when new data is introduced.

A typical workflow is shown in the diagram below:



Data Services Administrator
Cleansing Package Builder Data Steward
Data Services Tester
Create and Test
Learns that data is inconsistent and must be cleansed
Sends sample records to Cleansing Package Builder data steward
Creates a cleansing package and iterates until the sample records parse and standardize correctly
Publishes the cleansing package and notifies the Data Services tester
Refines the cleansing package
Creates a Data Cleanse job which references the cleansing package and runs the job against a larger set of records
Are the results satisfactory?
NO
YES
Sends a subset of records that parse incorrectly or additional sample data back to the data steward
Deploy
Promotes the cleansing package to Production version and notifies the Data Services administrator
Incorporates the cleansing package into production jobs
NO
Are the results satisfactory?
Maintain
YES
Monitors cleansed data
Are the results satisfactory?
YES
NO

For more information about the process of moving a cleansing package from development to production to maintenance, see the *Information Steward Administrator Guide.*

For more information about how to use the promotion management tool in the Central Management Console (CMC) to move cleansing packages (referred to as promoting "Objects" or "InfoObjects"), see the *Business Intelligence platform Administrator Guide.*

2.16.2.3 Configuring the Data Cleanse transform

Prerequisites for configuring the Data Cleanse transform include:

- Access to the necessary cleansing package.
- Access to the ATL file transferred from Cleansing Package Builder.
- Input field and attribute (output field) mapping information for user-defined pattern matching rules defined in the *Reference Data* tab of Cleansing Package Builder.

To configure the Data Cleanse transform:

1. Import the ATL file transferred from Cleansing Package Builder.

   Importing the ATL file brings the required information and automatically sets the following options:

   - Cleansing Package
   - Filter Output Fields
   - Input Word Breaker
   - Parser Configuration

   > Note
   >
   > You can install and use SAP-supplied person and firm cleansing package without modifications directly in Data Services. To do so, skip step 1 and manually set any required options in the Data Cleanse transform.

2. In the input schema, select the input fields that you want to map and drag them to the appropriate fields in the *Input* tab.

   - Name and firm data can be mapped either to discrete fields or multiline fields.
   - Custom data must be mapped to multiline fields.
   - Phone, date, email, Social Security number, and user-defined pattern data can be mapped either to discrete fields or multiline fields. The corresponding parser must be enabled.

3. In the *Options* tab, select the appropriate option values to determine how Data Cleanse will process your data.

   If you change an option value from its default value, a green triangle appears next to the option name to indicate that the value has been changed.

   The ATL file that you imported in step 1 sets certain options based on information in the cleansing package.

4. In the *Output* tab, select the fields that you want to output from the transform. In Cleansing Package Builder, output fields are referred to as attributes.

   Ensure that you map any attributes (output fields) defined in user-defined patterns in Cleansing Package Builder reference data.

Related Information

Transform configurations [page 308]
Data Quality transform editors [page 314]
To add a Data Quality transform to a data flow [page 312]

2.16.2.4 Ranking and prioritizing parsing engines

When dealing with multiline input, you can configure the Data Cleanse transform to use only specific parsers and to specify the order the parsers are run. Carefully selecting which parsers to use and in what order can be beneficial. Turning off parsers that you do not need significantly improves parsing speed and reduces the chances that your data will be parsed incorrectly.

You can change the parser order for a specific multiline input by modifying the corresponding parser sequence option in the Parser_Configuration options group of the Data Cleanse transform. For example, to change the order of parsers for the Multiline1 input field, modify the Parser_Sequence_Multiline1 option.

To change the selected parsers or the parser order: select a parser sequence, click OK at the message and then use the Ordered Options window to make your changes.

Related Information

Ordered options editor [page 317]

2.16.2.5 About parsing data

The Data Cleanse transform can identify and isolate a wide variety of data. Within the Data Cleanse transform, you map the input fields in your data to the appropriate input fields in the transform. Custom data containing operational or product data is always mapped to multiline fields. Person and firm data, phone, date, email, and Social Security number data can be mapped to either discrete input fields or multiline input fields.

The example below shows how Data Cleanse parses product data from a multiline input field and displays it in discrete output fields. The data also can be displayed in composite fields, such as *Standard Description*, which can be customized in Cleansing Package Builder to meet your needs.

Input data	Parsed data	
Glove ultra grip profit 2.3 large black synthetic leather elastic with Velcro Mechanix Wear	Product Category	Glove
	Size	Large
	Material	Synthetic Leather
	Trademark	Pro-Fit 2.3 Series

Input data	Parsed data	
	Cuff Style	Elastic Velcro
	Palm Type	Ultra-Grip
	Color	Black
	Vendor	Mechanix Wear
	Standard Description	Glove - Synthetic Leather, Black, size: Large, Cuff Style: Elastic Velcro, Ultra-Grip, Mechanix Wear

The examples below show how Data Cleanse parses name and firm data and displays it in discrete output fields. The data also can be displayed in composite fields which can be customized in Cleansing Package Builder to meet your needs.

	Phone	507.555.3423
	Date	August 20, 2003

The Data Cleanse transform parses up to six names per record, two per input field. For all six names found, it parses components such as prename, given names, family name, and postname. Then it sends the data to individual fields. The Data Cleanse transform also parses up to six job titles per record.

The Data Cleanse transform parses up to six firm names per record, one per input field.

2.16.2.5.1 About parsing phone numbers

Data Cleanse can parse both North American Numbering Plan (NANP) and international phone numbers. When Data Cleanse parses a phone number, it outputs the individual components of the number into the appropriate fields.

Phone numbering systems differ around the world. Data Cleanse recognizes phone numbers by their pattern and (for non-NANP numbers) by their country code, too.

Data Cleanse searches for North American phone numbers by commonly used patterns such as (234) 567-8901, 234-567-8901, and 2345678901. Data Cleanse gives you the option for some reformatting on output (such as your choice of delimiters).

Data Cleanse searches for non-North American numbers by pattern. The patterns used are specified in Cleansing Package Builder in the *Reference Data* tab. The country code must appear at the beginning of the number. Data Cleanse does not offer any options for reformatting international phone numbers. Also, Data Cleanse does not cross-compare to the address to see whether the country and city codes in the phone number match the address.

Related Information

About one-to-one mapping [page 477]

2.16.2.5.2 About parsing dates

Data Cleanse recognizes dates in a variety of formats and breaks those dates into components.

Data Cleanse can parse up to six dates from your defined record. That is, Data Cleanse identifies up to six dates in the input, breaks those dates into components, and makes dates available as output in either the original format or a user-selected standard format.

Related Information

About one-to-one mapping [page 477]

2.16.2.5.3 About parsing Social Security numbers

Data Cleanse parses U.S. Social Security numbers (SSNs) that are either by themselves or on an input line surrounded by other text.

Fields used

Data Cleanse outputs the individual components of a parsed Social Security number—that is, the entire SSN, the area, the group, and the serial.

How Data Cleanse parses Social Security numbers

Data Cleanse parses Social Security numbers in the following steps:

1. Identifies a potential SSN by looking for the following patterns:

Pattern	Digits per grouping	Delimited by
nnnnnnnnn	9 consecutive digits	not applicable
nnn nn nnnn	3, 2, and 4 (for area, group, and serial)	spaces
nnn-nn-nnnn	3, 2, and 4 (for area, group, and serial)	all supported delimiters

2. Performs a validity check on the first five digits only. The possible outcomes of this validity check are:

Outcome	Description
Pass	Data Cleanse successfully parses the data—and the Social Security number is output to a SSN output field.
Fail	Data Cleanse does not parse the data because it is not a valid Social Security number as defined by the U.S. government. The data is output as Extra, unparsed data.

Check validity

When performing a validity check, Data Cleanse does not verify that a particular 9-digit Social Security number has been issued, or that it is the correct number for any named person. Instead, it validates only the first 5 digits (area and group). Data Cleanse does not validate the last 4 digits (serial)—except to confirm that they are digits.

SSA data

Data Cleanse validates the first five digits based on a table from the Social Security Administration (*http://www.socialsecurity.gov/employer/ssns/HGJune2411_final.txt*). The rules and data that guide this check are available at *http://www.ssa.gov/history/ssn/geocard.html* . The Social Security number information that Data Cleanse references is included in the cleansing package.

> Note
>
> The Social Security administration no longer updates the table. The last time it was updated was in July, 2011. Therefore, Social Security validation performed in Data Cleans is based on data through July, 2011. For more

information about the Social Security Administration's Social Security number assignment process, see *http://www.ssa.gov/employer/randomizationfaqs.html* .

Outputs valid SSNs

Data Cleanse outputs only Social Security numbers that pass its validation. If an apparent SSN fails validation, Data Cleanse does not pass on the number as a parsed, but invalid, Social Security number.

Related Information

Reference Guide: Transforms, Data Cleanse output fields [page 1164]

2.16.2.5.4 About parsing email addresses

When Data Cleanse parses input data that it determines is an email address, it places the components of that data into specific fields for output. Below is an example of a simple email address:

```
joex@sap.com
```

By identifying the various data components (user name, host, and so on) by their relationships to each other, Data Cleanse can assign the data to specific attributes (output fields).

Output fields Data Cleanse uses

Data Cleanse outputs the individual components of a parsed email address—that is, the email user name, complete domain name, top domain, second domain, third domain, fourth domain, fifth domain, and host name.

What Data Cleanse does

Data Cleanse can take the following actions:

- Parse an email address located either in a discrete field or combined with other data in a multiline field.
- Break down the domain name into sub-elements.
- Verify that an email address is properly formatted.
- Flag that the address includes an internet service provider (ISP) or email domain name listed in the email type of Reference Data in Data Cleanse. This flag is shown in the Email_is_ISP output field.

What Data Cleanse does not verify

Several aspects of an email address are not verified by Data Cleanse. Data Cleanse does not verify:

- whether the domain name (the portion to the right of the @ sign) is registered.
- whether an email server is active at that address.
- whether the user name (the portion to the left of the @ sign) is registered on that email server (if any).
- whether the personal name in the record can be reached at this email address.

Email components

The output field where Data Cleanse places the data depends on the position of the data in the record. Data Cleanse follows the Domain Name System (DNS) in determining the correct output field.

For example, if `expat@london.home.office.city.co.uk` were input data, Data Cleanse would output the elements in the following fields:

Output field	Output value
Email	expat@london.home.office.city.co.uk
Email_User	expat
Email_Domain_All	london.home.office.city.co.uk
Email_Domain_Top	uk
Email_Domain_Second	co
Email_Domain_Third	city
Email_Domain_Fourth	office
Email_Domain_Fifth	home
Email_Domain_Host	london

Related Information

About one-to-one mapping [page 477]

2.16.2.5.5 About parsing user-defined patterns

Data Cleanse can parse patterns found in a wide variety of data such as:

- account numbers
- part numbers

- purchase orders
- invoice numbers
- VINs (vehicle identification numbers)
- driver license numbers

In other words, Data Cleanse can parse any alphanumeric sequence for which you can define a pattern.

The user-defined pattern matching (UDPM) parser looks for the pattern across each entire field.

Patterns are defined using regular expressions in the *Reference Data* tab of Cleansing Package Builder. Check with the cleansing package owner to determine any required mappings for input fields and output fields (attributes).

2.16.2.5.6 About parsing street addresses

Data Cleanse does not identify and parse individual address components. To parse data that contains address information, process it using a Global Address Cleanse or U.S. Regulatory Address Cleanse transform prior to Data Cleanse. If address data is processed by the Data Cleanse transform, it is usually output to the *Extra* fields.

Related Information

How address cleanse works [page 586]

2.16.2.5.7 About parsing firm names

Data Cleanse can parse firm data.

Data Cleanse accepts these firm names alone in a field or together with other data.

An exception to how Data Cleanse recombines contiguous word pieces is made for words that end with an *S*, such as Applebee's or Macy's. An input string of *Macy's* is broken into three individual tokens: MACY, ', S. Because the last token is an *S*, Data Cleanse first combines the tokens and looks up the term including the apostrophe (MACY'S). If the term is not found, Data Cleanse looks up the term without the apostrophe (MACYS). If that is not successful, Data Cleanse automatically keeps the tokens together (MACY'S) and adds the FIRM_MISCELLANEOUS classification to the term. Since words ending with *S* are automatically kept together, it is not necessary to add all possessive firm names to the dictionary.

2.16.2.5.8 About parsing name and title data

Data Cleanse can parse name and title data.

A person's name can consist of the following parts: prename, given names, family names, postname, and so on.

Data Cleanse can accept up to two names and titles as discrete components. Data Cleanse also accepts name and title data together with other data or alone in a field. The name line or multiline field may contain one or two names per field.

2.16.2.5.9 About one-to-one mapping

One-to-one mapping is an option in the Data Cleanse transform that controls how several parsers output the data.

The *One-to-one mapping* option is available for these parsers:

- Date
- Email
- Phone

When the option is set to *Yes*, the Data Cleanse transform outputs the data parsed from certain discrete input fields to their corresponding output fields. The output fields are "reserved" for parses from certain discrete input fields. This option more clearly shows the mapping of the input field that held the original data based on the parsed data in the output field. For example, if the input data in Phone1 through Phone5 were blank and the Phone6 field contained data, then on output, Phone1 through Phone5 fields continue to be blank and Phone6 contains the parsed data.

When *One-to-one mapping* is set to *Yes*, then all parsers that use this option are set to *Yes*. For example, you cannot set the *One-to-one mapping* option only for the phone parser.

When *One-to-one mapping* is set to *No*, the Data Cleanse transform parses and outputs the data in the order the data entered the parser. The data is not necessarily output to the same field that it was mapped to on output. The data is output to the first available field in the category.

Note

The examples in this section show Date fields. The same examples also apply to Phone and Email fields.

Example

Field	Input data	Output data when option is *No*	Output data when option is *Yes*
Date1	<blank>	1968/01/01	<blank>
Date2	1968/01/01	1968/02/02	1968/01/01
Date3	1968/02/02	1968/03/03	1968/02/02
Date4	<blank>	1968/04/04	<blank>
Date5	1968/03/03	<blank>	1968/03/03
Date6	1968/04/04	<blank>	1968/04/04

Multiline fields

The discrete Date, Email, and Phone fields are parsed before the Multiline fields, so that any unreserved fields can contain data from the Multiline fields.

Example

Field	Input data	Output data when option is *No*	Output data when option is *Yes*
Date1	<blank>	1968/01/01	<blank>
Date2	1968/01/01	1968/02/02	1968/01/01
Date3	<blank>	1968/03/03	<blank>
Date4	1968/02/02	1968/04/04	1968/02/02
Date5	<blank>	<blank>	1968/03/03 (not reserved, so Multiline input can be added here)
Date6	<blank>	<blank>	1968/04/04 (not reserved, so Multiline input can be added here)
Multi-line1	1968/03/03 1968/04/04	<blank>	<blank>

Extra fields

When the *One-to-one mapping* option is set to *Yes* and the input field contains multiple sets of data, only the first set of data is placed in the corresponding output field. All other sets of data are put in the Extra field.

Example

Field	Input data	Output data when option is *No*	Output data when option is *Yes*
Date1	1968/01/01 1968/02/02 1968/03/03 1968/04/04 1968/05/05 1968/06/06 1968/07/07 1968/08/08	1968/01/01	1968/01/01
Date2	<blank>	1968/02/02	<blank>
Date3	<blank>	1968/03/03	<blank>
Date4	<blank>	1968/04/04	<blank>
Date5	<blank>	1968/05/05	<blank>

Field	Input data	Output data when option is *No*	Output data when option is *Yes*
Date6	<blank>	1968/06/06	<blank>
Extra	<blank>	1968/07/07 1968/08/08	1968/02/02 1968/03/03 1968/04/04 1968/05/05 1968/06/06 1968/07/07 1968/08/08

Related Information

2.16.2.6 About standardizing data

Standard forms for individual variations are defined within a cleansing package using Cleansing Package Builder. Additionally, the Data Cleanse transform can standardize data to make its format more consistent. Data characteristics that the transform can standardize include case, punctuation, and abbreviations.

2.16.2.7 About assigning gender descriptions and prenames

Each variation in a cleansing package has a gender associated with it. By default, the gender is *unassigned*. You can assign a gender to a variation in the Advanced mode of Cleansing Package Builder. Gender descriptions are: strong male, strong female, weak male, weak female, and ambiguous.

Variations in the SAP-supplied name and firm cleansing package have been assigned genders.

You can use the Data Cleanse transform to output the gender associated with a variation to the GENDER output field.

The Prename output field always includes prenames that are part of the name input data. Additionally, when the *Assign Prenames* option is set to *Yes*, Data Cleanse populates the PRENAME output field when a strong male or strong female gender is assigned to a variation.

Dual names

When dual names are parsed, Data Cleanse offers four additional gender descriptions: female multi-name, male multi-name, mixed multi-name, and ambiguous multi-name. These genders are generated within Data Cleanse based on the assigned genders of the two names. The table below shows how the multi-name genders are assigned:

Dual name	Gender of first name	Gender of second name	Assigned gender for dual name
Bob and Sue Jones	strong male	strong female	mixed multi-name
Bob and Tom Jones	strong male	strong male	male multi-name
Sue and Sara Jones	strong female	strong female	female multi-name
Bob and Pat Jones	strong male	ambiguous	ambiguous multi-name

Chinese and Japanese given names

When a given name was parsed as the result of the rules intelligently combining given name characters as opposed to including the given name as a variation in the cleansing package, Data Cleanse generates the gender by combining the gender of the individual characters that make up the given name, using the table below.

	Strong female	*Strong male*	*Weak female*	*Weak male*	*Ambiguous*
Strong female	strong female	ambiguous	strong female	ambiguous	strong female
Strong male	ambiguous	strong male	ambiguous	strong male	strong male
Weak female	strong female	ambiguous	weak female	ambiguous	weak female
Weak male	ambiguous	strong male	ambiguous	weak male	weak male
Ambiguous	strong female	strong male	weak female	weak male	ambiguous

2.16.2.8 Prepare records for matching

If you are planning a data flow that includes matching, it is recommended that you first use Data Cleanse to standardize the data to enhance the accuracy of your matches. The Data Cleanse transform should be upstream from the Match transform.

The Data Cleanse transform can generate match standards or alternates for many name and firm fields as well as all custom output fields. For example, Data Cleanse can tell you that Patrick and Patricia are potential matches for the name Pat. Match standards can help you overcome two types of matching problems: alternate spellings (Catherine and Katherine) and nicknames (Pat and Patrick).

This example shows how Data Cleanse can prepare records for matching.

Table 8: Data source 1

Input record	Cleansed record	
Intl Marketing, Inc. Pat Smith, Accounting Mgr.	Given Name 1	Pat
	Match Standards	Patrick, Patricia
	Given Name 2	
	Family Name 1	Smith

Input record	Cleansed record	
	Title	Accounting Mgr.
	Firm	Intl. Mktg, Inc.

Table 9: Data source 2

Input record	Cleansed record	
Smith, Patricia R. International Marketing, Incorp.	Given Name 1	Patricia
	Match Standards	
	Given Name 2	R
	Family Name 1	Smith
	Title	
	Firm	Intl. Mktg, Inc.

When a cleansing package does not include an alternate, the match standard output field for that term will be empty. In the case of a multi-word output such as a firm name, when none of the variations in the firm name have an alternate, then the match standard output will be empty. However, if at least one variation has an alternate associated with it, the match standard is generated using the variation alternate where available and the variations for words that do not have an alternate.

2.16.2.9 Region-specific data

2.16.2.9.1 About domains

A domain describes a specific type of data or content. Domains enhance the ability of Data Cleanse to appropriately cleanse data according to the cultural standards of a region. Within an SAP-supplied person and firm cleansing package each supported locale is a domain. The table below illustrates how name parsing may vary by culture:

Domain	Name	Parsed Output			
		Given_Name1	Given_Name2	Family_Name1	Family_Name2
Spanish	Juan C. Sánchez	Juan	C.	Sánchez	
Portuguese	João A. Lopes	João		A.	Lopes
French	Jean Christophe Rousseau	Jean Christophe		Rousseau	
German	Hans Joachim Müller	Hans	Joachim	Müller	
English (U.S. and Canada)	James Andrew Smith	James	Andrew	Smith	

Each variation is automatically assigned to the Global domain and may also be assigned to one or more other domains. A variation may have a different meaning in each domain. In other words, the properties associated with a given variation, such as standard form and classification, may be specific to a domain. For example, the variation `AG` has different meanings in German and in U.S. English. In German, `AG` is an abbreviation for “Aktiengesellschaft” (a firm type) and is cleansed as "AG", while in English `AG` is an abbreviation for Agriculture and is cleansed as "Ag." You can control how Data Cleanse cleanses your data by specifying which domain or domains you want Data Cleanse to apply and in what order.

> Note
>
> Multiple domains are supported only in person and firm cleansing packages version 4.1 or higher. Variations in custom cleansing packages as well as person and firm cleansing packages created prior to Information Steward 4.1 are assigned only to the Global domain.

Global domain

The Global domain is a special content domain which contains all variations and their associated properties. If a variation is not associated with domain-specific information the Global domain serves as the default domain.

When you add a new variation, it is initially added to the Global domain. As necessary, you can then add it to other domains in order to assign any domain-specific information. You only need to add a variation to a domain other than the Global domain when the variation has properties such as gender, classification, standard form, and so on, which differ between the Global and other domains.

If you delete a variation from the Global domain, the variation is also deleted from all other domains it is associated with.

Controlling domain-specific cleansing

The Data Services administrator or tester can set the *Content Domain Sequence* in the Data Cleanse transform to control how Data Cleanse parses your domain-specific data such as name, gender title, and so on. In the examples below consider how gender would be applied for the name Jean based the following information:

Name	Domain	Gender
Jean	Global	AMBIGUOUS
Jean	French	STRONG_MALE
Jean	English (United States and Canada)	WEAK_FEMALE

When you do not want to favor any domain-specific properties, select only *GLOBAL*. The name Jean will be assigned an ambiguous gender because neither the French nor the English domain-specific information is considered.

When you have data from a single-domain region, specify a domain followed by Global. For example, when you specify EN_US followed by GLOBAL (*EN_US|GLOBAL*), the name Jean will be assigned a weak female gender.

When you have data from a multi-domain region, select the preferred sequence of domains ending with Global. For example, Benelux (Belgium, Netherlands, Luxembourg) includes the Dutch, French, and German domains. Depending on your cleansing preference you can order the domains in the desired sequence. For example, if you favor the Dutch domain you would specify *NL|FR|DE|GLOBAL*. When a variation is encountered in your data that has different properties in the selected content domains, the cleansing process uses the Dutch properties first if they exist. If there are no Dutch-specific properties then Data Cleanse uses the French properties, if there are neither Dutch-specific nor French-specific properties then it uses the German properties. If none of the three domains have specific properties, then Data Cleanse uses the properties that are specified in the Global domain.

Another example of a multi-domain region is Switzerland. Switzerland includes German, French, and Italian domains. Depending on your cleansing preference you can order the domains in the desired sequence. For example, if you favor the German domain you may select *DE|FR|IT|GLOBAL*. When a variation is encountered in your data that has different properties in the selected content domains, the cleansing process uses the German properties first if they exist. If there are no German-specific properties then Data Cleanse uses the French properties, if there are neither German-specific nor French-specific properties then it uses the Italian properties. If none of the three have a specific meaning then Data Cleanse uses the meaning that exists in the Global domain.

Specifying the content domain sequence

You can set the content domain sequence in three different levels.

Level	Option
Default	Data Cleanse *Content Domain Sequence* transform option. This option is required. If there are errors or the intermediate-level and top-level options are not specified, this setting is used.
Intermediate	The data in Option_Country, Option_Language, and/or Option_Region input options. If there are errors or the top-level option is not specified, this setting is used. These input fields are populated and mapped from the Global Address Cleanse transform output fields ISO_Country_Code_2Char, Language, and Region1, respectively. Using these input fields is optional.
Top	The data in Option_Content_Domain_Sequence input option. The data in this option is assigned through a preceding Query transform or other preprocessing step. Using this input field is optional.

Example

During processing, Data Cleanse assigns the content domain sequence based on the top-level option, if the option is set and is valid.

Level	Option	Output	Notes
Top	Input field: Option_Content_Domain_Sequence=FR|Global	The content domain sequence is French, and all of the data that isn't identified as French defaults to the Global domain.	This option overrides the intermediate and default settings, unless this option is invalid (for example, misspelled) or not set.

Intermediate	Input fields:
	Option_Country=MX
	Option_Language=<not set>
		The content domain sequence is Spanish (ES_MX, local to Mexico), and all of the data that isn't identified as Spanish	This option overrides the default setting, unless this option contains invalid data, or was not set.

Level	Option	Output	Notes
	Option_Region=<not set>	defaults to the Global domain.	In most cases, the content domain sequence can be identified based on the Option_Country input field only. However, there are certain countries that can use Option_Language or Option_Region to help determine the content domain sequence.
Default	Data Cleanse transform option: Content Domain Sequence=EN_US|Global	The content domain sequence is English (local to United States and Canada), and all of the data that isn't identified as English defaults to the Global domain.	This option is required and is used when there are errors in the top-level and intermediate-level options.

When using the intermediate level, you will find that some countries can use additional input data to determine the content domain sequence.

Option_Country input field	Additional input fields	Assigned content domain sequence	Notes

CA (Canada)	Option_Region=QC
	Option_Region=BC*
		FR|Global
		EN_US|Global
			The content domain sequence is always assigned to FR|Global when Option_Region is set to Quebec. Acceptable data includes Quebec or QC in any type of casing. Any other valid region (such as BC for British Columbia) returns a content domain sequence of EN_US|Global.

BE (Belgium)	Option_Language=FR
	Option_Language=NL*
		FR|Global
		NL|Global
			The content domain sequence is always assigned to FR|Global when Option_Language=FR. Any other specified language (such as NL for Dutch or EN_GB for British English), or if this option is blank, returns a content domain sequence of NL|Global.

CH (Switzerland)	Option_Language=FR
	Option_Language=IT
	Option_Language=RU*
		FR|Global
		IT|Global
		DE|Global
			The content domain sequence is always assigned to FR|Global or IT|Global when Option_Language=FR or IT, respectively. Any other specified language (such as RU for Russian), or if this option is

Option_Country input field	Additional input fields	Assigned content domain sequence	Notes
			blank, returns a content domain sequence of DE|Global.

i Note

*The content domain sequence is assigned independently from the output format.

- Reference Guide: Cleansing package options
- Reference Guide: Dynamic transform settings

Related Information

About output format [page 485]

2.16.2.9.2 About output format

Based on the specified domain in the output format, Data Cleanse uses certain output fields and formats the data in those fields according to the regional standards. You specify the domain in the *Output Format* of the Data Cleanse transform.

Based on regional standards, in some domains a compound given name is combined and output to the `Given Name1` field, while in other domains the first name is output to the `Given Name1` field and the second name is output to the `Given Name2` field.

Similarly, in some domains a compound family name is combined and output to the `Family Name1` field, while in other domains the first family name is output to the `Family Name1` field and the second family name is output to the `Family Name2` field.

In some domains the composite `Person` output field is comprised of the given name followed by the family name, while in other domains the composite `Person` output field is comprised of the family name followed by the given name.

The Data Cleanse transform requires that you specify an output format, even when your data is truly global.

When you have data from a single-domain region, specify the domain. For example, for Germany select *DE*, for China select *ZH*.

When you have data from a multi-domain region, you must select the preferred domain. Your data may be formatted differently depending on the domain you select.

For example, data from the Philippines may be output in English or Spanish output formats. As shown in the table below, the name **`Juan Carlos Sanchez Cruz`** will output in different fields depending on the selected output format.

Output field	Output format	
	English	Spanish
`Given Name1`	Juan	Juan
`Given Name2`	Carlos	Carlos
`Family Name1`	Sánchez Cruz	Sánchez
`Family Name2`		Cruz
`Person`	Juan Carlos Sánchez Cruz	Juan Carlos Sánchez Cruz

For Benelux data, you may choose to output your data in Dutch, French, or German output formats. As shown in the table below, the name **`H. D. BUDJHAWAN`** will output in different fields depending on the selected output format.

Output field	Output format		
	Dutch	French	German
`Given Name1`	H.D.	H. D.	H.
`Given Name2`			D.
`Family Name1`	Budjhawan	Budjhawan	Budjhawan
`Family Name2`			
`Person`	H.D. Budjhawan	H. D. Budjhawan	H. D. Budjhawan

You can modify the existing output format or add a new domain-specific output format by modifying the appropriate rules in your cleansing package.

Specifying the output format

You can set the output format in three different levels.

Level	Option
Default	Data Cleanse *Output format* transform option. This option is required. If there are errors or the intermediate-level and top-level options are not specified, this setting is used.
Intermediate	The data in Option_Country, Option_Language, and/or Option_Region input options. If there are errors or the top-level option is not specified, this setting is used. These input fields are populated and mapped from the Global Address Cleanse transform output fields ISO_Country_Code_2Char, Language, and Region1, respectively. Using these input fields is optional.
Top	The data in Option_Output_Format input option. The data in this option is assigned through a preceding Query transform or other preprocessing step. Using this input field is optional.

Example

During processing, Data Cleanse assigns the output format based on the top-level option, if the option is set and is valid.

Level	Option	Output	Notes
Top	Input field: Option_Output_Format=FR	The output format is French.	This option overrides the intermediate and default settings, unless this option is invalid (for example, misspelled) or not set.

Intermediate	Input fields:
	Option_Country=MX
	Option_Language=<not set>
	Option_Region=<not set>
		The output format is Spanish (local to Mexico).	This option overrides the default setting, unless this option contains invalid data, or was not set.
			In most cases, the output format can be identified based on the Option_Country input field only. However, there are certain countries that can use Option_Language or Option_Region to help determine the output format.

Default	Data Cleanse transform option: Output format=EN_US	The output format is English (local to United States).	This option is required and is used when there are errors in the top- and intermediate-level options.

When using the intermediate level, you will find that some countries can use additional input data to determine the output format.

Option_Country input field	Additional input fields	Assigned output format	Notes

CA (Canada)	Option_Region=QC
	Option_Region=BC*
		FR
		EN_US
			The output format is always assigned to FR when Option_Region is set to Quebec. Acceptable data includes Quebec or QC in any type of casing. Any other valid region (such as BC for British Columbia) returns an output format of EN_US.

BE (Belgium)	Option_Language=FR
	Option_Language=NL*
		FR
		NL
			The output format is always assigned to FR when Option_Language=FR. Any other specified language (such as NL for Dutch or EN_GB for British English), or

Option_Country input field	Additional input fields	Assigned output format	Notes
			if this option is blank, returns an output format of NL.

CH (Switzerland)	Option_Language=FR
	Option_Language=IT
	Option_Language=RU*
		FR
		IT
		DE
			The output format is always assigned to FR or IT when Option_Language=FR or IT, respectively. Any other specified language (such as RU for Russian), or if this option is blank, returns an output format of DE.

Note

*The output format is assigned independently of the content domain sequence.

Related Information

Reference Guide: Cleansing package options [page 1149]
Reference Guide: Dynamic transform settings [page 1129]

2.16.2.9.3 Customize prenames per country

When the input name does not include a prename, Data Cleanse generates the English prenames Mr. and Ms. To modify these terms, add a Query transform following the Data Cleanse transform and use the search_replace function to replace the terms with region-appropriate prenames.

2.16.2.9.4 Personal identification numbers

Data Cleanse can identify U.S. Social Security numbers and separate them into discrete components. If your data includes personal identification numbers other than U.S. Social Security numbers, you can create user-defined pattern rules to identify the numbers. User-defined pattern rules are part of the cleansing package and are defined in the *Edit Reference Data* tab of Cleansing Package Builder.

User-defined pattern rules are parsed in Data Cleanse with the *UDPM* parser. U.S. Social Security numbers are parsed in Data Cleanse with the *SSN* parser.

2.16.2.9.5 Text width in output fields

Many Japanese characters are represented in both fullwidth and halfwidth forms. Latin characters can be encoded in either a proportional or fullwidth form. In either case, the fullwidth form requires more space than the halfwidth or proportional form.

To standardize your data, you can use the *Character Width Style* option to set the character width for all output fields to either fullwidth or halfwidth. The normal width value reflects the normalized character width based on script type. Thus some output fields contain halfwidth characters and other fields contain fullwidth characters. For example, all fullwidth Latin characters are standardized to their halfwidth forms and all halfwidth katakana characters are standardized to their fullwidth forms. NORMAL_WIDTH does not require special processing and thus is the most efficient setting.

> Note
>
> Because the output width is based on the normalized width for the character type, the output data may be larger than the input data. You may need to increase the column width in the target table.

For template tables, selecting the *Use NVARCHAR for VARCHAR columns in supported databases box* changes the VARCHAR column type to NVARCHAR and allows for increased data size.

2.16.3 Geocoding

This section describes how the Geocoder transform works, different ways that you can use the transform, and how to understand your output.

> Note
>
> GeoCensus functionality in the USA Regulatory Address Cleanse transform will be deprecated in a future version of Data Services. It is recommended that you upgrade any data flows that currently use the GeoCensus functionality to use the Geocoder transform. For instructions on upgrading from GeoCensus to the Geocoder transform, see the *Upgrade Guide*.

How the Geocoder transform works

The Geocoder transform uses geographic coordinates expressed as latitude and longitude, addresses, and point-of-interest (POI) data. Using the transform, you can append addresses, latitude and longitude, census data, and other information to your data.

Based on mapped input fields, the Geocoder transform has three modes of geocode processing:

- Address geocoding
- Reverse geocoding
- POI textual search

Typically, the Geocoder transform is used in conjunction with the Global Address Cleanse or USA Regulatory Address Cleanse transform.

Related Information

Reference Guide: Transforms, Geocoder [page 1178]
Reference Guide: Data Quality Fields, Geocoder fields [page 1183]
Geocensus (USA Regulatory Address Cleanse) [page 671]

2.16.3.1 Address geocoding

In address geocoding mode, the Geocoder transform assigns geographic data. Based on the completeness of the input address data, the Geocoder transform can return multiple levels of latitude and longitude data. Appending different levels of latitude and longitude information to your data may help your organization target certain population sizes and other regional geographical data.

Prepare records for geocoding

The Geocoder transform works best when it has standardized and corrected address data, so to obtain the most accurate information you may want to place an address cleanse transform before the Geocoder transform in the work flow.

2.16.3.1.1 Latitude and longitude levels

Primary Number level

If your input data has a complete address (including the primary number), the Geocoder transform returns latitude and longitude coordinates to the exact location based on the directory type (range-based or parcel-based) that you subscribe to.

In general, the Geocoder transform uses geocoding directories to calculate latitude and longitude values for a house by interpolating between the beginning and ending point of a line segment, where the line segment represents a range of houses. The latitude and longitude values may be slightly offset from the exact location from where the house actually exists. This is called the primary range interpolated (PRI) assignment level.

Note

If you want to get an address-level assignment, the Primary_Number input field must be mapped and cannot be blank.

The Geocoder transform also supports parcel directories, which contain the most precise and accurate latitude and longitude values available for addresses, depending on the available country data. Parcel data is stored as points. Rather than getting you near the house, it takes you to the exact door. This is called the primary range exact (PRE) assignment level.

Postcode Centroid level

If an address has a postcode, you receive coordinates in the appropriate postcode area. The Geocoder transform has Postcode Full (PF), Postcode2 Partial (P2P) and Postcode1 (P1) assignment levels, depending on the available country data.

Locality Centroid level

If an address has a locality, you receive coordinates in the appropriate locality area. The Geocoder transform has Locality1 (L1), Locality2 (L2), Locality3 (L3) and Locality4 (L4) assignment levels, depending on the available country data.

2.16.3.1.2 Address geocoding field mapping

The following tables specify the input and output fields that are required, optional, or cannot be mapped in the address geocoding mode. The more input data you can provide, the better results you will obtain.

Input field mapping

Input field category	Address geocoding mode
Address	At least one required
Address POI	Optional
Latitude/Longitude	n/a
Max Records	n/a
Search Filter	n/a

Output field mapping

Output field category	Address geocoding mode
Address	n/a
Address POI	n/a
Assignment Level	Optional
Census	Optional
Distance	n/a
Info Code	Optional
Latitude/Longitude	Optional
Population	Optional
Results	n/a
Side of Street	Optional

2.16.3.1.3 Address geocoding scenario

Scenario: Use an address or an address and a point of interest to assign latitude and longitude information.

Number of output results: Single record

The following sections describe the required and optional input fields and available output fields to obtain results for this scenario. We also provide an example with sample data.

Required input fields

For required input fields, the Country field must be mapped. The more input data you can provide, the better results you will obtain.

Category	Input field name
Address	Country (required) Locality1–4 Postcode1–2 Primary_Name1–4 Primary_Number Primary_Postfix1

Category	Input field name
	Primary_Prefix1 Primary_Type1–4 Region1–2

Optional input fields

Category	Input field name
Address POI	POI_Name POI_Type

Available output fields

All output fields are optional.

Category	Output field name
Assignment Level	Assignment_Level Assignment_Level_Locality Assignment_Level_Postcode
Census	Census_Tract_Block Census_Tract_Block_Group Gov_County_Code Gov_Locality1_Code Gov_Region1_Code Metro_Stat_Area_Code Minor_Div_Code Stat_Area_Code
Info Code	Info_Code
Latitude/Longitude	Latitude Latitude_Locality Latitude_Postcode Latitude_Primary_Number

Category	Output field name
	Longitude Longitude_Locality Longitude_Postcode Longitude_Primary_Number
Population	Population_Class_Locality1
Side of Street	Side_Of_Primary_Address

Example

Input: You map input fields that contain the following data:

Input field name	Input value
Country	US
Postcode1	54601
Postcode2	4023
Primary_Name1	Front
Primary_Number	332
Primary_Type1	St.

Output: The mapped output fields contain the following results:

Output field name	Output value
Assignment_Level	PRE
Latitude	43.811616
Longitude	-91.256695

Related Information

Understanding your output [page 507]
Reference Guide: Data Quality fields, Geocoder fields, Input fields [page 1184]
Reference Guide: Data Quality fields, Geocoder fields, Output fields [page 1186]

2.16.3.2 Reverse geocoding

In reverse geocoding mode, the Geocoder transform identifies the closest address or point of interest based on an input reference location. Based on the input mapping, reverse geocoding can process in four modes:

- *Reverse with address input and single record output.*
  Use the address and optional address POI fields to determine a unique reference point, and output only the single closest record that matches the search filter.
  If search filter fields are not mapped, the Geocoder transform defaults to the nearest point of interest or address.
- *Reverse with address input and multiple record output.*
  Use the address and optional address POI fields to determine a unique reference point, and output the reference point data to output fields and multiple closest records that match the search filter fields to the Result_List field.
  The number of multiple records is determined by the Option_Max_Records input field if it is mapped and populated or the Max Records option.
- *Reverse with latitude/longitude input and single record output.*
  Use the latitude and longitude fields as the reference point, and output only the single closest record that matches the optional search filter fields.
  If the search filter fields are not mapped, the Geocoder transform defaults to the nearest point of interest or address.
- *Reverse with latitude/longitude input and multiple record output.*
  Use the latitude and longitude fields as the reference point, and output multiple closest records that match the search filter fields to the Result_List field.
  The number of multiple records is determined by the Option_Max_Records input field if it is mapped and populated or the Max Records option.
  If the search filter fields are not mapped, the Geocoder transform defaults to the nearest point of interest or address.

Note

- Mapping the Option_Radius input field lets you define the distance from the specified reference point and identify an area in which matching records are located.
- To find one or more locations that can be points of interest, addresses, or both, set the Search_Filter_Name or Search_Filter_Type input field. This limits the output matches to your search criteria.
- To return an address only, enter ADDR in the Search_Filter_Type input field.
- To return a point of interest only, enter the point-of-interest name or type.
- If you don't set a search filter, the transform returns both addresses and points of interest.

2.16.3.2.1 Reverse geocoding field mapping

The following tables specify the input and output fields that are required, optional, or cannot be mapped in the reverse geocoding mode. The more input data you can provide, the better results you will obtain.

Input field mapping

Input field category	Address input Single output	Address input Multiple output	Latitude/longitude input Single output	Latitude/longitude input Multiple output
Address	At least one required	At least one required	n/a	n/a
Address POI	Optional	Optional	n/a	n/a
Latitude/ Longitude	n/a	n/a	At least one required	At least one required
Max Records	n/a	At least one required	n/a	At least one required
Search Filter	At least one required	At least one required	Optional	Optional

Output field mapping

Output field category	Address input Single output	Address input Multiple output	Latitude/longitude input Single output	Latitude/longitude input Multiple output
Address	Optional	n/a	Optional	n/a
Address POI	Optional	n/a	Optional	n/a
Assignment Level	Optional	Optional	Optional	n/a
Census	Optional	n/a	Optional	n/a
Distance	Optional	n/a	Optional	n/a
Info Code	Optional	Optional	Optional	Optional
Latitude/ Longitude	Optional	Optional	Optional	n/a
Population	Optional	n/a	Optional	n/a
Results	n/a	Optional	n/a	Optional
Side of Street	Optional	Optional	Optional	n/a

2.16.3.2.2 Reverse geocoding scenarios

Reverse geocoding scenario 1

Scenario: Use latitude and longitude to find one or more addresses or points of interest.

The following sections describe the required and optional input fields and available output fields to obtain either single-record or multiple-record results for this scenario. We also provide an example with sample data.

Required input fields

For a single-record result, both Latitude and Longitude input fields must be mapped. For multiple-record results, the Latitude, Longitude, and Option_Max_Records input fields must all be mapped.

Category	Single-record results	Multiple-record results
	Input field name	Input field name
Latitude/Longitude	Latitude Longitude	Latitude Longitude
Max Records	n/a	Option_Max_Records

Optional input fields

Category	Single-record results	Multiple-record results
	Input field name	Input field name
Search Filter	Option Radius Search_Filter_Name Search_Filter_Type	Option_Radius Search_Filter_Name Search_Filter_Type

Available output fields

All output fields are optional.

Category	Single-record results	Multiple-record results
	Output field name	Output field name
Address	Address_Line Country_Code Locality1–4 Postcode Postcode1–2 Primary_Name1–4 Primary_Number Primary_Postfix1	n/a

Category	Single-record results	Multiple-record results
	Output field name	Output field name
	Primary_Prefix1 Primary_Range_High Primary_Range_Low Primary_Type1–4 Region1–2	
Address POI	POI_Name POI_Type	n/a
Assignment Level	Assignment_Level Assignment_Level_Locality Assignment_Level_Postcode	n/a
Census	Census_Tract_Block Census_Tract_Block_Group Gov_County_Code Gov_Locality1_Code Gov_Region1_Code Metro_Stat_Area_Code Minor_Div_Code Stat_Area_Code	n/a
Distance	Distance	n/a
Info Code	Info_Code	Info_Code
Latitude/Longitude	Latitude Latitude_Locality Latitude_Postcode Latitude_Primary_Number Longitude Longitude_Locality Longitude_Postcode Longitude_Primary_Number	n/a
Population	Population_Class_Locality1	n/a

Category	Single-record results Output field name	Multiple-record results Output field name
Results	n/a	Result_List Result_List_Count
Side of Street	Side_Of_Primary_Address	n/a

Example

The following example illustrates a scenario using latitude and longitude and a search filter to output a single point of interest closest to the input latitude and longitude.

Input: You map input fields that contain the following data:

Input field name	Input value
Latitude	43.811616
Longitude	-91.256695
Search_Filter_Name	BUSINESS OBJECTS

Output: The mapped output fields contain the following results:

Output field name	Output value
Address_Line	332 FRONT ST
Assignment_Level	PRE
Country_Code	US
Distance	1.3452
Locality1	LA CROSSE
Postcode	54601-4023
Postcode1	54601
Postcode2	4023
Primary_Name1	FRONT
Primary_Number	332
Primary_Type1	ST
POI_Name	BUSINESS OBJECTS
POI_Type	5800
Region1	WI

Reverse geocoding scenario 2

Scenario: Use an address or point of interest to find one or more closest addresses or points of interest. In addition, the Geocoder transform outputs latitude and longitude information for both the input reference point and the matching output results.

The following sections describe the required and optional input fields and available output fields to obtain either single-record or multiple-record results for this scenario. We also provide examples with sample data.

Required input fields

For required input fields, at least one input field in each category must be mapped.

Category	Single-record results	Multiple-record results
	Input field name	Input field name
Address	Address_Line Country Locality1–4 Postcode Postcode1–2 Primary_Name1–4 Primary_Number Primary_Postfix1 Primary_Prefix1 Primary_Range_High Primary_Range_Low Primary_Type1–4 Region1–2	Latitude Longitude
Max Records	n/a	Option_Max_Records
Search Filter	Option_Radius Search_Filter_Name Search_Filter_Type	Option_Radius Search_Filter_Name Search_Filter_Type

Optional input fields

Category	Single-record results Input field name	Multiple-record results Input field name
Address POI	POI_Name POI_Type	POI_Name POI_Type

Available output fields

All output fields are optional.

For a single-record result, the output fields are the results for the spatial search.

For multiple-record results, the output fields in the Assignment Level and Latitude/Longitude categories are the results for the reference address assignment. Output fields in the Results category are the results for the reverse geocoding.

Category	Single-record results Output field name	Multiple-record results Output field name
Address	Address_Line Country_Code Locality1–4 Postcode Postcode1–2 Primary_Name1–4 Primary_Number Primary_Postfix1 Primary_Prefix1 Primary_Range_High Primary_Range_Low Primary_Type1–4 Region1–2	n/a
Address POI	POI_Name POI_Type	n/a
Assignment Level	Assignment_Level	Assignment_Level

Category	Single-record results Output field name	Multiple-record results Output field name
	Assignment_Level_Locality Assignment_Level_Postcode	Assignment_Level_Locality Assignment_Level_Postcode
Census	Census_Tract_Block Census_Tract_Block_Group Gov_County_Code Gov_Locality1_Code Gov_Region1_Code Metro_Stat_Area_Code Minor_Div_Code Stat_Area_Code	n/a
Distance	Distance	n/a
Info Code	Info_Code	Info_Code
Latitude/Longitude	Latitude Latitude_Locality Latitude_Postcode Latitude_Primary_Number Longitude Longitude_Locality Longitude_Postcode Longitude_Primary_Number	Latitude Latitude_Locality Latitude_Postcode Latitude_Primary_Number Longitude Longitude_Locality Longitude_Postcode Longitude_Primary_Number
Population	Population_Class_Locality1	n/a
Results	n/a	Result_List Result_List_Count
Side of Street	Side_Of_Primary_Address	Side_Of_Primary_Address

Example

The following example illustrates a scenario using an address and a search filter to output a single point of interest closest to the input address. The request is to find the closest bank (POI type 6000) to the input location. The transform also outputs latitude and longitude information for the output result.

Input: You map input fields that contain the following data.

Input field name	Input value
Country	US
Postcode1	55601
Postcode2	4023
Primary_Name1	Front
Primary_Number	332
Primary_Type1	St.
POI_Name	BUSINESS OBJECTS
Search_Filter_Type	6000

Output: The mapped output fields contain the following results:

Output field name	Output value
Address_Line	201 MAIN ST
Assignment_Level	PRE
Country_Code	US
Distance	0.4180
Locality1	LA CROSSE
POI_Name	US BANK
POI_Type	6000
Postcode1	54601
Primary_Name1	MAIN
Primary_Number	201
Primary_Type1	ST
Region1	WI

2.16.3.3 POI textual search

In the POI textual search mode, the Geocoder transform uses address fields and POI name or type fields as search criteria to match with points of interest. The results are output in the Result_List XML output field.

The number of multiple records is determined by the Option_Max_Records input field if it is mapped and populated or the Max Records option.

2.16.3.3.1 POI textual search field mapping

The following tables specify the input and output fields that are required, optional, or cannot be mapped in the POI textual search mode. The more input data you can provide, the better results you will obtain.

Input field mapping

In the POI textual search mode, at least one input field in the address POI category must be mapped, which is the key difference between the POI textual search and address geocoding modes.

Input field category	Address geocoding mode
Address	At least one required
Address POI	At least one required
Latitude/Longitude	n/a
Max Records	At least one required
Search Filter	n/a

Output field mapping

Output field category	Address geocoding mode
Address	n/a
Address POI	n/a
Assignment Level	n/a
Census	n/a
Distance	n/a
Info Code	Optional
Latitude/Longitude	n/a
Population	n/a
Results	Optional
Side of Street	n/a

2.16.3.3.2 POI textual search scenario

Scenario: Use an address and point-of-interest information to identify a list of potential point-of-interest matches.

Number of output results: Multiple records. The number of records is determined by the Option_Max_Records input field (if populated), or the Max Records option.

The following sections describe the required input fields and available output fields to obtain results for this scenario. We also provide an example with sample data.

Required input fields

For required input fields, at least one input field in each category must be mapped. The Country field must be mapped. The more input data you can provide, the better results you will obtain.

Category	Input field name
Address	Country (required) Locality1–4 Postcode1–2 Primary_Name1–4 Primary_Number Primary_Postfix1 Primary_Prefix1 Primary_Type1–4 Region1–2
Address POI	POI_Name POI_Type
Max Records	Option_Max_Records

Optional input fields

Not applicable.

Available output fields

All output fields are optional.

Category	Output field name
Info Code	Info_Code
Results	Result_List Result_List_Count

Example

The following example illustrates a scenario using POI textual search to identify a list of potential point-of-interest matches (all “BUSINESS OBJECTS” records on Front Street).

Input: You map input fields that contain the following data:

Input field name	Input value
Country	US
Postcode1	54601
Postcode2	4023
Primary_Name1	Front
Primary_Type1	St.
POI_Name	BUSINESS OBJECTS
Option_Max_Records	10

Output: The mapped output fields contain the following results with one record:

Output field name	Output value
Result_List	Output as XML; example shown below
Result_List_Count	1

Result_List XML: The XML result for this example has one record.

```
<RESULT_LIST>
  <RECORD>
    <ADDRESS_LINE>332 FRONT ST</ADDRESS_LINE>
    <ASSIGNMENT_LEVEL>PRE</ASSIGNMENT_LEVEL>
    <COUNTRY_CODE>US</COUNTRY_CODE>
    <DISTANCE>0.3340</DISTANCE>
    <LATITUDE>43.811616</LATITUDE>
    <LOCALITY1>LA CROSSE</LOCALITY1>
    <LONGITUDE>-91.256695</LONGITUDE>
    <POI_NAME>BUSINESS OBJECTS</POI_NAME>
    <POI_TYPE>5800</POI_TYPE>
    <POSTCODE>56001-4023</POSTCODE>
    <POSTCODE1>56001</POSTCODE1>
    <POSTCODE2>4023</POSTCODE2>
    <PRIMARY_NAME1>FRONT</PRIMARY_NAME1>
    <PRIMARY_NUMBER>332</PRIMARY_NUMBER>
    <PRIMARY_TYPE1>ST</PRIMARY_TYPE1>
    <RANKING>1</RANKING>
    <REGION1>WI</REGION1>
  </RECORD>
</RESULT_LIST>
```

2.16.3.4 Understanding your output

Latitude and longitude

On output from the Geocoder transform, you will have latitude and longitude data. Latitude and longitude are denoted on output by decimal degrees; for example, 12.12345. Latitude (0-90 degrees north or south of the equator) shows a negative sign in front of the output number when the location is south of the equator. Longitude (0-180 degrees east or west of Greenwich Meridian in London, England) shows a negative sign in front of the output number when the location is within 180 degrees west of Greenwich.

Assignment level

You can understand the accuracy of the assignment based on the Assignment_Level output field. The return code of PRE means that you have the finest depth of assignment available to the exact location. The second finest depth of assignment is a return code of PRI, which is the primary address range, or house number. The most general output level is either P1 (Postcode level) or L1 (Locality level), depending on the value that you chose in the Best Assignment Level option.

Multiple results

For multiple-record results, the Result_List output field is output as XML which can contain the following output, depending on the available data.

Category	Output field name
Address	Address_Line Country_Code Locality1–4 Postcode Postcode1–2 Primary_Name1–4 Primary_Number Primary_Postfix1 Primary_Prefix1

Category	Output field name
	Primary_Range_High Primary_Range_Low Primary_Type1–4 Region1–2
Address POI	POI_Name POI_Type
Assignment Level	Assignment_Level
Distance	Distance
Latitude/Longitude	Latitude Longitude
Ranking	Ranking

Standardize address information

The geocoding data provided by vendors is not standardized. To standardize the address data that is output by the Geocoder transform, you can insert a Global Address Cleanse or USA Regulatory Address Cleanse transform in the data flow after the Geocoder transform. If you have set up the Geocoder transform to output multiple records, the address information in the XML output string must first be unnested before it can be cleansed.

Related Information

Reference Guide: Transforms, Geocoder options [page 1180]

2.16.3.5 Working with other transforms

Typically, the Geocoder transform is used in conjunction with the Global Address Cleanse or USA Regulatory Address Cleanse transform.

Global Address Cleanse transform

For the Geocoder transform to provide the most accurate information, make sure the Global Address Cleanse transform output fields are mapped to Geocoder transform input fields as follows:

Global Address Cleanse output	Geocoder input field
ISO_Country_Code_2Char	Country
Postcode1	Postcode1
Postcode2	Postcode2
Primary_Name1	Primary_Name1
Primary_Number	Primary_Number
Primary_Postfix1	Primary_Postfix1
Primary_Prefix1	Primary_Prefix1
Primary_Type1	Primary_Type1
Region1_Symbol	Locality1

It is also recommended that the Global Address Cleanse transform standardization options are set as follows:

Global Address Cleanse standardization option	Value
Assign Locality	Convert
Directional Style	Short
Primary Type Style	Short

➜ Tip

Postal address versus administrative address: The Global Address Cleanse transform uses postal addresses, while the Geocoder transform venders, NAVTEQ and TOMTOM, use administrative addresses. Although a postal alignment is performed with postal addresses, there are some gaps. For example, for one Canadian address, the locality from the Global Address Cleanse transform might return TORONTO, but the Geocoder directory stores NORTH YORK. In this case, when the Locality1 field is mapped on input, it results in an Address Not Found error. As a workaround for this issue, you can remove the Locality1 input field mapping to get a better geocoding assignment.

2.16.4 Match

2.16.4.1 Match and consolidation using Data Services and Information Steward

When manual review is necessary, use SAP Data Services to automatically implement the overall matching and consolidation process. This process stages the match groups for manual review in SAP Information Steward.

To implement this process, consider the following factors:

- Do you stage only suspect match groups (groups that do not meet a match score or threshold that you define) for manual review? Or do you stage all the match results including unique records for match review and let data stewards manually move suspect records or unique records to the group they should belong? Note that the target group in this case could be a suspect group or “high confidence” group.

- Do you want to enable best record creation within Information Steward? Or do you want the Information Steward manual review to only modify suspect match groups as necessary and have Data Services handle the best record creation after the manual review is complete?
- If you want to enable best record creation within Information Steward, when do you perform the best record creation for high confidence match groups?
  - Manually creating a best record for all match groups in a large data set might not be practical.
  - On the other hand, if you have already consolidated high-confidence match groups within Data Services, then you have already modified the original match group to include the best record values, and you cannot stage these modified match groups for manual review in Information Steward.

Consider the following approaches for match review:

- Engage data stewards and domain experts in manual review of suspect match groups only. They can modify the suspect match groups if necessary and create the best record for these match groups.
  1. The Data Services job performs automated matching, identifies suspect match groups, and populates only suspect match groups in a staging database. In this scenario, “high confidence match groups” must be separated from “suspect match groups”. The best record can be created for the “high confidence match groups” and those match groups can be consolidated within Data Services.
     This process can be accomplished by routing the “high confidence match groups” to another Match transform that is configured to create best records out of already matched groups of records.
  2. Data stewards and domain experts review the “suspect match groups” in Information Steward and make corrections as appropriate (for example unmatch or move a record). They can manually create the best record for these match groups.
- Engage data stewards and domain experts in manual review and correction of all match groups, but keep the best record creation and consolidation logic in Data Services.
  1. The Data Services job performs automated matching and populates all match results into the staging database. A match result table in the staging database contains suspect match groups, “high confidence” match groups, and unique records.
  2. Data stewards and domain experts review the suspect match groups in Information Steward and make corrections as appropriate. They can move the records between suspect match groups and “high confidence” match groups, or include a unique record in the appropriate match group.
  3. After the match review is finished, all match groups are processed in another Data Services job which creates the best record and consolidates all match groups.
     This process could be accomplished by a Match transform that is configured to create best records out of already matched groups of records.

> **Note**
>
> You can find examples of best record creation using Information Steward or Data Services by downloading the Data Quality Management Match blueprints. You can find more information about blueprints at *http://scn.sap.com/docs/DOC-8820*.

2.16.4.2 Matching strategies

Here are a few examples of strategies to help you think about how you want to approach the setup of your matching data flow.

Strategy	Description
Simple match	Use this strategy when your matching business rules consist of a single match criteria for identifying relationships in consumer, business, or product data.
Consumer Householding	Use this strategy when your matching business rules consist of multiple levels of consumer relationships, such as residential matches, family matches, and individual matches.
Corporate Householding	Use this strategy when your matching business rules consist of multiple levels of corporate relationships, such as corporate matches, subsidiary matches, and contact matches.
Multinational consumer match	Use this match strategy when your data consists of multiple countries and your matching business rules are different for different countries
Identify a person multiple ways	Use this strategy when your matching business rules consist of multiple match criteria for identifying relationships, and you want to find the overlap between all of those definitions.

Think about the answers to these questions before deciding on a match strategy:

- What does my data consist of? (Customer data, international data, and so on)
- What fields do I want to compare? (last name, firm, and so on.)
- What are the relative strengths and weaknesses of the data in those fields?

  > ➜ Tip
  >
  > You will get better results if you cleanse your data before matching. Also, data profiling can help you answer this question.

- What end result do I want when the match job is complete? (One record per family, per firm, and so on.)

Related Information

Association matching [page 579]

2.16.4.3 Match components

The basic components of matching are:

- Match sets
- Match levels
- Match criteria

Match sets

A match set is represented by a Match transform on your workspace. Each match set can have its own break groups, match criteria, and prioritization.

A match set has three purposes:

- To allow only select data into a given set of match criteria for possible comparison (for example, exclude blank SSNs, international addresses, and so on).
- To allow for related match scenarios to be stacked to create a multi-level match set.
- To allow for multiple match sets to be considered for association in an Associate match set.

Match levels

A match level is an indicator to what type of matching will occur, such as on individual, family, resident, firm, and so on. A match level refers not to a specific criteria, but to the broad category of matching.

You can have as many match levels as you want. However, the Match wizard restricts you to three levels during setup (more can be added later). You can define each match level in a match set in a way that is increasingly more strict. Multi-level matching feeds only the records that match from match level to match level (for example, resident, family, individual) for comparison.

Match component	Description
Family	The purpose of the family match type is to determine whether two people should be considered members of the same family, as reflected by their record data. The Match transform compares the last name and the address data. A match means that the two records represent members of the same family. The result of the match is one record per family.
Individual	The purpose of the individual match type is to determine whether two records are for the same person, as reflected by their record data. The Match transform compares the first name, last name, and address data. A match means that the two records represent the same person. The result of the match is one record per individual.
Resident	The purpose of the resident match type is to determine whether two records should be considered members of the same residence, as reflected by their record data. The Match transform compares the address data. A match means that the two records represent members of the same household. Contrast this match type with the family match type, which also compares last-name data. The result of the match is one record per residence.
Firm	The purpose of the firm match type is to determine whether two records reflect the same firm. This match type involves comparisons of firm and address data. A match means that the two records represent the same firm. The result of the match is one record per firm.

Match component	Description
Firm-Individual	The purpose of the firm-individual match type is to determine whether two records are for the same person at the same firm, as reflected by their record data. With this match type, we compare the first name, last name, firm name, and address data. A match means that the two records reflect the same person at the same firm. The result of the match is one record per individual per firm.

Match criteria

Match criteria refers to the field you want to match on. You can use criteria options to specify business rules for matching on each of these fields. They allow you to control how close to exact the data needs to be for that data to be considered a match.

For example, you may require first names to be at least 85% similar, but also allow a first name initial to match a spelled out first name, and allow a first name to match a middle name.

- Family level match criteria may include family (last) name and address, or family (last) name and telephone number.
- Individual level match criteria may include full name and address, full name and SSN, or full name and e-mail address.
- Firm level match criteria may include firm name and address, firm name and Standard Industrial Classification (SIC) Code, or firm name and Data Universal Numbering System (DUNS) number.

2.16.4.4 Match Wizard

2.16.4.4.1 Match wizard

The Match wizard can quickly set up match data flows, without requiring you to manually create each individual transform it takes to complete the task.

What the Match wizard does

The Match wizard:

- Builds all the necessary transforms to perform the match strategy you choose.
- Applies default values to your match criteria based on the strategy you choose.
- Places the resulting transforms on the workspace, connected to the upstream transform you choose.
- Detects the appropriate upstream fields and maps to them automatically.

What the Match wizard does not do

The Match wizard provides you with a basic match setup that in some cases, will require customization to meet your business rules.

The Match wizard:

- Does not alter any data that flows through it. To correct non-standard entries or missing data, place one of the address cleansing transforms and a Data Cleanse transform upstream from the matching process.
- Does not connect the generated match transforms to any downstream transform, such as a Loader. You are responsible for connecting these transforms.
- Does not allow you to set rule-based or weighted scoring values for matching. The Match wizard incorporates a "best practices" standard that set these values for you. You may want to edit option values to conform to your business rules.

Related Information

Combination method [page 551]

2.16.4.4.2 Before you begin

Prepare a data flow for the Match wizard

To maximize its usefulness, be sure to include the following in your data flow before you launch the Match wizard:

- Include a Reader in your data flow. You may want to match on a particular input field that our data cleansing transforms do not handle.
- Include one of the address cleansing transforms and the Data Cleanse transform. The Match wizard works best if the data you're matching has already been cleansed and parsed into discrete fields upstream in the data flow.
- If you want to match on any address fields, be sure that you pass them through the Data Cleanse transform. Otherwise, they will not be available to the Match transform (and Match Wizard). This rule is also true if you have the Data Cleanse transform before an address cleanse transform.

2.16.4.4.3 Use the Match Wizard

2.16.4.4.3.1 Select match strategy

The Match wizard begins by prompting you to choose a match strategy, based on your business rule requirements. The path through the Match wizard depends on the strategy you select here. Use these descriptions to help you decide which strategy is best for you:

- **Simple match.** Use this strategy when your matching business rules consist of a single match criteria for identifying relationships in consumer, business, or product data.
- **Consumer Householding.** Use this strategy when your matching business rules consist of multiple levels of consumer relationships, such as residential matches, family matches, and individual matches.
- **Corporate Householding.** Use this strategy when your matching business rules consist of multiple levels of corporate relationships, such as corporate matches, subsidiary matches, and contact matches.
- **Multinational consumer match.** Use this match strategy when your data consists of multiple countries and your matching business rules are different for different countries.

  > Note
  >
  > The multinational consumer match strategy sets up a data flow that expects Latin1 data. If you want to use Unicode matching, you must edit your data flow after it has been created.
- **Identify a person multiple ways.** Use this strategy when your matching business rules consist of multiple match criteria for identifying relationships, and you want to find the overlap between all of those definitions.

Source statistics

If you want to generate source statistics for reports, make sure a field that houses the physical source value exists in all of the data sources.

To generate source statistics for your match reports, select the *Generate statistics for your sources* checkbox, and then select a field that contains your physical source value.

Related Information

Unicode matching [page 580]

Association matching [page 579]

2.16.4.4.3.2 Identify matching criteria

Criteria represent the data that you want to use to help determine matches. In this window, you will define these criteria for each match set that you are using.

Match sets compare data to find similar records, working independently within each break group that you designate (later in the Match wizard). The records in one break group are not compared against those in any other break group.

To find the data that matches all the fields, use a single match set with multiple fields. To find the data that matches only in a specific combination of fields, use multiple match sets with two fields.

When working on student or snowbird data, an individual may use the same name but have multiple valid addresses.

Select a combination of fields that best shows which information overlaps, such as the family name and the SSN.

Data1	Data2	Data3	Data4
R. Carson	1239 Whistle Lane	Columbus, Ohio	555-23-4333
Robert T. Carson	52 Sunbird Suites	Tampa, Florida	555-23-4333

1. Enter the number of ways you have to identify an individual. This produces the corresponding number of match sets (transforms) in the data flow.
2. The default match set name appears in the *Name* field. Select a match set in the *Match sets* list, and enter a more descriptive name if necessary.
3. For each match set, choose the criteria you want to match on.

   Later, you will assign fields from upstream transforms to these criteria.
4. Select the option you want to use for comparison in the Compare using column. The options vary depending on the criteria chosen. The compare options are:
   - *Field similarity*
   - *Word similarity*
   - *Numeric difference*
   - *Numeric percent difference*
   - *Geo proximity*
5. Optional: If you choose to match on Custom, enter a name for the custom criteria in the Custom name column.
6. Optional: If you choose to match on Custom, specify how close the data must be for that criteria in two records to be considered a match. The values that result determine how similar you expect the data to be during the comparison process for this criteria only. After selecting a strategy, you may change the values for any of the comparison rules options in order to meet your specific matching requirements.Select one of the following from the list in the Custom exactness column:
   - *Exact*: Data in this criteria must be exactly the same; no variation in the data is allowed.
   - *Tight*: Data in this criteria must have a high level of similarity; a small amount of variation in the data is allowed.
   - *Medium*: Data in this criteria may have a medium level of similarity; a medium amount of variation in the data is allowed.
   - *Loose*: Data in this criteria may have a lower level of similarity; a greater amount of variation in the data is allowed.

2.16.4.4.3.3 Define match levels

Match levels allow matching processes to be defined at distinct levels that are logically related. Match levels refer to the broad category of matching not the specific rules of matching. For instance, a residence-level match would match on only address elements, a family-level would match on only Last Name and then the individual-level would match on First Name.

Multi-level matching can contain up to 3 levels within a single match set defined in a way that is increasingly more strict. Multi-level matching feeds only the records that match from match level to match level (that is, resident, family, individual) for comparison.

To define match levels:

1. Click the top level match, and enter a name for the level, if you don't want to keep the default name. The default criteria is already selected. If you do not want to use the default criteria, click to remove the check mark from the box.

   The default criteria selection is a good place to start when choosing criteria. You can add criteria for each level to help make finer or more precise matches.
2. Select any additional criteria for this level.
3. If you want to use criteria other than those offered, click *Custom* and then select the desired criteria.
4. Continue until you have populated all the levels that you require.

2.16.4.4.3.4 Select countries

Select the countries whose postal standards may be required to effectively compare the incoming data. The left panel shows a list of all available countries. The right panel shows the countries you already selected.

1. Select the country name in the All Countries list.
2. Click *Add* to move it into the Selected Countries list.
3. Repeat steps 1 and 2 for each country that you want to include.

   You can also select multiple countries and add them all by clicking the *Add* button.

The countries that you select are remembered for the next Match wizard session.

2.16.4.4.3.5 Group countries into tracks

Create tracks to group countries into logical combinations based on your business rules (for example Asia, Europe, South America). Each track creates up to six match sets (Match transforms).

1. Select the number of tracks that you want to create. The *Tracks* list reflects the number of tracks you choose and assigns a track number for each.
2. To create each track, select a track title, such as Track1.
3. Select the countries that you want in that track.
4. Click *Add* to move the selected countries to the selected track.

   Use the COUNTRY UNKNOWN (__) listing for data where the country of origin has not been identified.

   Use the COUNTRY OTHER (--) listing for data whose country of origin has been identified, but the country does not exist in the list of selected countries.
5. From Match engines, select one of the following engines for each track:

   > Note
   >
   > All match transforms generated for the track will use the selected Match engine.

   - *LATIN1* (Default)
   - *CHINESE*
   - *JAPANESE*

- *KOREAN*
- *TAIWANESE*
- *OTHER_NON_LATIN1*

The *Next* button is only enabled when all tracks have an entry and all countries are assigned to a track.

2.16.4.4.3.6 Select criteria fields

Select and deselect criteria fields for each match set and match level you create in your data flow. These selections determine which fields are compared for each record. Some criteria may be selected by default, based on the data input.

If there is only one field of the appropriate content type, you will not be able to change the field for that criteria within the Match Wizard.

To enable the *Next* button, you must select at least one non-match-standard field.

1. For each of the criteria fields you want to include, select an available field from the drop-down list, which contains fields from upstream source(s). The available fields are limited to the appropriate content types for that criteria. If no fields of the appropriate type are available, all upstream fields display in the menu.
2. Optional: Deselect any criteria fields you do not want to include.

2.16.4.4.3.7 Create break keys

Use break keys to create manageable groups of data to compare. The match set compares the data in the records within each break group only, not across the groups. Making the correct selections can save valuable processing time by preventing widely divergent data from being compared.

Break keys are especially important when you deal with large amounts of data, because the size of the break groups can affect processing time. Even if your data is not extensive, break groups will help to speed up processing.

Create break keys that group similar data that would most likely contain matches. Keep in mind that records in one break group will not be compared against records in any other break group.

For example, when you match to find duplicate addresses, base the break key on the postcode, city, or state to create groups with the most likely matches. When you match to find duplicate individuals, base the break key on the postcode and a portion of the name as the most likely point of match.

To create break keys:

1. In the How many fields column, select the number of fields to include in the break key.
2. For each break key, select the following:
    - the field(s) in the break key
    - the starting point for each field
    - the number of positions to read from each field
3. After you define the break keys, do one of the following:

- Click *Finish*. This completes the match transform.
- If you are performing multi-national matching, click *Next* to go to the Matching Criteria page.

2.16.4.4.4 After setup

Although the Match wizard does a lot of the work, there are some things that you must do to have a runnable match job. There are also some things you want to do to refine your matching process.

Connect to downstream transforms

When the Match wizard is complete, it places the generated transforms on the workspace, connected to the upstream transform you selected to start the Match wizard. For your job to run, you must connect each port from the last transform to a downstream transform. To do this, click a port and drag to connect to the desired object.

View and edit the new match transform

To see what is incorporated in the transform(s) the Match Wizard produces, right-click the transform and choose *Match Editor*.

View and edit Associate transforms

To see what is incorporated in the Associate transform(s) the Match Wizard produces, right-click the transform and choose *Associate Editor*.

Multinational matching

For the Multinational consumer match strategy, the wizard builds a Match transform for each track that you create.

> ⚠ Caution
>
> If you delete any tracks from the workspace after the wizard builds them, you must open the Case transform and delete any unwanted rules.

Related Information

Unicode matching [page 580]

2.16.4.5 Transforms for match data flows

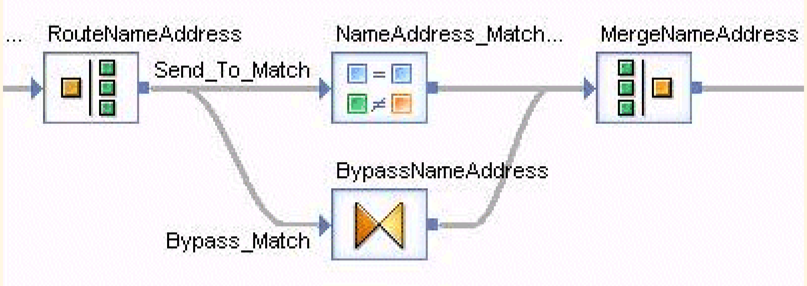
The Match and Associate transforms are the primary transforms involved in setting up matching in a data flow. These transforms perform the basic matching functions.

There are also other transforms that can be used for specific purposes to optimize matching.

Transform	Usage
Case	Routes data to a particular Match transform (match set). A common usage for this transform is to send USA-specific and international-specific data to different transforms. You can also use this transform to route blank records around a Match transform.
Merge	Performs the following functions: • Brings together data from Match transforms for Association matching. • Brings together matching records and blank records after being split by a Case transform.
Query	Creates fields, performs functions to help prepare data for matching, orders data, and so on.

Example

Any time you need to bypass records from a particular match process (usually in Associative data flows and any time you want to have records with blank data to bypass a match process) you will use the Case, Query, and Merge transforms.



- The Case transform has two routes: one route sends all records that meet the criteria to the Match transform, and one that sends all other records to the bypass match route.
- The Query transform adds the fields that the Match transform generates and that you output. (The output schema in the Match transform and the output schema in the Query transform must be identical for the routes to be merged.) The contents of the newly added fields in the Query transform may be populated with an empty string.
- The Merge transform merges the two routes into a single route.

2.16.4.5.1 To remove matching from the Match transform

You may want to place a transform that employs some of the functionality of a Match transform in your data flow, but does not include the actual matching features. For example, you may want to do candidate selection or prioritization in a data flow or a location in a data flow.

1. Right-click the Match transform in the object library, and choose New.
2. In the *Format name* field, enter a meaningful name for your transform. It's helpful to indicate which type of function this transform will be performing.
3. Click *OK*.
4. Drag and drop your new Match transform configuration onto the workspace and connect it to your data flow.
5. Right-click the new transform, and choose *Match Editor*.
6. Deselect the *Perform matching* option in the upper left corner of the Match editor.

Now you can add any available operation to this transform.

2.16.4.6 Working in the Match and Associate editors

Editors

The Match and Associate transform editors allow you to set up your input and output schemas. You can access these editors by double-clicking the appropriate transform icon on your workspace.

The Match and Associate editors allow you to configure your transform's options. You can access these editors by right-clicking the appropriate transform and choosing *Match Editor* (or *Associate Editor*).

Order of setup

> ➔ Tip
>
> The order that you set up your Match transform is important!

First, it is best to map your input fields. If you don't, and you add an operation in the Match editor, you may not see a particular field you want to use for that operation.

Secondly, you should configure your options in the Match editor before you map your output fields. Adding operations to the Match transform (such as Unique ID and Group Statistics) can provide you with useful Match transform-generated fields that you may want to use later in the data flow or add to your database.

> ➔ Remember
>
> Make sure that you:
>
> 1. Map your input fields.
> 2. Configure the options for the transform.

3. Map your output fields.

2.16.4.7 Physical and logical sources

Tracking your input data sources and other sources, whether based on an input source or based on some data element in the rows being read, throughout the data flow is essential for producing informative match reports. Depending on what you are tracking, you must create the appropriate fields in your data flow to ensure that the software generates the statistics you want, if you don't already have them in your database.

- Physical source: The filename or value attributed to the source of the input data.
- Logical source: A group of records spanning multiple input sources or a subset of records from a single input source.

Physical input sources

You track your input data source by assigning that physical source a value in a field. Then you will use this field in the transforms where report statistics are generated.

To assign this value, add a Query transform after the source and add a column with a constant containing the name you want to assign to this source.

i Note

If your source is a flat file, you can use the *Include file name* option to automatically generate a column containing the file name.

Logical input sources

If you want to count source statistics in the Match transform (for the Match Source Statistics Summary report, for example), you must create a field using a Query transform or a User-Defined transform, if you don't already have one in your input data sources.

This field tracks the various sources within a Reader for reporting purposes, and is used in the Group Statistics operation of the Match transform to generate the source statistics. It is also used in compare tables, so that you can specify which sources to compare.

2.16.4.7.1 Using sources

A source is the grouping of records on the basis of some data characteristic that you can identify. A source might be all records from one input file, or all records that contain a particular value in a particular field.

Sources are abstract and arbitrary—there is no physical boundary line between sources. Source membership can cut across input files or database records as well as distinguish among records within a file or database, based on how you define the source.

If you are willing to treat all your input records as normal, eligible records with equal priority, then you do not need to include sources in your job.

Typically, a match user expects some characteristic or combination of characteristics to be significant, either for selecting the best matching record, or for deciding which records to include or exclude from a mailing list, for example. Sources enable you to attach those characteristics to a record, by virtue of that record’s membership in its particular source.

Before getting to the details about how to set up and use sources, here are some of the many reasons you might want to include sources in your job:

- To give one set of records priority over others. For example, you might want to give the records of your house database or a suppression source priority over the records from an update file.
- To identify a set of records that match suppression sources, such as the DMA.
- To set up a set of records that should not be counted toward multi-source status. For example, some mailers use a seed source of potential buyers who report back to the mailer when they receive a mail piece so that the mailer can measure delivery. These are special-type records.
- To save processing time, by canceling the comparison within a set of records that you know contains no matching records. In this case, you must know that there are no matching records within the source, but there may be matches among sources. To save processing time, you could set up sources and cancel comparing within each source.
- To get separate report statistics for a set of records within an source, or to get report statistics for groups of sources.
- To protect a source from having its data overwritten by a best record or unique ID operation. You can choose to protect data based on membership in a source.

2.16.4.7.2 Source types

You can identify each source as one of three different types: Normal, Suppression, or Special. The software can process your records differently depending on their source type.

Source	Description
Normal	A Normal source is a group of records considered to be good, eligible records.
Suppress	A Suppress source contains records that would often disqualify a record from use. For example, if you’re using Match to refine a mailing source, a suppress source can help remove records from the mailing. Examples: • DMA Mail Preference File • American Correctional Association prisons/jails sources • No pandering or non-responder sources • Credit card or bad-check suppression sources

Source	Description
Special	A Special source is treated like a Normal source, with one exception. A Special source is not counted in when determining whether a match group is single-source or multi-source. A Special source can contribute records, but it's not counted toward multi-source status. For example, some companies use a source of seed names. These are names of people who report when they receive advertising mail, so that the mailer can measure mail delivery. Appearance on the seed source is not counted toward multi-source status.

The reason for identifying the source type is to set that identity for each of the records that are members of the source. Source type plays an important role in controling priority (order) of records in break group, how the software processes matching records (the members of match groups), and how the software produces output (that is, whether it includes or excludes a record from its output).

2.16.4.7.2.1 To manually define input sources

Once you have mapped in an input field that contains the source values, you can create your sources in the Match Editor.

1. In the Match Editor, select *Transform Options* in the explorer pane on the left, click the *Add* button, and select *Input Sources*.
   The new Input Sources operation appears under Transform Options in the explorer pane. Select it to view Input Source options.
2. In the *Value field* drop-down list, choose the field that contains the input source value.
3. In the *Define sources* table, create a source name, type a source value that exists in the Value field for that source, and choose a source type.
4. Choose value from the *Default source name* option. This name will be used for any record whose source field value is blank.

Be sure to click the Apply button to save any changes you have made, before you move to another operation in the Match Editor.

2.16.4.7.2.2 To automatically define input sources

To avoid manually defining your input sources, you can choose to do it automatically by choosing the *Auto generate sources* option in the Input Sources operation.

1. In the Match Editor, select *Transform Options* in the explorer pane on the left, click the *Add* button, and select *Input Sources*.
   The new Input Sources operation appears under Transform Options in the explorer pane. Select it to view Input Source options.

2. In the *Value field* drop-down list, choose the field that contains the input source value.
3. Choose value from the *Default source name* option. This name will be used for any record whose source field value is blank.
4. Select the *Auto generate sources* option.
5. Choose a value in the *Default type* option

   The default type will be assigned to to any source that does not already have the type defined in the Type field.
6. Select a field from the drop-down list in the *Type field* option.

Auto generating sources will create a source for each unique value in the Value field. Any records that do not have a value field defined will be assigned to the default source name.

2.16.4.7.3 Source groups

The source group capability adds a higher level of source management. For example, suppose you rented several files from two brokers. You define five sources to be used in ranking the records. In addition, you would like to see your job's statistics broken down by broker as well as by file. To do this, you can define groups of sources for each broker.

Source groups primarily affect reports. However, you can also use source groups to select multi-source records based on the number of source groups in which a name occurs.

Remember that you cannot use source groups in the same way you use sources. For example, you cannot give one source group priority over another.

2.16.4.7.3.1 To create source groups

You must have input sources in an Input Source operation defined to be able to add this operation or define your source groups.

1. Select a Match transform in your data flow, and choose *Tools* > *Match Editor* .
2. In the Match Editor, select *Transform Options* in the explorer pane on the left, click the *Add* button, and select *Source Groups*.
   The new Source Groups operation appears under Input Sources operation in the explorer pane. Select it to view Source Group options.
3. Confirm that the input sources you need are in the Sources column on the right.
4. Double-click the first row in the Source Groups column on the left, and enter a name for your first source group, and press Enter.
5. Select a source in the Sources column and click the *Add* button.
6. Choose a value for the *Undefined action* option.

   This option specifies the action to take if an input source does not appear in a source group.
7. If you chose Default as the undefined action in the previous step, you must choose a value in the *Default source group* option.

   This option is populated with source groups you have already defined. If an input source is not assigned to a source group, it will be assigned to this default source group.

8. If you want, select a field in the *Source group field* option drop-down list that contains the value for your source groups.

2.16.4.8 Match preparation

2.16.4.8.1 Prepare data for matching

Data correction and standardization

Accurate matches depend on good data coming into the Match transform. For batch matching, we always recommend that you include one of the address cleansing transforms and a Data Cleanse transform in your data flow before you attempt matching.

Filter out empty records

You should filter out empty records before matching. This should help performance. Use a Case transform to route records to a different path or a Query transform to filter or block records.

Remove noise words

You can perform a search and replace on words that are meaningless to the matching process. For matching on firm data, words such as Inc., Corp., and Ltd. can be removed. You can use the search and replace function in the Query transform to accomplish this.

Remove punctuation

To maximize your matching process, map the following Data Cleanse transform output fields into your Match transform. These fields output standarized data that has been converted to uppercase, has had punctuation removed, and so on. See the Data Cleanse output field section for more information.

- Match_Family_Name
- Match_Firm
- Match_Given_Name1
- Match_Given_Name2
- Match_Maturity_Postname
- Match_Phone
- Match_Prename

Break groups

Break groups organize records into collections that are potential matches, thus reducing the number of comparisons that the Match transform must perform. Include a Break Group operation in your Match transform to improve performance.

Match standards

You may want to include variations of name or firm data in the matching process to help ensure a match. For example, a variation of “Bill” might be “William”. When making comparisons, you may want to use the original data and one or more variations. You can add anywhere from one to five variations or match standards, depending on the type of data.

For example, If the first names are compared but don't match, the variations are then compared. If the variations match, the two records still have a chance of matching rather than failing, because the original first names were not considered a match.

Custom Match Standards

You can match on custom Data Cleanse output fields and associated aliases. Map the custom output fields from Data Cleanse and the custom fields will appear in the Match Editor's Criteria Fields tab.

Related Information

Set up for match standards criteria [page 548]
Reference Guide: Output fields [page 1164]

2.16.4.8.1.1 Fields to include for matching

To take advantage of the wide range of features in the Match transform, you will need to map a number of input fields, other than the ones that you want to use as match criteria.

> Example
>
> Here are some of the other fields that you might want to include. The names of the fields are not important, as long as you remember which field contains the appropriate data.

Field contents	Contains...
Logical source	A value that specifies which logical source a record originated. This field is used in the Group Statistics operation, compare tables, and also the Associate transform.
Physical source	A value that specifies which physical source a record originated. (For example, a source object, or a group of candidate-selected records) This field is used in the Match transform options, Candidate Selection operation, and the Associate transform.
Break keys	A field that contains the break key value for creating break groups. Including a field that already contains the break key value could help improve the performance of break group creation, because it will save the Match transform from doing the parsing of multiple fields to create the break key.
Criteria fields	The fields that contain the data you want to match on.
Count flags	A Yes or No value to specify whether a logical source should be counted in a Group Statistics operation.
Record priority	A value that is used to signify a record as having priority over another when ordering records. This field is used in Group Prioritization operations.
Apply blank penalty	A Yes or No value to specify whether Match should apply a blank penalty to a record. This field is used in Group Prioritization operations.
Starting unique ID value	A starting ID value that will then increment by 1 every time a unique ID is assigned. This field is used in the Unique ID operation.

This is not a complete list. Depending on the features you want to use, you may want to include many other fields that will be used in the Match transform.

2.16.4.8.2 Control record comparisons

Controlling the number of record comparisons in the matching process is important for a couple of reasons:

- **Speed.** By controlling the actual number of comparisons, you can save processing time.
- **Match quality.** By grouping together only those records that have a potential to match, you are assured of better results in your matching process.

Controlling the number of comparisons is primarily done in the Group Forming section of the Match editor with the following operations:

- Break group: Break up your records into smaller groups of records that are more likely to match.
- Candidate selection: Select only match candidates from a database table. This is primarily used for real-time jobs.

You can also use compare tables to include or exclude records for comparison by logical source.

Candidate selection [page 531]
Compare tables [page 535]

2.16.4.8.2.1 Break groups

When you create break groups, you place records into groups that are likely to match. For example, a common scenario is to create break groups based on a postcode. This ensures that records from different postcodes will never be compared, because the chances of finding a matching record with a different postcode are very small.

Break keys

You form break groups by creating a break key: a field that consists of parts of other fields or a single field, which is then used to group together records based on similar data.

Here is an example of a typical break key created by combining the five digits of the Postcode1 field and the first three characters of the Address_Primary_Name field.

Field (Start pos:length)	Data in field	Generated break key
Postcode1 (1:5)	10101	10101Mai
Address_Primary_Name (1:3)	Main	

All records that match the generated break key in this example are placed in the same break group and compared against one another.

Sorting of records in the break group

Records are sorted on the break key field.

You can add a Group Prioritization operation after the Break Groups operation to specify which records you want to be the drivers.

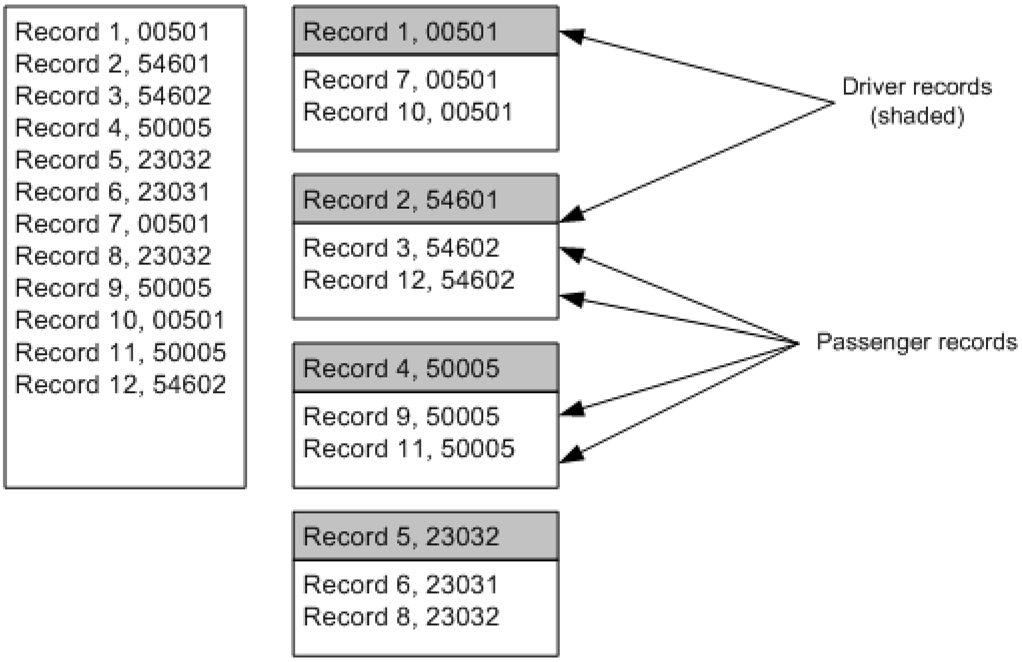
> ➜ Remember
>
> Order is important! If you are creating break groups using records from a Suppress-type source, be sure that the suppression records are the drivers in the break group.

Break group anatomy

Break groups consist of driver and passenger records. The driver record is the first record in the break group, and all other records are passengers.

The driver record is the record that drives the comparison process in matching. The driver is compared to all of the passengers first.

This example is based on a break key that uses the first three digits of the Postcode.



Phonetic break keys

You can also use the Soundex and Double Metaphone functions to create fields containing phonetic codes, which can then be used to form break groups for matching.

2.16.4.8.2.1.1 To create break groups

We recommend that you standardize your data before you create your break keys. Data can be treated differently that is inconsistently cased, for example.

1. Add a Break Groups operation to the *Group Forming* option group.

2. in the *Break key table*, add a row by clicking the Add button.
3. Select a field in the *field* column that you want to use as a break key.
   Postcode is a common break key to use.
4. Choose the start position and length (number of characters) you want used in your break key.
   You can use negative integers to signify that you want to start at the end of the actual string length, not the specified length of the field. For example, Field(-3,3) takes the last 3 characters of the string, whether the string has length of 10 or a length of 5.
5. Add more rows and fields as necessary.
6. Order your rows by selecting a row and clicking the *Move Up* and *Move Down* buttons.
   Ordering your rows ensures that the fields are used in the right order in the break key.

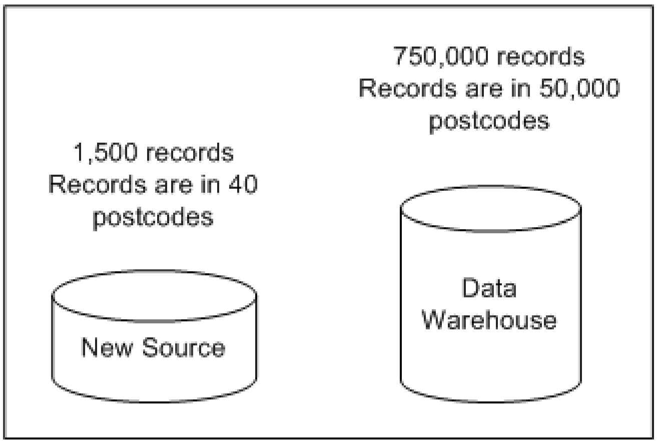
Your break key is now created.

2.16.4.8.2.2 Candidate selection

To speed processing in a match job, use the Candidate Selection operaton (Group forming option group) in the Match transform to append records from a relational database to an existing data collection before matching. When the records are appended, they are not logically grouped in any way. They are simply appended to the end of the data collection on a record-by-record basis until the collection reaches the specified size.

For example, suppose you have a new source of records that you want to compare against your data warehouse in a batch job. From this warehouse, you can select records that match the break keys of the new source. This helps narrow down the number of comparisons the Match transform has to make.

For example, here is a simplified illustration: Suppose your job is comparing a new source database—a smaller, regional file—with a large, national database that includes 15 records in each of 43,000 or so postcodes. Further assume that you want to form break groups based only on the postcode.



Notes	Regional	National	Total
Without candidate selection, the Match transform reads all of the records of both databases.	1,500	750,000	751,500

Notes	Regional	National	Total
With candidate selection, only those records that would be included in a break group are read.	1,500	About 600 (40 x 15)	2,100

2.16.4.8.2.2.1 Datastores and candidate selection

To use candidate selection, you must connect to a valid datastore. You can connect to any SQL-based or persistent cache datastore. There are advantages for using one over the other, depending on whether your secondary source is static (it isn't updated often) or dynamic (the source is updated often).

Persistent cache datastores

Persistent cache is like any other datastore from which you can load your candidate set. If the secondary source from which you do candidate selection is fairly static (that is, it will not change often), then you might want consider building a persistent cache, rather than using your secondary source directly, to use as your secondary table. You may improve performance.

You may also encounter performance gains by using a flat file (a more easily searchable format than a RDBMS) for your persistent cache. If the secondary source is not an RDBMS, such as a flat file, you cannot use it as a "datastore". In this case, you can create a persistent cache out of that flat file source and then use that for candidate selection.

i Note

A persistent cache used in candidate selection must be created by a data flow in double-byte mode. To do this, you will need to change the locale setting in the Data Services Locale Selector (set the code page to utf-8). Run the job to generate the persistent cache, and then you can change the code page back to its original setting if you want.

Cache size

Performance gains using persistent cache also depend on the size of the secondary source data. As the size of the data loaded in the persistent cache increases, the performance gains may decrease. Also note that if the original secondary source table is properly indexed and optimized for speed then there may be no benefit in creating a persistent cache (or even pre-load cache) out of it.

Related Information

Persistent cache datastores [page 229]

2.16.4.8.2.2.2 Auto-generation vs. custom SQL

There are cases where the Match transform can generate SQL for you, and there are times where you must create your own SQL. This is determined by the options you and how your secondary table (the table you are selecting match candidates from) is set up.

Use this table to help you determine whether you can use auto-generated SQL or if you must create your own.

> Note
>
> In the following scenarios, “input data” refers to break key fields coming from a transform upstream from the Match transform (such as a Query transform) or a break key fields coming from the Break Group operation within the Match transform itself.

Scenario	Auto-generate or Custom?
You have a single break key field in your input data, and you have the same field in your secondary table.	Auto-generate
You have multiple break key fields in your input data, and you have the same fields in your secondary table.	Auto-generate
You have multiple break key fields in your input data, and you have one break key field in your secondary table.	Auto-generate
You have a single break key field in your input data, and you have multiple break key fields in your secondary table.	Custom
You have multiple break key fields in your input data, but you have a different format or number of fields in your secondary table.	Custom
You want to select from multiple input sources.	Custom

2.16.4.8.2.2.3 Break keys and candidate selection

We recommend that you create a break key column in your secondary table (the table that contains the records you want to compare with the input data in your data flow) that matches the break key you create your break groups with in the Match transform. This makes setup of the Candidate Selection operation much easier. Also, each of these columns should be indexed.

We also recommend that you create and populate the database you are selecting from with a single break key field, rather than pulling substrings from database fields to create your break key. This can help improve the performance of candidate selection.

> Note
>
> Records extracted by candidate selection are appended to the end of an existing break group (if you are using break groups). So, if you do not reorder the records using a Group Prioritization operation after the Candidate Selection operation, records from the original source will always be the driver records in the break groups. If you are using candidate selection on a Suppress source, you will need to reorder the records so that the records from the Suppress source are the drivers.

2.16.4.8.2.2.4 To set up candidate selection

If you are using Candidate selection for a real-time job, be sure to deselect the *Split records into break groups* option in the Break Group operation of the Match transform.

To speed processing in a real-time match job, use the Candidate Selection operaton (Group forming option group) in the Match transform to append records from a relational database to an existing data collection before matching. When the records are appended, they are not logically grouped in any way. They are simply appended to the end of the data collection on a record-by-record basis until the collection reaches the specified size.

1. In the Candidate Selection operation, select a valid datastore from the *Datastore* drop-down list.
2. In the *Cache type* drop-down list, choose from the following values:

Option	Description
No_Cache	Captures data at a point in time. The data doesn't change until the job restarts.
Pre-load Cache	Use this option for static data.

3. Depending on how your input data and secondary table are structured, do one of the following:
   - Select *Auto-generate SQL*. Then select the *Use break column from database* option, if you have one, and choose a column from the *Break key field* drop-down list.

     > Note
     >
     > If you choose the *Auto-generate SQL* option, we recommend that you have a break key column in your secondary table and select the *Use break column from database* option. If you don't, the SQL that is created could be incorrect.

   - Select *Create custom SQL*, and either click the *Launch SQL Editor* button or type your *SQL* in the SQL edit box.
4. If you want to track your records from the input source, select *Use constant source value*.
5. Enter a value that represents your source in the *Physical source value* option, and then choose a field that holds this value in the *Physical source field* drop-down list.
6. In the *Column mapping* table, add as many rows as you want. Each row is a field that will be added to the collection.
   a) Choose a field in the *Mapped name* column.
   b) Choose a column from your secondary table (or from a custom query) in the *Column name* option that contains the same type of data as specified in the *Mapped name* column.

   If you have already defined your break keys in the Break Group option group, the fields used to create the break key are posted here, with the Break Group column set to YES.

2.16.4.8.2.2.5 Writing custom SQL

Use placeholders

To avoid complicated SQL statements, you should use placeholders (which are replaced with real input data) in your WHERE clause.

For example, let's say the customer database contains a field called MatchKey, and the record that goes through the cleansing process gets a field generated called MATCH_KEY. This field has a placeholder of [MATCHKEY]. The records that are selected from the customer database and appended to the existing data collection are those that contain the same value in MatchKey as in the transaction's MATCH_KEY. For this example, let's say the actual value is a 10-digit phone number.

The following is an example of what your SQL would look like with an actual phone number instead of the [MATCHKEY] placeholder.

```
SELECT ContactGivenName1, ContactGivenName2, ContactFamilyName, Address1, Address2,
City, Region, Postcode, Country, AddrStreet, AddrStreetNumber, AddrUnitNumber

FROM TblCustomer

WHERE MatchKey = '123-555-9876';
```

Caution

You must make sure that the SQL statement is optimized for best performance and will generate valid results. The Candidate Selection operation does not do this for you.

Replace placeholder with actual values

After testing the SQL with actual values, you must replace the actual values with placeholders ([MATCHKEY], for example).

Your SQL should now look similar to the following.

```
SELECT ContactGivenName1, ContactGivenName2, ContactFamilyName, Address1, Address2,
City, Region, Postcode, Country, AddrStreet, AddrStreetNumber, AddrUnitNumber

FROM TblCustomer

WHERE MatchKey = [MATCHKEY];
```

Note

Placeholders cannot be used for list values, for example in an IN clause:

```
WHERE status IN ([status])
```

If [status] is a list of values, this SQL statement will fail.

2.16.4.8.2.3 Compare tables

Compare tables are sets of rules that define which records to compare, sort of an additional way to create break groups. You use your logical source values to determine which records are compared or are not compared.

By using compare tables, you can compare records within sources, or you can compare records across sources, or a combination of both.

2.16.4.8.2.3.1 To set up a compare table

Be sure to include a field that contains a logical source value before you add a Compare table operation to the Match transform (in the Match level option group).

Here is an example of how to set up your compare table. Suppose you have two IDs (A and B), and you only want to compare across sources, not within the sources.

1. If no Compare Table is present in the Matching section, right-click *Matching* > **`<Level Name>`**, and select *Add* > *Compare* .
2. Set the *Default action* option to *No_Match*, and type **`None`** in the *Default logical source value* option.
   This tells the Match transform to not compare everything, but follow the comparison rules set by the table entries.

   > Note
   >
   > Use care when choosing logical source names. Typing “None” in the *Default logical source value* option will not work if you have a source ID called “None.”

3. In the *Compare actions* table, add a row, and then set the *Driver value* to *A*, and set the *Passenger value* to *B*.
4. Set *Action* to *Compare*.

   > Note
   >
   > Account for all logical source values. The example values entered above assumes that A will always be the driver ID. If you expect that a driver record has a value other than A, set up a table entry to account for that value and the passenger ID value. Remember that the driver record is the first record read in a collection.
   >
   > If you leave the *Driver value* or *Passenger value* options blank in the compare table, then it will mean that you want to compare all sources. So a Driver value of A and a blank passenger record with an action of compare will make a record from A compare against all other passenger records.

Sometimes data in collections can be ordered (or not ordered, as the case may be) differently than your compare table is expecting. This can cause the matching process to miss duplicate records.

In the example, the way you set up your Compare action table row means that you are expecting that the driver record should have a driver value of A, but if the driver record comes in with a value of B, and the passenger comes in with a value of A, it won't be compared.

To account for situations where a driver record might have a value of B and the passenger a value of A, for example, include another row in the table that does the opposite. This will make sure that any record with a value of A or B is compared, no matter which is the Driver or Passenger.

> Note
>
> In general, if you use a suppress source, you should compare within the other sources.This ensures that all of the matches of those sources are suppressed when any are found to duplicate a record on the suppress source, regardless of which record is the driver record.

2.16.4.8.3 Order and prioritize records

You may have data sources, such as your own data warehouse, that you might trust more than records from another source, such as a rented source, for example. You may also prefer newer records over older records, or more complete records over those with blank fields. Whatever your preference, the way to express this preference in the matching process is using priorities.

There are other times where you might want to ensure that your records move to a given operation, such as matching or best record, for example, in a particular order. For example, you might want your match groups to be ordered so that the first record in is the newest record of the group. In this case, you would want to order your records based on a date field.

Whatever the reason, there are a two ways to order your records, either before or after the comparison process:

- Sorting records in break groups or match groups using a value in a field.
- Using penalty scores. These can be defined per field, per record, or based on input source membership.

Match editor

You can define your priorities and order your records in the Group Prioritization operation, available in Group Forming and in the Post-match processing operations of each match level in the Match editor.

Types of priorities

There are a couple of different types of priorities to consider:

Priority	Brief description
Record priority	Prefers records from one input source over another.
Blank penalty	Assigns a lower priority to records in which a particular field is blank.

Pre-match ordering

When you create break groups, you can set up your *Group Forming* > *Group Prioritization* operation to order (or sort) on a field, besides ordering on the break key. This will ensure that the highest priority record is the first record (driver) in the break group.

You will also want to have Suppress-type input sources to be the driver records in a break group.

Post-match ordering

After the Match transform has created all of the match groups, and if order is important, you can use a Group Prioritization operation before a Group Statistics, Best Record, and Unique ID operations to ensure that the master record is the first in the match group.

> Tip
>
> If you are not using a blank penalty, order may not be as important to you, and you may not want to include a Group Prioritization operation before your post-match operations. However, you may get better performance out of a Best Record operation by prioritizing records and then setting the *Post only once per destination* option to Yes.

Blank penalty

Given two records, you may prefer to keep the record that contains the most complete data. You can use blank penalty to penalize records that contain blank fields.

Incorporating a blank penalty is appropriate if you feel that a blank field shouldn't disqualify one record from matching another, and you want to keep the more complete record. For example, suppose you are willing to accept a record as a match even if the Prename, Given_Name1, Given_Name2, Primary_Postfix and/or Secondary Number is blank. Even though you accept these records into your match groups, you can assign them a lower priority for each blank field.

2.16.4.8.3.1 To order records by sorting on a field

Be sure you have mapped the input fields into the Match transform that you want to order on, or they won't show up in the field drop-down list.

Use this method of ordering your records if you do not consider completeness of data important.

1. Enter a Prioritization name, and select the Priority Order tab.
2. In the *Priority fields* table, choose a field from the drop-down list in the *Input Fields* column.
3. In the *Field Order* column, choose *Ascending* or *Descending* to specify the type of ordering.
   For example, if you are comparing a Normal source to a Suppress source and you are using a source ID field to order your records, you will want to ensure that records from the Suppress source are first in the break group.
4. Repeat step 2 for each row you added.
5. Order your rows in the *Priority fields* table by using the *Move Up* and *Move Down* buttons.

The first row will be the primary order, and the rest will be secondary orders.

2.16.4.8.3.2 Penalty scoring system

The blank penalty is a penalty-scoring system. For each blank field, you can assess a penalty of any non-negative integer.

You can assess the same penalty for each blank field, or assess a higher penalty for fields you consider more important. For example, if you were targeting a mailing to college students, who primarily live in apartments or dormitories, you might assess a higher penalty for a blank Given_Name1 or apartment number.

Field	Blank penalty
Prename	5
Given_Name1	20
Given_Name2	5
Primary Postfix	5
Secondary Number	20

As a result, the records below would be ranked in the order shown (assume they are from the same source, so record priority is not a factor). Even though the first record has blank prename, Given_Name2, and street postfix fields, we want it as the master record because it does contain the data we consider more important: Given_Name1 and Secondary Number.

Prename (5)	Given Name1 (20)	Given Name2 (5)	Family Name	Prim Range	Prim Name	Prim Postfix (5)	Sec Number (20)	Blank-field penalty
	Maria		Ramirez	100	Main		6	5 + 5 + 5 = 15
Ms.	Maria	A	Ramirez	100	Main	St		20
Ms.			Ramirez	100	Main	St	6	20 + 5 = 25

2.16.4.8.3.3 Blank penalty interacts with record priority

The record priority and blank penalty scores are added together and considered as one score.

For example, suppose you want records from your house database to have high priority, but you also want records with blank fields to have low priority. Is source membership more important, even if some fields are blank? Or is it more important to have as complete a record as possible, even if it is not from the house database?

Most want their house records to have priority, and would not want blank fields to override that priority. To make this happen, set a high penalty for membership in a rented source, and lower penalties for blank fields:

Source	Record priority (penalty points)	Field	Blank penalty
House Source	100	Given Name1	20
Rented Source A	200	Given_Name2	5
Rented Source B	300	Primary Postfix	5
Rented Source C	400	Secondary Number	20

With this scoring system, a record from the house source always receives priority over a record from a rented source, even if the house record has blank fields. For example, suppose the records below were in the same match group.

Even though the house record contains five blank fields, it receives only 155 penalty points (100 + 5 + 20 + 5 + 5 + 20), while the record from source A receives 200 penalty points. The house record, therefore, has the lower penalty and the higher priority.

Source	Given Name1	Given Name2	Family	Prim Range	Prim Name	Sec Num	Post-code	Rec pri-ority	Blank Penalty	Total
House			Smith	100	Bren		55343	100	55	155
Source A	Rita	A	Smith	100	Bren	12A	55343	200	0	200
Source B	Rita		Smith	100	Bren	12	55343	300	10	310

You can manipulate the scores to set priority exactly as you'd like. In the example above, suppose you prefer a rented record containing first-name data over a house record without first-name data. You could set the first-name blank penalty score to 500 so that a blank first-name field would weigh more heavily than any source membership.

2.16.4.8.3.4 To define priority and penalty using field values

Be sure to map in any input fields that carry priority or blank penalty values.

This task tells Match which fields hold your record priority and blank penalty values for your records, and whether to apply these per record.

1. Add a Group Prioritization operation to the Group Forming or Post Match Processing section in the Match Editor.
2. Enter a Prioritization name (if necessary) and select the *Record Completeness* tab.
3. Select the *Order records based on completeness of data* option.
4. Select the *Define priority and penalty fields* option.
    - *Define only field penalties:* This option allows you to select a default record priority and blank penalties per field to generate your priority score.
    - *Define priority and penalty based on input source:* This allows you to define priority and blank penalty based on membership in an input source.

5. Choose a field that contains the record priority value from the *Record priority field* option.
6. In the *Apply blank penalty field* option, choose a field that contains the Y or N indicator for whether to apply a blank penalty to a record.
7. In the *Default record priority* option, enter a default record priority to use if a record priority field is blank or if you do not specify a record priority field.
8. Choose a *Default apply blank penalty* value (Yes or No). This determines whether the Match transform will apply blank penalty to a record if you didn't choose an apply blank penalty field or if the field is blank for a particular record.
9. In the *Blank penalty score* table, choose a field from the *Input Field* column to which you want to assign blank penalty values.
10. In the *Blank Penalty* column, type a blank penalty value to attribute to any record containing a blank in the field you indicated in *Input Field* column.

2.16.4.8.3.5 To define penalty values by field

This task lets you define your default priority score for every record and blank penalties per field to generate your penalty score.

1. Add a Group Prioritization operation to the Group Forming or Post Match Processing section in the Match Editor.
2. Enter a Prioritization name (if necessary) and select the *Record Completeness* tab.
3. Select the *Order records based on completeness of data* option.
4. Select the *Define only field penalties* option.
5. In the *Default record priority* option, enter a default record priority that will be used in the penalty score for every record.
6. Choose a *Default apply blank penalty* value (Yes or No). This determines whether the Match transform will apply blank penalty to a record if you didn't choose an apply blank penalty field or if the field is blank for a particular record.
7. In the *Blank penalty score* table, choose a field from the *Input Field* column to which you want to assign blank penalty values.
8. In the *Blank Penalty* column, type a blank penalty value to attribute to any record containing a blank in the field you indicated in *Input Field* column.

2.16.4.8.4 Prioritize records based on source membership

However you prefer to prioritize your sources (by sorting a break group or by using penalty scores), you will want to ensure that your suppress-type source records are the drivers in the break group and comparison process.

For example, suppose you are a charitable foundation mailing a solicitation to your current donors and to names from two rented sources. If a name appears on your house source and a rented source, you prefer to use the name from your house source.

For one of the rented sources, Source B, suppose also that you can negotiate a rebate for any records you do not use. You want to use as few records as possible from Source B so that you can get the largest possible rebate.

Therefore, you want records from Source B to have the lowest preference, or priority, from among the three sources.

Source	Priority
House source	Highest
Rented source A	Medium
Rented source B	Lowest

Suppress-type sources and record completeness

In cases where you want to use penalty scores, you will want your Suppress-type sources to have a low priority score. This makes it likely that normal records that match a suppress record will be subordinate matches in a match group, and will therefore be suppressed, as well. Within each match group, any record with a lower priority than a suppression source record is considered a suppress match.

For example, suppose you are running your files against the DMA Mail Preference File (a list of people who do not want to receive advertising mailings). You would identify the DMA source as a suppression source and assign a priority of zero.

Source	Priority
DMA Suppression source	0
House source	100
Rented source A	200
Rentd source B	300

Suppose Match found four matching records among the input records.

Matching record (name fields only)				Source	Priority
	Maria		Ramirez	House	100
Ms.			Ramirez	Source B	300
Ms.	Maria	A	Ramirez	Source A	200
Ms.	Maria	A	Ramirez	DMA	0

The following match group would be established. Based on their priority, Match would rank the records as shown. As a result, the record from the suppression file (the DMA source) would be the master record, and the others would be subordinate suppress matches, and thus suppressed, as well.

Source	Priority
DMA	0 (Master record)
House	100
Source A	200
Source B	300

2.16.4.8.4.1 To define penalties based on source membership

In this task, you can attribute priority scores and blank penalties to an input source, and thus apply these scores to any record belonging to that source. Just be sure you have your input sources defined before you attempt to complete this task.

1. Add a Group Prioritization operation to the Group Forming or Post Match Processing section in the Match Editor.
2. Enter a Prioritization name (if necessary) and select the *Record Completeness* tab.
3. Select the *Order records based on completeness of data* option.
4. Select the *Define priority and penalty based on input source* option.
5. In the *Source Attributes* table, select a source from the drop-down list.
6. Type a value in the *Priority* column to assign a record priority to that source.

   Remember that the lower the score, the higher the priority. For example, you would want to assign a very low score (such as 0) to a suppress-type source.
7. In the *Apply Blank Penalty* column, choose a Yes or No value to determine whether to use blank penalty on records from that source.
8. In the *Default record priority* option, enter a default record priority that will be used in the penalty score for every record that is not a member of a source.
9. Choose a *Default apply blank penalty* value (Yes or No). This determines whether to apply blank penalties to a record that is not a member of a source.
10. In the *Blank penalty score* table, choose a field from the *Input Field* column to which you want to assign blank penalty values.
11. In the *Blank Penalty* column, type a blank penalty value to attribute to any record containing a blank in the field you indicated in *Input Field* column.

2.16.4.8.5 Data Salvage

Data salvaging temporarily copies data from a passenger record to the driver record after comparing the two records. The data that's copied is data that is found in the passenger record but is missing or incomplete in the driver record. Data salvaging prevents blank matching or initials matching from matching records that you may not want to match.

For example, we have the following match group. If you did not enable data salvaging, the records in the first table would all belong to the same match group because the driver record, which contains a blank Name field, matches both of the other records.

Record	Name	Address	Postcode
1 (driver)		123 Main St.	54601
2	John Smith	123 Main St.	54601
3	Jack Hill	123 Main St.	54601

If you enabled data salvaging, the software would temporarily copy John Smith from the second record into the driver record. The result: Record #1 matches Record #2, but Record #1 does not match Record #3 (because John Smith doesn't match Jack Hill).

Record	Name	Address	Postcode
1 (driver)	John Smith (copied from record below)	123 Main St.	54601
2	John Smith	123 Main St.	54601
3	Jack Hill	123 Main St.	54601

The following example shows how this is used for a suppression source. Assume that the suppression source is a list of no-pandering addresses. In that case, you would set the suppression source to have the highest priority, and you would not enable data salvaging. That way, the software suppresses all records that match the suppression source records.

For example, a suppress record of 123 Main St would match 123 Main St #2 and 123 Main St Apt C; both of these would be suppressed.

2.16.4.8.5.1 Data salvaging and initials

When a driver record's name field contains an initial, instead of a full name, the software may temporarily borrow the full name if it finds one in the corresponding field of a matching record. This is one form of data salvaging.

For illustration, assume that the following three records represent potentially matching records (for example, the software has grouped these as members of a break group, based on address and ZIP Code data).

Note

Initials salvaging only occurs with the given name and family name fields.

Record	First name	Last name	Address	Notes
357	J	L	123 Main	Driver
391	Juanita	Lopez	123 Main	
839	Joanne	London	123 Main	Lowest ranking record

The first match comparison will be between the driver record (357) and the next highest ranking record (391). These two records will be called a match. Juanita and Lopez are temporarily copied to the name fields of record# 357.

The next comparison will be between record 357 and the next lower ranking record (839). With data salvaging, the driver record's name data is now Juanita Lopez (as "borrowed" from the first comparison). Therefore, record 839 will probably be considered not-to match record 357.

By retaining more information for the driver record, data salvaging helps improve the quality of your matching results.

Initials and suppress-type records

However, if the driver record is a suppress-type record, you may prefer to turn off data salvaging, to retain your best chance of identifying all the records that match the initialized suppression data. For example, if you want to suppress names with the initials JL (as in the case above, you would want to find all matches to JL regardless of the order in which the records are encountered in the break group.

If you have turned off data salvaging for the records of this suppression source, here is what happens during those same two match comparisons:

Record	First name	Last name	Address	Notes
357	J	L	123 Main	Driver
391	Juanita	Lopez	123 Main	
839	Joanne	London	123 Main	Lowest ranking record

The first match comparison will be between the driver record (357) and the next- highest ranking record (391). These two records will be called a match, since the driver record’s JL and Juanita Lopez will be called a match.

The next comparison will be between the driver record (357) and the next lower ranking record (839). This time these two records will also be called a match, since the driver record’s JL will match Joanne London.

Since both records 391 and 839 matched the suppress-type driver record, they are both designated as suppress matches, and, therefore, neither will be included in your output.

2.16.4.8.5.2 To control data salvaging using a field

You can use a field to control whether data salvage is enabled. If the field's value is Y for a record, data salvaging is enabled. Be sure to map the field into the Match transform that you want to use beforehand.

1. Open the Match Editor for a Match transform.
2. In the Transform Options window, click the *Data Salvage* tab.
3. Select the Enable data salvage option, and choose a default value for those records.
   The default value will be used in the cases where the field you choose is not populated for a particular record.
4. Select the *Specify data salvage by field* option, and choose a field from the drop-down menu.

2.16.4.8.5.3 To control data salvaging by source

You can use membership in an input source to control whether data salvage is enabled or disabled for a particular record. Be sure to create your input sources beforehand.

1. Open the Match Editor for a Match transform.
2. In the Transform Options window, click the *Data Salvage* tab.
3. Select the *Enable data salvage* option, and choose a default value for those records.
   The default value will be used if a record's input source is not specified in the following steps.
4. Select the *Specify data salvage by source* option.
5. In the table, choose a Source and then a Perform Data Salvage value for each source you want to use.

2.16.4.9 Match criteria

2.16.4.9.1 Overview of match criteria

Use match criteria in each match level to determine the threshold scores for matching and to define how to treat various types of data, such as numeric, blank, name data, and so on (your business rules).

You can do all of this in the Criteria option group of the Match Editor.

Match criteria

To the Match transform, match criteria represent the fields you want to compare. For example, if you wanted to match on the first ten characters of a given name and the first fifteen characters of the family name, you must create two criteria that specify these requirements.

Criteria provide a way to let the Match transform know what kind of data is in the input field and, therefore, what types of operations to perform on that data.

Pre-defined vs. custom criteria

There are two types of criteria:

- Pre-defined criteria are available for fields that are typically used for matching, such as name, address, and other data. By assigning a criteria to a field, the Match transform is able to identify what type of data is in the field, and allow it to perform internal operations to optimize the data for matching, without altering the actual input data.
- Data Cleanse custom (user-defined, non party-data) output fields are available as pre-defined criteria. Map the custom output fields from Data Cleanse and the custom fields appear in the Match Editor's Criteria Fields tab.
  Any other types of data (such as part numbers or other proprietary data), for which a pre-defined criteria does not exist, should be designated as a custom criteria. Certain functions can be performed on custom keys, such as abbreviation, substring, numeric matching, but the Match transform cannot perform some cross-field comparisons such as some name matching functions.

Match criteria pre-comparison options

The majority of your data standardization should take place in the address cleansing and Data Cleanse transforms. However, the Match transform can perform some preprocessing per criteria (and for matching purposes only; your actual data is not affected) to provide more accurate matches. The options to control this standardization are located in the Options and Multi Field Comparisons tabs of the Match editor. They include:

- Convert diacritical characters
- Convert text to numbers

- Convert to uppercase
- Remove punctuation
- Locale

For more information about these options, see the Match transform section of the *Reference Guide*.

2.16.4.9.1.1 To add and order a match criteria

You can add as many criteria as you want to each match level in your Match transform.

1. Select the appropriate match level or Match Criteria option group in the Option Explorer of the Match Editor, and right-click.
2. Choose *Criteria*.
3. Enter a name for your criteria in the *Criteria name* box.

   You can keep the default name for pre-defined criteria, but you should enter a meaningful criteria name if you chose a Custom criteria.
4. On the *Criteria Fields* tab, in the *Available criteria* list, choose the criteria that best represents the data that you want to match on. If you don't find what you are looking for, choose the Custom criteria.
5. In the *Criteria field mapping* table, choose an input field mapped name that contains the data you want to match on for this criteria.
6. Click the *Options* tab.
7. Configure the *Pre-comparison options* and *Comparison rules*.

   Be sure to set the Match score and No match score, because these are required.
8. If you want to enable multiple field (cross-field) comparison, click the *Multiple Fields Comparisons* tab, and select the *Compare multiple fields* option.
   a) Choose the type of multiple field comparison to perform:
      - *All selected fields in other records*: Compare each field to all fields selected in the table in all records.
      - *The same field in other records*: Compare each field only to the same field in all records.

   b) In the *Additional fields to compare* table, choose input fields that contain the data you want to include in the multiple field comparison for this criteria.

   > ➜ Tip
   >
   > You can use custom match criteria field names for multiple field comparison by typing in the *Custom name* column.

   > i Note
   >
   > If you enable multiple field comparison, any appropriate match standard fields are removed from the *Criteria field mapping* table on the *Criteria Fields* tab . If you want to include them in the match process, add them in the *Additional fields to compare* table.
9. Configure the *Pre-comparison* options for multiple field comparison.
10. To order your criteria in the Options Explorer of the Match Editor (or the Match Table), select a criteria and click the *Move Up* or *Move Down* buttons as necessary.

2.16.4.9.1.2 Set up for match standards criteria

Be sure you have created and mapped in match standard fields from the Data Cleanse transform.

1. In the Match transform, add a Person1_Given_Name1 match criteria by selecting it from the Person category. The editor automatically adds that criteria and its associated match standard criteria to the *Criteria field mapping* table.
2. Choose a field in the *Input field mapped name* column that best represents the data to be compared.

For Given_Name2 data (middle names), complete the above procedure, but use the following criteria:

- Person1_Given_Name2
- Person1_Given_Name2_Match_Std1
- Person1_Given_Name2_Match_Std2
- Person1_Given_Name2_Match_Std3

You can also use match standards for prename, maturity postname, honorary postname, firm, and firm location fields.

2.16.4.9.2 Matching methods

There are a number of ways to set up and order your criteria to get the matching results you want. Each of these ways have advantages and disadvantages, so consider them carefully.

Match method	Description
Rule-based	Allows you to control which criteria determines a match. This method is easy to set up.
Weighted-scoring	Allows you to assign importance, or weight, to any criteria. However, weighted-scoring evaluates every rule before determining a match, which might cause an increase in processing time.
Combination method	Same relative advantages and disadvantages as the other two methods.

2.16.4.9.2.1 Similarity score

The similarity score is the percentage that your data is alike. This score is calculated internally by the application when records are compared. Whether the application considers the records a match depends on the Match and No match scores you define in the Criteria option group (as well as other factors, but for now let's focus on these scores).

Example

This is an example of how similarity scores are determined. Here are some things to note:

- The comparison table below is intended to serve as an example. This is not how the matching process works in the weighted scoring method, for example.

- Only the first comparison is considered a match, because the similarity score met or exceeded the match score. The last comparison is considered a no-match because the similarity score was less than the no-match score.
- When a single criteria cannot determine a match, as in the case of the second comparison in the table below, the process moves to the next criteria, if possible.

Comparison	No match	Match	Similarity score	Matching?
Smith > Smith	72	95	100%	Yes
Smith > Smitt	72	95	80%	Depends on other criteria
Smith > Smythe	72	95	72%	No
Smith > Jones	72	95	20%	No

2.16.4.9.2.2 Rule-based method

With rule-based matching, you rely only on your match and no-match scores to determine matches within a criteria.

Example

This example shows how to set up this method in the Match transform.

Criteria	Record A	Record B	No match	Match	Similarity score
Given Name1	Mary	Mary	82	101	100
Family Name	Smith	Smitt	74	101	80
E-mail	msmith@sap.com	mary.smith@sap.com	79	80	91

By entering a value of 101 in the match score for every criteria except the last, the Given Name1 and Family Name criteria never determine a match, although they can determine a no match.

By setting the *Match score* and *No match score* options for the E-mail criteria with no gap, any comparison that reaches the last criteria must either be a match or a no match.

A match score of 101 ensures that the criteria does not cause the records to be a match, because two fields cannot be more than 100 percent alike.

Remember

Order is important! For performance reasons, you should have the criteria that is most likely to make the match or no-match decisions first in your order of criteria. This can help reduce the number of criteria comparisons.

2.16.4.9.2.3 Weighted-scoring method

In a rule-based matching method, the application gives all of the criteria the same amount of importance (or weight). That is, if any criteria fails to meet the specified match score, the application determines that the records do not match.

When you use the weighted scoring method, you are relying on the total contribution score for determining matches, as opposed to using match and no-match scores on their own.

Contribution values

Contribution values are your way of assigning weight to individual criteria. The higher the value, the more weight that criteria carries in determining matches. In general, criteria that might carry more weight than others include account numbers, Social Security numbers, customer numbers, Postcode1, and addresses.

> Note
>
> All contribution values for all criteria that have them must total 100. You do not need to have a contribution value for all of your criteria.

You can define a criteria's contribution value in the Contribution to weighted score option in the Criteria option group.

Contribution and total contribution score

The Match transform generates the contribution score for each criteria by multiplying the contribution value you assign with the similarity score (the percentage alike). These individual contribution scores are then added to get the total contribution score.

Weighted match score

In the weighted scoring method, matches are determined only by comparing the total contribution score with the weighted match score. If the total contribution score is equal to or greater than the weighted match score, the records are considered a match. If the total weighted score is less than the weighted match score, the records are considered a no-match.

You can set the weighted match score in the *Weighted match score* option of the Level option group.

> Example
>
> The following table is an example of how to set up weighted scoring. Notice the various types of scores that we have discussed. Also notice the following:

- When setting up weighted scoring, the *No match score* option must be set to -1, and the *Match score* option must be set to 101. These values ensure that neither a match nor a no-match can be found by using these scores.
- We have assigned a contribution value to the E-mail criteria that gives it the most importance.

Criteria	Record A	Record B	No match	Match	Similarity score	Contribution value	Contribution score (similarity X contribution value)
First Name	Mary	Mary	-1	101	100	25	25
Last Name	Smith	Smitt	-1	101	80	25	20
E-mail	ms@ sap.com	msmith@ sap.com	-1	101	84	50	42
							Total contribution score: 87

If the weighted match score is 87, then any comparison whose total contribution score is 87 or greater is considered a match. In this example, the comparison is a match because the total contribution score is 87.

2.16.4.9.2.4 Combination method

This method combines the rule-based and weighted scoring methods of matching.

Criteria	Record A	Record B	No match	Match	Sim score	Contribution value	Contribution score (actual similarity X contribution value)	
First Name	Mary	Mary	59	101	100	25		25
Last Name	Smith	Hope	**59**	101	**22**	N/A **(No Match)**		N/A
E-mail	ms@ sap.com	msmith@ sap.com	49	101	N/A	N/A		N/A
							Total contribution score	N/A

2.16.4.9.3 Matching business rules

An important part of the matching process is determining how you want to handle various forms of and differences in your data. For example, if every field in a record matched another record's fields, except that one field was blank and the other record's field was not, would you want these records to be considered matches?

Figuring out what you want to do in these situations is part of defining your business rules. Match criteria are where you define most of your business rules, while some name-based options are set in the Match Level option group.

2.16.4.9.3.1 Matching on strings, abbreviations, and initials

Initials and acronyms

Use the *Initials adjustment score* option to allow matching initials to whole words. For example, "International Health Providers" can be matched to "IHP".

Abbreviations

Use the *Abbreviation adjustment score* option to allow matching whole words to abbreviations. For example, "International Health Providers" can be matched to "Intl Health Providers".

String data

Use the *Substring adjustment score* option to allow matching longer strings to shorter strings. For example, the string "Mayfield Painting and Sand Blasting" can match "Mayfield painting".

2.16.4.9.3.2 Extended abbrevation matching

Extended abbreviation matching offers functionality that handles situations not covered by the *Initials adjustment score*, *Substring adjustment score*, and *Abbreviation adjustment score* options. For example, you might encounter the following situations:

- Suppose you have localities in your data such as La Crosse and New York. However, you also have these same localities listed as LaCrosse and NewYork (without spaces). Under normal matching, you cannot designate these (La Crosse/LaCrosse and New York/NewYork) as matching 100%; the spaces prevent this. (These would normally be 94 and 93 percent matching.)
- Suppose you have Metropolitan Life and MetLife (an abbreviation and combination of Metropolitan Life) in your data. The *Abbreviation adjustment score* option cannot detect the combination of the two words.

If you are concerned about either of these cases in your data, you should use the *Ext abbreviation adjustment score* option.

How the adjustment score works

The score you set in the *Ext abbreviation adjustment score* option tunes your similarity score to consider these types of abbreviations and combinations in your data.

The adjustment score adds a penalty for the non-matched part of the words. The higher the number, the lower the penalty. A score of 100 means no penalty and score of 0 means maximum penalty.

Example

String 1	String 2	Sim score when Adj score is 0	Sim score when Adj score is 50	Sim score when Adj score is 100	Notes
MetLife	Metropolitan Life	58	79	100	
MetLife	Met Life	93	96	100	
MetLife	MetropolitanLife	60	60	60	This score is due to string comparison. Extended Abbreviation scoring was not needed or used because both strings being compared are each one word.

2.16.4.9.3.3 Name matching

Part of creating your business rules is to define how you want names handled in the matching process. The Match transform gives you many ways to ensure that variations on names or multiple names, for example, are taken into consideration.

Note

Unlike other business rules, these options are set up in the match level option group, because they affect all appropriate name-based match criteria.

Two names; two persons

With the *Number of names that must match* option, you can control how matching is performed on match keys with more than one name (for example, comparing "John and Mary Smith" to "Dave and Mary Smith"). Choose whether only one name needs to match for the records to be identified as a match, or whether the Match transform should disregard any persons other than the first name it parses.

With this method you can require either one or both persons to match for the record to match.

Two names; one person

With the *Compare Given_Name1 to Given_Name2* option, you can also compare a record's Given_Name1 data (first name) with the second record's Given_Name2 data (middle name). With this option, the Match transform can correctly identify matching records such as the two partially shown below. Typically, these record pairs represent sons or daughters named for their parents, but known by their middle name.

Record #	First name	Middle name	Last name	Address
170	Leo	Thomas	Smith	225 Pushbutton Dr
198	Tom		Smith	225 Pushbutton Dr

Hyphenated family names

With the *Match on hyphenated family name* option, you can control how matching is performed if a Family_Name (last name) field contains a hyphenated family name (for example, comparing "Smith-Jones" to "Jones"). Choose whether both criteria must have both names to match or just one name that must match for the records to be called a match.

2.16.4.9.3.3.1 Match compound family names

The Approximate Substring Score assists in setting up comparison of compound family names. The Approximate Substring score is assigned to the words that do not match to other words in a compared string.This option loosens some of the requirements of the Substring Adjustment score option in the following ways:

- First words do not have to match exactly.
- The words that do match can use initials and abbreviations adjustments (For example, Rodriguez and RDZ).
- Matching words have to be in the same order, but there can be non-matching words before or after the matching words.
- The Approximate Substring score is assigned the leftover words and spaces in the compared string.

The Approximate Substring option will increase the score for some matches found when using the Substring Matching Score.

Example

When comparing CRUZ RODRIGUEZ and GARCIA CRUZ DE RDZ, the similarity scores are:

- Without setting any adjusments, the Similarity score is 48.
- When you set the Substring adjustment score to 80 and the Abbreviation score to 80, the Similarity score is 66.
- When you set the Approximate substring adjustment score to 80 and the Abbreviation score to 80, the Similarity score is 91.

2.16.4.9.3.4 Numeric data matching

Use the *Numeric words match exactly* option to choose whether data with a mixture of numbers and letters should match exactly. You can also specify *how* this data must match. This option applies most often to address data and custom data, such as a part number.

The numeric matching process is as follows:

1. The string is first broken into words. The word breaking is performed on all punctuation and spacing, and then the words are assigned a numeric attribute. A numeric word is any word that contains at least one number from 0 to 9. For example, 4L is considered a numeric word, whereas FourL is not.
2. Numeric matching is performed according to the option setting that you choose (as described below).

Option values and how they work

Option value	Description
Any_Position	With this value, numeric words must match exactly; however, the position of the word is *not* important. For example: • Street address comparison: "4932 Main St # 101" and "# 101 4932 Main St" are considered a match. • Street address comparison: "4932 Main St # 101" and "# 102 4932 Main St" are *not* considered a match. • Part description: "ACCU 1.4L 29BAR" and "ACCU 29BAR 1.4L" are considered a match.
Same_Position	This value specifies that numeric words must match exactly; however, this option differs from the Any_Position option in that the position of the word *is* important. For example, 608-782-5000 will match 608-782-5000, but it will not match 782-608-5000.
Any_Position_Consider_Punctuation	This value performs word breaking on all punctuation and spaces *except* on the decimal separator (period or comma) so that all decimal numbers are not broken. For example, the string 123.456 is considered a single numeric word as opposed to two numeric words. The position of the numeric word is not important; however, decimal separators do impact the matching process. For example: • Part description: "ACCU 29BAR 1.4L" and "ACCU 1.4L 29BAR" are considered a match. • Part description: "ACCU 1,4L 29BAR" and "ACCU 29BAR 1.4L" are *not* considered a match because there is a decimal indicator between the 1 and the 4 in both cases. • Financial data: "25,435" and "25.435" are not considered a match.
Any_Position_Ignore_Punctuation	This value is similar to the Any_Position_Consider_Punctuation value, except that decimal separators do *not* impact the matching process. For example:

Option value	Description
	- Part description: "ACCU 29BAR 1.4L" and "ACCU 1.4L 29BAR" are considered a match. - Part description: "ACCU 1,4L 29BAR" and "ACCU 29BAR 1.4L" are also considered a match even though there is a decimal indicator between the 1 and the 4. - Part description: "ACCU 29BAR 1.4L" and "ACCU 1.5L 29BAR" are not considered a match.

2.16.4.9.3.5 Blank field matching

In your business rules, you can control how the Match transform treats field comparisons when one or both of the fields compared are blank.

For example, the first name field is blank in the second record shown below. Would you want the Match transform to consider these records matches or no matches? What if the first name field were blank in both records?

Record #1	Record #2
John Doe	_____ Doe
204 Main St	204 Main St
La Crosse WI	La Crosse WI
54601	54601

There are some options in the Match transform that allow you to control the way these are compared. They are:

- Both fields blank operation
- Both fields blank score
- One field blank operation
- One field blank score

Blank field operations

The "operation" options have the following value choices:

Option	Description
Eval	If you choose Eval, the Match transform scores the comparison using the score you enter at the *One field blank score* or *Both fields blank score* option.
Ignore	If you choose Ignore, the score for this field rule does not contribute to the overall weighted score for the record comparison. In other words, the two records shown above could still be considered duplicates, despite the blank field.

Blank field scores

The "Score" options control how the Match transform scores field comparisons when the field is blank in one or both records. You can enter any value from 0 to 100.

To help you decide what score to enter, determine if you want the Match transform to consider a blank field 0 percent similar to a populated field or another blank field, 100 percent similar, or somewhere in between.

Your answer probably depends on what field you're comparing. Giving a blank field a high score might be appropriate if you're matching on a first or middle name or a company name, for example.

Example

Here are some examples that may help you understand how your settings of these blank matching options can affect the overall scoring of records.

One field blank operation for Given_Name1 field set to Ignore

Note that when you set the blank options to Ignore, the Match transform redistributes the contribution allotted for this field to the other criteria and recalculates the contributions for the other fields.

Fields compared	Record A	Record B	% alike	Contribution	Score (per field)
Postcode	54601	54601	100	20 (or 22)	22
Address	100 Water St	100 Water St	100	40 (or 44)	44
Family_Name	Hamilton	Hammilton	94	30 (or 33)	31
Given_Name1	Mary		—	10 (or 0)	—
					Weighted score: **97**

One field blank operation for Given_Name1 field set to Eval; One field blank score set to 0

Fields compared	Record A	Record B	% alike	Contribution	Score (per field)
Postcode	54601	54601	100	20	20
Address	100 Water St	100 Water St	100	40	40
Family_Name	Hamilton	Hammilton	94	30	28
Given_Name1	Mary		0	10	0
					Weighted score: **88**

One field blank operation for Given_Name1 field set to Eval; One field blank score set to 100

Fields compared	Record A	Record B	% alike	Contribution	Score (per field)
Postcode	54601	54601	100	20	20
Address	100 Water St	100 Water St	100	40	40
Family_Name	Hamilton	Hammilton	94	30	28
Given_Name1	Mary		100	10	10
					Weighted score: **98**

2.16.4.9.3.6 Multiple field (cross-field) comparison

In most cases, you use a single field for comparison. For example, Field1 in the first record is compared with Field1 in the second record.

However, there are situations where comparing multiple fields can be useful. For example, suppose you want to match telephone numbers in the Phone field against numbers found in fields used for Fax, Mobile, and Home. Multiple field comparison makes this possible.

When you enable multiple field comparison in the Multiple Field Comparison tab of a match criteria in the Match Editor, you can choose to match selected fields against either all of the selected fields in each record, or against only the same field in each record.

ℹ Note

By default, Match performs multiple field comparison on fields where match standards are used. For example, Person1_Given_Name1 is automatically compared to Person1_Given_Name_Match_Std1-6. Multiple field comparison does not need to be explicitly enabled, and no additional configuration is required to perform multiple field comparison against match standard fields.

2.16.4.9.3.6.1 Comparing selected fields to all selected fields in other records

When you compare each selected field to all selected fields in other records, all fields that are defined in that match criteria are compared against each other.

➜ Remember

“Selected” fields include the criteria field and the other fields you define in the *Additional fields to compare* table.

- If one or more field comparisons meets the settings for Match score, the two rows being compared are considered matches.
- If one or more field comparisons exceeds the No match score, the rule will be considered to pass and any other defined criteria/weighted scoring will be evaluated to determine if the two rows are considered matches.

Example

Example of comparing selected fields to all selected fields in other records

Your input data contains two firm fields.

Row ID	Firm1	Firm2
1	Firstlogic	Postalsoft
2	SAP BusinessObjects	Firstlogic

With the Match score set to 100 and No match score set to 99, these two records are considered matches. Here is a summary of the comparison process and the results.

- First, Row 1 Firm1 (Firstlogic) is compared to Row 2 Firm1 (SAP).
  Normally, the rows would fail this comparison, but with multi-field comparison activated, a No Match decision is not made yet.
- Next, Row 1 Firm2 is compared to Row 2 Firm2 and so on until all other comparisons are made between all fields in all rows. Because Row 1 Firm1 (Firstlogic) and Row 2 Firm2 (Firstlogic) are 100% similar, the two records are considered matches.

2.16.4.9.3.6.2 Comparing selected fields to the same fields in other records

When you compare each selected field to the same field in other records, each field defined in the Multiple Field Comparison tab of a match criteria are compared only to the same field in other records. This sets up, within this criteria, what is essentially an OR condition for passing the criteria. Each field is used to determine a match: If Field_1, Field_2, or Field_3 passes the match criteria, consider the records a match. The No Match score for one field does not automatically fail the criteria when you use multi-field comparison.

➜ Remember

“Selected” fields include the criteria field and the other fields you define in the *Additional fields to compare* table.

Example

Example of comparing selected fields to the same field in other records

Your input data contains a phone, fax, and cell phone field. If any one of these input field's data is the same between thte rows, the records are found to be matches.

Row ID	Phone	Fax	Cell
1	608-555-1234	608-555-0000	608-555-4321
2	608-555-4321	608-555-0000	608-555-1111

With a Match score of 100 and a No match score of 99, the phone and the cell phone number would both fail the match criteria, if defined individually. However, because all three fields are defined in one criteria and the selected records being compared to the same records, the fact that the fax number is 100% similar calls these records a match.

i Note

In the example above, Row 1's cell phone and Row 2's phone would not be considered a match with the selection of the *the same field to other records* option because it only compares within the same field in this case. If this cross-comparison is needed, select the *all selected fields in other records* option instead.

2.16.4.9.3.7 Proximity matching

Proximity matching gives you the ability to match records based on their proximity instead of comparing the string representation of data. You can match on geographic, numeric, and date proximity.

Related Information

Match on Geographic proximity [page 560]
Match on numeric or date proximity [page 561]

2.16.4.9.3.7.1 Match on Geographic proximity

Geographic Proximity finds duplicate records based on geographic proximity, using latitude and longitude information. This is not driving distance, but Geographic distance. This option uses WGS 84 (GPS) coordinates.

The Geographic proximity option can:

- Search on objects within a radial range. This can help a company that wants to send a mailing out to customers within a certain distance from their business location.
- Search on the nearest location. This can help a consumer find a store location closest to their address.

2.16.4.9.3.7.2 Set up Geographic Proximity matching - criteria fields

To select the fields for Geographic Proximity matching, follow these steps:

1. Access the Match Editor, add a new criteria.
2. From Available Criteria, expand *Geographic*.
3. Select *LATITUDE_LONGITUDE*.
   This will make the two criteria fields available for mapping.
4. Map the correct latitude and longitude fields. You must map both fields.

2.16.4.9.3.7.3 Set up Geographic Proximity matching - criteria options

You must have the Latitude and Longitude fields mapped before you can use this option.

To perform geographic proximity matching, follow these steps:

1. From Compare data using, select *Geo Proximity*.

This filters the options under Comparison Rules to show only applicable options.

2. Set the Distance unit option to one of the following:
   - *Miles*
   - *Feet*
   - *Kilometers*
   - *Meters*
3. Enter the *Max Distance* you want to consider for the range.
4. Set the *Max Distance Score*.

> i Note
>
> A distance equal to Max distance will receive a score of Max distance score. Any distance less than the Max distance will receive a proportional score between Max distance score and 100. For example, a proximity of 10 miles will have higher score than a 40 miles.

> i Note
>
> If the data for Max Distance may change from row to row, you should dynamically input the data using the Option_Field_Algorithm_Geo_Proximity_**`<logical_name>`**_Max_Distance field.

Related Information

Reference Guide: Dynamic transform settings [page 1129]
Reference Guide: Match transform input fields [page 1307]

2.16.4.9.3.7.4 Match on numeric or date proximity

The Match Transform's numeric proximity options find duplicates based on numerical closeness of data. You can find duplicates based on numeric values and date values. The following options are available in the Match Criteria Editor Options tab for numeric and date matching:

Numeric difference

Finds duplicates based on the numeric difference for numeric or date values. For example, you can use this option to find duplicates based on date values in a specific range (for example, plus or minus 35 days), regardless of character-based similarity.

Numeric percent difference

Finds duplicates based on the percentage of numeric difference for numeric values. Here are two examples where this might be useful :

- Finance data domain : You can search financial data to find all monthly mortgage payments that are within 5 percent of a given value.
- Product data domain, you can search product data to find all the steel rods that are within 10% tolerance of a given diameter.

2.16.4.10 Post-match processing

2.16.4.10.1 Best record

A key component in most data consolidation efforts is salvaging data from matching records—that is, members of match groups—and posting that data to a best record, or to all matching records.

You can perform these functions by adding a Best Record post-match operation.

Operations happen within match groups

The functions you perform with the Best Record operation involve manipulating or moving data contained in the master records and subordinate records of match groups. Match groups are groups of records that the Match transform has found to be matching, based on the criteria you have created.

A master record is the first record in the Match group. You can control which record this is by using a Group Prioritization operation before the Best Record operation.

Subordinate records are all of the remaining records in a match group.

To help illustrate this use of master and subordinate records, consider the following match group:

Record	Name	Phone	Date	Group rank
#1	John Smith		11 Apr 2001	Master
#2	John Smyth	788-8700	12 Oct 1999	Subordinate
#3	John E. Smith	788-1234	22 Feb 1997	Subordinate
#4	J. Smith	788-3271		Subordinate

Because this is a match group, all of the records are considered matching. As you can see, each record is slightly different. Some records have blank fields, some have a newer date, all have different phone numbers.

A common operation that you can perform in this match group is to move updated data to all of the records in a match group. You can choose to move data to the master record, to all the subordinate members of the match group, or to all members of the match group. The most recent phone number would be a good example here.

Another example might be to salvage useful data from matching records before discarding them. For example, when you run a drivers license file against your house file, you might pick up gender or date-of-birth data to add to your house record.

Post higher priority records first

The operations you set up in the Best Record option group should always start with the highest priority member of the match group (the master) and work their way down to the last subordinate, one at a time. This ensures that data can be salvaged from the higher-priority record to the lower priority record.

So, be sure that your records are prioritized correctly, by adding a Group Prioritization post-match operation before your Best Record operation.

2.16.4.10.1.1 Best record strategies

We provide you with strategies that help you set up some more common best record operation quickly and easily. If none of these strategies fit your needs, you can create a custom best record strategy, using your own Python code.

Best record strategies act as a criteria for taking action on other fields. If the criteria is not met, no action is taken.

Example

In our example of updating a phone field with the most recent data, we can use the Date strategy with the Newest priority to update the master record with the latest phone number in the match group. This latter part (updating the master record with the latest phone number) is the action. You can also update all of the records in the match group (master and all subordinates) or only the subordinates.

⚠ Restriction

The date strategy does not parse the date, because it does not know how the data is formatted. Be sure your data is pre-formatted as YYYYMMDD, so that string comparisons work correctly. You can also do this by setting up a custom strategy, using Python code to parse the date and use a date compare.

2.16.4.10.1.1.1 Custom best record strategies and Python

In the pre-defined strategies for the Best Record strategies, the Match transform auto-generates the Python code that it uses for processing. Included in this code, are variables that are necessary to manage the processing.

Common variables

The common variables you see in the generated Python code are:

Variable	Description
SRC	Signifies the source field.
DST	Signifies the destination field.
RET	Specifies the return value, indicating whether the strategy passed or failed (must be either "T" or "F").

NEWDST and NEWGRP variables

Use the NEWDST and NEWGRP variables to allow the posting of data in your best-record action to be independent of the strategy fields. If you do not include these variables, the strategy field data must also be updated.

Variable	Description
NEWDST	New destination indicator. This string variable will have a value of "T" when the destination record is new or different than the last time the strategy was evaluated and a value of "F" when the destination record has not changed since last time. The NEWDST variable is only useful if you are posting to multiple destinations, such as ALL or SUBS in the *Posting destination* option.
NEWGRP	New group indicator. This string variable will have a value of "T" when the match group is different than the last time the strategy was evaluated and a value of "F" when the match group has not changed since last time.

NEWDST example

The following Python code was generated from a NON_BLANK strategy with options set this way:

Option	Setting
Best record strategy	NON_BLANK
Strategy priority	Priority option not available for the NON_BLANK strategy.
Strategy field	NORTH_AMERICAN_PHONE1_NORTH_AMERICAN_PHONE_STANDARDIZED.
Posting destination	ALL
Post only once per destination	YES

Here is what the Python code looks like.

```
# Setup local temp variable to store updated compare condition
dct = locals()

# Store source and destination values to temporary variables
# Reset the temporary variable when the destination changes
if (dct.has_key('BEST_RECORD_TEMP') and NEWDST.GetBuffer() == u'F'):
  DESTINATION = dct['BEST_RECORD_TEMP']
else:
  DESTINATION =
DST.GetField(u'NORTH_AMERICAN_PHONE1_NORTH_AMERICAN_PHONE_STANDARDIZED')

SOURCE = SRC.GetField(u'NORTH_AMERICAN_PHONE1_NORTH_AMERICAN_PHONE_STANDARDIZED')

if len(SOURCE.strip()) > 0 and len(DESTINATION.strip()) == 0:
  RET.SetBuffer(u'T')
  dct['BEST_RECORD_TEMP'] = SOURCE
else:
  RET.SetBuffer(u'F')
  dct['BEST_RECORD_TEMP'] = DESTINATION

# Delete temporary variables
del SOURCE
del DESTINATION
```

Example

NEWDST and NEWGRP

Suppose you have two match groups, each with three records.

Match group	Records
Match group 1	Record A
	Record B
	Record C
Match group 2	Record D
	Record E
	Record F

Each new destination or match group is flagged with a "T".

NEWGRP	NEWDST	Comparison
(T or F)	(T or F)	
T (New match group)	T (New destination "A")	Record A > Record B
F	F	A > C
F	T (New destination "B")	B > A
F	F	B > C
F	T (New destination "C")	C > A
F	F	C > B
T (New match group)	T (New destination "D")	D > E

NEWGRP (T or F)	NEWDST (T or F)	Comparison
F	F	D > F
F	T (New destination "E")	E > D
F	F	E > F
F	T (New destination "F")	F > D
F	F	F > E

2.16.4.10.1.1.2 To create a pre-defined best record strategy

Be sure to add a Best Record post-match operation to the appropriate match level in the Match Editor. Also, remember to map any pertinent input fields to make them available for this operation.

This procedure allows you to quickly generate the criteria for your best record action. The available strategies reflect common use cases.

1. Enter a name for this Best Record operation.
2. Select a strategy from the *Best record strategy* option.
3. Select a priority from the *Strategy priority* option.
   The selection of values depends on the strategy you chose in the previous step.
4. Select a field from the *Strategy field* drop-down menu.
   The field you select here is the one that acts as a criteria for determining whether a best record action is taken.

Example

The strategy field you choose must contain data that matches the strategy you are creating. For example, if you are using a newest date strategy, be sure that the field you choose contains date data.

2.16.4.10.1.1.3 To create a custom best record strategy

1. Add a best record operation to your Match transform.
2. Enter a name for your best record operation.
3. In the *Best record strategy* option, choose Custom.
4. Choose a field from the *Strategy field* drop-down list.
5. Click the *View/Edit Python* button to create your custom Python code to reflect your custom strategy.
   The Python Editor window appears.

2.16.4.10.1.2 Best record actions

Best record actions are the functions you perform on data if a criteria of a strategy is met.

Example

Suppose you want to update phone numbers of the master record. You would only want to do this if there is a subordinate record in the match group that has a newer date, which signifies a potentially new phone number for that person.

The action you set up would tell the Match transform to update the phone number field in the master record (action) if a newer date in the date field is found (strategy).

2.16.4.10.1.2.1 Sources and destinations

When working with the best record operation, it is important to know the differences between sources and destinations in a best record action.

The source is the field from which you take data and the destination is where you post the data. A source or destination can be either a master or subordinate record in a match group.

Example

In our phone number example, the subordinate record has the newer date, so we take data from the phone field (the source) and post it to the master record (the destination).

2.16.4.10.1.2.2 Posting once or many times per destination

In the Best Record options, you can choose to post to a destination once or many times per action by setting the *Post only once per destination* option.

You may want your best record action to stop after the first time it posts data to the destination record, or you may want it to continue with the other match group records as well. Your choice depends on the nature of the data you're posting and the records you're posting to. The two examples that follow illustrate each case.

If you post only once to each destination record, then once data is posted for a particular record, the Match transform moves on to either perform the next best record action (if more than one is defined) or to the next record.

If you don't limit the action in this way, all actions are performed each time the strategy returns True.

Regardless of this setting, the Match transform always works through the match group members in priority order. When posting to record #1 in the figure below, without limiting the posting to only once, here is what happens:

Match group	Action
Record #1 (master)	
Record #2 (subordinate)	First, the action is attempted using, as a source, that record from among the other match group records that has the highest priority (record #2).
Record #3 (subordinate)	Next, the action is attempted with the next highest priority record (record #3) as the source.
Record #4 (subordinate)	Finally, the action is attempted with the lowest priority record (record #4) as the source.

The results In the case above, record #4 was the last source for the action, and therefore could be a source of data for the output record. However, if you set your best record action to post only once per destination record, here is what happens:

Match group	Action
Record #1 (master)	
Record #2 (subordinate)	First, the action is attempted using, as a source, that record from among the other match group records that has the highest priority (record #2). If this attempt is successful, the Match transform considers this best record action to be complete and moves to the next best record action (if there is one), or to the next output record. If this attempt is not successful, the Match transform moves to the match group member with the next highest priority and attempts the posting operation.
Record #3 (subordinate)	
Record #4 (subordinate)	

In this case, record #2 was the source last used for the best record action, and so is the source of posted data in the output record.

2.16.4.10.1.2.3 To create a best record action

The best record action is the posting of data from a source to a destination record, based on the criteria of your best record strategy.

1. Create a strategy, either pre-defined or custom.
2. Select the record(s) to post to in the *Posting destination* option.
3. Select whether you want to post only once or multiple times to a destination record in the *Post only once per destination* option.
4. In the *Best record action fields table*, choose your source field and destination field.
   When you choose a source field, the *Destination field* column is automatically populated with the same field. You need to change the destination field if this is not the field you want to post your data to.

5. If you want to create a custom best record action, choose Yes in the *Custom* column.
   You can now access the Python editor to create custom Python code for your custom action.

2.16.4.10.1.3 Destination protection

The Best Record and Unique ID operations in the Match transform offer you the power to modify existing records in your data. There may be times when you would like to protect data in particular records or data in records from particular input sources from being overwritten.

The Destination Protection tab in these Match transform operations allow you the ability to protect data from being modified.

2.16.4.10.1.3.1 To protect destination records through fields

1. In the Destination Protection tab, select *Enable destination protection*.
2. Select a value in the *Default destination protection* option drop-down list.

   This value determines whether a destination is protected if the destination protection field does not have a valid value.
3. Select the *Specify destination protection by field* option, and choose a field from the *Destination protection field* drop-down list (or *Unique ID protected field*).

   The field you choose must have a Y or N value to specify the action.

Any record that has a value of Y in the destination protection field will be protected from being modified.

2.16.4.10.1.3.2 To protect destination records based on input source membership

You must add an Input Source operation and define input sources before you can complete this task.

1. In the Destination Protection tab, select *Enable destination protection*.
2. Select a value in the *Default destination protection* option drop-down list.

   This value determines whether a destination (input source) is protected if you do not specifically define the source in the table below.
3. Select the *Specify destination protection by source* option.
4. Select an input source from the first row of the *Source name* column, and then choose a value from the *Destination protected* (or *Unique ID protected*) column.
   Repeat for every input source you want to set protection for. Remember that if you do not specify for every source, the default value will be used.

2.16.4.10.2 Unique ID

A unique ID refers to a field within your data which contains a unique value that is associated with a record or group of records. You could use a unique ID, for example, in your company's internal database that receives updates at some predetermined interval, such as each week, month, or quarter. Unique ID applies to a data record in the same way that a national identification number might apply to a person; for example, a Social Security number (SSN) in the United States, or a National Insurance number (NINO) in the United Kingdom. It creates and tracks data relationships from run to run. With the Unique ID operation, you can set your own starting ID for new key generation, or have it dynamically assigned based on existing data. The Unique ID post-match processing operation also lets you begin where the highest unique ID from the previous run ended.

Unique ID works on match groups

Unique ID doesn't necessarily assign IDs to individual records. It can assign the same ID to every record in a match group (groups of records found to be matches).

If you are assigning IDs directly to a break group, use the *Group number field* option to indicate which records belong together. Additionally, make sure that the records are sorted by group number so that records with the same group number value appear together.

If you are assigning IDs to records that belong to a match group resulting from the matching process, the *Group number field* is not required and should not be used.

> **i Note**
>
> If you are assigning IDs directly to a break group and the *Group number field* is not specified, Match treats the entire data collection as one match group.

2.16.4.10.2.1 Unique ID processing options

The Unique ID post-match processing operation combines the update source information with the master database information to form one source of match group information. The operation can then assign, combine, split, and delete unique IDs as needed. You can accomplish this by using the *Processing operation* option.

Operation	Description
Assign	Assigns a new ID to unique records that don't have an ID or to all members of a group that don't have an ID. In addition, the assign operation copies an existing ID if a member of a match group already has an ID. Each record is assigned a value. ● Records in a match group where one record had an input unique ID will share the value with other records in the match group which had no input value. The first value encountered will be shared. Order affects this; if you have a priority field that can be sequenced

Operation	Description
	using ascending order, place a Prioritization post-match operation prior to the Unique ID operation. • Records in a match group where two or more records had different unique ID input values will each keep their input value. • If all of the records in a match group do not have an input unique ID value, then the next available ID will be assigned to each record in the match group. If the GROUP_NUMBER input field is used, then records with the same group number must appear consecutively in the data collection. Note Use the GROUP_NUMBER input field only when processing a break group that may contain smaller match groups. If the GROUP_NUMBER field is not specified, Unique ID assumes that the entire collection is one group.
AssignCombine	Performs both an Assign and a Combine operation. Each record is assigned a value. • Records that did not have an input unique ID value and are not found to match another record containing an input unique ID value will have the next available ID assigned to it. These are "add" records that could be unique records or could be matches, but not to another record that had previously been assigned a unique ID value. • Records in a match group where one or more records had an input unique ID with the same or different values will share the first value encountered with all other records in the match group. Order affects this; if you have a priority field that can be sequenced using ascending order, place a Prioritization post-match operation prior to the Unique ID operation. If the GROUP_NUMBER input field is used, then records with the same group number must appear consecutively in the data collection. Note Use the GROUP_NUMBER input field only when processing a break group that may contain smaller match groups. If the GROUP_NUMBER field is not specified, Unique ID assumes that the entire collection is one group.
Combine	Ensures that records in the same match group have the same Unique ID. For example, this operation could be used to assign all the members of a household the same unique ID. Specifically, if a household has two members that share a common unique ID, and a third person moves in with a different unique ID, then the Combine operation could be used to assign the same ID to all three members. The first record in a match group that has a unique ID is the record with the highest priority. All other records in the match group are given this record's ID (assuming the record is not protected). The Combine operation does not assign a unique ID to any record that does not al-

Operation	Description
	ready have a unique ID. It only combines the unique ID of records in a match group that already have a unique ID. If the GROUP_NUMBER input field is used, then records with the same group number must appear consecutively in the data collection. Note Use the GROUP_NUMBER input field only when processing a break group that may contain smaller match groups. If the GROUP_NUMBER field is not specified, Unique ID assumes that the entire collection is one group.
Delete	Deletes unique IDs from records that no longer need them, provided that they are not protected from being deleted. If you are using a file and are recycling IDs, this ID is added to the file. When performing a delete, records with the same unique ID should be grouped together. When Match detects that a group of records with the same unique ID is about to be deleted: ● If any of the records are protected, all records in the group are assumed to be protected. ● If recycling is enabled, the unique ID will be recycled only once, even though a group of records had the same ID.
Split	Changes a split group's unique records, so that the records that do not belong to the same match group will have a different ID. The record with the group's highest priority will keep its unique ID. The rest will be assigned new unique IDs. For this operation, you must group your records by unique ID, rather than by match group number. For example: ● Records in a match group where two or more records had different unique ID input values or blank values will each retain their input value, filled or blank depending on the record. ● Records that did not have an input unique ID value and did not match any record with an input unique ID value will have a blank unique ID on output. ● Records that came in with the same input unique ID value that no longer are found as matches have the first record output with the input value. Subsequent records are assigned new unique ID values.

2.16.4.10.2.2 Unique ID protection

The output for the unique ID depends on whether an input field in that record has a value that indicates that the ID is protected.

- If the protected unique ID field is not mapped as an input field, Match assumes that none of the records are protected.
- There are two valid values allowed in this field: Y and N. Any other value is converted to Y.
  A value of N means that the unique ID is not protected and the ID posted on output may be different from the input ID.

a value of Y means that the unique ID is protected and the ID posted on output will be the same as the input ID.

- If the protected unique ID field is mapped as an input field, a value other than N means that the record's input data will be retained in the output unique ID field.

These rules for protected fields apply to all unique ID processing operations.

2.16.4.10.2.3 Unique ID limitations

Because some options in the unique ID operation are based on reading a file or referring to a field value, there may be implications for when you are running a multi-server or real-time server environment and sharing a unique ID file.

- If you are reading from or writing to a file, the unique ID file must be on a shared file system.
- Recycled IDs are used in first-in, first-out order. When Match recycles an ID, it does not check whether the ID is already present in the file. You must ensure that a particular unique ID value is not recycled more than once.

2.16.4.10.2.4 To assign unique IDs using a file

1. In the Unique ID option group, select the *Value from file* option.
2. Set the file name and path in the *File* option.

   This file must be an XML file and must adhere to the following structure:

   ```
   <UniqueIdSession>
       <CurrentUniqueId>477</CurrentUniqueId>
   </UniqueIdSession>
   ```

   > Note
   >
   > The value of 477 is an example of a starting value. However, the value must be 1 or greater.

2.16.4.10.2.5 To assign a unique ID using a constant

Similar to using a file, you can assign a starting unique ID by defining that value.

1. Select the *Constant value* option.
2. Set the *Starting value* option to the desired ID value.

2.16.4.10.2.6 Assign unique IDs using a field

The Field option allows you to send the starting unique ID through a field in your data source or from a User-Defined transform, for example.

The starting unique ID is passed to the Match transform before the first new unique ID is requested. If no unique ID is received, the starting number will default to 1.

> ⚠ Caution
>
> Use caution when using the Field option. The field that you use must contain the unique ID value you want to begin the sequential numbering with. This means that each record you process must contain this field, and each record must have the same value in this field.
>
> For example, suppose the value you use is 100,000. During processing, the first record or match group will have an ID of 100,001. The second record or match group receives an ID of 100,002, and so on.
>
> The value in the first record that makes it to the Match transform contains the value where the incrementing begins.
>
> There is no way to predict which record will make it to the Match transform first (due to sorting, for example); therefore, you cannot be sure which value the incrementing will begin at.

2.16.4.10.2.6.1 To assign unique IDs using a field

1. Select the *Field* option.
2. In the *Starting unique ID field* option, select the field that contains the starting unique ID value.

2.16.4.10.2.7 To assign unique IDs using GUID

You can use Globally Unique Identifiers (GUID) as unique IDs.

Select the *GUID* option.

GUID is also known as the Universal Unique Identifier (UUID). The UUID variation used for unique ID is a time-based 36-character string with the format: `TimeLow-TimeMid-TimeHighAndVersion-ClockSeqAndReservedClockSeqLow-Node`

For more information about UUID, see the Request for Comments (RFC) document.

Related Information

UUID RFC: http://www.ietf.org/rfc/rfc4122.txt

2.16.4.10.2.8 To recycle unique IDs

If unique IDs are dropped during the Delete processing option, you can write those IDs back to a file to be used later.

1. In the Unique ID option group, set the *Processing operation* option to *Delete*.
2. Select the *Value from file* option.
3. Set the file name and path in the *File* option.
4. Set the *Recycle unique IDs* option to *Yes*. This is the same file that you might use for assigning a beginning ID number.

2.16.4.10.2.8.1 Use your own recycled unique IDs

If you have some IDs of your own that you would like to recycle and use in a data flow, you can enter them in the file you want to use for recycling IDs and posting a starting value for your IDs. Enter these IDs in an XML tag of <R></R>. For example:

```
<UniqueIdSession>
    <CurrentUniqueId>477</CurrentUniqueId>
    <R>214</R>
    <R>378</R>

</UniqueIdSession>
```

2.16.4.10.2.9 Destination protection

The Best Record and Unique ID operations in the Match transform offer you the power to modify existing records in your data. There may be times when you would like to protect data in particular records or data in records from particular input sources from being overwritten.

The Destination Protection tab in these Match transform operations allow you the ability to protect data from being modified.

2.16.4.10.2.9.1 To protect destination records through fields

1. In the Destination Protection tab, select *Enable destination protection*.
2. Select a value in the *Default destination protection* option drop-down list.

   This value determines whether a destination is protected if the destination protection field does not have a valid value.
3. Select the *Specify destination protection by field* option, and choose a field from the *Destination protection field* drop-down list (or *Unique ID protected field*).

   The field you choose must have a Y or N value to specify the action.

Any record that has a value of Y in the destination protection field will be protected from being modified.

2.16.4.10.2.9.2 To protect destination records based on input source membership

You must add an Input Source operation and define input sources before you can complete this task.

1. In the Destination Protection tab, select *Enable destination protection*.
2. Select a value in the *Default destination protection* option drop-down list.

   This value determines whether a destination (input source) is protected if you do not specifically define the source in the table below.
3. Select the *Specify destination protection by source* option.
4. Select an input source from the first row of the *Source name* column, and then choose a value from the *Destination protected* (or *Unique ID protected*) column.
   Repeat for every input source you want to set protection for. Remember that if you do not specify for every source, the default value will be used.

2.16.4.10.3 Group statistics

The Group Statistics post-match operation should be added after any match level and any post-match operation for which you need statistics about your match groups or your input sources.

This operation can also counts statistics from logical input sources that you have already identified with values in a field (pre-defined) or from logical sources that you specify in the Input Sources operation.

This operation also allows you to exclude certain logical sources based on your criteria.

> i Note
>
> If you choose to count input source statistics in the Group Statistics operation, Match will also count basic statistics about your match groups.

Group statistics fields

When you include a Group Statistics operation in your Match transform, the following fields are generated by default:

- GROUP_COUNT
- GROUP_ORDER
- GROUP_RANK
- GROUP_TYPE

In addition, if you choose to generate source statistics, the following fields are also generated and available for output:

- SOURCE_COUNT
- SOURCE_ID

- SOURCE_ID_COUNT
- SOURCE_TYPE_ID

Related Information

Reference Guide: Transforms, Match, Output fields [page 1308]

Management Console Guide: Data Quality Reports, Match Source Statistics Summary report [page 2028]

2.16.4.10.3.1 To generate only basic statistics

This task will generate statistics about your match groups, such as how many records in each match group, which records are masters or subordinates, and so on.

1. Add a Group Statistics operation to each match level you want, by selecting *Post Match Processing* in a match level, clicking the *Add* button, and selecting *Group Statistics*.
2. Select *Generate only basic statistics*.
3. Click the *Apply* button to save your changes.

2.16.4.10.3.2 To generate statistics for all input sources

Before you start this task, be sure that you have defined your input sources in the Input Sources operation.

Use this procedure if you are interested in generating statistics for all of your sources in the job.

1. Add a Group Statistics operation to the appropriate match level.
2. Select the *Generate source statistics from input sources* option.

This will generate statistics for all of the input sources you defined in the Input Sources operation.

2.16.4.10.3.3 To count statistics for input sources generated by values in a field

For this task, you do not need to define input sources with the Input Sources operation. You can specify input sources for Match using values in a field.

Using this task, you can generate statistics for all input sources identified through values in a field, or you can generate statistics for a sub-set of input sources.

1. Add a Group Statistics operation to the appropriate match level.
2. Select the *Generate source statistics from source values* option.
3. Select a field from the *Logical source field* drop-down list that contains the values for your logical sources.

4. Enter a value in the *Default logical source value* field.
   This value is used if the logical source field is empty.
5. Select one of the following:

Option	Description
Count all sources	Select to count all sources. If you select this option, you can click the Apply button to save your changes. This task is complete.
Choose sources to count	Select to define a sub-set of input sources to count. If you select this option, you can proceed to step 6 in the task.

6. Choose the appropriate value in the *Default count flag* option.
   Choose Yes to count any source not specified in the *Manually define logical source count flags table*. If you do not specify any sources in the table, you are, in effect, counting all sources.
7. Select *Auto-generate sources* to count sources based on a value in a field specified in the *Predefined count flag field* option.
   If you do not specify any sources in the *Manually define logical source count flags table*, you are telling the Match transform to count all sources based on the (Yes or No) value in this field.
8. In the *Manually define logical source count flags table*, add as many rows as you need to include all of the sources you want to count.

   > Note
   >
   > This is the first thing the Match transform looks at when determining whether to count sources.

9. Add a source value and count flag to each row, to tell the Match transform which sources to count.

> Tip
>
> If you have a lot of sources, but you only want to count two, you could speed up your set up time by setting the *Default count flag* option to No, and setting up the *Manually define logical source count flags table* to count those two sources. Using the same method, you can set up Group Statistics to count everything and not count only a couple of sources.

2.16.4.10.4 Output flag selection

By adding an Output Flag Selection operation to each match level (Post Match Processing) you want, you can flag specific record types for evaluation or routing downstream in your data flow.

Adding this operation generates the Select_Record output field for you to include in your output schema. This output field is populated with a Y or N depending on the type of record you select in the operation.

Your results will appear in the Match Input Source Output Select report. In that report, you can determine which records came from which source or source group and how many of each type of record were output per source or source group.

Record type	Description
Unique	Records that are not members of any match group. No matching records were found. These can be from sources with a normal or special source.

Record type	Description
Single source masters	Highest ranking member of a match group whose members all came from the same source. Can be from normal or special sources.
Single source subordinates	A record that came from a normal or special source and is a subordinate member of a match group.
Multiple source masters	Highest ranking member of a match group whose members came from two or more sources. Can be from normal or special sources.
Multiple source subordinates	A subordinate record of a match group that came from a normal or special source whose members came from two or more sources.
Suppression matches	Subordinate member of a match group that includes a higher-priority record that came from a suppress-type source. Can be from normal or special source.
Suppression uniques	Records that came from a suppress source for which no matching records were found.
Suppression masters	A record that came from a suppress source and is the highest ranking member of a match group.
Suppression subordinates	A record that came from a suppress-type source and is a subordinate member of a match group.

2.16.4.10.4.1 To flag source record types for possible output

1. In the Match editor, for each match level you want, add an Output Flag Select operation.
2. Select the types of records for which you want to populate the Select_Record field with Y.

   The Select_Record output field can then be output from the Match transform for use downstream in the data flow. This is most helpful if you later want to split off suppression matches or suppression masters from your data (by using a Case transform, for example).

2.16.4.11 Association matching

Association matching combines the matching results of two or more match sets (transforms) to find matches that could not be found within a single match set.

You can set up association matching in the Associate transform. This transform acts as another match set in your data flow, from which you can derive statistics.

This match set has two purposes. First, it provides access to any of the generated data from all match levels of all match sets. Second, it provides the overlapped results of multiple criteria, such as name and address, with name and SSN, as a single ID. This is commonly referred to as association matching.

Group numbers

The Associate transform accepts a group number field, generated by the Match transforms, for each match result that will be combined. The transform can then output a new associated group number.

The Associate transform can operate either on all the input records or on one data collection at a time. The latter is needed for real-time support.

> Example
>
> Association example
>
> Say you work at a technical college and you want to send information to all of the students prior to the start of a new school year. You know that many of the students have a temporary local address and a permanent home address.
>
> In this example, you can match on name, address, and postal code in one match set, and match on name and Social Security number (SSN), which is available to the technical college on every student, in another match set.
>
> Then, the Associate transform combines the two match sets to build associated match groups. This lets you identify people who may have multiple addresses, thereby maximizing your one-to-one marketing and mailing efforts.

2.16.4.12 Unicode matching

Unicode matching lets you match Unicode data. You can process any non-Latin1 Unicode data, with special processing for Chinese, Japanese, Korean and Taiwanese (or CJKT) data.

Chinese, Japanese, Korean, and Taiwanese matching

Regardless of the country-specific language, the matching process for CJKT data is the same. For example, the Match transform:

- Considers half-width and full-width characters to be equal.
- Considers native script numerals and Arabic numerals to be equal. It can interpret numbers that are written in native script. This can be controlled with the Convert text to numbers option in the Criteria options group.
- Includes variations for popular, personal, and firm name characters in the referential data.
- Considers firm words, such as Corporation or Limited, to be equal to their variations (Corp. or Ltd.) during the matching comparison process. To find the abbreviations, the transform uses native script variations of the English alphabets during firm name matching.
- Ignores commonly used optional markers for province, city, district, and so on, in address data comparison.
- Intelligently handles variations in a building marker.

Japanese-specific matching capabilities

With Japanese data, the Match transform considers:

- Block data markers, such as chome and banchi, to be equal to those used with hyphenated data.
- Words with or without Okurigana to be equal in address data.
- Variations of *no* marker, *ga* marker, and so on, to be equal.
- Variations of a hyphen or dashed line to be equal.

Unicode match limitations

The Unicode match functionality does not:

- Perform conversions of simplified and traditional Chinese data.
- Match between non-phonetic scripts like kanji, simplified Chinese, and so on.

Route records based on country ID before matching

Before sending Unicode data into the matching process, you must first, as best you can, separate out the data by country to separate match transforms. This can be done by using a Case transform to route country data based on the country ID.

> ➡ Tip
>
> The Match wizard can do this for you when you use the multi-national strategy.

Inter-script matching

Inter-script matching allows you to process data that may contain more than one script by converting the scripts to Latin1. For example one record has Latin1 and other has katakana, or one has Latin and other has Cyrillic. Select *Yes* to enable Inter-script matching. If you prefer to process the data without converting it to Latin1, leave the Inter-script Matching option set *No*. Here are two examples of names matched using inter-script matching:

Name	Can be matched to...
Viktor Ivanov	Виктор Иванов
Takeda Noburu	スッセ フレ

Locale

The Locale option specifies the locale setting for the criteria field. Setting this option is recommended if you plan to use the Text to Numbers feature to specify the locale of the data for locale-specific text-to-number conversion for the purpose of matching. Here a four examples of text-to-number conversion:

Language	Text	Numbers
French	quatre mille cinq cents soixante-sept	4567
German	dreitausendzwei	3002
Italian	cento	100
Spanish	ciento veintisiete	127

For more information on these matching options, see the Match Transform section of the *Reference Guide*

2.16.4.12.1 To set up Unicode matching

1. Use a Case transform to route your data to a Match transform that handles that type of data.
2. Open the *AddressJapan_MatchBatch* Match transform configuration, and save it with a different name.
3. Set the *Match engine* option in the Match transform options to a value that reflects the type of data being processed.
4. Set up your criteria and other desired operations. For more information on Match Criteria options, see the Match Transform section of the *Reference Guide*.

Example

- When possible, use criteria for parsed components for address, firm, and name data, such as Primary_Name or Person1_Family_Name1.
- If you have parsed address, firm, or name data that does not have a corresponding criteria, use the Address_Data1-5, Firm_Data1-3, and Name_Data1-3 criteria.
- For all other data that does not have a corresponding criteria, use the Custom criteria.

2.16.4.13 Phonetic matching

You can use the Double Metaphone or Soundex functions to populate a field and use it for creating break groups or use it as a criteria in matching.

Match criteria

There are instances where using phonetic data can produce more matches when used as a criteria, than if you were to match on other criteria such as name or firm data.

Matching on name field data produces different results than matching on phonetic data. For example:

Name	Comparison score
Smith	72% similar
Smythe	

Name	Phonetic key (primary)	Comparison score
Smith	SMO	100% similar
Smythe	SMO	

Criteria options

If you intend to match on phonetic data, set up the criteria options this way

Option	Value
Compare algorithm	Field
Check for transposed characters	No
Intials adjustment score	0
Substring adjustment score	0
Abbreviation adjustment score	0

Match scores

If you are matching only on the phonetic criteria, set your match score options like this:

Option	Value
Match score	100
No match score	99

If you are matching on multiple criteria, including a phonetic criteria, place the phonetic criteria first in the order of criteria and set your match score options like this:

Option	Value
Match score	101
No match score	99

Blank fields

Remember that when you use break groups, records that have no value are not in the same group as records that have a value (unless you set up matching on blank fields). For example, consider the following two input records:

Mr Johnson	100 Main St	La Crosse	WI	54601
Scott Johnson	100 Main St	La Crosse	WI	54601

After these records are processed by the Data Cleanse transform, the first record will have an empty first name field and, therefore, an empty phonetic field. This means that there cannot be a match, if you are creating break groups. If you are not creating break groups, there cannot be a match if you are not blank matching.

Length of data

The length you assign to a phonetic function output is important. For example:

First name (last name)	Output
S (Johnson)	S
Scott (Johnson)	SKT

Suppose these two records represent the same person. In this example, if you break on more than one character, these records will be in different break groups, and therefore will not be compared.

2.16.4.14 Set up for match reports

We offer many match reports to help you analyze your match results. For more information about these individual reports, see the *Management Console Guide*.

Include Group Statistics in your Match transform

If you are generating the Match Source Statistics Summary report, you must include a Group Statistics operation in your Match and Associate transform(s).

If you want to track your input source statistics, you may want to include an Input Sources operation in the Match transform to define your sources and, in a Group Statistics operation select to generate statistics for your input sources.

> **Note**
>
> You can also generate input source statistics in the Group Statistics operation by defining input sources using field values. You do not necessarily need to include an Input Sources operation in the Match transform.

Turn on report data generation in transforms

In order to generate the data you want to see in match reports other than the Match Source Statistics report, you must set the *Generate report statistics* option to Yes in the Match and Associate transform(s).

By turning on report data generation, you can get information about break groups, which criteria were instrumental in creating a match, and so on.

> ℹ Note
>
> Be aware that turning on the report option can have an impact on your processing performance. It's best to turn off reports after you have thoroughly tested your data flow.

Define names for match sets, levels, and operations

To get the most accurate data in your reports, make sure that you have used unique names in the Match and Associate transforms for your match sets, levels, and each of your pre- and post-match operations, such as Group Prioritization and Group Statistics. This will help you better understand which of these elements is producing the data you are looking at.

Insert appropriate output fields

There are three output fields you may want to create in the Match transform, if you want that data posted in the Match Duplicate Sample report. They are:

- Match_Type
- Group_Number
- Match_Score

2.16.5 Address Cleanse

This section describes how to prepare your data for address cleansing, how to set up address cleansing, and how to understand your output after processing.

Related Information

What is address cleanse? [page 586]
Prepare your input data [page 589]
Determine which transform(s) to use [page 590]
Identify the country of destination [page 593]

Set up the reference files [page 594]
Define the standardization options [page 596]
Supported countries [page 611]

2.16.5.1 How address cleanse works

Address cleanse provides a corrected, complete, and standardized form of your original address data. With the USA Regulatory Address Cleanse transform and for some countries with the Global Address Cleanse transform, address cleanse can also correct or add postal codes. With the DSF2 Walk Sequencer transform, you can add walk sequence information to your data.

What happens during address cleanse?

The USA Regulatory Address Cleanse transform and the Global Address Cleanse transform cleanse your data in the following ways:

- Verify that the locality, region, and postal codes agree with one another. If your data has just a locality and region, the transform usually can add the postal code and vice versa (depending on the country).
- Standardize the way the address line looks. For example, they can add or remove punctuation and abbreviate or spell-out the primary type (depending on what you want).
- Identify undeliverable addresses, such as vacant lots and condemned buildings (USA records only).
- Assign diagnostic codes to indicate why addresses were not assigned or how they were corrected. (These codes are included in the *Reference Guide*).

Reports

The USA Regulatory Address Cleanse transform creates the USPS Form 3553 (required for CASS) and the NCOALink Summary Report. The Global Address Cleanse transform creates reports about your data including the Canadian SERP—Statement of Address Accuracy Report, the Australia Post's AMAS report, and the New Zealand SOA Report.

Related Information

Reference Guide: Data Quality Fields, USA Regulatory Address Cleanse fields [page 1349]

2.16.5.1.1 The transforms

The following table lists the address cleanse transforms and their purpose.

Transform	Description
DSF2 Walk Sequencer	When you perform DSF2 walk sequencing in the software, the software adds delivery sequence information to your data, which you can use with presorting software to qualify for walk-sequence discounts. Remember The software does not place your data in walk sequence order.
Global Address Cleanse and engines	Cleanses your address data from any of the supported countries (not for U.S. certification). You must set up the Global Address Cleanse transform in conjunction with one or more of the Global Address Cleanse engines (Canada, Global Address, or USA). With this transform you can create Canada Post's Software Evaluation and Recognition Program (SERP)—Statement of Address Accuracy Report, Australia Post's Address Matching Processing Summary report (AMAS), and the New Zealand Statement of Accuracy (SOA) report.
USA Regulatory Address Cleanse	Identifies, parses, validates, and corrects USA address data (within the Latin 1 code page) according to the U.S. Coding Accuracy Support System (CASS). Can create the USPS Form 3553 and output many useful codes to your records. You can also run in a non-certification mode as well as produce suggestion lists. Some options include: DPV, DSF2 (augment), eLOT, EWS, GeoCensus, LACSLink, NCOALink, RDI, SuiteLink, suggestion lists (not for certification), and Z4Change.
Global Suggestion Lists	Offers suggestions for possible address matches for your USA, Canada, and global address data. This transform is usually used for real time processing and does not standardize addresses. Use a Country ID transform before this transform in the data flow. Also, if you want to standardize your address data, use the Global Address Cleanse transform after the Global Suggestion Lists transform in the data flow.
Country ID	Identifies the country of destination for the record and outputs an ISO code. Use this transform before the Global Suggestion Lists transform in your data flow. (It is not necessary to place the Country ID transform before the Global Address Cleanse or the USA Regulatory Address Cleanse transforms.)

2.16.5.1.2 Input and output data and field classes

Input data

The address cleanse transforms accept discrete, multiline, and hybrid address line formats.

Output data

There are two ways that you can set the software to handle output data. Most use a combination of both.

Concept	Description
Multiline	The first method is useful when you want to keep output address data in the same arrangement of fields as were input. The software applies intelligent abbreviation, when necessary, to keep the data within the same field lengths. Data is capitalized and standardized according to the way you set the standardization style options.
Discrete	The second method is useful when you want the output addresses broken down into smaller elements than you input. Also, you can retrieve additional fields created by the software, such as the error/status code. The style of some components is controlled by the standardization style options; most are not. The software does not apply any intelligent abbreviation to make components fit your output fields.

When you set up the USA Regulatory Address Cleanse transform or the Global Address Cleanse transform, you can include output fields that contain specific information:

Generated Field Address Class	Generated Field Class
Delivery	Parsed: Contains the parsed input with some standardization applied. The fields subjected to standardization are locality, region, and postcode. Best: Contains the parsed data when the address is unassigned or the corrected data for an assigned address. Corrected: Contains the assigned data after directory lookups and will be blank if the address is not assigned.
Dual	Parsed, Best, and Corrected: Contain the DUAL address details that were available on input.
Official	Parsed: Contains the parsed input with some standardization applied. Best: Contains the information from directories defined by the Postal Service when an address is assigned. Contains the parsed input when an address is unassigned.

Generated Field Address Class	Generated Field Class
	Corrected: Contains the information from directories defined by the Postal Service when an address is assigned and will be blank if the address is not assigned.

2.16.5.2 Prepare your input data

Before you start address cleansing, you must decide which kind of address line format you will input. Both the USA Regulatory Address Cleanse transform and the Global Address Cleanse transform accept input data in the same way.

⚠ Caution

The USA Regulatory Address Cleanse Transform does not accept Unicode data. If an input record has characters outside the Latin1 code page (character value is greater than 255), the USA Regulatory Address Cleanse transform will not process that data. Instead, the input record is sent to the corresponding standardized output field without any processing. No other output fields (component, for example) will be populated for that record. If your Unicode database has valid U.S. addresses from the Latin1 character set, the USA Regulatory Address Cleanse transform processes as usual.

Accepted address line formats

The following tables list the address line formats: multiline, hybrid, and discrete.

ℹ Note

For all multiline and hybrid formats listed, you are not required to use all the multiline fields for a selected format (for example Multiline1-12). However, you must start with Multiline1 and proceed consecutively. You cannot skip numbers, for example, from Multiline1 to Multiline3.

Multiline and multiline hybrid formats				
Example 1	**Example 2**	**Example 3**	**Example 4**	**Example 5**
Multiline1	Multiline1	Multiline1	Multiline1	Multiline1
Multiline2	Multiline2	Multiline2	Multiline2	Multiline2
Multiline3	Multiline3	Multiline3	Multiline3	Multiline3
Multiline4	Multiline4	Multiline4	Multiline4	Multiline4
Multiline5	Multiline5	Locality3	Multiline5	Multiline5
Multiline6	Multiline6	Locality2	Locality2	Multiline6
Multiline7	Multiline7	Locality1	Locality1	Locality1

Multiline and multiline hybrid formats				
Example 1	**Example 2**	**Example 3**	**Example 4**	**Example 5**
Multiline8	Lastline	Region1	Region1	Region1
Country (Optional)	Country (Optional)	Postcode (Global) or Postcode1 (USA Reg.)	Postcode (Global) or Postcode1 (USA Reg.)	Postcode (Global) or Postcode1 (USA Reg.)
		Country (Optional)	Country (Optional)	Country (Optional)

Discrete line formats			
Example 1	**Example 2**	**Example 3**	**Example 4**
Address_Line	Address_Line	Address_Line	Address_Line
Lastline	Locality3 (Global)	Locality2	Locality1
Country (Optional)	Locality2	Locality1	Region1
	Locality1	Region1	Postcode (Global) or Postcode1 (USA Reg.)
	Region1	Postcode (Global) or Postcode1 (USA Reg.)	Country (Optional)
	Postcode (Global) or Postcode1 (USA Reg.)	Country (Optional)	
	Country (Optional)		

2.16.5.3 Determine which transform(s) to use

You can choose from a variety of address cleanse transforms based on what you want to do with your data. There are transforms for cleansing global and/or U.S. address data, cleansing based on USPS regulations, using business rules to cleanse data and cleansing global address data transactionally.

Related Information

Cleanse global address data [page 591]
Cleanse U.S. data only [page 591]
Cleanse USA data and global data [page 592]
Cleanse address data using multiple business rules [page 592]
Cleanse your address data transactionally [page 593]

2.16.5.3.1 Cleanse global address data

To cleanse your address data for any of the software-supported countries (including Canada for SERP, Software Evaluation and Recognition Program, certification and Australia for AMAS, Address Matching Approval System, certification), use the Global Address Cleanse transform in your project with one or more of the following engines:

- Canada
- Global Address
- USA

> ➜ Tip
>
> Cleansing U.S. data with the USA Regulatory Address Cleanse transform is usually faster than with the Global Address Cleanse transform and USA engine. This scenario is usually true even if you end up needing both transforms.

You can also use the Global Address Cleanse transform with the Canada, USA, Global Address engines in a real time data flow to create suggestion lists for those countries.

Start with a sample transform configuration

The software includes a variety of Global Address Cleanse sample transform configurations (which include at least one engine) that you can copy to use for a project.

Related Information

Supported countries [page 611]
Cleanse U.S. data and global data [page 592]
Reference Guide: Transforms, Transform configurations [page 1123]

2.16.5.3.2 Cleanse U.S. data only

To cleanse U.S. address data, use the USA Regulatory Address Cleanse transform for the best results. With this transform, and with DPV, LACSLink, and SuiteLink enabled, you can produce a CASS-certified mailing and produce a USPS Form 3553. If you do not intend to process CASS-certified lists, you should still use the USA Regulatory Address Cleanse transform for processing your U.S. data. Using the USA Regulatory Address Cleanse transform on U.S. data is more efficient than using the Global Address Cleanse transform.

With the USA Regulatory Address Cleanse transform you can add additional information to your data such as DSF2, EWS, eLOT, NCOALink, and RDI. And you can process records one at a time by using suggestion lists.

Start with a sample transform configuration

The software includes a variety of USA Regulatory Address Cleanse sample transform configurations that can help you set up your projects.

Related Information

Reference Guide: Transforms, Data Quality transforms, Transform configurations [page 1123]
Introduction to suggestion lists [page 676]

2.16.5.3.3 Cleanse U.S. data and global data

What should you do when you have U.S. addresses that need to be certified and also addresses from other countries in your database? In this situation, you should use both the Global Address Cleanse transform and the USA Regulatory Address Cleanse transform in your data flow.

> ➡ Tip
>
> Even if you are not processing U.S. data for USPS certification, you may find that cleansing U.S. data with the USA Regulatory Address Cleanse transform is faster than with the Global Address Cleanse transform and USA engine.

2.16.5.3.4 Cleanse address data using multiple business rules

When you have two addresses intended for different purposes (for example, a billing address and a shipping address), you should use two of the same address cleanse transforms in a data flow.

One or two engines?

When you use two Global Address Cleanse transforms for data from the same country, they can share an engine. You do not need to have two engines of the same kind. If you use one engine or two, it does not affect the overall processing time of the data flow.

In this situation, however, you may need to use two separate engines (even if the data is from the same country). Depending on your business rules, you may have to define the settings in the engine differently for a billing address or for a shipping address. For example, in the Standardization Options group, the Output Country Language option can convert the data used in each record to the official country language or it can preserve the language used in each record. For example, you may want to convert the data for the shipping address but preserve the data for the billing address.

2.16.5.3.5 Cleanse your address data transactionally

The Global Suggestion Lists transform, best used in transactional projects, is a way to complete and populate addresses with minimal data, or it can offer suggestions for possible matches. For example, the Marshall Islands and the Federated States of Micronesia were recently removed from the USA Address directory. Therefore, if you previously used the USA engine, you'll now have to use the Global Address engine. The Global Suggestion Lists transform can help identify that these countries are no longer in the USA Address directory.

This easy address-entry system is ideal in call center environments or any transactional environment where cleansing is necessary at the point of entry. It's also a beneficial research tool when you need to manage bad addresses from a previous batch process.

Place the Global Suggestion Lists transform after the Country ID transform and before a Global Address Cleanse transform that uses a Global Address, Canada, and/or USA engine.

Integrating functionality

Global Suggestion Lists functionality is designed to be integrated into your own custom applications via the Web Service. If you are a programmer looking for details about how to integrate this functionality, see "Integrate Global Suggestion Lists" in the *Integrator Guide*.

Start with a sample transform configuration

Data Quality includes a Global Suggestion Lists sample transform that can help you when setting up a project.

Related Information

Introduction to suggestion lists [page 676]

2.16.5.4 Identify the country of destination

The Global Address Cleanse transform includes Country ID processing. Therefore, you do not need to place a Country ID transform before the Global Address Cleanse transform in your data flow.

In the Country ID Options option group of the Global Address Cleanse transform, you can define the country of destination or define whether you want to run Country ID processing.

Constant country

If all of your data is from one country, such as Australia, you do not need to run Country ID processing or input a discrete country field. You can tell the Global Address Cleanse transform the country and it will assume all records are from this country (which may save processing time).

Assign default

You'll want to run Country ID processing if you are using two or more of the engines and your input addresses contain country data (such as the two-character ISO code or a country name), or if you are using only one engine and your input source contains many addresses that cannot be processed by that engine. Addresses that cannot be processed are not sent to the engine. The transform will use the country you specify in this option group as a default.

Related Information

To set a constant country [page 612]
Set a default country [page 611]

2.16.5.5 Set up the reference files

The USA Regulatory Address Cleanse transform and the Global Address Cleanse transform and engines rely on directories (reference files) in order to cleanse your data.

Directories

To correct addresses and assign codes, the address cleanse transforms rely on databases called postal directories. The process is similar to the way that you use the telephone directory. A telephone directory is a large table in which you look up something you know (a person's name) and read off something you don't know (the phone number).

In the process of looking up the name in the phone book, you may discover that the name is spelled a little differently from the way you thought. Similarly, the address cleanse transform looks up street and city names in the postal directories, and it corrects misspelled street and city names and other errors.

Sometimes it doesn't work out. We've all had the experience of looking up someone and being unable to find their listing. Maybe you find several people with a similar name, but you don't have enough information to tell which listing was the person you wanted to contact. This type of problem can prevent the address cleanse transforms from fully correcting and assigning an address.

Besides the basic address directories, there are many specialized directories that the USA Regulatory Address Cleanse transform uses:

- DPV®
- DSF2®
- Early Warning System (EWS)
- eLOT®
- GeoCensus
- LACSLink®
- NCOALink®
- RDI™
- SuiteLink™
- Z4Change

These features help extend address cleansing beyond the basic parsing and standardizing.

Define directory file locations

You must tell the transform or engine where your directory (reference) files are located in the Reference Files option group. Your system administrator should have already installed these files to the appropriate locations based on your company's needs.

⚠ Caution

Incompatible or out-of-date directories can render the software unusable. The system administrator must install weekly, monthly or bimonthly directory updates for the USA Regulatory Address Cleanse Transform; monthly directory updates for the Australia and Canada engines; and quarterly directory updates for the Global Address engine to ensure that they are compatible with the current software.

Substitution files

If you start with a sample transform, the Reference Files options are filled in with a substitution variable (such as $$RefFilesAddressCleanse) by default. These substitution variables point to the reference data folder of the software directory by default.

You can change that location by editing the substitution file associated with the data flow. This change is made for every data flow that uses that substitution file.

2.16.5.5.1 View directory expiration dates in the trace log

You can view directory expiration information for a current job in the trace log. To include directory expiration information in the trace log, perform the following steps.

1. Right click on the applicable job icon in Designer and select *Execute*.
2. In the *Execution Properties* window, open the *Execution Options* tab (it should already be open by default).
3. Select *Print all trace messages*.

Related Information

Using Logs [page 426]

2.16.5.6 Define the standardization options

Standardization changes the way the data is presented after an assignment has been made. The type of change depends on the options that you define in the transform. These options include casing, punctuation, sequence, abbreviations, and much more. It helps ensure the integrity of your databases, makes mail more deliverable, and gives your communications with customers a more professional appearance.

For example, the following address was standardized for capitalization, punctuation, and postal phrase (route to RR).

Input	Output

Multiline1 = route 1 box 44a
Multiline2 = stodard wisc
	Address_Line = RR 1 BOX 44A
	Locality1 = STODDARD
	Region1 = WI
	Postcode1 = 54658

Global Address Cleanse transform

In the Global Address Cleanse transform, you set the standardization options in the Standardization Options option group.

You can standardize addresses for all countries and/or for individual countries (depending on your data). For example, you can have one set of French standardization options that standardize addresses within France only, and another set of Global standardization options that standardize all other addresses.

USA Regulatory Address Cleanse transform

If you use the USA Regulatory Address Cleanse transform, you set the standardization options on the *Options* tab in the Standardization Options section.

2.16.5.7 Process Japanese addresses

The Global Address Cleanse transform's Global Address engine parses Japanese addresses. The primary purpose of this transform and engine is to parse and normalize Japanese addresses for data matching and cleansing applications.

> i Note
>
> The Japan engine only supports kanji and katakana data. The engine does not support Latin data.

A significant portion of the address parsing capability relies on the Japanese address database. The software has data from the Ministry of Public Management, Home Affairs, Posts and Telecommunications (MPT) and additional data sources. The enhanced address database consists of a regularly updated government database that includes regional postal codes mapped to localities.

Related Information

Standard Japanese address format [page 598]
Special Japanese address formats [page 602]
Sample Japanese address [page 604]

2.16.5.7.1 Standard Japanese address format

A typical Japanese address includes the following components.

Address component	Japanese	English	Output field(s)
Postal code	〒 654-0153	654-0153	Postcode_Full
Prefecture	兵庫県	Hyogo-ken	Region1_Full
City	神戸市	Kobe-shi	Locality1_Full
Ward	須磨区	Suma-ku	Locality2_Full
District	南落合	Minami Ochiai	Locality3_Full
Block number	1 丁目	1 chome	Primary_Name_Full1
Sub-block number	25 番地	25 banchi	Primary_Name_Full2
House number	2 号	2 go	Primary_Number_Full

An address may also include building name, floor number, and room number.

Postal code

Japanese postal codes are in the *nnn-nnnn* format. The first three digits represent the area. The last four digits represent a location in the area. The possible locations are district, sub-district, block, sub-block, building, floor, and company. Postal codes must be written with Arabic numbers. The post office symbol 〒 is optional.

Before 1998, the postal code consisted of 3 or 5 digits. Some older databases may still reflect the old system.

Prefecture

Prefectures are regions. Japan has forty-seven prefectures. You may omit the prefecture for some well known cities.

City

Japanese city names have the suffix 市 (-shi). In some parts of the Tokyo and Osaka regions, people omit the city name. In some island villages, they use the island name with a suffix 島 (-shima) in place of the city name. In some rural areas, they use the county name with suffix 郡 (-gun) in place of the city name.

Ward

A city is divided into wards. The ward name has the suffix 区(-ku). The ward component is omitted for small cities, island villages, and rural areas that don't have wards.

District

A ward is divided into districts. When there is no ward, the small city, island village, or rural area is divided into districts. The district name may have the suffix 町 (-cho/-machi), but it is sometimes omitted. 町 has two possible pronunciations, but only one is correct for a particular district.

In very small villages, people use the village name with suffix 村 (-mura) in place of the district.

When a village or district is on an island with the same name, the island name is often omitted.

Sub-district

Primarily in rural areas, a district may be divided into sub-districts, marked by the prefix 字 (aza-). A sub-district may be further divided into sub-districts that are marked by the prefix 小字 (koaza-), meaning small aza. koaza may be abbreviated to aza. A sub-district may also be marked by the prefix 大字 (oaza-), which means large aza. Oaza may also be abbreviated to aza.

Here are the possible combinations:

- oaza
- aza
- oaza and aza
- aza and koaza
- oaza and koaza

> Note
>
> The characters 大字(oaza-), 字(aza-), and 小字 (koaza-) are frequently omitted.

Sub-district parcel

A sub-district aza may be divided into numbered sub-district parcels, which are marked by the suffix 部 (-bu), meaning *piece*. The character 部 is frequently omitted.

Parcels can be numbered in several ways:

- Arabic numbers (1, 2, 3, 4, and so on)
  石川県七尾市松百町８部３番地１号
- Katakana letters in iroha order (イ, ロ, ハ, ニ, and so on)

- 石川県小松市里川町ナ部23番地
- Kanji numbers, which is very rare (甲, 乙, 丙, 丁, and so on)
  愛媛県北条市上難波甲部311番地

Sub-division

A rural district or sub-district (oaza/aza/koaza) is sometimes divided into sub-divisions, marked by the suffix 地割 (-chiwari) which means division of land. The optional prefix is 第 (dai-)

The following address examples show sub-divisions:

岩手県久慈市旭町10地割1番地

岩手県久慈市旭町第10地割1番地

Block number

A district is divided into blocks. The block number includes the suffix 丁目 (-chome). Districts usually have between 1 and 5 blocks, but they can have more. The block number may be written with a Kanji number. Japanese addresses do not include a street name.

東京都渋谷区道玄坂２丁目２５番地１２号

東京都渋谷区道玄坂二丁目２５番地１２号

Sub-block number

A block is divided into sub-blocks. The sub-block name includes the suffix 番地 (-banchi), which means numbered land. The suffix 番地 (-banchi) may be abbreviated to just 番 (-ban).

House number

Each house has a unique house number. The house number includes the suffix 号 (-go), which means number.

Block, sub-block, and house number variations

Block, sub-block, and house number data may vary.

Dashes

The suffix markers 丁目(chome), 番地 (banchi), and 号(go) may be replaced with dashes.

東京都文京区湯島 2 丁目 18 番地 12 号

東京都文京区湯島 2-18-12

Sometimes block, sub-block, and house number are combined or omitted.

東京都文京区湯島 2 丁目 18 番 12 号

東京都文京区湯島 2 丁目 18 番地 12

東京都文京区湯島 2 丁目 18-12

No block number

Sometimes the block number is omitted. For example, this ward of Tokyo has numbered districts, and no block numbers are included. 二番町 means district number 2.

東京都 千代田区 二番町 9 番地 6 号

Building names

Names of apartments or buildings are often included after the house number. When a building name includes the name of the district, the district name is often omitted. When a building is well known, the block, sub-block, and house number are often omitted. When a building name is long, it may be abbreviated or written using its acronym with English letters.

The following are the common suffixes:

Suffix	Romanized	Translation
ビルディング	birudingu	building
ビルヂング	birudingu	building
ビル	biru	building
センター	senta-	center
プラザ	puraza	plaza
パーク	pa-ku	park
タワー	tawa-	tower
会館	kaikan	hall

Suffix	Romanized	Translation
棟	tou	building (unit)
庁舎	chousha	government office building
マンション	manshon	condominium
団地	danchi	apartment complex
アパート	apa-to	apartment
荘	sou	villa
住宅	juutaku	housing
社宅	shataku	company housing
官舎	kansha	official residence

Building numbers

Room numbers, apartment numbers, and so on, follow the building name. Building numbers may include the suffix 号室 (-goshitsu). Floor numbers above ground level may include the suffix 階 (-kai) or the letter F. Floor numbers below ground level may include the suffix 地下<n>階 (chika <n> kai) or the letters B<n>F (where <n> represents the floor number). An apartment complex may include multiple buildings called Building A, Building B, and so on, marked by the suffix 棟 (-tou).

The following address examples include building numbers.

- Third floor above ground
  東京都千代田区二番町９番地６号　バウエプタ３Ｆ
- Second floor below ground
  東京都渋谷区道玄坂 2-25-12 シティバンク地下２階
- Building A Room 301
  兵庫県神戸市須磨区南落合 1-25-10　須磨パークヒルズ　A 棟 301 号室
- Building A Room 301
  兵庫県神戸市須磨区南落合 1-25-10　須磨パークヒルズ　A-301

2.16.5.7.2 Special Japanese address formats

Hokkaido regional format

The Hokkaido region has two special address formats:

- super-block

- numbered sub-districts

Super-block

A special super-block format exists only in the Hokkaido prefecture. A super-block, marked by the suffix 条 (-joh), is one level larger than the block. The super-block number or the block number may contain a directional 北 (north), 南 (south), 東 (east), or 西 (west). The following address example shows a super-block 4 Joh.

北海道札幌市西区二十四軒４条４丁目１３番地７号

Numbered sub-districts

Another Hokkaido regional format is numbered sub-district. A sub-district name may be marked with the suffix 線 (-sen) meaning number instead of the suffix 字 (-aza). When a sub-district has a 線 suffix, the block may have the suffix 号 (-go), and the house number has no suffix.

The following is an address that contains first the sub-district 4 sen and then a numbered block 5 go.

北海道旭川市西神楽４線５号３番地１１

Accepted spelling

Names of cities, districts and so on can have multiple accepted spellings because there are multiple accepted ways to write certain sounds in Japanese.

Accepted numbering

When the block, sub-block, house number or district contains a number, the number may be written in Arabic or Kanji. For example, 二番町 means district number 2, and in the following example it is for Niban-cho.

東京都千代田区二番町九番地六号

P.O. Box addresses

P.O. Box addresses contain the postal code, Locality1, prefecture, the name of the post office, the box marker, and the box number.

Note

The Global Address Cleanse transform recognizes P.O. box addresses that are located in the Large Organization Postal Code (LOPC) database only.

The address may be in one of the following formats:

- Prefecture, Locality1, post office name, box marker (私書箱), and P.O. box number.
- Postal code, prefecture, Locality1, post office name, box marker (私書箱), and P.O. box number.

The following address example shows a P.O. Box address:

The Osaka Post Office Box marker #1

大阪府大阪市大阪支店私書箱1号

Large Organization Postal Code (LOPC) format

The Postal Service may assign a unique postal code to a large organization, such as the customer service department of a major corporation. An organization may have up to two unique postal codes depending on the volume of mail it receives. The address may be in one of the following formats:

- Address, company name
- Postal code, address, company name

The following is an example of an address in a LOPC address format.

100-8798 東京都千代田区霞が関1丁目3-2 日本郵政 株式会社

2.16.5.7.3 Sample Japanese address

This address has been processed by the Global Address Cleanse transform and the Global Address engine.

2.16.5.8 Process Chinese addresses

The Global Address Cleanse transform's Global Address engine parses Chinese addresses. The primary purpose of this transform and engine is to parse and normalize addresses for data matching and cleansing applications.

2.16.5.8.1 Chinese address format

Chinese addresses are written starting with the postal code, followed by the largest administrative region (for example, province), and continue to the smallest unit (for example, room number and mail receiver). When people send mail between different prefectures, they often include the largest administrative region in the address. The addresses contain detailed information about where the mail will be delivered. Buildings along the street are numbered sequentially, sometimes with odd numbers on one side and even numbers on the other side. In some instances both odd and even numbers are on the same side of the street.

Postal Code

In China, the postal code is a six-digit number to identify the target deliver point of the address, and often has the prefix **邮编**

Country

"**中华人民共和国**" (People's Republic of China) is the full name of China. "**中国**" (PRC) is often used as an abbreviation of the country name. For mail delivered within China, the domestic addresses often omit the country name of the target address.

Province

In China, "provinces" are similar to a "state" in the United States. China has 34 province-level divisions, including:

- *Provinces*(**省** shěng)
- *Autonomous regions*(**自治区** zìzhìqū)

- *Municipalities*(直辖市 zhíxiáshì)
- *Special administrative regions*(特别行政区 tèbié xíngzhèngqū)

Prefecture

Prefecture-level divisions are the second level of the administrative structure, including:

- *Prefectures* (地区 dìqū)
- *Autonomous prefectures* (自治州 zìzhìzhōu)
- *Prefecture-level cities* (地级市 dìjíshì)
- *Leagues* (盟 méng)

County

The county is the sub-division of Prefecture, including:

- *Counties* (县 xiàn)
- *Autonomous counties* (自治县 zìzhìxiàn)
- *County-level cities*(县级市 xiànjíshì)
- *Districts* (市辖区 shìxiáqū)
- *Banners* (旗 qí)
- *Autonomous banners* (自治旗 zìzhìqí)
- *Forestry areas* (林区 línqū)
- *Special districts* (特区 tèqū)

Township

Township level division includes:

- *Townships* (乡 xiāng)
- *Ethnic townships* (民族乡 mínzúxiāng)
- *Towns* (镇 zhèn)
- *Subdistricts* (街道办事处 jiēdàobànshìchù)
- *District public offices* (区公所 qūgōngsuǒ)
- *Sumu*(苏木 sūmù)
- *Ethnic sumu* (民族苏木 mínzúsūmù)

Village

Village includes:

- *Neighborhood committees*(社区居民委员会 jūmínwěiyuánhùi)
- *Neighborhoods or communities* (社区)
- *Village committees*(村民委员会 cūnmínwěiyuánhùi) or *Village groups* (村民小组 cūnmínxiǎozǔ)
- *Administrative villages*(行政村 xíngzhèngcūn)

Street information

Specifies the delivery point where the mail receiver can be found within it. In China, the street information often has the form of street (road) name -> House number. For example, 上海市浦东新区晨晖路 1001 号

- *Street name*: The street name is usually followed by one of these suffixes 路, 大道, 街, 大街, and so on.
- *House number*:
  The house number is followed by the suffix 号, the house number is a unique number within the street/road.

Residential community

In China, the residential community might be used for mail delivery. Especially for some famous residential communities in major cities, the street name and house number might be omitted. The residential community does not have a naming standard and it is not strictly required to be followed by a typical marker. However, it is often followed by the typical suffixes, such as 新村, 小区, and so on (for example, 新村, 小区).

Building name

Building is often followed by the building marker, such as 大厦, 大楼 and so on, though it is not strictly required (for example, 中华大厦). Building name in the residential communities is often represented by a number with a suffix of 号，幢 and so on (for example: 上海市浦东新区晨晖路 100 弄 10 号 101 室).

Common metro address

This address includes the District name, which is common for metropolitan areas in major cities.

Address component	Chinese	English	Output field
Postcode	510030	510030	Postcode_Full
Country	中国	China	Country
Province	广东省	Guangdong Province	Region1_Full
City name	广州市	Guangzhou City	Locality1_Full

Address component	Chinese	English	Output field
District name	越秀区	Yuexiu District	Locality2_Full
Street name	西湖路	Xihu Road	Primary_Name_Full1
House number	99 号	No. 99	Primary_Number_Full

Rural address

This address includes the Village name, which is common for rural addresses.

Address component	Chinese	English	Output field
Postcode	5111316	5111316	Postcode_Full
Country	中国	China	Country
Province	广东省	Guangdong Province	Region1_Full
City name	广州市	Guangzhou City	Locality1_Full
County-level City name	增城市	Zengcheng City	Locality2_Full
Town name	荔城镇	Licheng Town	Locality3_Full
Village name	联益村	Lianyi Village	Locality4_Full
Street name	光大路	Guangda Road	Primary_Name_Full1
House number	99 号	No. 99	Primary_Number_Full

2.16.5.8.2 Sample Chinese address

2.16.5.9 Supported countries (Global Address Cleanse)

There are several countries supported by the Global Address Cleanse transform. The level of correction varies by country and by the engine that you use. Complete coverage of all addresses in a country is not guaranteed.

For the Global Address engine, country support depends on which sets of postal directories you have purchased.

For Japan, the assignment level is based on data provided by the Ministry of Public Management Home Affairs, Posts and Telecommunications (MPT).

During Country ID processing, the transform can identify many countries. However, the Global Address Cleanse transform's engines may not provide address correction for all of those countries.

Related Information

To process U.S. territory with the USA engine [page 611]
Reference Guide: Country ISO codes and assignment engines [page 1395]

2.16.5.9.1 To change the default output country name

When you use the USA engine to process addresses from American Samoa, Guam, Northern Mariana Islands, Palau, Puerto Rico, and the U.S. Virgin Islands, the output region is AS, GU, MP, PW, PR, or VI, respectively. The output country, however, is the United States (US).

If you do not want the output country as the United States when processing addresses with the USA engine, set the *Use Postal Country Name* option to *No*.

These steps show you how to set the Use Postal Country Name in the Global Address Cleanse transform.

1. Open the *Global Address Cleanse* transform.
2. On the *Options* tab, expand ▶ *Standardization Options* ▶ *Country* ▶ *Options* ◀.
3. For the *Use Postal Country Name* option, select *No*.

Related Information

Supported countries (Global Address Cleanse) [page 611]

2.16.5.9.2 Set a default country

> i Note
>
> Run Country ID processing only if you are:

- Using two or more of the engines and your input addresses contain country data (such as the two-character ISO code or a country name).
- Using only one engine, but your input data contains addresses from multiple countries.

1. Open the *Global Address Cleanse* transform.
2. On the *Options* tab, expand *Country ID Options*, and then for the *Country ID Mode* option select *Assign*.
   This value directs the transform to use *Country ID* to assign the country. If *Country ID* cannot assign the country, it will use the value in *Country Name*.
3. For the *Country Name* option, select the country that you want to use as a default country.

   The transform will use this country only when *Country ID* cannot assign a country. If you do not want a default country, select *None*.
4. For the *Script Code* option, select the type of script code that represents your data.

   The *LATN* option provides script code for most types of data. However, if you are processing Japanese data, select *KANA*

Related Information

Identify the country of destination [page 593]

To set a constant country [page 612]

2.16.5.9.3 To set a constant country

1. Open the *Global Address Cleanse* transform.
2. On the *Options* tab, expand *Country ID Options*, and then for the *Country ID Mode* option select *Constant*.
   This value tells the transform to take the country information from the *Country Name* and *Script Code* options (instead of running *Country ID* processing).
3. For the *Country Name* option, select the country that represents all your input data.
4. For the *Script Code* option, select the type of script code that represents your data.

   The *LATN* option provides script code for most types of data. However, if you are processing Japanese data, select *KANA*

Related Information

Identify the country of destination [page 593]

Set a default country [page 611]

2.16.5.10 New Zealand certification

New Zealand certification enables you to process New Zealand addresses and qualify for mailing discounts with the New Zealand Post.

2.16.5.10.1 To enable New Zealand certification

You need to purchase the New Zealand directory data and obtain a customer number from the New Zealand Post before you can use the New Zealand certification option.

To process New Zealand addresses that qualify for mailing discounts:

1. In the Global Address Cleanse Transform, enable ▶ *Report and Analysis* ▸ *Generate Report Data* ◀.
2. In the Global Address Cleanse Transform, set ▶ *Country Options* ▸ *Disable Certification* ◀ to *No*.

   > Note
   >
   > The software does not produce the New Zealand Statement of Accuracy (SOA) report when this option is set to *Yes*.

3. In the Global Address Transform, complete all applicable options in the ▶ *Global Address* ▸ *Report Options* ▸ *New Zealand* ◀ subgroup.
4. In the Global Address Cleanse Transform, set ▶ *Engines* ▸ *Global Address* ◀ to *Yes*.

After you run the job and produce the New Zealand Statement of Accuracy (SOA) report, you need to rename the New Zealand Statement of Accuracy (SOA) report and New Zealand Statement of Accuracy (SOA) Production Log before submitting your mailing. For more information on the required naming format, See *New Zealand SOA Report and SOA production log file* [page 613].

Management Console Guide: New Zealand Statement of Accuracy (SOA) report [page 2012]
Reference Guide: Report options for New Zealand [page 1217]

2.16.5.10.2 New Zealand SOA Report and SOA production log file

New Zealand Statement of Accuracy (SOA) Report

The New Zealand Statement of Accuracy (SOA) report includes statistical information about address cleansing for New Zealand.

New Zealand Statement of Accuracy (SOA) Production Log

The New Zealand Statement of Accuracy (SOA) production log contains identical information as the SOA report in a pipe-delimited ASCII text file (with a header record). The software creates the SOA production log by extracting data from the Sendrightaddraccuracy table within the repository. The software appends a new record to the Sendrightaddraccuracy table each time a file is processed with the DISABLE_CERTIFICATION option set to *No*. If the DISABLE_CERTIFICATION option is set to *Yes*, the software does not produce the SOA report and an entry will not be appended to the Sendrightaddraccuracy table. Mailers must retain the production log file for at least 2 years.

The default location of the SOA production log is `<INSTALL_DIR>\Data Services\DataQuality\certifications\CertificationLogs`.

Mailing requirements

The SOA report and production log are only required when you submit the data processed for a mailing and want to receive postage discounts. Submit the SOA production log at least once a month. Submit an SOA report for each file that is processed for mailing discounts.

File naming format

The SOA production log and SOA report must have a file name in the following format:

Production Log -

```
[SOA% (9999)]_[SOA Expiry Date (YYYYMMDD)]_[SOA ID].txt
```

SOA Report -

```
[SOA% (9999)]_[SOA Expiry Date (YYYYMMDD)]_[SOA ID].PDF
```

Example

An SOA with:

SOA % = 94.3%

SOA expiry date = 15 Oct 2008

SOA ID = AGD07_12345678

The file names will be:

Production Log - `0943_20081015_AGD07_12345678.txt`

SOA Report - `0943_20081015_AGD07_12345678.pdf`

Related Information

Management Console Guide: New Zealand Statement of Accuracy (SOA) report [page 2012]
Management Console Guide: Exporting New Zealand SOA certification logs [page 1879]
Reference Guide: Report options for New Zealand [page 1217]

2.16.5.10.3 The New Zealand certification blueprint

Do the following to edit the blueprint, run the job for New Zealand certification, and generate the SOA production log file:

1. Import `nz_sendright_certification.atl` located in the DataQuality\certifications folder in the location where you installed the software. The default location is **<INSTALL_DIR>**`\Data Services\DataQuality\certifications`.
   The import adds the following objects to the repository:
   - The project DataQualityCertifications
   - The job Job_DqBatchNewZealand_SOAProductionLog
   - The data flow DF_DqBatchNewZealand_SOAProductionLog
   - The datastore DataQualityCertifications
   - The file format DqNewZealandSOAProductionLog
2. Edit the datastore DataQualityCertifications. Follow the steps listed in *Editing the datastore* [page 616].
3. Optional: By default, the software places the SOA Production Log in **<INSTALL_DIR>**`\Data Services\DataQuality\certifications\CertificationLogs`. If the default location is acceptable, ignore this step. If you want to output the production log file to a different location, edit the substitution parameter configuration. From the Designer, access *Tools* › *Substitution Parameter Configurations* and change the path location in Configuration1 for the substitution parameter $$CertificationLogPath to the location of your choice.
4. Run the job Job_DqBatchNewZealand_SOAProductionLog.
   The job produces an SOA Production Log called `SOAPerc_SOAExpDate_SOAId.txt` in the default location or the location you specified in the substitution parameter configuration.
5. Rename the `SOAPerc_SOAExpDate_SOAId.txt` file using data in the last record in the log file and the file naming format described in *New Zealand SOA Report and SOA production log file* [page 613].

Related Information

New Zealand SOA Report and SOA production log file [page 613]
Management Console Guide: New Zealand Statement of Accuracy (SOA) report [page 2012]

2.16.5.10.4 Editing the datastore

After you download the blueprint `.zip` file to the appropriate folder, unzip it, and import the .atl file in the software, you must edit the DataQualityCertifications datastore.

To edit the datastore:

1. Select the *Datastores* tab of the Local Object Library, right-click DataQualityCertifications and select *Edit*.
2. Click *Advanced* to expand the Edit Datastore DataQualityCertifications window.

   > Note
   >
   > Skip step 3 if you have Microsoft SQL Server 2000 or 2005 as a datastore database type.

3. Click *Edit*.
4. Find the column for your database type, change *Default configuration* to **`Yes`**, and click *OK*.

   > Note
   >
   > If you are using a version of Oracle other than Oracle 9i, perform the following substeps:

   a) In the toolbar, click *Create New Configuration*.
   b) Enter your information, including the Oracle database version that you are using, and then click *OK*.
   c) Click *Close* on the Added New Values - Modified Objects window.
   d) In the new column that appears to the right of the previous columns, select *Yes* for the *Default configuration*.
   e) Enter your information for the *Database connection name*, *User name*, and *Password* options.
   f) In *DBO*, enter your schema name.
   g) In *Code Page*, select *cp1252* and then click *OK*.
5. At the Edit Datastore DataQualityCertifications window, enter your repository connection information in place of the CHANGE_THIS values. (You may have to change three or four options, depending on your repository type.)
6. Expand the *Aliases* group and enter your owner name in place of the CHANGE_THIS value. If you are using Microsoft SQL Server, set this value to **`DBO`**.
7. Click *OK*.
   If the window closes without any error message, then the database is successfully connected.

2.16.5.11 Global Address Cleanse Suggestion List option

The Global Address Cleanse transform's Suggestion List processing option is used in transactional projects to complete and populate addresses that have minimal data. Suggestion lists can offer suggestions for possible matches if an exact match is not found.

This option is beneficial in situations where you want to extract addresses not completely assigned by an automated process, and run through the system to find a list of possible matches. Based on the given input address, the Global Address Cleanse transform performs an error-tolerant search in the address directory and returns a list of possible matches. From the suggestion list returned, you can select the correct suggestion and update the database accordingly.

ℹ Note

No certification with suggestion lists: If you use the Canada engine or Global Address engine for Australia and New Zealand, you cannot certify your mailing for SERP, AMAS, or New Zealand certification.

Start with a sample transform

If you want to use the suggestion lists feature, it is best to start with the sample transforms that is configured for it. The sample transform, GlobalSuggestions_AddressCleanse is configured to cleanse Latin-1 address data in any supported country using the Suggestion List feature.

Related Information

Extracting data quality XML strings using extract_from_xml function [page 370]
Reference Guide: Suggestion List options [page 1215]

2.16.5.12 Global Suggestion List transform

The Global Suggestion List transform allows you to query addresses with minimal data (allowing the use of wildcards), and it can offer a list of suggestions for possible matches.

It is a beneficial tool for a call center environment, where operators need to enter minimum input (number of keystrokes) to find the caller's delivery address. For example, if the operator is on the phone with a caller from the United Kingdom, the application prompts for the postcode and address range. Global Suggestion List is used to look up the address with quick-entry.

The Global Suggestion List transform requires the two-character ISO country code on input. Therefore, you may want to place a transform, such as the Country ID transform, that outputs the ISO_Country_Code_2Char field before the Global Suggestion Lists transform. The Global Suggestion List transform is available for use with the Canada, Global Address, and USA engines.

ℹ Note

No certification with suggestion lists: If you use the Canada, Global Address, or USA engines for Australia and New Zealand, you cannot certify your mailing for SERP, CASS, AMAS, or New Zealand certification.

ℹ Note

This option does not support processing of Japanese or Chinese address data.

Start with a sample transform

If you want to use the Global Suggestion List transform, it is best to start with one of the sample transforms that is configured for it. The following sample tranforms are available.

Sample transform	Description
GlobalSuggestions	A sample transform configured to generate a suggestion list for Latin-1 address data in any supported country.
UKSuggestions	A sample transform configured to generate a suggestion list for partial address data in the United Kingdom.

2.16.6 Beyond the basic address cleansing

The USA Regulatory Address Cleanse transform offers many additional address cleanse features for U.S. addresses. These features extend address cleansing beyond the basic parsing and standardizing. To read about the USA Regulatory Address Cleanse transform and its options, see the *Reference Guide*.

2.16.6.1 USPS DPV®

Delivery Point Validation® is a USPS product developed to assist users in validating the accuracy of their address information. DPV compares Postcode2 information against the DPV directories to identify known addresses and potential problems with the address that may cause an address to become undeliverable.

DPV is available for U.S. data in the USA Regulatory Address Cleanse transform only.

> **Note**
>
> DPV processing is required for CASS certification. If you are not processing for CASS certification, you can choose to run your jobs in non-certified mode and still enable DPV.

> **Caution**
>
> If you choose to disable DPV processing, the software will not generate the CASS-required documentation and your mailing won't be eligible for postal discounts.

Related Information

To enable DPV [page 624]

Run DPV in non certified mode [page 625]

2.16.6.1.1 Benefits of DPV

DPV can be beneficial in the following areas:

- Mailing: DPV helps to screen out undeliverable-as-addressed (UAA) mail and helps to reduce mailing costs.
- Information quality: DPV increases the level of data accuracy through the ability to verify an address down to the individual house, suite, or apartment instead of only block face.
- Increased assignment rate: DPV may increase assignment rate through the use of DPV tiebreaking to resolve a tie when other tie-breaking methods are not conclusive.
- Preventing mail-order-fraud: DPV can eliminate shipping of merchandise to individuals who place fraudulent orders by verifying valid delivery addresses and Commercial Mail Receiving Agencies (CMRA).

2.16.6.1.2 DPV security

The USPS has instituted processes that monitor the use of DPV. Each company that purchases the DPV functionality is required to sign a legal agreement stating that it will not attempt to misuse the DPV product. If a user abuses the DPV product, the USPS has the right to prohibit the user from using DPV in the future.

2.16.6.1.2.1 DPV false positive addresses

The USPS has included false positive addresses in the DPV directories as an added security to prevent DPV abuse. Depending on what type of user you are and your license key codes, the software's behavior varies when it encounters a false positive address. The following table explains the behaviors for each user type:

User type	Software behavior	Read about:
End users	DPV processing is terminated.	Obtaining DPV unlock code from SAP Support
End users with a stop processing alternative agreement	DPV processing continues.	Sending false positive logs to the USPS
Service providers	DPV processing continues.	Sending false positive logs to the USPS

Related Information

Stop Processing Alternative [page 620]
Obtaining DPV unlock code from SAP [page 622]
Sending DPV false positive logs to the USPS [page 622]

2.16.6.1.2.2 Stop Processing Alternative

End users may establish a Stop Processing Alternative agreement with the USPS and SAP.

Establishing a stop processing agreement allows you to bypass any future directory locks. The Stop Processing Alternative is not an option in the software, it is a key code that you obtain from SAP Support.

First you must obtain the proper permissions from the USPS and then provide proof of permission to SAP Support. Support will then provide a key code that disables the directory locking function in the software.

➜ Remember

When you obtain the Stop Processing Alternative key code from SAP Support, enter it into the SAP License Manager. With the Stop Processing Alternative key code in place, the software takes the following actions when a false positive is encountered:

- Marks the record as a false positive.
- Generates a log file containing the false positive address.
- Notes the path to the log files in the error log.
- Generates a US Regulatory Locking Report containing the path to the log file.
- Continues processing your job.

Even though your job continues processing, you are required to send the false positive log file to the USPS to notify them that a false positive address was detected. The USPS must release the list before you can use it for processing.

Related Information

Sending DPV false positive logs to the USPS [page 622]

2.16.6.1.2.3 DPV false positive logs

The software generates a false positive log file any time it encounters a false positive record, regardless of how your job is set up. The software creates a separate log file for each mailing list that contains a false positive. If multiple false positives exist within one mailing list, the software writes them all to the same log file.

2.16.6.1.2.3.1 DPV log file name and location

The software stores DPV log files in the directory specified in the *USPS Log Path* option in the Reference Files group.

ℹ Note

The USPS log path that you enter must be writable. An error is issued if you have entered a path that is not writable.

Log file naming convention

The software automatically names DPV false positive logs with the following format: `dpvl####.log`

The #### portion of the naming format is a number between 0001 and 9999. For example, the first log file generated is `dpvl0001.log`, the next one is `dpvl0002.log`, and so on.

ℹ Note

When you have set the data flow degree of parallelism to greater than 1, or you have enabled the run as a separate process option, the software generates one log per thread or process. During a job run, if the software encounters only one false positive record, one log will be generated. However, if it encounters more than one false positive record and the records are processed on different threads or processes, then the software will generate one log for each thread that processes a false positive record.

Related Information

Performance Optimization Guide: Using parallel execution [page 2137]

2.16.6.1.2.4 DPV locking for end users

This locking behavior is applicable for end users or users who are DSF2 licensees that have DSF2 disabled in the job

When the software finds a false positive address, DPV processing is discontinued for the remainder of the data flow. The software also takes the following actions:

- Marks the record as a false positive address.
- Issues a message in the error log stating that a DPV false positive address was encountered.
- Includes the false positive address and lock code in the error log.
- Continues processing your data flow without DPV processing.
- Generates a lock code.
- Generates a false positive log.
- Generates a US Regulatory Locking Report that contains the false positive address and the lock code. (Report generation must be enabled in the USA Regulatory Address Cleanse transform.)

To restore DPV functionality, users must obtain a DPV unlock code from SAP Support.

Related Information

Obtaining LACSLink unlock code from SAP Support [page 622]

2.16.6.1.2.5 Obtaining DPV unlock code from SAP

These steps are applicable for end users who do not have a Stop Processing Alternative agreement with the USPS. When you receive a processing message that DPV false positive addresses are present in your address list, use the SAP USPS Unlock Utility to obtain an unlock code.

1. Navigate to *https://websmp205.sap-ag.de/bosap-unlock* to open the SAP Service Market Place (SMP) unlock utility page.
2. Click *Retrieve USPS Unlock Code*.
3. Click *Search* and select an applicable Data Services system from the list.
4. Enter the lock code found in the `dpvx.txt` file (location is specified in the *DPV Path* option in the Reference Files group).
5. Select DPV as the lock type.
6. Select BOJ-EIM-DS as the component.
7. Enter the locking address that is listed in the `dpvx.txt` file.
8. Attach the `dpvl####.log` file (location is specified in the *USPS Log Path* option in the Reference Files group).
9. Click *Submit*.
   The unlock code displays.
10. Copy the unlock code and paste it into the `dpvw.txt` file, replacing all contents of the file with the unlock code (location is specified in the *DPV path* option of the Reference Files group).
11. Remove the record that caused the lock from the database, and delete the `dpvl####.log` file before processing the list again.

    Tip

    Keep in mind that you can only use the unlock code once. If the software detects another false-positive (even if it is the same record), you must retrieve a new LACSLink unlock code.

If an unlock code could not be generated, a message is still created and is processed by a Technical Customer Assurance engineer (during regular business hours).

> Note
>
> If you are an end user who has a Stop Processing Alternative agreement, follow the steps to send the false positive log to the USPS.

2.16.6.1.2.6 Sending DPV false positive logs to the USPS

Service providers should follow these steps after receiving a processing message that DPV false positive addresses are present in their address list. End users with a Stop Processing Alternative agreement should follow these steps after receiving a processing message that DPV false positive addresses are present in their address list.

1. Send an email to the USPS NCSC at Dsf2stop@usps.gov, and include the following information:
   - Type “DPV False Positive” as the subject line
   - Attach the `dpvl####.log` file or files that were generated by the software (location is specified in the *USPS Log Path* directory option in the Reference Files group)

   The USPS NCSC uses the information to determine whether the list can be returned to the mailer.
2. After the USPS NCSC has released the list that contained the locked or false positive record:
   - Delete the corresponding log file or files
   - Remove the record that caused the lock from the list and reprocess the file

If you are an end user who does not have a Stop Processing Alternative agreement, follow the steps to retrieve the DPV unlock code from SAP Support.

Related Information

Obtaining DPV lock code from SAP BusinessObjects Support [page 622]

2.16.6.1.3 DPV monthly directories

DPV directories are shipped monthly with the USPS directories in accordance with USPS guidelines.

The directories expire in 105 days. The date on the DPV directories must be the same date as the Address directory.

Do not rename any of the files. DPV will not run if the file names are changed. Here is a list of the DPV directories:

- `dpva.dir`
- `dpvb.dir`
- `dpvc.dir`
- `dpvd.dir`
- `dpv_vacant.dir`
- `dpv_no_stats.dir`

2.16.6.1.4 Required information in the job setup

When you set up for DPV processing, the following options in the USPS License Information group are required:

- *Customer Company Name*
- *Customer Company Address*
- *Customer Company Locality*
- *Customer Company Region*

- *Customer Company Postcode1*
- *Customer Company Postcode2*

2.16.6.1.5 To enable DPV

> i Note
>
> DPV is required for CASS.

In addition to the required customer company information that you enter into the USPS License Information group, set the following options to perform DPV processing:

1. Open the USA Regulatory Address Cleanse transform.
2. Open the *Options* tab. Expand the Assignment Options group, and select Yes for the *Enable DPV* option.
3. In the Reference Files group, enter the path for your DPV directories in the *DPV Path* option.

   > i Note
   >
   > DPV can run only when the location for all the DPV directories have been entered and none of the DPV directory files have been renamed.

4. Set a directory for the DPV log file in the *USPS Path* option. Use the substitution variable $ $CertificationLogPath if you have it set up.
5. In the Report and Analysis group, select Yes for the *Generate Report Data* option.

2.16.6.1.6 DPV output fields

Several output fields are available for reporting DPV processing results:

- DPV_CMRA
- DPV_Footnote
- DPV_NoStats
- DPV_Status
- DPV_Vacant

For full descriptions of these output fields, refer to the *Reference Guide* or view the Data Services Help information that appears when you open the Output tab of the USA Regulatory Address Cleanse transform.

Related Information

Reference Guide: Data Quality fields, USA Regulatory Address Cleanse fields, Output fields [page 1353]

2.16.6.1.7 Non certified mode

You can set up your jobs with DPV disabled if you are not a CASS customer but you want a Postcode2 added to your addresses. The non-CASS option, *Assign Postcode2 Not DPV Validated*, enables the software to assign a Postcode2 when an address does not DPV-confirm.

> ⚠ Caution
>
> If you choose to disable DPV processing, the software does not generate the CASS-required documentation and your mailing won't be eligible for postal discounts.

2.16.6.1.7.1 Enable Non-Certified mode

To run your job in non certified mode, follow these setup steps:

1. In the Assignment Options group, set the *Enable DPV* option to No.
2. In the Non Certified options group, set the *Disable Certification* to Yes.
3. In the Non Certified options group, set the *Assign Postcode2 Not DPV Validated* to Yes.

> ⚠ Caution
>
> The software blanks out all Postcode2 information in your data if you disable DPV processing and you disable the *Assign Postcode2 Not DPV Validated* option. This includes Postcode2 information provided in your input file.

2.16.6.1.8 DPV performance

Due to additional time required to perform DPV processing, you may see a change in processing time. Processing time may vary with the DPV feature based on operating system, system configuration, and other variables that may be unique to your operating environment.

You can decrease the time required for DPV processing by loading DPV directories into system memory before processing.

2.16.6.1.8.1 Memory usage

You may need to install additional memory on your operating system for DPV processing. We recommend a minimum of 768 MB to process with DPV enabled.

To determine the amount of memory required to run with DPV enabled, check the size of the DPV directories (recently about 600 MB[1]) and add that to the amount of memory required to run the software.

The size of the DPV directories will vary depending on the amount of new data in each directory release.

Make sure that your computer has enough memory available before performing DPV processing.

To find the amount of disk space required to cache the directories, see the *Supported Platforms* document in the SAP Support portal. Find link information in the SAP Information resources table (see the link below).

Related Information

SAP Business Objects information resources, Supported platforms (Product Availability Matrix) [page 169]

2.16.6.1.8.2 Cache DPV directories

To better manage memory usage when you have enabled DPV processing, choose to cache the DPV directories.

2.16.6.1.8.3 To cach DPV directories

To set up your job for DPV caching, follow these steps:

1. In the Transform Performance group, set the *Cache DPV Directories* option to Yes.
2. In the same group, set the *Insufficient Cache Memory Action* to one of the following:

Option	Description
Error	Software issues an error and terminates the transform.
Continue	Software attempts to continue initialization without caching.

2.16.6.1.8.4 Running multiple jobs with DPV

When running multiple DPV jobs and loading directories into memory, you should add a 10-second pause between jobs to allow time for the memory to be released. For more information about setting this properly, see your operating system manual.

If you don't add a 10-second pause between jobs, there may not be enough time for your system to release the memory used for caching the directories from the first job. The next job waiting to process may error out or access the directories from disk if there is not enough memory to cache directories. This may result in performance degradation.

[1] The directory size is subject to change each time new DPV directories are installed.

2.16.6.1.9 DPV information in US Addressing Report

The US Addressing Report automatically generates when you have enabled reporting in your job. The following sections of the US Addressing Report contain DPV information:

- DPV Return Codes
- Delivery Point Validation (DPV) Summary

For information about the US Addressing Report, or other Data Quality reports, see the *Management Console Guide*.

Related Information

Management Console: Data Quality reports, US Addressing Report [page 2004]

2.16.6.1.10 DPV No Stats indicators

The USPS uses No Stats indicators to mark addresses that fall under the No Stats category. The software uses the No Stats table when you have DPV or DSF2 turned on in your job. The USPS puts No Stats addresses in three categories:

- Addresses that do not have delivery established yet.
- Addresses that receive mail as part of a drop.
- Addresses that have been vacant for a certain period of time.

2.16.6.1.10.1 No Stats table

You must install the No Stats table (`dpv_no_stats.dir`) before the software performs DPV or DSF2 processing. The No Stats table is supplied by SAP BusinessObjects with the DPV directory install.

The software automatically checks for the No Stats table in the directory folder that you indicate in your job setup. The software performs DPV and DSF2 processing based on the install status of the directory.

dpv_no_stats.dir	Results
Installed	The software automatically outputs No Stats indicators when you include the DPV_NoStats output field in your job.
Not installed	The software automatically skips the No Stats processing and does not issue an error message. The software will perform DPV processing but won't populate the DPV_NoStat output field.

2.16.6.1.10.2 No Stats output field

Use the DPV_NoStats output field to post No Stat indicator information to an output file.

No Stat means that the address is a vacant property, it receives mail as a part of a drop, or it does not have an established delivery yet.

Related Information

DPV output fields [page 624]

2.16.6.1.11 DPV Vacant indicators

The software provides vacant information in output fields and reports using DPV vacant counts. The USPS DPV vacant lookup table is supplied by SAP BusinessObjects with the DPV directory install.

The USPS uses DPV vacant indicators to mark addresses that fall under the vacant category. The software uses DPV vacant indicators when you have DPV or DSF2 enabled in your job.

> ➜ Tip
>
> The USPS defines vacant as any delivery point that was active in the past, but is currently not occupied (usually over 90 days) and is not currently receiving mail delivery. The address could receive delivery again in the future. "Vacant" does not apply to seasonal addresses.

2.16.6.1.11.1 DPV address-attribute output field

Vacant indicators for the assigned address are available in the DPV_Vacant output field.

> i Note
>
> The US Addressing Report contains DPV Vacant counts in the DPV Summary section.

Related Information

DPV output fields [page 624]

Management Console: Data Quality reports, US Addressing Report [page 2003]

2.16.6.2 LACSLink®

LACSLink is a USPS product that is available for U.S. records with the USA Regulatory Address Cleanse transform only. LACSLink processing is required for CASS certification.

LACSLink updates addresses when the physical address does not move but the address has changed. For example, when the municipality changes rural route addresses to street-name addresses. Rural route conversions make it easier for police, fire, ambulance, and postal personnel to locate a rural address. LACSLink also converts addresses when streets are renamed or post office boxes renumbered.

LACSLink technology ensures that the data remains private and secure, and at the same time gives you easy access to the data. LACSLink is an integrated part of address processing; it is not an extra step. To obtain the new addresses, you must already have the old address data.

Related Information

How LACSLink works [page 632]
To control memory usage for LACSLink processing [page 636]
To disable LACSLink [page 635]
LACSLink security [page 629]

2.16.6.2.1 Benefits of LACSLink

LACSLink processing is required for all CASS customers.

If you process your data without LACSLink enabled, you won't get the CASS-required reports or postal discounts.

2.16.6.2.2 LACSLink security

The USPS has instituted processes that monitor the use of LACSLink. Each company that purchases the LACSLink functionality is required to sign a legal agreement stating that it will not attempt to misuse the LACSLink product. If a user abuses the LACSLink product, the USPS has the right to prohibit the user from using LACSLink in the future.

2.16.6.2.2.1 LACSLink false positive addresses

The USPS has included false positive addresses in the LACSLink directories as an added security to prevent LACSLink abuse. Depending on what type of user you are and your license key codes, the software's behavior varies when it encounters a false positive address. The following table explains the behaviors for each user type:

User type	Software behavior	Read about:
End users	LACSLink processing is terminated.	Obtaining the LACSLink unlock code from SAP Support
End users with a Stop Processing Alternative agreement	LACSLink processing continues.	Sending false positive logs to the USPS
Service providers	LACSLink processing continues.	Sending false positive logs to the USPS

Related Information

Alternate stop processing agreements [page 620]
Obtaining LACSLink unlock code from SAP [page 631]
Sending LACSLink false positive logs to the USPS [page 632]

2.16.6.2.2.2 LACSLink false positive logs

The software generates a false-positive log file any time it encounters a false positive record, regardless of how your job is set up. The software creates a separate log file for each mailing list that contains a false positive. If multiple false positives exist within one mailing list, the software writes them all to the same log file.

2.16.6.2.2.2.1 LACSLink log file location

The software stores LACSLink log files in the directory specified for the *USPS Log Path* in the Reference Files group.

> i Note
>
> The USPS log path that you enter must be writable. An error is issued if you have entered a path that is not writable.

The software names LACSLink false positive logs `lacsl`**`<###>`**`.log`, where **`<###>`** is a number between 001 and 999. For example, the first log file generated is `lacsl001.log`, the next one is `lacsl002.log`, and so on.

> i Note
>
> When you have set the data flow degree of parallelism to greater than 1, the software generates one log per thread. During a job run, if the software encounters only one false positive record, one log will be generated. However, if it encounters more than one false positive record and the records are processed on different threads, then the software will generate one log for each thread that processes a false positive record.

Related Information

Performance Optimization Guide: Using parallel execution [page 2137]

2.16.6.2.2.3 LACSLink locking for end users

This locking behavior is applicable for end users or users who are DSF2 licensees that have DSF2 disabled in the job.

When the software finds a false positive address, LACSLink processing is discontinued for the remainder of the job processing. The software takes the following actions:

- Marks the record as a false positive address.
- Issues a message in the error log that a LACSLink false positive address was encountered.
- Includes the false positive address and lock code in the error log.
- Continues processing your data flow without LACSLink processing.
- Generates a lock code.
- Generates a false positive error log.
- Generates a US Regulatory Locking Report that contains the false positive address and the lock code (Report generation must be enabled in the USA Regulatory Address Cleanse transform.

To restore LACSLink functionality, users must obtain a LACSLink unlock code from SAP Support.

2.16.6.2.2.4 Obtaining LACSLink unlock code from SAP

These steps are applicable for end users who do not have a Stop Processing Alternative agreement with the USPS. When you receive a processing message that LACSLink false positive addresses are present in your address list, use the SAP USPS Unlock Utility to obtain an unlock code.

1. Navigate to *https://websmp205.sap-ag.de/bosap-unlock* to open the SAP Service Market Place (SMP) unlock utility page.
2. Click *Retrieve USPS Unlock Code*.
3. Click *Search* and select an applicable Data Services system from the list.
4. Enter the lock code found in the `lacsx.txt` file (location is specified in the *LACSLink Path* option in the Reference Files group).
5. Select LACSLink as the lock type.
6. Select BOJ-EIM-DS as the component.
7. Enter the locking address that is listed in the `lacsx.txt` file.
8. Attach the `lacsl####.log` file (location specified in the *USPS Log Path* option in the Reference Files group).
9. Click *Submit*.
   The unlock code displays.
10. Copy the unlock code and paste it into the `lacsw.txt` file, replacing all contents of the file with the unlock code (location is specified in the *LACSLink path* option in the Reference Files group).

11. Remove the record that caused the lock from the database, and delete the lacsl####.log file before processing the list again.

   > ➜ Tip
   >
   > Keep in mind that you can only use the unlock code once. If the software detects another false-positive (even if it is the same record), you must retrieve a new LACSLink unlock code.

If an unlock code could not be generated, a message is still created and is processed by a Technical Customer Assurance engineer (during regular business hours).

> i Note
>
> If you are an end user who has a Stop Processing Alternative agreement, follow the steps to send the false positive log to the USPS.

2.16.6.2.2.5 Sending LACSLink false positive logs to the USPS

Service providers should follow these steps after receiving a processing message that LACSLink false positive addresses are present in their address list. End users with a Stop Processing Alternative agreement should follow these steps after receiving a processing message that LACSLink false positive addresses are present in their address list.

1. Send an email to the USPS at Dsf2stop@usps.gov. Include the following:
   ○ Type “LACSLink False Positive” as the subject line
   ○ Attach the `lacsl###.log` file or files that were generated by the software (location specified in the *USPS Log Files* option in the Reference Files group).

   The USPS NCSC uses the information to determine whether or not the list can be returned to the mailer.
2. After the USPS NCSC has released the list that contained the locked or false positive record:
   ○ Delete the corresponding log file or files
   ○ Remove the record that caused the lock from the list and reprocess the file

If you are an end user who does not have a Stop Processing Alternative agreement, follow the steps to retrieve the LACSLink unlock code from SAP Support.

Related Information

Obtaining LACSLink unlock code from SAP [page 631]

2.16.6.2.3 How LACSLink works

LACSLink provides a new address when one is available. LACSLink follows these steps when processing an address:

1. The USA Regulatory Address Cleanse transform standardizes the input address.
2. The transform looks for a matching address in the LACSLink data.
3. If a match is found, the transform outputs the LACSLink-converted address and other LACSLink information.

Related Information

To control memory usage for LACSLink processing [page 636]
LACSLink (USA Regulatory Address Cleanse) [page 629]

2.16.6.2.4 Conditions for address processing

The transform does not process all of your addresses with LACSLink when it is enabled. Here are the conditions under which your data is passed into LACSLink processing:

- The address is found in the address directory, and it is flagged as a LACS-convertible record within the address directory.
- The address is found in the address directory, and, even though a rural route or highway contract default assignment was made, the record wasn't flagged as LACS convertible.
- The address is not found in the address directory, but the record contains enough information to be sent into LACSLink.

For example, the following table shows an address that was found in the address directory as a LACS-convertible address.

Original address	After LACSLink conversion
RR2 BOX 204 DU BOIS PA 15801	463 SHOWERS RD DU BOIS PA 15801-66675

2.16.6.2.5 Sample transform configuration

LACSLink processing is enabled by default in the sample transform configuration because it is required for CASS certification. The sample transform configuration is named USARegulatory_AddressCleanse and is found under the USA_Regulatory_Address_Cleanse group in the Object Library.

2.16.6.2.6 LACSLink directory files

SAP ships the LACSLink directory files with the U.S. National Directory update. The LACSLink directory files require about 600 MB of additional hard drive space. The LACSLink directories include the following:

- `lacsw.txt`
- `lacsx.txt`
- `lacsy.ll`
- `lacsz.ll`

⚠ Caution

The LACSLink directories must reside on the hard drive in the same directory as the LACSLink supporting files. Do not rename any of the files. LACSLink will not run if the file names are changed.

2.16.6.2.6.1 Directory expiration and updates

LACSLink directories expire in 105 days. LACSLink directories must have the same date as the other directories that you are using from the U.S. National Directories.

2.16.6.2.7 To enable LACSLink

LACSLink is enabled by default in the USA Regulatory Address Cleanse transform. If you need to re-enable the option, follow these steps:

1. Open the USA Regulatory Address Cleanse transform and open the *Options* tab.
2. Expand the Processing Options group
3. select Yes in the *Enable LACSLink* option.
4. Enter the LACSLink path for the *LACSLink Path* option In the Reference Files group. You can use the substitution variable $$RefFilesAddressCleanse if you have it set up.
5. Complete the required fields in the USPS License Information group.

2.16.6.2.7.1 Required information in the job setup

All users running LACSLink must include required information in the USPS License Information group. The required options include the following:

- Customer Company Name
- Customer Company Address
- Customer Company Locality
- Customer Company Region
- Customer Company Postcode1
- Customer Company Postcode2
- Customer Company Phone

2.16.6.2.7.2 To disable LACSLink

LACSLink is enabled by default in the USA Regulatory Address Cleanse transform configuration because it is required for CASS processing. Therefore, you must disable CASS certification in order to disable LACSLink.

1. In the USA Regulatory Address Cleanse transform configuration, open the *Options* tab.
2. Open the Non Certified Options group.
3. Select Yes for the *Disable Certification* option.
4. Open the Assignment Option group.
5. Select No for the *Enable LACSLink* option.

Related Information

LACSLink® [page 629]

2.16.6.2.7.3 Reasons for errors

If your job setup is missing information in the USPS License Information group, and you have DPV and/or LACSLink enabled in your job, you will get error messages based on these specific situations:

Reason for error	Description
Missing required options	When your job setup does not include the required parameters in the USPS License Information group, and you have DPV and/or LACSLink enabled in your job, the software issues a verification error.
Unwritable Log File directory	If the path that you specified for the *USPS Log Path* option in the Reference Files group is not writable, the software issues an error.

2.16.6.2.8 LACSLink output fields

Several output fields are available for reporting LACSLink processing results.

You must enable LACSLink, and include these output fields in your job setup, before the software posts information to these fields.

Field name	Length	Description
LACSLINK_QUERY	50	Returns the pre-conversion address, populated only when LACSLink is enabled and a LACSLink lookup was attempted.

Field name	Length	Description
		This address will be in the standard USPS format (as shown in USPS Publication 28). However, when an address has both a unit designator and secondary unit, the unit designator is replaced by the character “#”. blank: No LACSLink lookup attempted.
LACSLINK_RETURN_CODE	2	Returns the match status for LACSLink processing: A = LACSLink record match. A converted address is provided in the address data fields. 00 = No match and no converted address. 09 = LACSLink matched an input address to an old address, which is a "high-rise default" address; no new address is provided. 14 = Found a LACSLink record, but couldn't convert the data to a deliverable address. 92 = LACSLink record matched after dropping the secondary number from input address. blank = No LACSLink lookup attempted.
LACSLINK_INDICATOR	1	Returns the conversion status of addresses processed by LACSLink. Y = Address converted by LACSLink (the LACSLink_Return_Code value is A). N = Address looked up with LACSLink but not converted. F = The address was a false-positive. S = LACSLink conversion was made, but it was necessary to drop the secondary information. blank: No LACSLink lookup attempted.

2.16.6.2.9 To control memory usage for LACSLink processing

The transform performance improves considerably if you cache the LACSLink directories. For the amount of disk space required to cache the directories, see the *Supported Platforms* document available in the *SAP Support* › *Documentation* › *Supported Platforms/PARs* section of the SAP Service Marketplace: *http://service.sap.com/bosap-support*.

If you do not have adequate system memory to load the LACSLink directories and the *Insufficient Cache Memory Action* is set to Error, a verification error message is displayed at run-time and the transform terminates. If the Continue option is chosen, the transform attempts to continue LACSLink processing without caching.

Open the *Options* tab of your USA Regulatory Address Cleanse transform configuration in your data flow. Follow these steps to load the LACSLink directories into your system memory:

1. Open the Transform Performance option group.
2. Select Yes for the *Cache LACSLink Directories* option.

Related Information

LACSLink (USA Regulatory Address Cleanse) [page 629]

2.16.6.2.10 LACSLink information in US Addressing Report

The US Addressing Report automatically generates when you have enabled reporting in your job. The following table lists the LACSLink sections in the US Addressing Report:

Section	Information
Locatable Address Conversion (LACSLink) Summary	Record counts and percentages for the following information: • LACSLink converted addresses • Addresses not LACSLink converted
LACSLink Return Codes	Record counts and percentages for the following information: • Converted • Secondary dropped • No match • Can't convert • High-rise default

2.16.6.2.11 USPS Form 3553

The USPS Form 3553 reports LACSLink counts. The LACS/LACSLink field shows the number of records that have a LACSLink Indicator of Y or S, if LACSLink processing is enabled. If LACSLink processing is not enabled, this field shows the number of LACS code count.

2.16.6.3 SuiteLink™

SuiteLink is an option in the USA Regulatory Address Cleanse transform.

SuiteLink uses a USPS directory that contains multiple files of specially indexed address information, such as secondary numbers and unit designators, for locations identified as high-rise default buildings.

With SuiteLink, you can build accurate and complete addresses by adding suite numbers to high-rise business addresses. With the secondary address information added to your addresses, more of your pieces are sorted by delivery sequence and delivered with accuracy and speed.

SuiteLink is required for CASS

SuiteLink is required when you process in CASS mode (and the *Disable certification* option is set to No). If you have disabled SuiteLink in your job setup, but you are in CASS mode, an error message is issued and processing does not continue.

2.16.6.3.1 Benefits of SuiteLink

Businesses that depend on website, mail, or in-store orders from customers will find that SuiteLink is a powerful money-saving tool. Also, businesses that have customers that reside in buildings which house several businesses will appreciate getting their marketing materials, bank statements, and orders delivered right to their door.

The addition of secondary number information to your addresses allows for the most efficient and cost-effective delivery sequencing and postage discounts.

Note

SuiteLink is required for those preparing CASS-compliant mailing lists.

2.16.6.3.2 How SuiteLink works

The software uses the data in the SuiteLink directories to add suite numbers to applicable addresses. The software matches a company name, a known high-rise address, and the CASS-certified postcode2 in your database to data in SuiteLink. When there is a match, the software creates a complete business address that includes the suite number.

Example

Assign suite number

This example shows a record that is processed through SuiteLink, and the output record with the assigned suite number.

The input record contains:

- Firm name (in FIRM input field)
- Known high-rise address
- CASS-certified postcode2

The SuiteLink directory contains:

- secondary numbers
- unit designators

The output record contains:

- the correct suite number

Input record	Output record
Telera 910 E Hamilton Ave Fl2 Campbell CA 95008 0610	TELERA 910 E HAMILTON AVE STE 200 CAMPBELL CA 95008 0625

2.16.6.3.3 SuiteLink directory

The SuiteLink directory is distributed monthly.

You must use SuiteLink directories with a `zip4us.dir` directory for the same month. (Enter the `zip4us.dir` path in the *Address Directory1* option of the Reference Files group in the USA Regulatory Address Cleanse transform.) For example, the December 2011 SuiteLink directory can be used with only the December 2011 `zip4us.dir` directory.

You cannot use a SuiteLink directory that is older than 60 days based on its release date. The software warns you 15 days before the directory expires. As with all directories, the software won't process your records with an expired SuiteLink directory.

2.16.6.3.4 To enable SuiteLink

SuiteLink is enabled by default in any of the sample transform configurations that are set up to be CASS-compliant (and the Disable certification option is set to No). For example, SuiteLink is enabled if you use the USA Regulatory_AddressCleanse sample transform configuration.

1. Open the USA Regulatory Address Cleanse transform in your data flow.
2. Open the *Options* tab.
3. Expand the Assignment Options group and set the *Enable SuiteLink* option to Yes.
4. In the Reference Files group, enter the SuiteLink directory path in the *SuiteLink Path* option. You can use the substitution variable $$RefFilesAddressCleanse if you have it set up with the directory location that contains your SuiteLink directories.
5. Optional: In the Transform Performance option group, set the *Cache SuiteLink Directories* option to Yes so that the SuiteLink directories are cached in memory.

   ℹ Note

   Ensure that you have sufficient RAM to cache the SuiteLink directories before you enable this option.

2.16.6.3.5 Improve processing speed

You may increase SuiteLink processing speed if you load the SuiteLink directories into memory. To activate this option, go to the Transform Performance group and set the *Cache SuiteLink Directories* to Yes.

2.16.6.3.6 SuiteLink return codes in US Addressing Report

SuiteLink return code information is available in the SuiteLink Return Codes section of the US Addressing Report.

The US Addressing Report shows the record count and percentage for the following return codes:

A = Secondary exists and assignment made

00 = Lookup was attempted but no assignment

2.16.6.4 USPS DSF2®

DSF2 is a USPS-licensed product that you can use to validate addresses, add delivery sequence information, and add DSF2 address attributes to addresses.

Two DSF2 features are supported in Data Services:

- DSF2 Augment in the USA Regulatory Address Cleanse transform
- DSF2 Walk Sequence in the DSF2 Walk Sequencer transform

> Note
>
> USPS DSF2 data is available only to USPS-certified DSF2 licensees.

Related Information

DSF2 Walk sequencing [page 645]

2.16.6.4.1 Validate addresses

DSF2 helps reduce the quantity of undeliverable-as-addressed (UAA) mail and keeps mailing costs down. DSF2 uses DPV® to validate addresses and identify inaccurate or incomplete addresses.

Related Information

DPV overview [page 618]

2.16.6.4.2 Add address attributes

DSF2 adds address attributes (information about the addresses) to your data. Use the attribute information to create more targeted mailings.

2.16.6.4.3 Add delivery sequence information

DSF2 adds delivery sequence information to your data, which you can use to qualify for walk-sequence discounts. This information is sometimes called walk sequencing or pseudo sequencing.

Related Information

Walk sequencing [page 645]
Pseudo sequencing [page 646]

2.16.6.4.4 Benefits of DSF2

Those who want to target their mail to specific types of addresses and those who want to earn additional postal discounts will appreciate what DSF2 can do.

The DSF2 address-attribute data provides mailers with knowledge about the address above and beyond what is necessary to accurately format the addresses. Address-attribute data allows mailers to produce more targeted mailings.

For example, If you plan to send out a coupon for your lawn-care service business, you do not want to send it to apartment dwellers (they may not have a lawn). You want your coupon to go to residential addresses that are not centralized in an apartment building.

With the DSF2 information you can walk-sequence your mailings to achieve the best possible postal discounts by using the DSF2 Walk Sequencer transform.

2.16.6.4.5 Becoming a DSF2 licensee

Before you can perform DSF2 processing in the software, you must complete the USPS DSF2 certification procedures and become licensed by the USPS.

Part of certification is processing test jobs in Data Services to prove that the software complies with the license agreement. When you are ready to take these tests, contact SAP BusinessObjects Business User Support to obtain access to the DSF2 features in Data Services.

Related Information

Reference Guide: DSF2 license process [page 1392]

2.16.6.4.6 DSF2 directories

DSF2 processing requires the following data:

Data	Notes
DPV directories	The software uses DPV directories to verify addresses and identify inaccurate addresses. SAP supplies the DPV directories with the U.S. National Directory delivery. Note DPV directories are included with the DSF2 tables. Do not use the DPV directories included with the DSF2 tables. Use the DPV directories from SAP with the U.S. National Directory delivery.
eLOT directories	The software uses eLOT directories to assign walk sequence numbers. SAP supplies the eLOT directories with the U.S. National Directory delivery. Note eLOT directories are included with the DSF2 tables. Do not use the eLOT directories included with the DSF2 tables. Use the eLOT directories from SAP with the U.S. National Directory delivery.
DSF2 tables	The software uses DSF2 tables to assign address attributes. Note DSF2 tables are supplied by the USPS and not SAP. In addition, the DSF2 tables include DPV and eLOT directories. Do not use the DPV and eLOT directories included with the DSF2 tables. Use the DPV and eLOT directories from SAP with the U.S. National Directory delivery.
Delivery statistics file	The software uses the delivery statistics file to provide counts of business and residential addresses per ZIP Code (Postcode1) per Carrier Route (Sort-

Data	Notes
	code). SAP supplies the delivery statistics file with the U.S. National Directory delivery.

You must specify the location of these directory files in the USA Regulatory Address Cleanse transform, except for the delivery statistics file. Set the location of the delivery statistics file (dsf.dir) in the DSF2 Walk Sequencer transform. Also, to meet DSF2 requirements, you must install updated directories monthly.

2.16.6.4.7 DSF2 augment processing

Set up DSF2 augment processing in the USA Regulatory Address Cleanse transform.

DSF2 processing requires DPV information, therefore, enable DPV in your job setup.

If you plan to use the output information from the DSF2 augment processing for walk sequence processing, you must also enable eLOT.

> ℹ Note
>
> DSF2 augment is available only in batch mode. You cannot add augment information to your data in real time.

2.16.6.4.7.1 DSF2 Augment directory expiration

The DSF2 directories are distributed monthly. You must use the DSF2 directories with U.S. National directories that are labeled for the same month. For example, the May 2011 DSF2 directories can be used with only the May 2011 National directories.

The DSF2 Augment data expires in 60 days instead of the 105 day expiration for the U.S. National directories. Because directories must all have the same base date (MM/YYYY), DSF2 users who have Yes set for the Enable DSF2 Augment option must update all of the U.S. National directories and other directories they use (for example, LACSLink or DPV) at the same time as the DSF2 Augment directories. The software will remind users to update the directories with a warning message that appears 15 days before the directory expires.

> ➔ Remember
>
> As with all directories, the software will not process your records with expired DSF2 directories.

2.16.6.4.7.2 Identify the DSF2 licensee

When you perform DSF2 processing, you must provide the following information: The DSF2-licensed company and the client for whom the company is processing this job.

You must complete the following options in the USPS License Information group for DSF2 processing:

- DSF2 Licensee ID
- Licensee Name
- List Owner NAICS Code
- List ID
- Customer Company Name
- Customer Company Address
- Customer Company Locality
- Customer Company Region
- Customer Company Postcode1
- Customer Company Postcode2
- List Received Date
- List Return Date

> ℹ Note
>
> If you are performing DSF2 and NCOALink processing in the same instance of the USA Regulatory Address Cleanse transform, then the information that you enter in the USPS License Information group must apply to both DSF2 and NCOALink processing. If, for example, the *List ID* is different for DSF2 and NCOALink, you will need to include two USA Regulatory Address Cleanse transforms: One for NCOALink and another for DSF2.

2.16.6.4.7.3 To enable DSF2 Augment

Before you can process with DSF2, you must first become a certified licensee.

In addition to the required customer company information that you enter into the USPS License Information group, set the following options to perform DSF2 Augment processing:

1. In the USA Regulatory Address Cleanse transform, open the *Options* tab.
2. Expand the Report and Analysis group and set the *Generate Report Data* option to Yes.
3. Expand the Reference Files group and enter the path for the options *DSF2 Augment Path*, *DPV Path*, and *eLOT Directory*, or use the $$RefFilesAddressCleanse substitution variable if you have it set up.
4. Also in the Reference Files group, enter a path for the *USPS Log Path* option, or use the $ $CertificationLogPath substitution variable if you have it set up.
5. Optional. Expand the Transform Performance group and set the *Cache DPV Directories* and *Cache DSF2 Augment Directories* to Yes.
6. Expand the Assignment Options group and set the *Enable DSF2 Augment*, *Enable DPV*, and *Enable eLOT* to Yes.
7. Include the DSF2 address attributes output fields in your output file setup.

2.16.6.4.7.4 DSF2 output fields

When you perform DSF2 Augment processing in the software, address attributes are available in the following output fields for every address that was assigned. Be sure to include the fields containing information you'll need in your output file setup:

- DSF2_Business_Indicator
- DSF2_Delivery_Type
- DSF2_Drop_Count
- DSF2_Drop_Indicator
- DSF2_Educational_Ind
- DSF2_LACS_Conversion_Ind
- DSF2_Record_Type
- DSF2_Seasonal_Indicator
- DSF2_Throwback_Indicator

> ℹ Note
>
> A blank output in any of these fields means that the address was not looked up in the DSF2 directories.

Related Information

Reference Guide: Data Quality fields, USA Regulatory Address Cleanse fields [page 1349]

2.16.6.4.7.5 Improve processing speed

You can cache DSF2 data to improve DSF2 processing speed.

To cache DSF2 data, Set the *Cache DSF2 Augment Directories* option in the Transform Performance group to Yes. The software caches only the directories needed for adding address attributes.

2.16.6.4.8 DSF2 walk sequencing

When you perform DSF2 walk sequencing in the software, the software adds delivery sequence information to your data, which you can use with presorting software to qualify for walk-sequence discounts.

> ➜ Remember
>
> The software does not place your data in walk sequence order.

Include the DSF2 Walk Sequencer transform to enable walk sequencing.

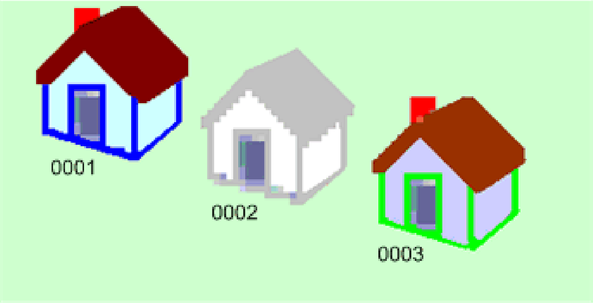
Related Information

Reference Guide: Transforms, Data Quality transforms, DSF2® Walk Sequencer [page 1172]

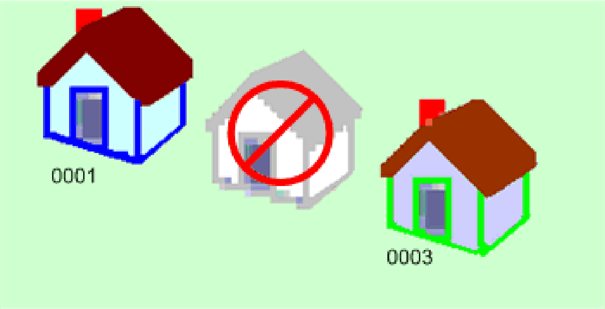
2.16.6.4.8.1 Pseudo sequencing

DSF2 walk sequencing is often called pseudo sequencing because it mimics USPS walk sequencing. Where USPS walk-sequence numbers cover every address, DSF2 processing provides pseudo sequence numbers for only the addresses in that particular file.

Walk sequencing includes every U.S. address, whether or not they're included in your list or mailing.



Pseudo sequencing includes only the addresses in your list. In the illustration below, assume the middle house is not included in your list.



The software uses DSF2 data to assign sequence numbers for all addresses that are DPV-confirmed delivery points (DPV_Status = Y). Other addresses present in your output file that are not valid DPV-confirmed delivery points (DPV_Status = S, N, or D) will receive "0000" as their sequence number. All other addresses will have a blank sequence number.

> Note
>
> When you walk-sequence your mail with the software, remember the following points:
>
> - (Batch only.) DSF2 walk sequencing is available only in batch mode. You cannot assign sequence numbers in real time.
> - Reprocess if you have made file changes. If your data changes in any way, you must re-assign sequence numbers. Sequence numbers are valid only for the data file as you process it at the time.

2.16.6.4.9 Break key creation

Break keys create manageable groups of data. They are created when there are two or more fields to compare.

The DSF2 Walk Sequencer transform automatically forms break groups before it adds walk sequence information to your data. The software creates break groups based on the Postcode1 and Sortcode_Route fields.

Set options for how you want the software to configure the fields in the Data Collection Config group. Keeping the default settings optimizes the data flow and allows the software to make the break key consistent throughout the data.

Option	Default value
Replace NULL with space	Yes

Option	Default value
Right pad with spaces	Yes

2.16.6.4.10 Enable DSF2 walk sequencing

To enable DSF2 walk sequence, include the DSF2 Walk Sequencer transform in your data flow.

2.16.6.4.10.1 Required information

When you set up for DSF2 walk sequence processing, the following options in the USPS License Information group are required:

- Licensee Name
- DSF2 Licensee ID
- List ID

2.16.6.4.10.2 To enable DSF2 walk sequencing

The input file for the DSF2 Walk Sequencer transform must have been pre-processed with CASS-certified software (such as the USA Regulatory Address Cleanse transform). To obtain an additional postage discount, include the DSF2_Business_Indicator output field information from CASS-certified software.

In addition to the required USPS License Information fields, make the following settings in the DSF2 Walk Sequencer transform:

1. Optional. Select Yes or No in the Common group, *Run as Separate Process* option. Select No if you are gathering DSF2 statistics. Select Yes to save processing time (if you don't need DSF2 statistics).
2. Enter the file path and file name (dsf.dir) to the Delivery Statistics directory in the *DelStats Directory* option in the Reference Files group. You may use the $$RefFilesAddressCleanse substitution parameter if you have it set up.
3. Enter the processing site location in the *Site Location* option of the Processing Options group. This is applicable only if you have more than one site location for DSF2 processing.
4. Make the following settings in the Data Collection Configuration group:
   - Select Yes or No in the *Replace Null With Space* option as desired.
   - Select Yes or No for the *Right Pad With Spaces* option as desired.
   - Select Yes or No for the *Pre Sorted Data* option (optional). We recommend that you keep the default setting of No so that Data Services sorts your data based on the break key fields (instead of using another software program).

2.16.6.4.11 DSF2 walk sequence input fields

Here is a list of the DSF2 walk sequence input fields.

> Note
>
> These fields must have been output from CASS-certified software processing before they can be used as input for the DSF2 Walk Sequencer transform:

- Postcode1
- Postcode2
- Sortcode_Route
- LOT
- LOT_Order
- Delivery_Point
- DPV_Status
- DSF2_Business_Indicator (optional)

The software uses the information in these fields to determine the way the records should be ordered (walk sequenced) if they were used in a mailing list. The software doesn't physically change the order of your database. The software assigns walk-sequence numbers to each record based on the information it gathers from these input fields.

> Note
>
> All fields are required except for the DSF2_Business_Indicator field.

The optional DSF2_Business_Indicator field helps the software determine if the record qualifies for saturation discounts. Saturation discounts are determined by the percentage of residential addresses in each carrier route. See the *USPS Domestic Mail Manual* for details about all aspects of business mailing and sorting discounts.

Related Information

Reference Guide: Transforms, DSF2® Walk Sequencer, Input fields [page 1176]

2.16.6.4.12 DSF2 walk-sequence output fields

The software outputs walk-sequence number information to the following fields:

- Active_Del_Discount
- Residential_Sat_Discount
- Sortcode_Route_Discount
- Walk_Sequence_Discount
- Walk_Sequence_Number

Related Information

Reference Guide: Data Quality fields, DSF2 Walk Sequencer, DSF2 Walk Sequencer output fields [page 1177]

2.16.6.4.13 DSF2 reporting

There are reports and log files that the software generates for DSF2 augment and walk sequencing.

Find complete information about these reports and log files in the *Management Console Guide*.

Delivery Sequence Invoice Report

The USPS requires that you submit the Delivery Sequence Invoice report if you claim DSF2 walk-sequence discounts for this job.

US Addressing Report

- The US Addressing Report is generated by the USA Regulatory Address Cleanse transform.
- The Second Generation Delivery Sequence File Summary and Address Delivery Types sections of the US Addressing Report shows counts and percentages of addresses in your file that match the various DSF2 categories (if NCOALink is enabled). The information is listed for pre and post NCOALink processing.

DSF2 Augment Statistics Log File

The USPS requires that DSF2 licensees save information about their processing in the DSF2 log file. The USPS dictates the contents of the DSF2 log file and requires that you submit it to them monthly.

Log files are available to users with administrator or operator permissions.

Related Information

Management Console Guide: Administrator, Administrator management, Exporting DSF2 certification log [page 1877]
Management Console Guide: Data Quality reports, Delivery Sequence Invoice Report [page 2001]
Management Console Guide: Data Quality reports, US Addressing Report [page 2003]

2.16.6.4.13.1 DSF2 Augment Statistics Log File

The DSF2 Augment Statistics Log File is stored in the repository. The software generates the log file to the repository where you can export them by using the Data Services Management Console (for Administrators or Operators only).

The naming format for the log file is as follows:

```
[DSF2_licensee_ID][mm][yy].dat
```

The USPS dictates the contents of the DSF2 log file and requires that you submit it to them monthly. For details, read the *DSF2 Licensee Performance Requirements* document, which is available on the USPS RIBBS website (*http://ribbs.usps.gov/dsf2/documents/tech_guides*).

You must submit the DSF2 log file to the USPS by the third business day of each month by e-mail.

Log file retention and automatic deletion

You must submit the Augment Statistics Log File to the USPS every month. The software deletes log files on a periodic basis (default is 30 days), which can be controlled through Data Services Application Settings in the Central Management Console. To avoid losing monthly log information, set the *History Retention Period* to more than 31 days (we recommend a setting of 50 days).

In addition to sending monthly log files to the USPS, you are required to have the data available for the USPS to examine for several years after the job is processed. (Make sure you are aware of current USPS rules for data retention by checking your USPS licensing agreement.) To ensure that you retain all required reports and logs before the data is deleted from the repository, we recommend that you export the required reports and logs from the repository to a local folder on a monthly basis. This also prevents the repository contents from becoming so large that the export process “times out” due to the volume of statistics retained.

2.16.6.5 NCOALink® overview

The USPS Move Update standard helps users and the USPS to reduce the number of records that are returned because the address is out of date. NCOALink is a part of this effort. Move Updating is the process of checking addresses against the National Change of Address (NCOA) database to make sure your data is updated with current addresses.

When you process your data using NCOALink, you update your records for individuals or businesses that have moved and have filed a Change of Address (COA) form with the USPS. Other programs that are a part of Move

Update, and that are supported in the USA Regulatory Address Cleanse transform, include ANKLink®, and SuiteLink®.

The USPS requires that your lists comply with Move Update standards in order for it to qualify for the discounted postal rates available for First-Class presorted mailings. You can meet this requirement through the NCOALink process.

> Note
>
> Mover ID is the name under which SAP Data Services is certified for NCOALink.

Related Information

ANKLink overview [page 655]
SuiteLink™ [page 637]

2.16.6.5.1 The importance of move updating

The USPS requires move updating on all First Class presorted mailings. To help mailers meet this requirement, the USPS offers certain options, including NCOALink.

To keep accurate address information for your contacts, you must use a USPS method for receiving your contacts' new addresses. Not only is move updating good business, it is required for all First-Class mailers who claim presorted or automation rates. As the USPS expands move-updating requirements and more strictly enforces the existing regulations, move updating will become increasingly important.

Related Information

ANKLInk [page 655]

2.16.6.5.2 Benefits of NCOALink

By using NCOALink in the USA Regulatory Address Cleanse transform, you are updating the addresses in your lists with the latest move data. With NCOALink, you can:

- Improve mail deliverability.
- Reduce the cost and time needed to forward mail.
- Meet the USPS move-updating requirement for presorted First Class mail.
- Prepare for the possible expansion of move-update requirements.

2.16.6.5.3 How NCOALink works

When processing addresses with NCOALink enabled, the software follows these steps:

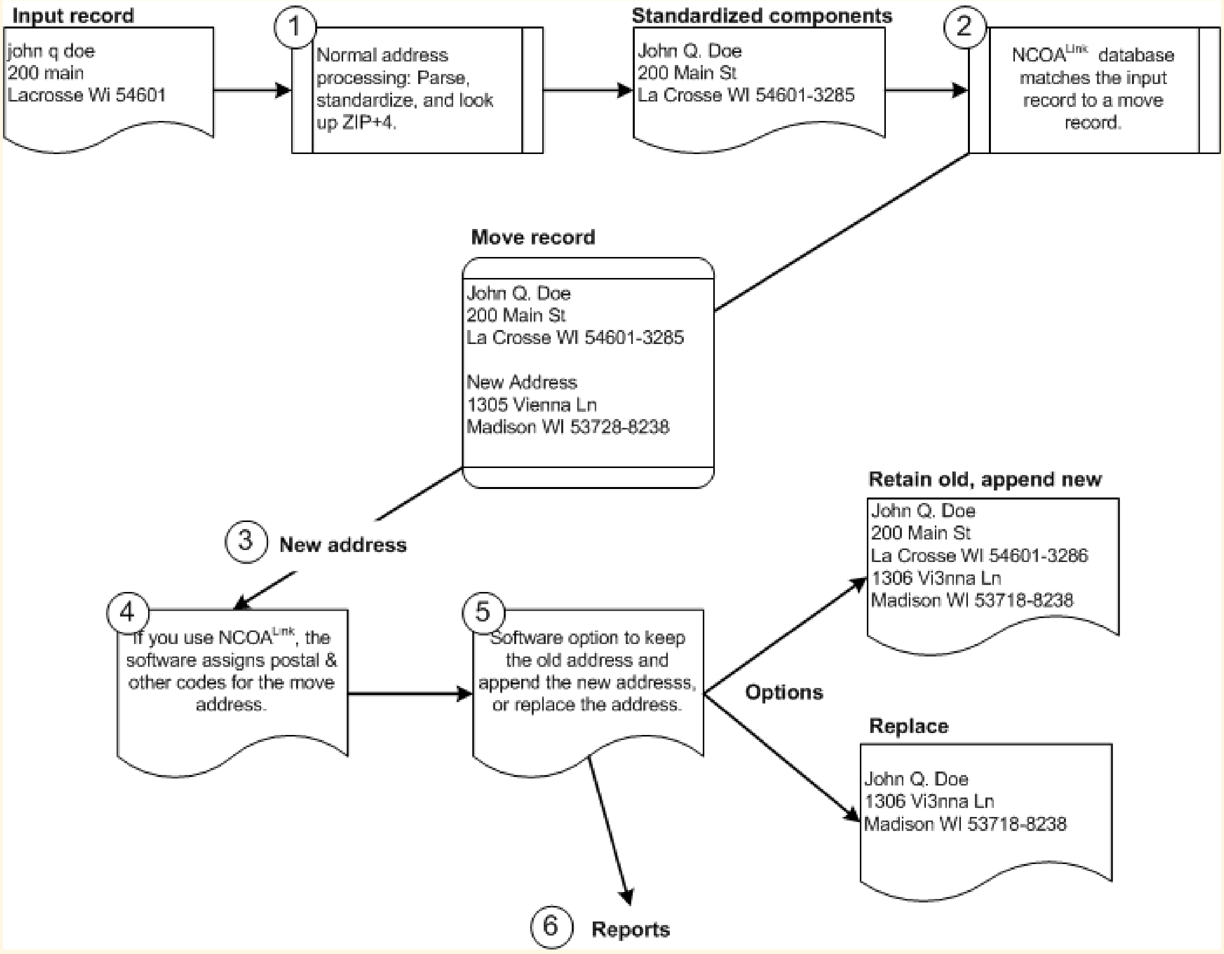
1. The USA Regulatory Address Cleanse transform standardizes the input addresses. NCOALink requires parsed, standardized address data as input.
2. The software searches the NCOALink database for records that match your parsed, standardized records.
3. If a match is found, the software receives the move information, including the new address, if one is available.
4. The software looks up move records that come back from the NCOALink database to assign postal and other codes.
5. Depending on your field class selection, the output file contains:
    - The original input address. The complete and correct value found in the directories, standardized according to any settings that you defined in the Standardization Options group in the Options tab. (CORRECT)
    - The address components that have been updated with move-updated address data. (MOVE-UPDATED)

      Note

      The transform looks for the move-updated address information in the U.S. National Directories. When the move-updated address is not found in the U.S. National Directories, the software populates the Move Updated fields with information found in the Move Update Directories only. The Move Updated fields that are populated as a result of standardizing against the U.S. National Directories will not be updated.
    - The move-updated address data if it exists and if it matches in the U.S. National directories. Or the field contains the original address data if a move does not exist or if the move does not match in the U.S. National Directories. (BEST)

    Based on the *Apply Move to Standardized Fields* option in the NCOALink group, standardized components can contain either original or move-updated addresses.
6. The software produces the reports and log files required for USPS compliance.

Example



1. NCOALink requires parsed, standardized address data as input. Therefore, before NCOALink processing, the software performs its normal processing on the address data.
2. The software searches the NCOALink database for a record that matches your parsed, standardized record.
3. The software receives the move information, including the new address if one is available.
4. The software looks up the move record that comes back from the NCOALink database, to assign postal and other codes.
5. At your option, the software can either retain the old address and append the new, or replace the old address with the new.
6. The software produces the reports and log files that you will need for USPS compliance.

2.16.6.5.4 NCOALink provider levels

NCOALink users fall in one of three categories of providers. Specify the service provider in the USPS License Information group of options under *Provider Level*.

Note

Only provider levels supported in your registered keycodes display in the selection list.

Provider level	Description
Full Service Provider (FSP)	Provides NCOALink processing to third parties.
Limited Service Provider (LSP)	Provides NCOALink processing to third parties and internally.
End User Mailer (EUM)	Provides NCOALInk processing to in-house lists only.

2.16.6.5.5 NCOALink brokers and list administrators

An NCOALink user may have a broker or list administrator who owns the lists they are processing. When there is a broker or list administrator involved, add contact information in the NCOALink group under *Contact Detail list* › *Contact Details*.

Broker

A broker directs business to an NCOALink service provider.

List administrator

A list administrator maintains and stores lists. List administrators are different than brokers in two ways:

- List administrators don't send move-updated files back to the list owner.
- List administrators may have an NCOALink license.

If a list administrator, a broker, or both are involved in your job, you must complete Contact Detail List for each of them separately. You can duplicate a group of options by right-clicking the group name and choosing *Duplicate Option*.

2.16.6.5.6 Address not known (ANKLink)

Undeliverable-as-addressed (UAA) mail costs the mailing industry and the USPS a lot of money each year. The software provides NCOALink as an additional solution to UAA mail. With NCOALink, you also can have access to the USPS's ANKLink data.

2.16.6.5.6.1 About ANKLink

NCOALink limited service providers and end users receive change of address data for the preceding 18 months. The ANKLink option enhances that information by providing additional data about moves that occurred in the previous months 19 through 48.

> ➜ Tip
>
> If you are an NCOALink full service provider you already have access to the full 48 months of move data (including the new addresses).

> i Note
>
> The additional 30 months of data that comes with ANKLink indicates only that a move occurred and the date of the move; the new address is not provided.

The ANKLink data helps you make informed choices regarding a contact. If the data indicates that the contact has moved, you can choose to suppress that contact from the list or try to acquire the new address from an NCOALINK full service provider.

If you choose to purchase ANKLink to extend NCOALINK information, then the DVD you receive from the USPS will contain both the NCOALink 18-month full change of address information and the additional 30 month ANKLink information which indicates that a move has occurred.

If an ANKLink match exists, it is noted in the ANKLINK_RETURN_CODE output field and in the NCOALink Processing Summary report.

2.16.6.5.6.2 ANKLink data

ANKLink is a subset of NCOALink. You can request ANKLink data from the USPS National Customer Support Center (NCSC) by calling 1-800-589-5766 or by e-mail at ncoalink@usps.gov. ANKLink data is not available from SAP.

The software detects if you're using ANKLink data. Therefore, you do not have to specify whether you're using ANKLink in your job setup.

2.16.6.5.6.3 ANKLink support for NCOALink provider levels

The software supports three NCOALink provider levels defined by the USPS. Software options vary by provider level and are activated based on the software package that you purchased. The following table shows the provider levels and support:

Provider level	Provide service to third parties	COA data (months)	Data received from USPS	Support for ANKLink
Full Service Provider (FSP)	Yes Third party services must be at least 51% of all processing.	48	Weekly	No (no benefit)
Limited Service Provider (LSP)	Yes LSPs can both provide services to third parties and use the product internally.	18	Weekly	Yes
End User Mailer (EUM)	No	18	Monthly	Yes

➡ Tip

If you are an NCOALink EUM, you may request a stop processing alternative agreement from the USPS. After you are approved by the USPS you may purchase the software's stop processing alternative functionality which allows DPV and LACSLink processing to continue after a false positive address record is detected.

Related Information

Stop Processing Alternative Agreement [page 620]

2.16.6.5.7 Software performance

In our tests, the software ran slower with NCOALink enabled than with it disabled. Your processing speed depends on the computer running the software and the percentage of input records affected by a move (more moves equals slower performance).

Related Information

Improve NCOALink processing performance [page 660]

2.16.6.5.8 Getting started with NCOALink

Before you begin NCOALink processing you need to perform the following tasks:

- Complete the USPS certification process to become an NCOALink service provider or end user. For information about certification, see the NCOALink Certification section following the link below.
- Understand the available output strategies and performance optimization options.
- Configure your job.

2.16.6.5.9 What to expect from the USPS and SAP

NCOALink, and the license requirements that go with it, has created a new dimension in the relationship among mailers (you), the USPS, and vendors. It's important to be clear about what to expect from everyone.

2.16.6.5.9.1 Move updating is a business decision for you to make

NCOALink offers an option to replace a person's old address with their new address. You as a service provider must decide whether you accept move updates related to family moves, or only individual moves. The USPS recommends that you make these choices only after careful thought about your customer relationships. Consider the following examples:

- If you are mailing checks, account statements, or other correspondence for which you have a fiduciary responsibility, then move updating is a serious undertaking. The USPS recommends that you verify each move by sending a double postcard, or other easy-reply piece, before changing a financial record to the new address.
- If your business relationship is with one spouse and not the other, then move updating must be handled carefully with respect to divorce or separation. Again, it may make sense for you to take the extra time and expense of confirming each move before permanently updating the record.

2.16.6.5.9.2 NCOALink security requirements

Because of the sensitivity and confidentiality of change-of-address data, the USPS imposes strict security procedures on software vendors who use and provide NCOALink processing.

One of the software vendor's responsibilities is to check that each list input to the USA Regulatory Address Cleanse transform contains at least 100 unique records. Therefore the USA Regulatory Address Cleanse transform checks your input file for at least 100 unique records. These checks make verification take longer, but they are required by the USPS and they must be performed.

If the software finds that your data does not have 100 unique records, it issues an error and discontinues processing.

The process of checking for 100 unique records is a pre-processing step. So if the software does not find 100 unique records, there will be no statistics output or any processing performed on the input file.

Related Information

Desinger Guide: Getting started with NCOALink [page 656]

2.16.6.5.9.2.1 How the software checks for 100 unique records

When you have NCOALink enabled in your job, the software checks for 100 unique records before any processing is performed on the data. The software checks the entire database for 100 unique records. If it finds 100 unique records, the job is processed as usual. However, if the software does not find 100 unique records, it issues an error stating that your input data does not have 100 unique records, or that there is not enough records to determine uniqueness.

For the 100 unique record search, a record consists of all mapped input fields concatenated in the same order as they are mapped in the transform. Each record must be identical to another record for it to be considered alike (not unique).

Example

Comparing records

The example below illustrates how the software concatenates the fields in each record, and determines non-unique records. The first and last row in this example are not unique.

332	FRONT	STREET	NORTH	LACROSSE	WI	54601
332	FRONT	STREET	SOUTH	LACROSSE	WI	54601
331	FRONT	STREET	SOUTH	LACROSSE	WI	54601
332	FRONT	STREET	NORTH	LACROSSE	WI	54601

2.16.6.5.9.2.2 Finding unique records in multiple threads

Sometimes input list have 100 unique records but the user still receives an error message stating that the list does not have 100 unique records. This can happen when there is a low volume of data in lists. To work around this problem, users can adjust the Degree of Parallelism (DOP) setting in their job.

Low volume of data and DOP > 1

When an NCOALink job is set up with the DOP greater than 1, each thread checks for unique records within the first collection it processes and shares knowledge of the unique records it found with all other threads. The first thread to finish processing it's collection counts the unique records found by all threads up to that point in time and makes a decision regarding whether or not the 100 record minimum check has been satisfied. That thread may not necessarily be thread 1. For example, say your list has 3,050 records and you have the DOP set for 4. If the number of records per collection is 1000, each thread will have a collection of 1000 records except for the last thread which will only have 50 records. The thread processing 50 records is likely to finish its collection sooner and it may make the pass/fail decision before 100 unique records have been encountered. You may be able to successfully run this job if you lower the DOP. In this example, you could lower it to 3.

2.16.6.5.10 About the NCOALink daily delete file

If you are a service provider, then every day before you perform NCOALink processing, you must download the daily delete file and install it in the same folder that your NCOALink directories are located.

The daily delete file contains records that are pending deletion from the NCOALink data. For example, if Jane Doe filed a change of address with the USPS and then didn’t move, Jane’s record would be in the daily delete file. Because the change of address is stored in the NCOALink directories, and they are updated only weekly or monthly, the daily delete file is needed in the interim, until the NCOALink directories are updated again.

Download the daily delete file from the USPS's electronic product fulfillment website at *https://epf.usps.gov/* . Before you can access the file, you must complete and submit the Electronic Product Fulfillment Web Access Request Form (Form 5116) to the USPS. You can obtain this form from the same website.

> Note
>
> If you are an end user, you only need the daily delete file for processing Stage I or II files. It is not required for normal NCOALink processing.

Here are some important points to know about the daily delete file:

- The software will fail verification if NCOALink is enabled, a stage test is being performed, and the daily delete file isn't installed.
- USA Regulatory Address Cleanse transform supports only the ASCII version of the daily delete file.
- Do not rename the daily delete file. It must be named `dailydel.dat`.
- The software will issue a verification warning if the daily delete file is more than three days old.

2.16.6.5.10.1 To install the NCOALink daily delete file

To download and install the NCOALink daily delete file, follow these steps:

1. Go to the USPS Electronic Product Fulfillment site at *https://epf.usps.gov/* .
2. Before you download the daily delete file for the first time, you must complete and fax the PS Form 5116 (Electronic Product Fulfillment Web Access Request Form) to the USPS Licensing Department.

   When completing the form, make sure that you select the NCOALink or NCOALink with ANKLink option, as appropriate. This allows you to access the daily delete file.
3. Log into the USPS Electronic Product Fulfillment site and download the NCOALink Daily Delete [TEXT] file to a location where the `.tar` file can be extracted. If your computer browser has pop-up blockers enabled, you may need to override them.

4. Extract the `dailyDeletes_txt.tar` file.
5. Copy the `dailydel.dat` file to the same location where your NCOALink directories are stored.
6. Repeat steps 3–5 every day before you perform NCOALink processing.

2.16.6.5.11 Output file strategies

You can configure your output file to meet your needs. Depending on the Field Class Selection that you choose, components in your output file contain Correct, Move-updated, or Best information:

- CORRECT: Outputs the original input address. The complete and correct value found in the directories, standardized according to any settings that you defined in the Standardization Options group in the Options tab. (CORRECT)
- MOVE-UPDATED: Outputs the address components that have been updated with move-updated address data.

  > Note
  >
  > The transform looks for the move-updated address information in the U.S. National Directories. When the move-updated address is not found in the U.S. National Directories, the software populates the Move Updated fields with information found in the Move Update Directories only. The Move Updated fields that are populated as a result of standardizing against the U.S. National Directories will not be updated.

- BEST: Outputs the move-updated address data if it exists and if it matches in the U.S. National directories. Or the field contains the original address data if a move does not exist or if the move does not match in the U.S. National Directories.

Based on the *Apply Move to Standardized Fields* option setting in the NCOA option group, standardized components can contain original or move-updated addresses.

By default the output option *Apply Move to Standardized Fields* is set to Yes and the software updates standardized fields to contain details about the updated address available through NCOALink.

If you want to retain the old addresses in the standardized components and append the new ones to the output file, you must change the *Apply Move to Standardized Fields* option to No. Then you can use output fields such as NCOALINK_RETURN_CODE to determine whether a move occurred. One way to set up your output file is to replicate the input file format, then append extra fields for move data. In the output records not affected by a move, most of the appended fields will be blank. Alternatively, you can create a second output file specifically for move records. Two approaches are possible:

- Output each record once, placing move records in the second output file and all other records in the main output file.
- Output move records twice; once to the main output file, and a second time to the second output file.

Both of these approaches require that you use an output filter to determine whether a record is a move.

2.16.6.5.12 Improving NCOALink processing performance

Many factors affect performance when processing NCOALink data. Generally the most critical factor is the volume of disk access that occurs. Often the most effective way to reduce disk access is to have sufficient memory available to cache data. Other critical factors that affect performance include hard drive speed, seek time, and the sustained transfer rate. When the time spent on disk access is minimized, the performance of the CPU becomes significant.

Related Information

Finding unique records in multiple threads [page 658]

2.16.6.5.12.1 Operating systems and processors

The computation involved in most of the software and NCOALink processing is very well-suited to the microprocessors found in most computers, such as those made by Intel and AMD. RISC style processors like those found in most UNIX systems are generally substantially slower for this type of computation. In fact a common PC can often run a single job through the software and NCOALink about twice as fast as a common UNIX system. If you're looking for a cost-effective way of processing single jobs, a Windows server or a fast workstation can produce excellent results. Most UNIX systems have multiple processors and are at their best processing several jobs at once.

You should be able to increase the degree of parallelism (DOP) in the data flow properties to maximize the processor or core usage on your system. Increasing the DOP depends on the complexity of the data flow.

2.16.6.5.12.2 Memory

NCOALink processing uses many gigabytes of data. The exact amount depends on your service provider level, the data format, and the specific release of the data from the USPS.

In general, if performance is critical, and especially if you are an NCOALink full service provider and you frequently run very large jobs with millions of records, you should obtain as much memory as possible. You may want to go as far as caching the entire NCOALink data set. You should be able to cache the entire NCOALink data set using 20 GB of RAM, with enough memory left for the operating system.

2.16.6.5.12.3 Data storage

If at all possible, the hard drive you use for NCOALink data should be fully dedicated to that process, at least while your job is running. Other processes competing for the use of the same physical disk drive can greatly reduce your NCOALink performance.

To achieve even higher transfer rates you may want to explore the possibility of using a RAID system (redundant array of independent discs).

When the software accesses NCOALink data directly instead of from a cache, the most significant hard drive feature is the average seek time.

2.16.6.5.12.4 Data format

The software supports both hash and flat file versions of NCOALink data. If you have ample memory to cache the entire hash file data set, that format may provide the best performance. The flat file data is significantly smaller, which means a larger share can be cached in a given amount of RAM. However, accessing the flat file data involves binary searches, which are slightly more time consuming than the direct access used with the hash file format.

2.16.6.5.12.5 Memory usage

The optimal amount of memory depends on a great many factors. The “Auto” option usually does a good job of deciding how much memory to use, but in some cases manually adjusting the amount can be worthwhile.

2.16.6.5.12.6 Performance tips

Many factors can increase or decrease NCOALink processing speed. Some are within your control and others may be inherent to your business. Consider the following factors:

- Cache size—Using too little memory for NCOALink caching can cause unnecessary random file access and time-consuming hard drive seeks. Using far too much memory can cause large files to be read from the disk into the cache even when only a tiny fraction of the data will ever be used. The amount of cache that works best in your environment may require some testing to see what works best for your configuration and typical job size.
- Directory location—It’s best to have NCOALink directories on a local solid state drive or a virtual RAM drive. Using a local solid state drive or virtual RAM drive eliminates all I/O for NCOALink while processing your job. If you have the directories on a hard drive, it’s best to use a defragmented local hard drive. The hard drive should not be accessed for anything other than the NCOALink data while you are running your job.
- Match rate—The more records you process that have forwardable moves, the slower your processing will be. Retrieving and decoding the new addresses takes time, so updating a mailing list regularly will improve the processing speed on that list.
- Input format—Ideally you should provide the USA Regulatory Address Cleanse transform with discrete fields for the addressee’s first, middle, and last name, as well as for the pre-name and post-name. If your input has only a name line, the transform will have to take time to parse it before checking NCOALink data.
- File size—Larger files process relatively faster than smaller files. There is overhead when processing any job, but if a job includes millions of records, a few seconds of overhead becomes insignificant.

2.16.6.5.13 To enable NCOALink processing

You must have access to the following files:

- NCOALink directories
- Current version of the USPS daily delete file
- DPV data files

- LACSLink data files

If you use a copy of the sample transform configuration, USARegulatoryNCOALink_AddressCleanse, NCOALink, DPV, and LACSLink are already enabled.

1. Open the *USA Regulatory Address Cleanse* transform and open the *Options* tab.
2. Set values for the options as appropriate for your situation.

   For more information about the USA Regulatory Address Cleanse transform fields, see the *Reference Guide*. The table below shows fields that are required only for specific provider levels.

Option group	Option name or subgroup	End user without stop processing alternative agreement	End user with stop processing alternative agreement	Full or limited service provider
	Licensee Name	yes	yes	yes
	List Owner NAICS Code	yes	yes	yes
USPS License Information	*List ID*	no	no	yes
	Customer Company Name	no	yes	yes
	Customer Company Address	no	yes	yes
	Customer Company Locality	no	yes	yes
	Customer Company Region	no	yes	yes
	Customer Company Postcode1	no	yes	yes
	Customer Company Postcode2	no	yes	yes
	Customer Company Phone	no	no	no
	List Processing Frequency	yes	yes	yes
	List Received Date	no	no	yes
	List Return Date	no	no	yes
	Provider Level	yes	yes	yes
NCOALink	*PAF Details subgroup*	no	no	All options are required, except Customer Parent Company Name and Customer Alternate Company Name.
	Service Provider Options subgroup	no	no	All options are required, except Buyer Company Name and Postcode for Mail Entry.

➜ Tip

If you are a service provider and you need to provide contact details for multiple brokers, expand the NCOALink group, right-click *Contact Details* and click *Duplicate Option*. An additional group of contact detail fields will be added below the original group.

2.16.6.5.14 NCOALink log files

The software automatically generates the USPS-required log files and names them according to USPS requirements. The software generates these log files to the repository where you can export them by using the Management Console.

The software creates one log file per license ID. At the beginning of each month, the software starts new log files. Each log file is then appended with information about every NCOALink job processed that month for that specific license ID.

The software produces the following move-related log files:

- CSL (Customer Service log)
- PAF (Processing Acknowlagement Form) customer Information log
- BALA (Broker/Agent/List Administrator) log

The PAF Customer Information Log File and the BALA Log File are not required for end users.The following table shows the log files required for Limited or Full Service Providers:

Log file	Description
CSL	This log file contains one record per list that you process. Each record details the results of change-of-address processing.
PAF customer information log	This log file contains the information that you provided for the PAF. The log file lists each unique PAF entry. If a list is processed with the same PAF information, the information appears just once in the log file. When contact information for the list administrator has changed, then information for both the list administrator and the corresponding broker are written to the PAF log file.

Log file	Description
BALA	This log file contains all of the contact information that you entered for the broker or list administrator. The log file lists information for each broker or list administrator just once. The USPS requires the Broker/Agent/List Administrator log file from service providers, even in jobs that do not involve a broker or list administrator. The software produces this log file for every job if you're a certified service provider.

Log file retention and automatic deletion

You must submit the NCOALink log files to the USPS every month. The software deletes log files on a periodic basis (default is 30 days), which can be controlled through Data Services Application Settings in the Central Management Console. To avoid losing monthly log information, set the *History Retention Period* to more than 31 days (we recommend a setting of 50 days).

In addition to sending monthly log files to the USPS, you are required to have the data available for the USPS to examine for several years after the job is processed. (Make sure you are aware of current USPS rules for data retention by checking your USPS licensing agreement.) To ensure that you retain all required reports and logs before the data is deleted from the repository, we recommend that you export the required reports and logs from the repository to a local folder on a monthly basis. This also prevents the repository contents from becoming so large that the export process “times out” due to the volume of statistics retained.

Administrators Guide: Setting the history retention period [page 58]

2.16.6.5.14.1 Log file names

The software follows the USPS file-naming scheme for the following log files:

- Customer Service log
- PAF Customer Information log
- Broker/Agent/List Administrators log

The table below describes the naming scheme for NCOALink log files. For example, `P1234C10.DAT` is a PAF Log file generated in December 2010 for a licensee with the ID 1234.

Character 1		Characters 2 -5	Character 6		Characters 7-8	Extension
Log type		Platform ID	Month		Year	
B	Broker log	Exactly four characters long	1	January	Two characters , for example 10 for 2010	.DAT
C	Customer service log		2	February		
P	PAF log		3	March		
			4	April		
			5	May		
			6	June		
			7	July		
			8	August		
			9	September		
			A	October		
			B	November		
			C	December		

For example, `P1234C10.DAT` is a PAF Log file generated in December 2010 for a licensee with the ID 1234.

2.16.6.6 USPS eLOT®

eLOT is available for U.S. records in the USA Regulatory Address Cleanse transform only.

eLOT takes line of travel one step further. The original LOT narrowed the mail carrier's delivery route to the block face level (Postcode2 level) by discerning whether an address resided on the odd or even side of a street or thoroughfare.

eLOT narrows the mail carrier's delivery route walk sequence to the house (delivery point) level. This allows you to sort your mailings to a more precise level.

Related Information

To enable eLOT [page 667]
Set up the reference files [page 594]

2.16.6.6.1 To enable eLOT

1. Open the USA Regulatory Address Cleanse transform.
2. Open the *Options* tab, expand the Assignment Options group, and select Yes for the *Enable eLOT* option.
3. In the *Reference Files* group, set the path for your eLOT directory.

   You can use the subtitution variable $$RefFilesAddressCleanse for this option if you have it set up.

2.16.6.7 Early Warning System (EWS)

EWS helps reduce the amount of misdirected mail caused when valid delivery points are created between national directory updates. EWS is available for U.S. records in the USA Regulatory Address Cleanse transform only.

2.16.6.7.1 Overview of EWS

The EWS feature is the solution to the problem of misdirected mail caused by valid delivery points that appear between national directory updates. For example, suppose that 300 Main Street is a valid address and that 300 Main Avenue does not exist. A mail piece addressed to 300 Main Avenue is assigned to 300 Main Street on the assumption that the sender is mistaken about the correct suffix.

Now consider that construction is completed on a house at 300 Main Avenue. The new owner signs up for utilities and mail, but it may take a couple of months before the delivery point is listed in the national directory. All the mail intended for the new house at 300 Main Avenue will be mis-directed to 300 Main Street until the delivery point is added to the national directory.

The EWS feature solves this problem by using an additional directory which informs CASS users of the existence of 300 Main Avenue long before it appears in the national directory. When using EWS processing, the previously mis-directed address now defaults to a 5-digit assignment.

2.16.6.7.2 Start with a sample transform configuration

If you want to use the USA Regulatory Address Cleanse transform with the EWS option turned on, it is best to start with the sample transform configuration for EWS processing named USARegulatoryEWS_AddressCleanse.

2.16.6.7.3 EWS directory

The EWS directory contains four months of rolling data. Each week, the USPS adds new data and drops a week's worth of old data. The USPS then publishes the latest EWS data. Each Friday, SAP converts the data to our format (`EWyymmdd.zip`) and posts it on the SAP Buisiness User Support site at *https://service.sap.com/bosap-downloads-usps*.

2.16.6.7.4 To enable EWS

EWS is already enabled when you use the software's EWS sample transform, USARegulatoryEWS_AddressCleanse. These steps show how to manually set EWS.

1. Open the USA Regulatory Address Cleanse transform.
2. Open the *Options* tab and expand the Assignment Options group.
3. Select Enable for the *Enable EWS* option.
4. Expand the Reference Files group and enter a path for the *EWS Directory* option, or use the substitution variable $$RefFilesAddressCleanse if you have it set up.

Related Information

Early Warning System (EWS) [page 667]

2.16.6.8 USPS RDI®

The RDI (Residential Delivery Indicator) option is available in the USA Regulatory Address Cleanse transform. RDI determines whether a given address is for a residence or non residence.

Parcel shippers can find RDI information to be very valuable because some delivery services charge higher rates to deliver to residential addresses. The USPS, on the other hand, does not add surcharges for residential deliveries. When you can recognize an address as a residence, you have increased incentive to ship the parcel with the USPS instead of with a competitor that applies a residential surcharge.

According to the USPS, 91-percent of U.S. addresses are residential. The USPS is motivated to encourage the use of RDI by parcel mailers.

You can use RDI if you are processing your data for CASS certification or if you are processing in a non-certified mode. In addition, RDI does not require that you use DPV processing.

2.16.6.8.1 Start with a sample transform

If you want to use the RDI feature with the USA Regulatory Address Cleanse transform, it is best to start with the sample transform configuration, USARegulatoryRDI_AddressCleanse.

Sample transforms are located in the Transforms tab of the Object Library. This sample is located under USA_Regulatory_Address_Cleanse transforms.

2.16.6.8.2 How RDI works

After you install the RDI directories and enable RDI processing, the software determines whether the address represented by an 11-digit postcode (Postcode1, Postcode2, and the DPBC) is a residential address. (The software can sometimes do the same with a postcode2.)

The software indicates whether an address is for a residence in the output component, RDI_INDICATOR.

Using the RDI feature involves only a few steps:

1. Install the RDI directories.
2. Specify where the directories are located.
3. Enable RDI processing in the software.
4. Run the job.

Related Information

Enable RDI [page 670]

2.16.6.8.2.1 Compatibility

RDI has the following compatibility with other options in the software:

- RDI is allowed in both CASS and non-CASS processing modes.
- RDI is allowed with or without DPV processing.

2.16.6.8.3 RDI directory files

SAP ships the RDI directory files with the U.S. National Directory update.

RDI requires the following directories:

File	Description
`rts.hs11`	For 11-digit postcode lookups (Postcode2 plus DPBC). This file is used when an address contains an 11-digit postcode. Determination is based on the delivery point.
`rts.hs9`	For 9-digit postcode lookups (Postcode2). This file is based on a ZIP+4.This is possible only when the addresses for that ZIP+4 are for all residences or for no residences.

2.16.6.8.3.1 Specify RDI directory path

In the Reference Files group, specify the location of your RDI directories in the *RDI Path* option. If RDI processing is disabled, the software ignores the *RDI Path* setting.

2.16.6.8.4 To enable RDI

If you use a copy of the USARegulatoryRDI_AddressCleanse sample transform in your data flow, RDI is already enabled. However, if you are starting from a USA Regulatory Address Cleanse transform, make sure you enable RDI and set the location for the following RDI directories: `rts.hs11` and `rts.hs9`.

1. Open the *USA Regulatory Address Cleanse* transform.
2. In the *Options* tab expand the Reference Files group, and enter the location of the RDI directories in the *RDI Path* option, or use the substitution variable $$RefFilesAddressCleanse if you have it set up.
3. Expand the Assignment Options group, and select *Yes* for the *Enable RDI* option.

2.16.6.8.5 RDI output field

For RDI, the software uses a single output component that is always one character in length. The RDI component is populated only when the *Enable RDI* option in the Assignment Options group is set to Yes.

Job/Views field	Length	Description
RDI_INDICATOR	1	This field contains the RDI value that consists of one of the following values: Y = The address is for a residence. N = The address is not for a residence.

2.16.6.8.6 RDI in reports

A few of the software's reports have additional information because of the RDI feature.

2.16.6.8.6.1 CASS Statement, USPS Form 3553

The USPS Form 3553 contains an entry for the number of residences. (The CASS header record also contains this information.)

2.16.6.8.6.2 Statistics files

The statistics file contains RDI counts and percentages.

2.16.6.9 GeoCensus (USA Regulatory Address Cleanse)

The GeoCensus option of the USA Regulatory Address Cleanse transform offers geographic and census coding for enhanced sales and marketing analysis. It is available for U.S. records only.

> ℹ Note
>
> GeoCensus functionality in the USA Regulatory Address Cleanse transform will be deprecated in a future version. It is recommended that you upgrade any data flows that currently use the GeoCensus functionality to use the Geocoder transform. For instructions on upgrading from GeoCensus to the Geocoder transform, see the *Upgrade Guide*.

Related Information

How GeoCensus works [page 671]
GeoCensus data and directories [page 673]
To enable GeoCensus coding [page 674]
Geocoding [page 489]

2.16.6.9.1 How GeoCensus works

By using GeoCensus, the USA Regulatory Address Cleanse transform can append latitude, longitude, and census codes such as census tract and Metropolitan Statistical Area (MSA) to your records, based on ZIP+4 codes. MSA is an aggregation of US counties into Metropolitan Statistical Areas assigned by the US Office of Management and Budget. You can apply the GeoCensus codes during address standardization and postcode2 assignment for simple, “one-pass” processing.

The transform cannot, by itself, append demographic data to your records. The transform lays the foundation by giving you census coordinates via output fields. To append demographic information, you need a demographic database from another vendor. When you obtain one, we suggest that you use the matching process to match your records to the demographic database, and transfer the demographic information into your records. (You would use the MSA and census tract information as match criteria, then use the Best Record transform to post income and other information.)

Likewise, the transform does not draw maps. However, you can use the latitude and longitude assigned by the transform as input to third-party mapping applications. Those applications enable you to plot the locations of your customers and filter your database to cover a particular geographic area.

2.16.6.9.2 The software provides census coordinates

The software cannot, by itself, append demographic data to your records. The software simply lays the foundation by giving you census coordinates. To append demographic information, you need a demographic database from another vendor. When you get that, we suggest that you use our Match transform to match your records to the demographic database and transfer the demographic information into your records. (In technical terms, you would use the MSA and Census block/tract information as match fields, then use the Best Record post-match operation in the Match transform to transfer income and other information.

Likewise, the software does not draw maps. However, you can use the latitude and longitude assigned by the software as input to third-party mapping software. Those programs enable you to plot the locations of your customers and filter your database to cover a particular geographic area.

Related Information

Best record [page 562]

2.16.6.9.3 Get the most from the GeoCensus data

You can combine GeoCensus with the functionality of mapping software to view your geo-enhanced information. It will help your organization build its sales and marketing strategies. Here are some of the ways you can use the GeoCensus data, with or without mapping products.

Information type	How GeoCensus can help
Market analysis	You can use mapping applications to analyze market penetration, for instance. Companies striving to gain a clearer understanding of their markets employ market analysis. This way they can view sales, marketing, and demographic data on maps, charts, and graphs. The result is a more finely targeted marketing program. You will understand both where your customers are and the penetration you have achieved in your chosen markets.
Predictive modeling and target marketing	You can more accurately target your customers for direct response campaigns using geographic selections. Predictive modeling or other analytical techniques allow you to identify the characteristics of your ideal customer. This method incorporates demographic information used to enrich your customer database. From this analysis, it is possible to identify the best prospects for mailing or telemarketing programs.

Information type	How GeoCensus can help
Media planning	For better support of your advertising decisions, you may want to employ media planning. Coupling a visual display of key markets with a view of media outlets can help your organization make more strategic use of your advertising dollars.
Territory management	GeoCensus data provides a more accurate market picture for your organization. It can help you distribute territories and sales quotas more equitably.
Direct sales	Using GeoCensus data with market analysis tools and mapping software, you can track sales leads gathered from marketing activities.

2.16.6.9.4 GeoCensus directories

The path and file names for the following directories must be defined in the Reference Files option group of the USA Regulatory Address Cleanse transform before you can begin GeoCensus processing. You can use the substitution variable $$RefFilesDataCleanse.

Directory name	Description
ageo1-10	Address-level GeoCensus directories are required if you choose *Address* for the *Geo Mode* option under the Assignment Options group.
cgeo2.dir	Centriod-level GeoCensus directory is required if you choose *Centroid* for the *Geo Mode* option under the Assignment Options group.

2.16.6.9.5 GeoCensus mode options

To activate GeoCensus in the transform, you need to choose a mode in the *Geo Mode* option in the Assignment Options group.

Mode	Description
Address	Processes Address-level GeoCensus only.
Both	Attempts to make an Address-level GeoCensus assignment first. If no assignment is made, it attempts to make a Centroid-level GeoCensus assignment.
Centroid	Processes Centroid-level GeoCensus only.
None	Turns off GeoCensus processing.

2.16.6.9.6 GeoCensus output fields

You must include at least one of the following generated output fields in the USA Regulatory Address Cleanse transform if you plan to use the GeoCensus option:

- AGeo_CountyCode
- AGeo_Latitude
- AGeo_Longitude
- AGeo_MCDCode
- AGeo_PlaceCode
- AGeo_SectionCode
- AGeo_StateCode
- CGeo_BSACode
- CGeo_Latitude
- CGeo_Longitude
- CGeo_Metrocode
- CGeo_SectionCode

Find descriptions of these fields in the *Reference Guide*.

2.16.6.9.7 Sample transform configuration

To process with the GeoCensus feature in the USA Regulatory Address Cleanse transform, it is best to start with the sample transform configuration created for GeoCensus. Find the sample configuration, USARegulatoryGeo_AddressCleanse, under USA_Regulatory_Address_Cleanse in the Object Library.

2.16.6.9.8 To enable GeoCensus coding

If you use a copy of the USARegulatoryGeo_AddressCleanse sample transform file in your data flow, GeoCensus is already enabled. However, if you are starting from a USA Regulatory Address Cleanse transform, make sure you define the directory location and define the *Geo Mode* option.

1. Open the *USA Regulatory Address Cleanse* transform.
2. In the *Options* tab, expand the *Reference Files* group.
3. Set the locations for the `cgeo.dir` and `ageo1-10.dir` directories based on the Geo Mode you choose.
4. Expand the Assignment Options group, and select either *Address*, *Centroid*, or *Both* for the *Geo Mode* option.

   If you select *None*, the transform will not perform GeoCensus processing.

Related Information

GeoCensus (USA Regulatory Address Cleanse) [page 671]

2.16.6.10 Z4Change (USA Regulatory Address Cleanse)

The Z4Change option is based on a USPS directory of the same name. The Z4Change option is available in the USA Regulatory Address Cleanse transform only.

2.16.6.10.1 Use Z4Change to save time

Using the Z4Change option can save a lot of processing time, compared with running all records through the normal ZIP+4 assignment process.

Z4Change is most cost-effective for databases that are large and fairly stable—for example, databases of regular customers, subscribers, and so on. In our tests, based on files in which five percent of records were affected by a ZIP+4 change, total batch processing time was one third the normal processing time.

When you are using the transform interactively—that is, processing one address at a time—there is less benefit from using Z4Change.

2.16.6.10.2 USPS rules

Z4Change is to be used only for updating a database that has previously been put through a full validation process. The USPS requires that the mailing list be put through a complete assignment process every three years.

2.16.6.10.3 Z4Change directory

The Z4Change directory, `z4change.dir`, is updated monthly and is available only if you have purchased the Z4Change option for the USA Regulatory Address Cleanse transform.

The Z4Change directory contains a list of all the ZIP Codes and ZIP+4 codes in the country.

2.16.6.10.4 Start with a sample transform

If you want to use the Z4Change feature in the USA Regulatory Address Cleanse transform, it is best to start with the sample transform, USARegulatoryZ4Change_AddressCleanse.

2.16.6.10.5 To enable Z4Change

If you use a copy of the Z4Change transform configuration file sample (USARegulatoryZ4Change_AddressCleanse) in your data flow, Z4Change is already enabled. However, if you are starting from a USA Regulatory Address Cleanse transform, make sure you define the directory location and define the *Z4Change Mode* option.

1. Open the *USA Regulatory Address Cleanse* transform.
2. On the *Options* tab, expand the Reference Files group.
3. Set the location for the `z4change.dir` directory in the *Z4Change Directory* option.
4. Expand Z4Change options group and select *Yes* for the *Enable Z4Change* option.
5. In the Z4Change option group, enter the month and year that the input records were most recently ZIP+4 updated in the *Last ZIP+4 Assign Date* option.

2.16.6.11 Suggestion lists overview

Suggestion List processing is used in transactional projects with the USA Regulatory Address Cleanse, Global Address Cleanse, and the Global Suggestion List transforms. Use suggestion lists to complete and populate addresses that have minimal data. Suggestion lists can offer suggestions for possible matches if an exact match is not found. This section is only about suggestion lists in the USA Regulatory Address Cleanse transform.

> Note
>
> Suggestion list processing is not available for batch processing. In addition, if you have suggestion lists enabled, you are not eligible for CASS discounts and the software will not produce the required CASS documentation.

Related Information

Reference Guide: Global Address Cleanse suggestion lists [page 1257]
Integrator Guide: Using Data Services as a web service provider [page 2218]
Extracting data quality XML strings using extract_from_xml function [page 370]

2.16.6.11.1 Introduction to suggestion lists

Ideally, when the USA Regulatory Address Cleanse transform looks up an address in the USPS postal directories (City/ZCF), it finds exactly one matching record with a matching combination of locality, region, and postcode. Then, during the look-up in the USPS national ZIP+4 directory, the software should find exactly one record that matches the address.

Breaking ties

Sometimes it's impossible to pinpoint an inut address to one matching record in the directory. At other times, the software may find several directory records that are near matches to the input data.

When the software is close to a match, but not quite close enough, it assembles a list of the near matches and presents them as suggestions. When you choose a suggestion, the software tries again to assign the address.

Example

Incomplete last line

Given the incomplete last line below, the software could not reliably choose one of the four localities. But if you choose one, the software can proceed with the rest of the assignment process.

Input record	Possible matches in the City/ZCF directories

Line1= 1000 vine
Line2= lacr wi
	La Crosse, WI 54603
	Lancaster, WI 53813
	La Crosse, WI 54601
	Larson, WI 54947

Example

Missing directional

The same can happen with address lines. A common problem is a missing directional. In the example below, there is an equal chance that the directional could be North or South. The software has no basis for choosing one way or the other.

Input record	Possible matches in the ZIP+4 directory

Line1 = 615 losey blvd
Line2 = 54603
	600-699 Losey Blvd N
	600-698 Losey Blvd S

Example

Missing suffix

A missing suffix would cause similar behavior as in the example above.

Input record	Possible matches in the ZIP+4 directory

Line1 = 121 dorn
Line2 = 54601
	100-199 Dorn Pl
	101-199 Dorn St

Example

Misspelled street names

A misspelled or incomplete street name could also result in the need to be presented with address suggestions.

Input record	Possible matches in the ZIP+4 directory

Line1 = 4100 marl
Line2 = minneapolis mn
	4100-4199 Marshall 55421
	4100-4199 Maryland 55427

2.16.6.11.1.1 More information is needed

When the software produces a suggestion list, you need some basis for selecting one of the possible matches. Sometimes you need more information before choosing a suggestion.

Example

- Operators taking information over the phone can ask for more information from the customer to decide which suggestion list to choose.
- Operators entering data from a consumer coupon that is a little smudged may be able to choose a suggestion based on the information that is not smudged.

2.16.6.11.1.2 CASS rule

The USPS does not permit SAP Data Services to generate a USPS Form 3553 when suggestion lists are used in address assignment. The USPS suspects that users may be tempted to guess, which may result in misrouted mail that is expensive for the USPS to handle.

Therefore, when you use the suggestion list feature, you cannot get a USPS Form 3553 covering the addresses that you assign. The form is available only when you process in batch mode with the *Disable Certification* option set to No.

You must run addresses from real-time processes through a batch process in order to be CASS compliant. Then the software generates a USPS Form 3553 that covers your entire mailing database, and your list may be eligible for postal discounts.

2.16.6.11.1.3 Integrating functionality

Suggestion Lists functionality is designed to be integrated into your own custom applications via the Web Service. For information about integrating Data Services for web applications, see the *Integrator Guide*.

2.16.6.11.1.4 Sample suggestion lists blueprint

If you want to use the suggestion lists feature, it is best to start with one of the sample transforms configured for it. The sample transform is named USARegulatorySuggestions_Address_Cleanse. It is available for the USA Regulatory Address Cleanse transform.

2.16.6.12 Multiple data source statistics reporting

Statistics based on logical groups

For the USA Regulatory Address Cleanse transform, an input database can be a compilation of lists, with each list containing a field that includes a unique identifier. The unique identifier can be a name or a number, but it must reside in the same field across all lists.

The software collects statistics for each list using the Data_Source_ID input field. You map the field that contains the unique identifier in your list to the software's Data_Source_ID input field. When the software generates reports, some of the reports will contain a summary for the entire list, and a separate summary per list based on the value mapped into the Data_Source_ID field.

> ⚠ Restriction
>
> For compliance with NCOALink reporting restrictions, the USA Regulatory Address Cleanse transform does not support processing multiple mailing lists associated with different PAFs. Therefore, for NCOALink processing, all records in the input file are considered to be a single mailing list and are reported as such in the Customer Service Log (CSL) file.

> ⚠ Restriction
>
> The Gather Statistics Per Data Source functionality is not supported when the *Enable Parse Only* or *Enable Geo Only* options in the Non Certified Options group are set to Yes.

Related Information

Gathering statistics per list [page 680]

2.16.6.12.1 Data_Source_ID field

The software tracks statistics for each list based on the Data_Source_ID input field.

Example

In this example, there are five mailing lists combined into one list for input into the USA Regulatory Address Cleanse transform. Each list has a common field named List_ID, and a unique identifier in the List_ID field: N, S, E, W, C. The input mapping looks like this:

Transform input field name	Input schema column name	Type
DATA_SOURCE_ID	LIST_ID	varchar(80)

To obtain DPV statistics for each List_ID, process the job and then open the US Addressing report.

The first DPV Summary section in the US Addressing report lists the Cumulative Summary, which reports the totals for the entire input set. Subsequent DPV Summary sections list summaries per Data_Source_ID. The example in the table below shows the counts and percentages for the entire database (cumulative summary) and for Data_Source_ID “N”.

Statistic	DPV cumulative summary count	%	DPV summary for Data_Source_ID “N”	%
DPV Validated Addresses	1,968	3.94	214	4.28
Addresses Not DPV Valid	3,032	6.06	286	5.72
CMRA Validated Addresses	3	0.01	0	0.00
DPV Vacant Addresses	109	0.22	10	0.20
DPV NoStats Addresses	162	0.32	17	0.34

Related Information

Group statistics reporting [page 683]

2.16.6.12.2 Gathering statistics per list

Before setting up the USA Regulatory Address Cleanse transform to gather statistics per list, identify the field that uniquely identifies each list. For example, a mailing list that is comprised of more than one source might contain lists that have a field named LIST_ID that uniquely identifies each list.

1. Open the USA Regulatory Address Cleanse transform in the data flow and then click the *Options* tab.
2. Expand the Report and Analysis group and select Yes for the *Generate Report Data* and the *Gather Statistics Per Data Source* options.
3. Click the *Input* tab and click the *Input Schema Column Name* field next to the Data_Source_ID field for uniquely identifying a list.
   A drop menu appears.
4. Click the drop menu and select the input field from your database that you've chosen as the common field for uniquely identifying a list. In the scenario above, that would be the LIST_ID field.

5. Continue with the remaining job setup tasks and execute your job.

2.16.6.12.3 Physical Source Field and Cumulative Summary

Some reports include a report per list based on the Data_Source_ID field (identified in the report footer by “Physical Source Field”), and a summary of the entire list (identified in the report footer by “Cumulative Summary”). However, the Address Standardization, Address Information Code, and USA Regulatory Locking reports do not include a Cumulative Summary. The records in these reports are sorted by the Data Source ID value.

Note

When you enable NCOALink, the software reports a summary per list only for the following sections of the NCOALink Processing Summary Report:

- NCOALink Move Type Summary
- NCOALink Return Code Summary
- ANKLink Return Code Summary

Special circumstances

There are some circumstances when the words “Cumulative Summary” and“ Physical Source Field” will not appear in the report footer sections.

- When the *Gather Statistics Per Data Source* option is set to No
- When the *Gather Statistics Per Data Source* option is set to Yes and there is only one Data Source ID value present in the list but it is empty

2.16.6.12.3.1 USPS Form 3553 and group reporting

The USPS Form 3553 includes a summary of the entire list and a report per list based on the Data_Source_ID field.

Example

Cumulative Summary

The USPS Form 3553 designates the summary for the entire list with the words “Cumulative Summary”. It appears in the footer as highlighted in the Cumulative Summary report sample below. In addition, the Cumulative Summary of the USPS Form 3553 contains the total number of lists in the job in Section B, field number 5, *Number of Lists* (highlighted below).

PS Form 3553, September 2008

Physical Source Field: 1

Page 2 of 11

2.16.6.12.3.2 Group statistics reports

Reports that show both cumulative statistics (summaries for the entire mailing list) and group statistics (based on the Physical Source Field) include the following reports:

- Address Validation Summary
- Address Type Summary
- US Addressing

Reports that do not include a Cumulative Summary include the following:

- Address Information Code Summary
- Address Standardization
- US Regulatory Locking

Related Information

Sample data from US Addressing Report [page 679]

2.16.7 Data Quality support for native data types

The Data Quality transforms generally process incoming data types as character data. Therefore, if a noncharacter data type is mapped as input, the software converts the data to a character string before passing it through the Data Quality transforms.

Some Data Quality data types are recognized and processed as the same data type as they were input. For example, if a date type field is mapped to a Data Quality date type input field, the software has the following advantages:

- Sortation: The transform recognizes and sorts the incoming data as the specified data type.
- Efficiency: The amount of data being converted to character data is reduced making processing more efficient.

Related Information

Reference Guide: Data Quality transforms [page 1123]
Reference Guide: Data types [page 1027]

2.16.7.1 Data Quality data type definitions

The Data Quality transforms have four field attributes to define the field:

- Name
- Type
- Length
- Scale

These attributes are listed in the Input and output tab of the transform editor.

In the Input tab, the attribute Name is listed under the *Transform Input Field Name* column. The Type, Length, and Scale attributes are listed under the *Type* column in the format <type>(<length>, <scale>).

The Output tab also contains the four field attributes listed above. The attribute Name is listed under the *Field_Name* column. The Type, Length, and Scale attributes are listed under the *Type* column in the format <type>(<length>, <scale>).

2.16.8 Data Quality support for NULL values

The Data Quality transforms process NULL values as NULL.

A field that is NULL is passed through processing with the NULL marker preserved unless there is data available to populate the field on output. When there is data available, the field is output with the data available instead of NULL. The benefit of this treatment of NULL is that the Data Quality transforms treat a NULL marker as unknown instead of empty.

ℹ Note

If all fields of a record contain NULL, the transform will not process the record, and the record will not be a part of statistics and reports.

Related Information

Reference Guide: Data Quality transforms [page 1123]
Reference Guide: NULL values and empty strings [page 1715]

2.17 Design and Debug

This section covers the following Designer features that you can use to design and debug jobs:

- Use the View Where Used feature to determine the impact of editing a metadata object (for example, at table). See which data flows use the same object.
- Use the View Data feature to view sample source, transform, and target data in a data flow after a job executes.
- Use the Design-Time Data Viewer feature to view and analyze the input and output for a data set in real time as you design a transform.
- Use the Interactive Debugger to set breakpoints and filters between transforms within a data flow and view job data row-by-row during a job execution.
- Use the Difference Viewer to compare the metadata for similar objects and their properties.
- Use the auditing data flow feature to verify that correct data is processed by a source, transform, or target object.

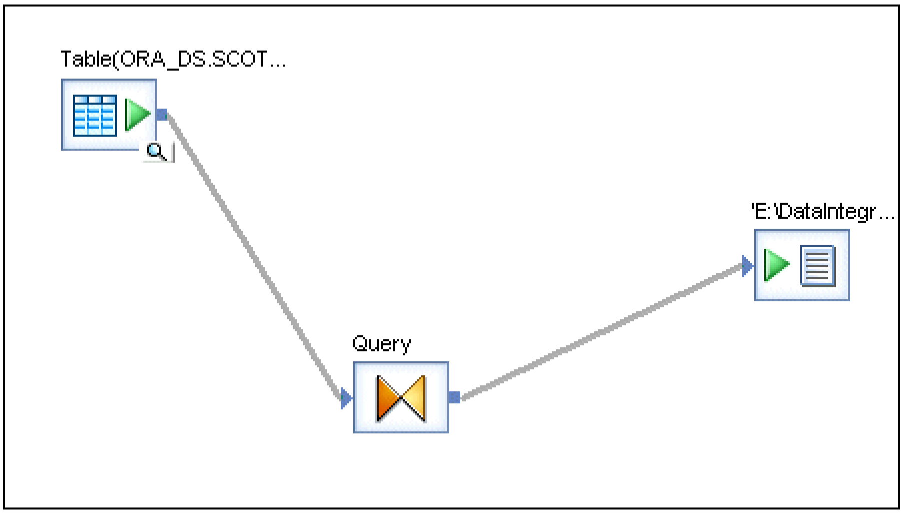
Related Information

Using View Where Used [page 686]
Using View Data [page 688]
Using the Design-Time Data Viewer [page 699]
Using the interactive debugger [page 701]
Comparing Objects [page 714]
Using Auditing [page 452]

2.17.1 Using View Where Used

When you save a job, work flow, or data flow the software also saves the list of objects used in them in your repository. Parent/child relationship data is preserved. For example, when the following parent data flow is saved, the software also saves pointers between it and its three children:

- a table source
- a query transform
- a file target



You can use this parent/child relationship data to determine what impact a table change, for example, will have on other data flows that are using the same table. The data can be accessed using the *View Where Used* option.

For example, while maintaining a data flow, you may need to delete a source table definition and re-import the table (or edit the table schema). Before doing this, find all the data flows that are also using the table and update them as needed.

To access the *View Where Used* option in the Designer you can work from the object library or the workspace.

2.17.1.1 Accessing View Where Used from the object library

You can view how many times an object is used and then view where it is used.

2.17.1.1.1 To access parent/child relationship information from the object library

1. View an object in the object library to see the number of times that it has been used.

   The Usage column is displayed on all object library tabs except:

   ○ Projects

- Jobs
- Transforms

Click the Usage column heading to sort values. For example, to find objects that are not used.

2. If the *Usage* is greater than zero, right-click the object and select *View Where Used*.

   The *Output* window opens. The Information tab displays rows for each parent of the object you selected. The type and name of the selected object is displayed in the first column's heading.

   The As column provides additional context. The As column tells you how the selected object is used by the parent.

   Other possible values for the As column are:

   - For XML files and messages, tables, flat files, etc., the values can be Source or Target
   - For flat files and tables only:

As	Description
Lookup()	Lookup table/file used in a `lookup` function
Lookup_ext()	Lookup table/file used in a `lookup_ext` function
Lookup_seq()	Lookup table/file used in a `lookup_seq` function

   - For tables only:

As	Description
Comparison	Table used in the Table Comparison transform
Key Generation	Table used in the Key Generation transform

3. From the *Output* window, double-click a parent object.

   The workspace diagram opens highlighting the child object the parent is using.

   Once a parent is open in the workspace, you can double-click a row in the output window again.

   - If the row represents a different parent, the workspace diagram for that object opens.
   - If the row represents a child object in the same parent, this object is simply highlighted in the open diagram.
     This is an important option because a child object in the *Output* window might not match the name used in its parent. You can customize workspace object names for sources and targets.
     The software saves both the name used in each parent and the name used in the object library. The Information tab on the *Output* window displays the name used in the object library. The names of objects used in parents can only be seen by opening the parent in the workspace.

2.17.1.2 Accessing View Where Used from the workspace

From an open diagram of an object in the workspace (such as a data flow), you can view where a parent or child object is used:

- To view information for the open (parent) object, select *View* > *Where Used*, or from the tool bar, select the *View Where Used* button.
  The *Output* window opens with a list of jobs (parent objects) that use the open data flow.
- To view information for a child object, right-click an object in the workspace diagram and select the *View Where Used* option.
  The *Output* window opens with a list of parent objects that use the selected object. For example, if you select a table, the *Output* window displays a list of data flows that use the table.

2.17.1.3 Limitations

- This feature is not supported in central repositories.
- Only parent and child pairs are shown in the *Information* tab of the Output window.
  For example, for a table, a data flow is the parent. If the table is also used by a grandparent (a work flow for example), these are not listed in the *Output* window display for a table. To see the relationship between a data flow and a work flow, open the work flow in the workspace, then right-click a data flow and select the *View Where Used* option.
- The software does not save parent/child relationships between functions.
  - If function `A` calls function `B`, and function `A` is not in any data flows or scripts, the *Usage* in the object library will be zero for both functions. The fact that function `B` is used once in function `A` is not counted.
  - If function `A` is saved in one data flow, the usage in the object library will be `1` for both functions `A` and `B`.
- Transforms are not supported. This includes custom ABAP transforms that you might create to support an SAP applications environment.
- The Designer counts an object's usage as the number of times it is used for a unique purpose. For example, in data flow `DF1` if table `DEPT` is used as a source twice and a target once the object library displays its *Usage* as `2`. This occurrence should be rare. For example, a table is not often joined to itself in a job design.

2.17.2 Using View Data

View Data provides a way to scan and capture a sample of the data produced by each step in a job, even when the job does not execute successfully. View imported source data, changed data from transformations, and ending data at your targets. At any point after you import a data source, you can check on the status of that data—before and after processing your data flows.

Use View Data to check the data while designing and testing jobs to ensure that your design returns the results you expect. Using one or more View Data panes, you can view and compare sample data from different steps. View Data information is displayed in embedded panels for easy navigation between your flows and the data.

Use View Data to look at:

- Sources and targets
  View Data allows you to see data before you execute a job. Armed with data details, you can create higher quality job designs. You can scan and analyze imported table and file data from the object library as well as see the data for those same objects within existing jobs. After you execute the job, you can refer back to the source data again.
- Transforms

- Lines in a diagram

ℹ Note

- View Data displays blob data as `<blob>`.
- View Data is not supported for SAP IDocs. For SAP and PeopleSoft, the Table Profile tab and Column Profile tab options are not supported for hierarchies.

Related Information

Viewing data passed by transforms [page 712]
Using the interactive debugger [page 701]

2.17.2.1 Accessing View Data

2.17.2.1.1 To view data for sources and targets

You can view data for sources and targets from two different locations:

1. *View Data button*

   View Data buttons appear on source and target objects when you drag them into the workspace. Click the View data button (magnifying glass icon) to open a View Data pane for that source or target object.
2. *Object library*

   View Data in potential source or target objects from the Datastores or Formats tabs.

   Open a View Data pane from the object library in one of the following ways:
   - Right-click a table object and select *View Data*.
   - Right-click a table and select *Open* or *Properties*.
     The Table Metadata, XML Format Editor, or Properties window opens. From any of these windows, you can select the View Data tab.

To view data for a file, the file must physically exist and be available from your computer's operating system. To view data for a table, the table must be from a supported database.

Related Information

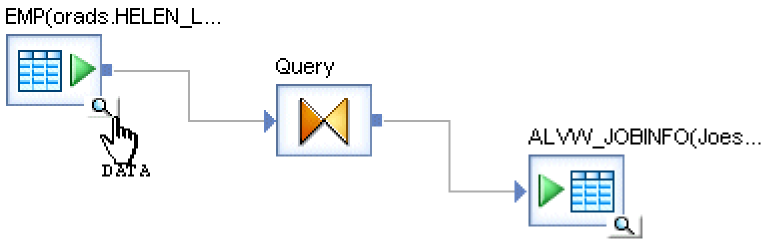
Viewing data in the workspace [page 690]

2.17.2.2 Viewing data in the workspace

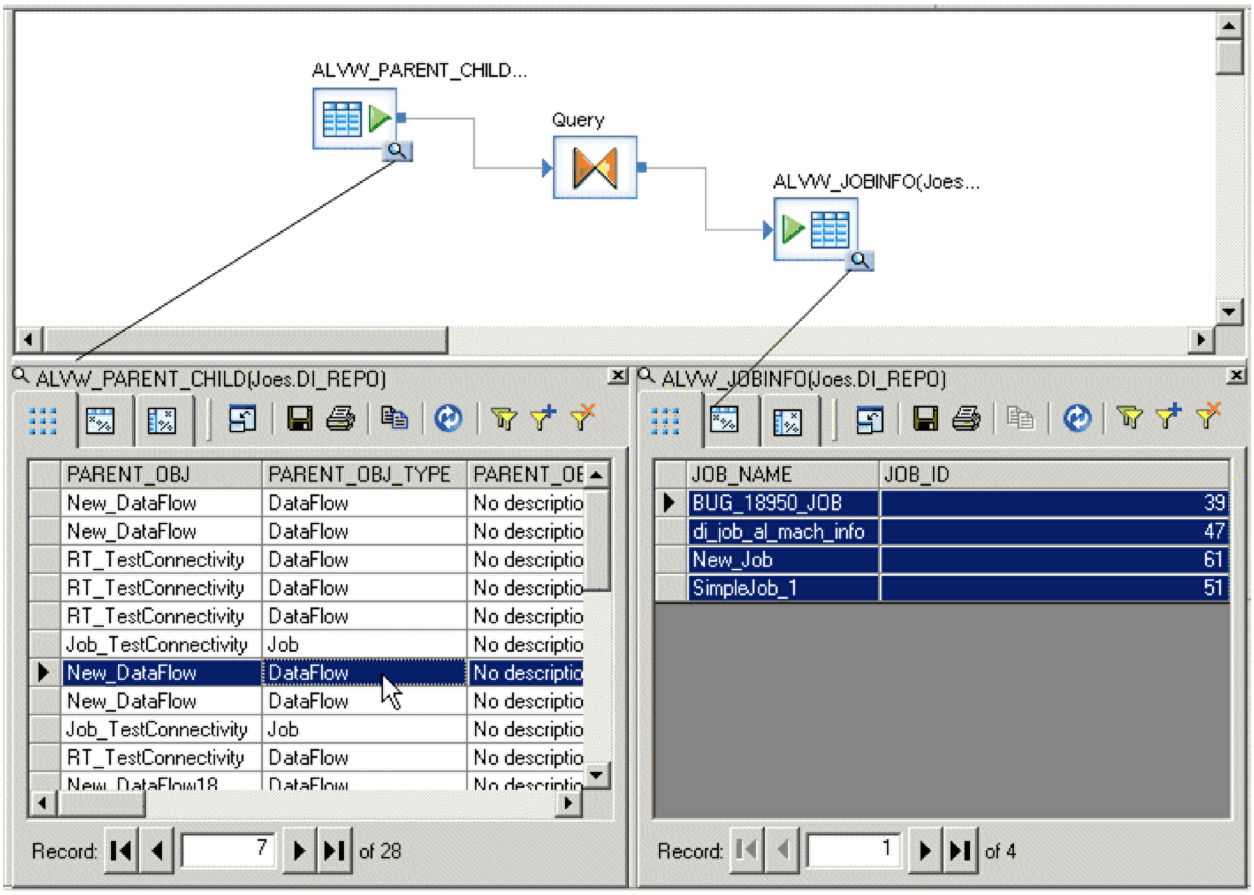
View Data can be accessed from the workspace when magnifying glass buttons appear over qualified objects in a data flow. This means:

For sources and targets, files must physically exist and be accessible from the Designer, and tables must be from a supported database.

To open a View Data pane in the Designer workspace, click the magnifying glass button on a data flow object.



A large View Data pane appears beneath the current workspace area. Click the magnifying glass button for another object and a second pane appears below the workspace area. (Note that the first pane area shrinks to accommodate the presence of the second pane).



ALVW_PARENT_CHILD(Joes.DI_REPO)

PARENT_OBJ	PARENT_OBJ_TYPE	PARENT_OE
New_DataFlow	DataFlow	No descriptio
New_DataFlow	DataFlow	No descriptio
RT_TestConnectivity	DataFlow	No descriptio
RT_TestConnectivity	DataFlow	No descriptio
RT_TestConnectivity	DataFlow	No descriptio
Job_TestConnectivity	Job	No descriptio
New_DataFlow	DataFlow	No descriptio
New_DataFlow	DataFlow	No descriptio
Job_TestConnectivity	Job	No descriptio
RT_TestConnectivity	DataFlow	No descriptio
New_DataFlow18	DataFlow	No descriptio

Record: 7 of 28

ALVW_JOBINFO(Joes.DI_REPO)

JOB_NAME	JOB_ID
BUG_18950_JOB	39
di_job_al_mach_info	47
New_Job	61
SimpleJob_1	51

Record: 1 of 4

You can open two View Data panes for simultaneous viewing. When both panes are filled and you click another View Data button, a small menu appears containing window placement icons. The black area in each icon indicates the pane you want to replace with a new set of data. Click a menu option and the data from the latest selected object replaces the data in the corresponding pane.

The description or path for the selected View Data button displays at the top of the pane.

- For sources and targets, the description is the full object name:
  - `<ObjectName>` (`<Datastore.Owner>`) for tables
  - `<FileName>` (`<File Format Name>`) for files
- For View Data buttons on a line, the path consists of the object name on the left, an arrow, and the object name to the right.
  For example, if you select a View Data button on the line between the query named Query and the target named ALVW_JOBINFO(joes.DI_REPO), the path would indicate:

```
Query -> ALVW_JOBINFO(Joes.DI_REPO)
```

You can also find the View Data pane that is associated with an object or line by:

- Rolling your cursor over a View Data button on an object or line. The Designer highlights the View Data pane for the object.

- Looking for grey View Data buttons on objects and lines. The Designer displays View Data buttons on open objects with grey rather than white backgrounds.

Related Information

Viewing data passed by transforms [page 712]

2.17.2.3 View Data Properties

You can access View Data properties from tool bar buttons or the right-click menu.

View Data displays your data in the rows and columns of a data grid. The number of rows displayed is determined by a combination of several conditions:

- Sample size — The number of rows sampled in memory. Default sample size is 1000 rows for imported source and target objects. Maximum sample size is 5000 rows. Set sample size for sources and targets from *Tools* > *Options* > *Designer* > *General* > *View Data sampling size*.
  When using the interactive debugger, the software uses the Data sample rate option instead of sample size.
- Filtering
- Sorting

If your original data set is smaller or if you use filters, the number of returned rows could be less than the default.

You can see which conditions have been applied in the *navigation bar*.

Related Information

Filtering [page 692]
Sorting [page 694]
Starting and stopping the interactive debugger [page 705]

2.17.2.3.1 Filtering

You can focus on different sets of rows in a local or new data sample by placing fetch conditions on columns.

2.17.2.3.1.1 To view and add filters

1. In the View Data tool bar, click the Filters button, or right-click the grid and select *Filters*.

The Filters window opens.

2. Create filters.

   The Filters window has three columns:

   a) Column—Select a name from the first column. Select *{remove filter}* to delete the filter.
   b) Operator—Select an operator from the second column.
   c) Value—Enter a value in the third column that uses one of the following data type formats

Data Type	Format
Integer, double, real	standard
date	yyyy.mm.dd
time	hh24:mm:ss
datetime	yyyy.mm.dd hh24:mm.ss
varchar	'abc'

3. In the *Concatenate all filters using* list box, select an operator (*AND*, *OR*) for the engine to use in concatenating filters.

   Each row in this window is considered a filter.

4. To see how the filter affects the current set of returned rows, click *Apply*.
5. To save filters and close the Filters window, click *OK*.

   Your filters are saved for the current object and the local sample updates to show the data filtered as specified in the Filters dialog. To use filters with a new sample, see *Using Refresh*.

Related Information

Using Refresh [page 694]

2.17.2.3.1.2 To add a filter for a selected cell

1. Select a cell from the sample data grid.
2. In the View Data tool bar, click the Add Filter button, or right-click the cell and select *Add Filter*.

   The Add Filter option adds the new filter condition, <column> = <cell value>, then opens the Filters window so you can view or edit the new filter.

3. When you are finished, click *OK*.

To remove filters from an object, go to the View Data tool bar and click the Remove Filters button, or right-click the grid and select *Remove Filters*. All filters are removed for the current object.

2.17.2.3.2 Sorting

You can click one or more column headings in the data grid to sort your data. An arrow appears on the heading to indicate sort order: ascending (up arrow) or descending (down arrow).

To change sort order, click the column heading again. The priority of a sort is from left to right on the grid.

To remove sorting for an object, from the tool bar click the Remove Sort button, or right-click the grid and select *Remove Sort*.

Related Information

Using Refresh [page 694]

2.17.2.3.3 Using Refresh

To fetch another data sample from the database using new filter and sort settings, use the *Refresh* command. After you edit filtering and sorting, in the tool bar click the Refresh button in the tool bar, or right-click the data grid and select *Refresh*.

To stop a refresh operation, click the Stop button. While the software is refreshing the data, all View Data controls except the *Stop* button are disabled.

2.17.2.3.4 Using Show/Hide Columns

You can limit the number of columns displayed in View Data by using the *Show/Hide Columns* option from:

- The tool bar.
- The right-click menu.
- The arrow shortcut menu, located to the right of the *Show/Hide Columns* tool bar button. This option is only available if the total number of columns in the table is ten or fewer. Select a column to display it.

You can also "quick hide" a column by right-clicking the column heading and selecting *Hide* from the menu.

2.17.2.3.4.1 To show or hide columns

1. Click the Show/Hide columns tool bar button, or right-click the data grid and select *Show/Hide Columns*.

   The Column Settings window opens.
2. Select the columns that you want to display or click one of the following buttons: *Show*, *Show All*, *Hide*, or *Hide All*.
3. Click *OK*.

2.17.2.3.5 Opening a new window

To see more of the data sample that you are viewing in a View Data pane, open a full-sized View Data window. From any View Data pane, click the Open Window tool bar button to activate a separate, full-sized View Data window. Alternatively, you can right-click and select *Open in new window* from the menu.

2.17.2.4 View Data tool bar options

The following options are available on View Data panes.

Icon	Option	Description
	Open in new window	Opens the View Data pane in a larger window.
	Save As	Saves the data in the View Data pane.
	Print	Prints View Data pane data.
	Copy Cell	Copies View Data pane cell data.
	Refresh data	Fetches another data sample from existing data in the View Data pane using new filter and sort settings.
	Open Filters window	Opens the Filters window.
	Add a Filter	Adds a filter to a selected cell.
	Remove Filter	Removes all filters in the View Data pane.
	Remove Sort	Removes sort settings for the object you select.

Icon	Option	Description
	Show/hide navigation	Shows or hides the navigation bar which appears below the data table.
	Show/hide columns	

Related Information

Opening a new window [page 695]
Using Refresh [page 694]
Filtering [page 692]
Sorting [page 694]
To add a filter for a selected cell [page 693]
Using Show/Hide Columns [page 694]

2.17.2.5 View Data tabs

The View Data panel for objects contains three tabs:

- Data tab
- Profile tab
- Column Profile tab

Use tab options to give you a complete profile of a source or target object. The Data tab is always available. The Profile and Relationship tabs are supported with the Data Profiler. Without the Data Profiler, the Profile and Column Profile tabs are supported for some sources and targets (see *Release Notes* for more information).

Related Information

Viewing the profiler results [page 443]

2.17.2.5.1 Data tab

The Data tab allows you to use the properties of *View Data*. It also indicates nested schemas such as those used in XML files and messages. When a column references nested schemas, that column is shaded yellow and a small table icon appears in the column heading.

Related Information

View Data Properties [page 692]

2.17.2.5.1.1 To view a nested schema

1. Double-click a cell.

   The data grid updates to show the data in the selected cell or nested table.

   In the Schema area, the selected cell value is marked by a special icon. Also, tables and columns in the selected path are displayed in blue, while nested schema references are displayed in grey.

   In the Data area, data is shown for columns. Nested schema references are shown in angle brackets; for example, **`<CompanyName>`**.
2. Continue to use the data grid side of the panel to navigate. For example:
   - Select a lower-level nested column and double-click a cell to update the data grid.
   - Click the at the top of the data grid to move up in the hierarchy.

     
     "DS1.aab.T1".Supplier.CompanyName

   - See the entire path to the selected column or table displayed to the right of the Drill Up button. Use the path and the data grid to navigate through nested schemas.

2.17.2.5.2 Profile tab

If you use the Data Profiler, the Profile tab displays the profile attributes that you selected on the *Submit Column Profile Request* option.

The Profile tab allows you to calculate statistical information for any set of columns you choose. This optional feature is not available for columns with nested schemas or for the LONG data type.

Related Information

Executing a profiler task [page 438]

2.17.2.5.2.1 To use the Profile tab without the Data Profiler

1. Select one or more columns.

   Select only the column names you need for this profiling operation because Update calculations impact performance.

   You can also right-click to use the Select All and Deselect All menu options.
2. Click *Update*.
3. The statistics appear in the Profile grid.

   The grid contains six columns:

Column	Description
Column	Names of columns in the current table. Select names from this column, then click *Update* to populate the profile grid.
Distinct Values	The total number of distinct values in this column.
NULLs	The total number of NULL values in this column.
Min	Of all values, the minimum value in this column.
Max	Of all values, the maximum value in this column.
Last Updated	The time that this statistic was calculated.

   Sort values in this grid by clicking the column headings. Note that Min and Max columns are not sortable.

In addition to updating statistics, you can click the *Records* button on the Profile tab to count the total number of physical records in the object you are profiling.

The software saves previously calculated values in the repository and displays them until the next update.

2.17.2.5.3 Column Profile tab

The Column Profile tab allows you to calculate statistical information for a single column. If you use the Data Profiler, the Relationship tab displays instead of the Column Profile.

> **Note**
>
> This optional feature is not available for columns with nested schemas or the LONG data type.

Related Information

To view the relationship profile data generated by the Data Profiler [page 446]

2.17.2.5.3.1 To calculate value usage statistics for a column

1. Enter a number in the *Top* box.

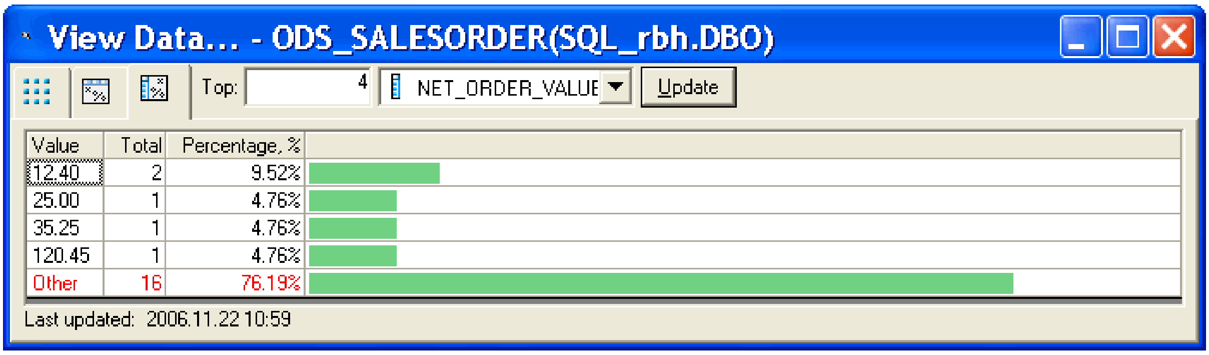
   This number is used to find the most frequently used values in the column. The default is 10, which means that the software returns the top 10 most frequently used values.
2. Select a column name in the list box.
3. Click *Update*.

   The Column Profile grid displays statistics for the specified column. The grid contains three columns:

Column	Description
Value	A top (most frequently used) value found in your specified column, or *Other* (remaining values that are not used as frequently).
Total	The total number of rows in the specified column that contain this value.
Percentage	The percentage of rows in the specified column that have this value compared to the total number of values in the column.

The software returns a number of values up to the number specified in the *Top* box plus an additional value called *Other*.

So if you enter 4 in the Top box, you will get up to five returned values (the top-four-used values in the specified column, plus the Other category). Results are saved in the repository and displayed until you perform a new update.



View Data... - ODS_SALESORDER(SQL_rbh.DBO)

Top: 4 NET_ORDER_VALUE Update

Value	Total	Percentage, %
12.40	2	9.52%
25.00	1	4.76%
35.25	1	4.76%
120.45	1	4.76%
Other	16	76.19%

Last updated: 2006.11.22 10:59

For example, statistical results in the preceding table indicate that of the four most frequently used values in the NET_ORDR_VALUE column, 9.52% use the value 12.40, 4.76% use the value 25.00, and so on. You can also see that the four most frequently used values (the "top four") are used in approximately 24% of all cases because approximately 76% is shown in the Other category. For this example, the total number of rows counted during the calculation for each top value is 21.

2.17.3 Using the Design-Time Data Viewer

The Design-Time Data Viewer lets you view and analyze the input and output for a data set in real time as you design a transform. The data flow does not need to be complete or valid, although it must use a valid, accessible source that contains data.

Use the Design-Time Data Viewer to view the data while designing a transform to ensure that your design returns the results that you expect. The Design-Time Data Viewer displays as input and output panes in the transform editor so that you can compare the data before and after the transform acts on it.

To use the Design-Time Data Viewer for the Global Address Cleanse, Geocoder, and USA Regulatory Address Cleanse transforms, you must have access to the Data Quality reference data (directories).

Related Information

Viewing Design-Time Data [page 700]
Configuring the Design-Time Data Viewer [page 700]

2.17.3.1 Viewing Design-Time Data

1. To view the input and output data for transforms in the transform editor, select *Debug* > *View Design-Time Data*.

   Input and output data panes open in the transform editor. Each pane may contain several tabbed views depending on how many inputs and outputs the selected transform has. For example, although most transforms have only one output, the Validation transform has three outputs.
2. To view the data for a different input or output, click the appropriate tab in the View Data pane.
3. To view the input and output data automatically after you modify a transform, select *Debug* > *View Automatically*.
4. To filter the number of data rows displayed in the panes, select *Debug* > *Filter Input Dataset*. Setting the filter may help increase performance while you are designing the transform and have the Design-Time Data Viewer feature set to update automatically.

   By default, the filter displays the first 50 rows. You can configure the number of rows that are displayed in the *Options* window.
5. To close the Design-Time Data Viewer panes, click the x in the upper-right corner of the pane.

Related Information

Configuring the Design-Time Data Viewer [page 700]

2.17.3.2 Configuring the Design-Time Data Viewer

You can configure the number of data rows that are displayed in the Design-Time Data Viewer panes as well as the time that is allowed for updates before it times out.

1. To configure the Design-Time Data Viewer options, select *Debug* › *Options*.
   A window opens and displays the available options.
2. Edit the options as necessary.

Option	Description
Number of rows to read from any source when filtered	Specifies the number of rows that are read from the source if the Filter Input Dataset menu item is selected. By default, the filter reads the first 50 rows of data from the source.
Time-out interval for automatic mode	Specifies the amount of time, in seconds, allowed to update the data if the View Automatically menu item is selected before timing out and returning an error.
Time-out interval for manual mode	Specifies the amount of time, in seconds, allowed to update the data if the View Automatically menu item is deselected before timing out and returning an error.

3. Click *OK* to close the window.

2.17.3.3 Specifying variables for expressions

You can specify variables for use in transformation expressions. The value of the variable is used in design-time data calculations. You can also set values for global variables that are used only for design-time calculations.

1. To configure the Design-Time Data Viewer options, select *Debug* › *Options*.
   A window opens and displays the available options.
2. In the Variables area, enter the name, data type, and value for the variable.
3. To import a global variable, click the *Import* button. All global variables from each job in the repository populate the table.
4. Enter the value for each imported global value.
   Variable values set in the Design-Time Data Viewer options are only used for design-time data calculations.
5. To remove a variable from the table, select it and click the *Delete* button.
6. Click *OK* to close the window.

2.17.4 Using the interactive debugger

The Designer includes an interactive debugger that allows you to examine and modify data row-by-row (during a debug mode job execution) by placing filters and breakpoints on lines in a data flow diagram. The interactive debugger provides powerful options to debug a job.

> Note
>
> A repository upgrade is required to use this feature.

2.17.4.1 Before starting the interactive debugger

Like executing a job, you can start the interactive debugger from the *Debug* menu when a job is active in the workspace. Select *Start debug*, set properties for the execution, then click *OK*. The debug mode begins. The Debug mode provides the interactive debugger's windows, menus, and tool bar buttons that you can use to control the pace of the job and view data by pausing the job execution using filters and breakpoints.

While in debug mode, all other Designer features are set to read-only. To exit the debug mode and return other Designer features to read/write, click the *Stop debug* button on the interactive debugger toolbar.

All interactive debugger commands are listed in the Designer's *Debug* menu. The Designer enables the appropriate commands as you progress through an interactive debugging session.

Before you start a debugging session, however, you might want to set the following:

- Filters and breakpoints
- Interactive debugger port between the Designer and an engine.

2.17.4.1.1 Setting filters and breakpoints

You can set any combination of filters and breakpoints in a data flow before you start the interactive debugger. The debugger uses the filters and pauses at the breakpoints you set.

If you do not set predefined filters or breakpoints:

- The Designer will optimize the debug job execution. This often means that the first transform in each data flow of a job is pushed down to the source database. Consequently, you cannot view the data in a job between its source and the first transform unless you set a predefined breakpoint on that line.
- You can pause a job manually by using a debug option called *Pause Debug* (the job pauses before it encounters the next transform).

Related Information

Push-down optimizer [page 713]

2.17.4.1.1.1 To set a filter or breakpoint

1. In the workspace, open the job that you want to debug.
2. Open one of its data flows.
3. Right-click the line that you want to examine and select *Set Filter/Breakpoint*.

   A line is a line between two objects in a workspace diagram.

   The Breakpoint window opens. Its title bar displays the objects to which the line connects.
4. Set and enable a filter or a breakpoint using the options in this window.

A debug filter functions as a simple Query transform with a WHERE clause. Use a filter to reduce a data set in a debug job execution. Note that complex expressions are not supported in a debug filter.

Place a debug filter on a line between a source and a transform or two transforms. If you set a filter and a breakpoint on the same line, The software applies the filter first. The breakpoint can only see the filtered rows.

Like a filter, you can set a breakpoint between a source and transform or two transforms. A breakpoint is the location where a debug job execution pauses and returns control to you.

Choose to use a breakpoint with or without conditions.

- If you use a breakpoint without a condition, the job execution pauses for the first row passed to a breakpoint.
- If you use a breakpoint with a condition, the job execution pauses for the first row passed to the breakpoint that meets the condition.

A breakpoint condition applies to the after image for UPDATE, NORMAL and INSERT row types and to the before image for a DELETE row type.

Instead of selecting a conditional or unconditional breakpoint, you can also use the Break after 'n' row(s) option. In this case, the execution pauses when the number of rows you specify pass through the breakpoint.

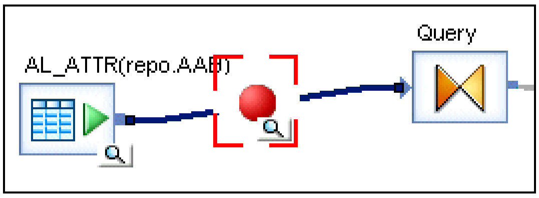
5. Click *OK*.

The Breakpoint enabled icon appears on the selected line.

The software provides the following filter and breakpoint conditions:

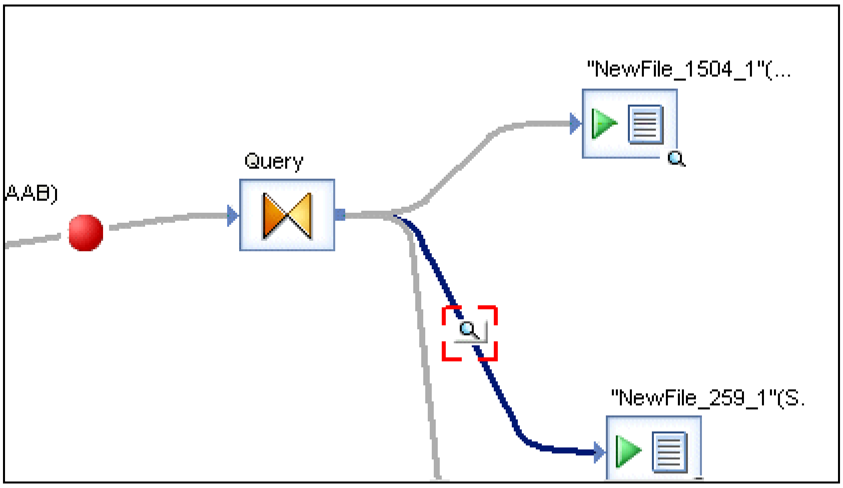
Icon	Description
⚪	Breakpoint disabled
🔴	Breakpoint enabled
▽	Filter disabled
▼	Filter enabled
▽⚪	Filter and breakpoint disabled
▼🔴	Filter and breakpoint enabled
▼⚪	Filter enabled and breakpoint disabled
▽🔴	Filter disabled and breakpoint enabled

In addition to the filter and breakpoint icons that can appear on a line, the debugger highlights a line when it pauses there. A red locator box also indicates your current location in the data flow. For example, when you start the interactive debugger, the job pauses at your breakpoint. The locator box appears over the breakpoint icon as shown in the following diagram:



A View Data button also appears over the breakpoint. You can use this button to open and close the View Data panes.

As the debugger steps though your job's data flow logic, it highlights subsequent lines and displays the locator box at your current position.



Related Information

Panes [page 706]

2.17.4.1.2 Changing the interactive debugger port

The Designer uses a port to an engine to start and stop the interactive debugger. The interactive debugger port is set to `5001` by default.

2.17.4.1.2.1 To change the interactive debugger port setting

1. Select *Tools* > *Options* > *Designer* > *Environment* .

2. Enter a value in the *Interactive Debugger* box.
3. Click *OK*.

2.17.4.2 Starting and stopping the interactive debugger

A job must be active in the workspace before you can start the interactive debugger. You can select a job from the object library or from the project area to activate it in the workspace. Once a job is active, the Designer enables the *Start Debug* option on the *Debug* menu and tool bar.

2.17.4.2.1 To start the interactive debugger

1. In the project area, right-click a job and select *Start debug*.

   Alternatively, in the project area you can click a job and then:

   - Press `Ctrl`+`F8`.
   - From the *Debug* menu, click *Start debug*.
   - Click the *Start debug* button on the tool bar.

   The Debug Properties window opens. The Debug Properties window includes three parameters similar to the Execution Properties window (used when you just want to run a job).

   You will also find more information about the Trace and Global Variable options.

   The options unique to the Debug Properties window are:

   - *Data sample rate*—The number of rows cached for each line when a job executes using the interactive debugger. For example, in the following data flow diagram, if the source table has 1000 rows and you set the *Data sample rate* to `500`, then the Designer displays up to 500 of the last rows that pass through a selected line. The debugger displays the last row processed when it reaches a breakpoint.

     
   - *Exit the debugger when the job is finished*—Click to stop the debugger and return to normal mode after the job executes. Defaults to cleared.
2. Enter the debug properties that you want to use or use the defaults.
3. Click *OK*.

   The job you selected from the project area starts to run in debug mode. The Designer:

- Displays the interactive debugger windows.
- Adds `Debugging Job` **`<JobName>`** to its title bar.
- Enables the appropriate *Debug* menu and tool bar options.
- Displays the debug icon in the status bar.
- Sets the user interface to read-only.

> i Note
>
> You cannot perform any operations that affect your repository (such as dropping objects into a data flow) when you execute a job in debug mode.

When the debugger encounters a breakpoint, it pauses the job execution. You now have control of the job execution. The interactive debugger windows display information about the job execution up to this point. They also update as you manually step through the job or allow the debugger to continue the execution.

Related Information

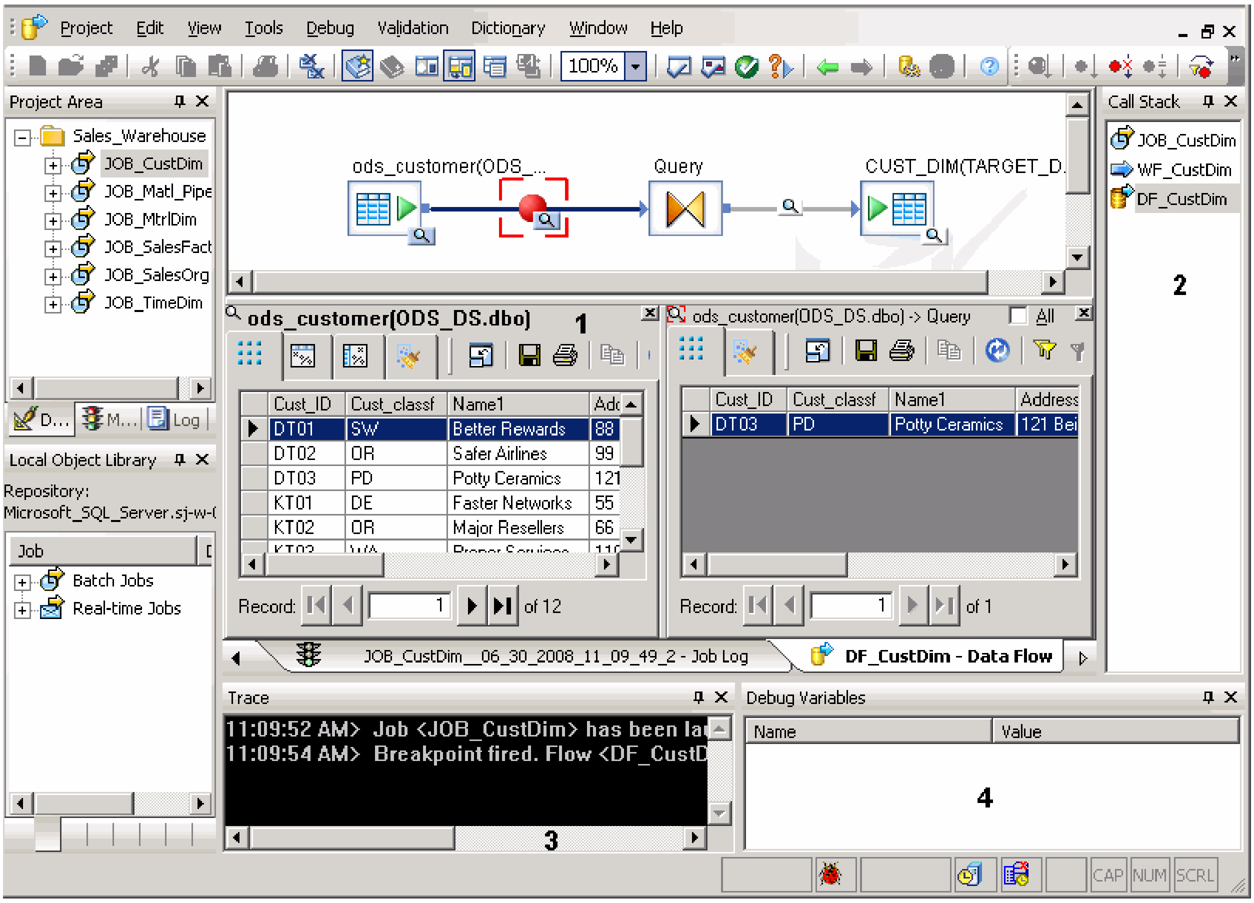
Reference Guide: Parameters [page 840]

2.17.4.2.2 To stop a job in debug mode and exit the interactive debugger

Click the *Stop Debug* button on the tool bar, press *Shift*+*F8*, or from the *Debug* menu, click *Stop debug*.

2.17.4.3 Panes

When you start a job in the interactive debugger, the Designer displays three additional panes as well as the View Data panes beneath the work space. The following diagram shows the default locations for these panes.



ods_customer(ODS_DS.dbo)

Cust_ID	Cust_classf	Name1	Add
DT01	SW	Better Rewards	88
DT02	OR	Safer Airlines	99
DT03	PD	Potty Ceramics	121
KT01	DE	Faster Networks	55
KT02	OR	Major Resellers	66
KT03	WA	Proper Services	11(

ods_customer(ODS_DS.dbo) -> Query

Cust_ID	Cust_classf	Name1	Address
DT03	PD	Potty Ceramics	121 Bei

Trace

```
11:09:52 AM> Job <JOB_CustDim> has been la
11:09:54 AM> Breakpoint fired. Flow <DF_CustD
```

1. View Data panes
2. Call Stack pane
3. Trace pane
4. Debug Variable pane

Each pane is docked in the Designer's window. To move a debugger pane, double-click its control bar to release it, then click and drag its title bar to re-dock it.

The Designer saves the layout you create when you stop the interactive debugger. Your layout is preserved for your next Designer session.

You can resize or hide a debugger pane using its control buttons. To show or hide a debugger pane manually, use the *Debug* menu or the tool bar.

Related Information

Debug menu options and tool bar [page 711]

2.17.4.3.1 Call stack window

The Call Stack window lists the objects in the path encountered so far (before either the job completes, encounters a breakpoint, or you pause it).

For example, for the job JOB_CustDim that includes a work flow and data flow, the Call Stack window might display:

JOB_CustDim

WF_CustDim

DF_CustDim

You can double-click an object in the Call Stack window to open it in the workspace. Similarly, if you click an object in a diagram, the Call Stack window highlights the object.

2.17.4.3.2 Trace window

The Trace window displays the debugger's output status and errors. For example:

```
11:22:06 AM> Job <GO> has been launched in debug mode.
11:22:07 AM> Breakpoint fired. Flow <aaa>: from <Query> to <"NewFile_773"(Simple)>
```

When the job completes, this window displays the following:

Job **`<JobName>`** finished. Stop debugger.

When the job completes the debugger gives you a final opportunity to examine data. When you must exit the debugger, select the *Stop Debug* button on the tool bar, press *shift*+*F8*, or select *DebugStop Debug*.

2.17.4.3.3 Debug Variables window

The Debug Variables window displays global variables in use by the job at each breakpoint.

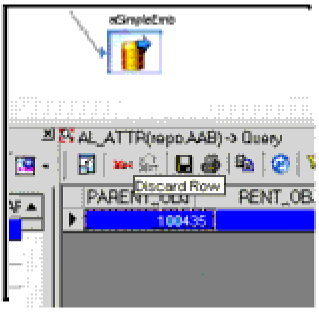
2.17.4.3.4 View Data pane

The View Data pane for lines uses the same tool bar and navigation options described for the View Data feature.

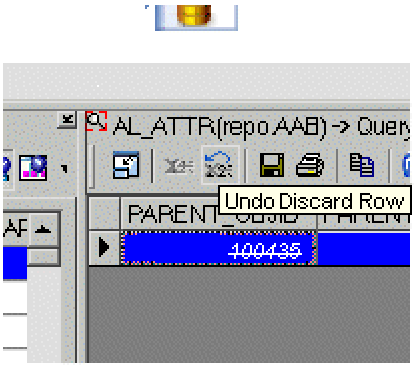
The following View Data pane options are unique to the interactive debugger:

- Allows you to view data that passes through lines.
- Displays (above the View Data tool bar) the names of objects to which a line connects using the format: **`<TableName>`**(**`<DatastoreName>`**.**`<TableOwnerName>`**)-> **`<QueryName>`**.
- Displays data one row at a time by default.
- Provides the *All* check box which allows you to see more than one row of processed data.

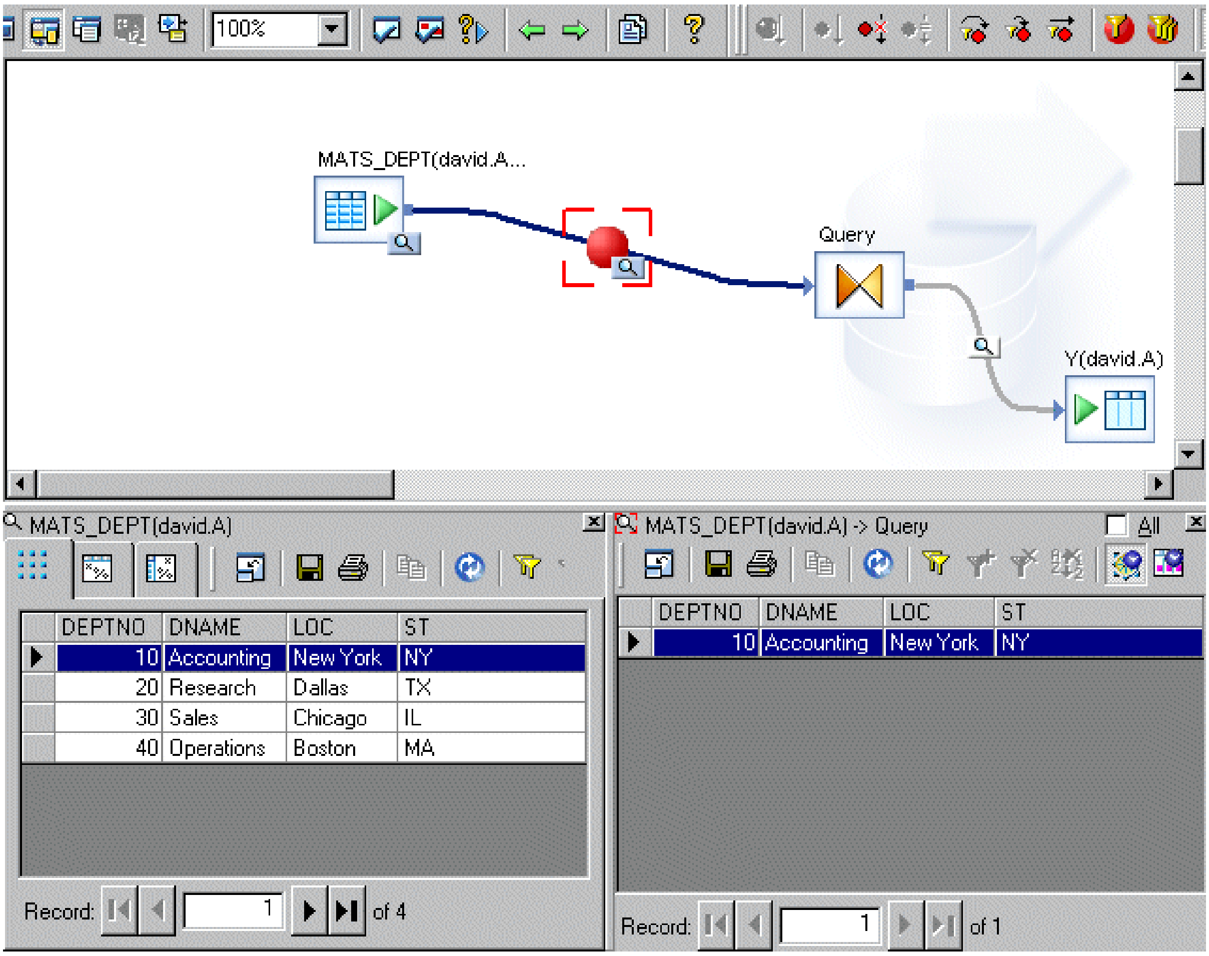
- Allows you to edit data in a cell.
  For example, You might want to fix an error temporarily to continue with a debugger run. You can fix the job design later to eliminate the error permanently.
  To edit cell data:
  - Deselect the *All* check box so that only has one row displayed.
  - Double-click a cell or right-click it and select *Edit cell*.
- Uses a property called the *Data sample rate*.
- Allows you to flag a row that you do not want the next transform to process.
  To discard a row from the next step in a data flow process, select it and click *Discard Row*.



Discarded row data appears in the strike-through style in the View Data pane (for example, 100345).
If you accidentally discard a row, you can undo the discard immediately afterwards. Select the discarded row and click *Undo Discard Row*.



Alternatively, right-click a row and select either Discard Row or *Undo Discard Row* from the shortcut menu.
For example, if a source in a data flow has four rows and you set the Data sample rate to 2 when you start the debugger, it displays the first row processed at a pre-defined breakpoint.

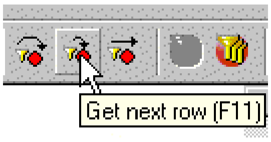


DEPTNO	DNAME	LOC	ST
10	Accounting	New York	NY
20	Research	Dallas	TX
30	Sales	Chicago	IL
40	Operations	Boston	MA

Record: 1 of 4

DEPTNO	DNAME	LOC	ST
10	Accounting	New York	NY

Record: 1 of 1



If you use the *Get Next Row* option, then the next row at the same breakpoint is displayed.

If you want to see both rows, select the *All* check box on the upper-right corner of this pane. The row displayed at the bottom of the table is the last row processed.

At this point, you have viewed two rows that have passed through a line.

If you click *Get Next Row* again, only the last two rows processed are displayed because you set the sample size to 2.

.

Related Information

Using View Data [page 688]

2.17.4.3.5 Filters and Breakpoints window

You can manage interactive debugger filters and breakpoints using the Filters/Breakpoints window. You can open this window from the Debug menu or tool bar.

Lines that contain filters or breakpoints are listed in the far-left side of the Filters/Breakpoints window. To manage these, select the line(s) that you want to edit, select a command from the list and click Execute. You can also select a single line on the left and view/edit its filters and breakpoints on the right side of this window. When you are finished using the Filters/Breakpoints window, click OK.

2.17.4.4 Debug menu options and tool bar

Once you start the interactive debugger, you can access appropriate options from the Designer's *Debug* menu and tool bar.

Image	Option	Description	Key Commands
	Execute	Opens the Execution Properties window from which you can select job properties then execute a job outside the debug mode. Available when a job is active in the workspace.	F8
	Start debug	Opens the Debug Properties window from which you can select job properties then execute a job in debug mode (start the debugger). Other Designer operations are set to read-only until you stop the debugger. Available when a job is active in the workspace.	Ctrl+F8
	Stop debug	Stops a debug mode execution and exits the debugger. All Designer operations are reset to read/write.	Shift+F8
	Pause debug	Allows you to manually pause the debugger. You can use this option instead of a breakpoint.	None
	Step over	Allows you to manually move to the next line in a data flow by stepping over a transform in the workspace. Use this option to see the first row in a data set after it is transformed. The workspace displays a red square on the line to indicate the path you are using. If the transform you step over has multiple outputs, the Designer provides a popup menu from which you can select the logic branch you want to take.	F10
	Get next row	Allows you to stay at the current breakpoint and view the next row of data in the data set.	F11
	Continue	Allows you to give control of the job back to the Designer. The debugger continues until: • You use the Pause debug option. • Another breakpoint is encountered.	Ctrl+F10

Image	Option	Description	Key Commands
		• The job completes.	
	Show Filters/ Breakpoints	Shows all filters and breakpoints that exist in a job. When not selected, all filters and breakpoints are hidden from view. This option is always available in the Designer.	None
	Set Filter/ Breakpoints...	Opens a dialog from which you can set, remove, edit, enable or disable filters and breakpoints. You can also set conditions for breakpoints. From the workspace, you can right-click a line and select the same option from a short cut menu. Available when a data flow is active in the workspace.	F9
	Filters/Breakpoints...	Opens a dialog with which you can manage multiple filters and breakpoints in a data flow. Also offers the same functionality as the Set Filters/Breakpoints window. This option is always available in the Designer.	Alt+F9
	Call Stack	Shows or hides the Call Stack window.	None
	Variables	Shows or hides the Debug Variables window.	None
	Trace	Shows or hides the Trace window.	None

2.17.4.5 Viewing data passed by transforms

To view the data passed by transforms, execute the job in debug mode.

2.17.4.5.1 To view data passed by transforms

1. In the project area, right-click a job and click *Start debug*.

   The Debug Properties window opens.
2. Clear the *Exit the debugger when the job is finished* check box.
3. You can enter a value in the *Data sample rate* text box or leave the default value, which is 500.
4. Click *OK*.

2.17.4.5.2 To view sample data in debug mode

1. While still in debug mode after the job completes, in the project area, click the name of the data flow to view.
2. Click the View Data button displayed on a line in the data flow.
3. Navigate through the data to review it. When done, click the *Stop debug* button on the toolbar.

2.17.4.6 Push-down optimizer

When the software executes a job, it normally pushes down as many operations as possible to the source database to maximize performance. Because the interactive debugger requires a job execution, the following push-down rules apply:

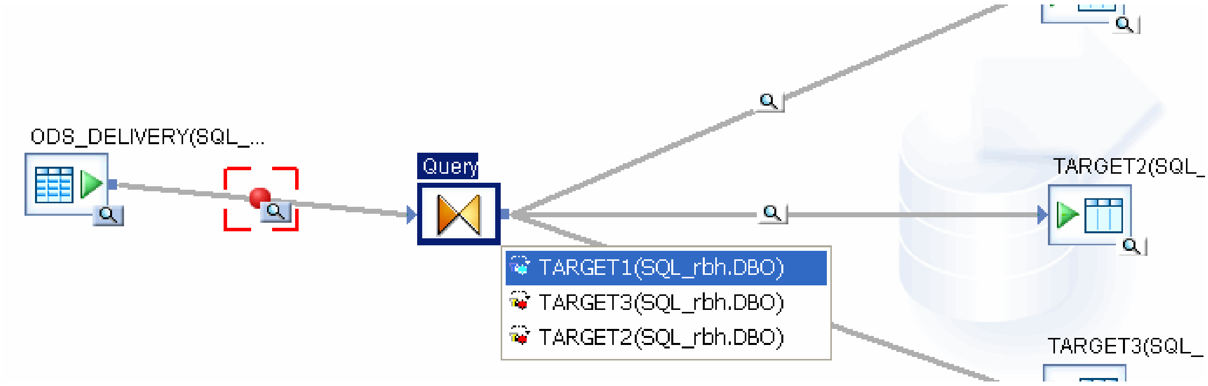
- Query transforms
  The first transform after a source object in a data flow is optimized in the interactive debugger and pushed down to the source database if both objects meet the push-down criteria and if you have not placed a breakpoint on the line before the first transform.
- Breakpoints
  The software does not push down any operations if you set a pre-defined breakpoint. Pre-defined breakpoints are breakpoints defined before you start the interactive debugger.
  After the interactive debugger is started, if the first transform is pushed down, the line is disabled during the debugging session. You cannot place a breakpoint on this line and you cannot use the View Data pane.
- Filters
  If the input of a pre-defined filter is a database source, it is pushed down. Pre-defined filters are interactive debugger filters defined before you start the interactive debugger.

Related Information

Performance Optimization Guide: Push-down operations [page 2116]

2.17.4.7 Limitations

- The interactive debugger can be used to examine data flows. Debug options are not available at the work flow level.
- A repository upgrade is required to use this feature.
- The debugger cannot be used with ABAP data flows.
- All objects in a data flow must have a unique name. For example, if there are several outputs for a transform you can choose which path to use. If any of these objects have the same name, the result of your selection is unpredictable.



2.17.5 Comparing Objects

The software allows you to compare any two objects and their properties by using the Difference Viewer utility. You can compare:

- two different objects
- different versions of the same object
- an object in the local object library with its counterpart in the central object library

You can compare just the top-level objects, or you can include the object's dependents in the comparison.

Objects must be of the same type; for example, you can compare a job to another job or a custom function to another custom function, but you cannot compare a job to a data flow.

2.17.5.1 To compare two different objects

1. In the local or central object library, right-click an object name.
2. From the shortcut menu, highlight *Compare*, and from the submenu, click one of the following options (availability depends on the object you selected):

Option	Description
Object to central	Compares the selected object to its counterpart in the central object library.
Object with dependents to central	Compares the selected object and its dependent objects to its counterpart in the central object library.
Object to...	Compares the selected object to another similar type of object.
Object with dependents to...	Compares the selected object and its dependents to another similar type of object.

   The cursor changes to a target icon.
3. When you move the cursor over an object that is eligible for comparison, the target cursor changes color. Click on the desired object.

The *Difference Viewer* window opens in the workspace.

The window identifies changed items with a combination of icons, color, and background shading. Some of these properties are configurable.

Depending on the object type, the panes show items such as the object's properties and the properties of and connections (links) between its child objects.

2.17.5.2 To compare two versions of the same object

If you are working in a multiuser environment and using a central object library, you can compare two objects that have different versions or labels.

1. In the central object library, right-click an object name, and from the shortcut menu click *Show History*.
2. In the *History* window, Ctrl-click the two versions or labels you want to compare.
3. Click *Show Differences* or *Show Differences with Dependents*.

   The *Difference Viewe*r window opens in the workspace.
4. Close the *History* window.

Related Information

Designer Guide: Working in a Multi-user Environment, Viewing object history [page 822]

2.17.5.3 Overview of the Difference Viewer window

The first object you selected appears in the left pane of the window, and the second object appears on the right. Following each object name is its location.

The Difference Viewer window includes the following features:

- toolbar
- navigation bar
- status bar
- shortcut menu

Also, when a Difference Viewer window is active, the main designer window also contains a menu called Difference Viewer. The next section describes these features.

You can have multiple Difference Viewer windows open at a time in the workspace. To refresh a Difference Viewer window, press F5.

Expanding or collapsing any property set also expands or collapses the compared object's corresponding property set.

2.17.5.3.1 Toolbar

The toolbar includes the following buttons.

Navigation buttons

- First Difference (Alt+Home)
- Previous Difference (Alt+left arrow)
- Current Difference
- Next Difference (Alt+right arrow)
- Last Difference (Alt+End)

Filter buttons

- Enable filter(s)—Click to open the Filters dialog box.
    - *Hide non-executable elements*—Select this option to remove from view those elements that do not affect job execution.
    - *Hide identical elements*—Select this option to remove from view those elements that do not have differences.
- Disable filters—Removes all filters applied to the comparison.

Show levels

Show Level 1 shows only the objects you selected for comparison, Show Level 2 expands to the next level, etc. Show All Levels expands all levels of both trees.

Find (Ctrl+F)

Click *Find* to open a text search dialog box.

Open in new window

Click to open the currently active Difference Viewer in a separate window. You must close this window before continuing.

2.17.5.3.2 Navigation bar

The vertical navigation bar contains colored bars that represent each of the differences throughout the comparison. The colors correspond to those in the status bar for each difference. An arrow in the navigation bar indicates the difference that is currently highlighted in the panes. You can click on the navigation bar to select a difference (the cursor point will have a star on it). The purple brackets in the bar indicate the portion of the comparison that is currently in view in the panes.

See the next section for more information on how to navigate through differences.

2.17.5.3.3 Status bar

The status bar at the bottom of the window includes a key that illustrates the color scheme and icons that identify the differences between the two objects.

Icon	Difference	Description
✖	Deleted	The item does not appear in the object in the right pane.
▲	Changed	The differences between the items are highlighted in blue (the default) text.
➡	Inserted	The item has been added to the object in the right pane.
!	Consolidated	This icon appears next to an item if items within it have differences. Expand the item by clicking its plus sign to view the differences

You can change the color of these icons by right-clicking in the Difference Viewer window and clicking Configuration.

The status bar also includes a reference for which difference is currently selected in the comparison (for example, the currently highlighted difference is 9 of 24 total differences in the comparison).

The status bar also indicates that there is at least one filter applied to this comparison.

Related Information

Shortcut menu [page 717]

2.17.5.3.4 Shortcut menu

Right-clicking in the conbody of the Difference Viewer window displays a shortcut menu that contains all the toolbar commands plus:

- View — Toggle to display or hide the status bar, navigation bar, or secondary toolbar (an additional toolbar that appears at the top of the window; you might find this useful if you have the Differences Viewer open in a separate window).
- Layout — Use to reposition the navigation bar.
- Configuration — Click to modify viewing options for elements with differences.

Related Information

To change the color scheme [page 718]

2.17.5.3.4.1 To change the color scheme

The status bar at the bottom of the Difference Viewer window shows the current color scheme being used to identify deleted, changed, inserted, or consolidated items in the comparison panes. You can customize this color scheme as follows.

1. Right-click in the conbody of the Difference Viewer window to display the shortcut toolbar.
2. Click Configuration to open the Configuration window.
3. Click a marker (Inserted, Deleted, Changed, or Consolidated) to change.
4. Click the Color sample to open the Color palette.
5. Click a Basic color or create a custom color.
6. Click *OK*.
7. Click another marker to change it, or click *OK* to close the Configuration window.

2.17.5.3.4.2 To change the background shading

Items with differences appear with a background default color of grey. You can customize this background.

1. Right-click in the conbody of the Difference Viewer window to display the shortcut toolbar.
2. Click Configuration to open the Configuration window.
3. Click a marker to change, or select the *Apply for all markers* check box.
4. Click the Background sample to open the Color palette.
5. Click a Basic color or create a custom color.
6. Click *OK*.
7. To apply different background colors to different markers, click the marker to configure and repeat steps 4 through 6.
8. Click *OK* to close the Configuration window.

2.17.5.3.5 Difference Viewer menu

When a Difference Viewer window is active in the workspace, the main Designer window contains a menu called Difference Viewer. The menu contains the same commands as the toolbar.

2.17.5.4 Navigating through differences

The Difference Viewer window offers several options for navigating through differences.

You can navigate through the differences between the objects using the navigation buttons on the toolbar. For example, clicking the Next Difference button highlights the next item that differs in some way from the compared object. The item is marked with the appropriate icon and only the differing text appears highlighted in the color assigned to that type of difference.

You can also use the navigation bar. Select an item in either pane that has a difference. Note that an arrow appears next to the colored bar that corresponds to that item. You can click on these bars to jump to different places in the comparison, for example to view only inserted items (with a default color of green). The purple brackets in the bar indicate the portion of the comparison that is currently in view in the panes. Use the scroll bar in either pane to adjust the bracketed view.

For text-based items such as scripts, click the magnifying glass to view the text in a set of new panes that appear below the main object panes. Use the scroll bars for these panes to navigate within them. Click the magnifying glass (or any other item) to close the text panes.

2.17.6 Calculating column mappings

SAP Data Services can calculate information about target tables and columns and the sources used to populate them, for example for impact and lineage or auto documentation reports.

Calculating column mappings populates the internal ALVW_MAPPING view and the AL_COLMAP_NAMES table. The ALVW_MAPPING view provides current data to metadata reporting applications like Impact and Lineage Analysis. If you need to generate a report about a data flow that processes nested (NRDM) data, query the AL_COLMAP_NAMES table using a custom report.

Whenever a column mapping calculation is in progress, the Designer displays a status icon at the bottom right of the window. You can double-click this icon to cancel the process.

To calculate column mappings, you can:

- Enable the option in the Designer to automatically calculate column mappings.
- Execute the column mapping process manually from either the Designer or the Impact and Lineage Analysis application in the Management Console.

Related Information

Reference Guide: Metadata in Repository Tables and Views, Storing nested column-mapping data [page 1731]

2.17.6.1 To automatically calculate column mappings

To set the option to automatically calculate column mapping information, in the Designer select ▶ *Tools* > *Options* > *Designer* > *General* > *Automatically calculate column mappings* ◀. This option is selected by default.

Note that if the Designer option *Automatically calculate column mappings* is cleared, any subsequent changes made to the data flow require that you manually recalculate the column mappings to ensure the ALVW_MAPPING view and the AL_COLMAP_NAMES table have the most current information.

2.17.6.2 To manually calculate column mappings

If the Designer option *Automatically calculate column mappings* is cleared and you want to generate reports, you can manually calculate the mappings. You can manually calculate column mappings at any time in either the Designer or the Management Console.

In the Designer, right-click in the object library and select ▶ *Repository* > *Calculate column mappings* ◀.

In the Management Console:

1. Select *Impact and Lineage Analysis*.
2. Open the *Settings* control panel.
3. Click the *Refresh Usage Data* tab.
4. Select the Job Server that is associated with the repository you want to use.
5. Click *Calculate Column Mapping*.

On the Impact and Lineage Analysis *Overview* tab, you can expand *Data Flow Column Mapping Calculation* to view a list of data flows and the calculation status of each. If the mapping calculation is complete, the *Status* indicator is checked.

2.18 Recovery Mechanisms

Recovery mechanisms are available in SAP Data Services for batch jobs only.

Related Information

Recovering from unsuccessful job execution [page 721]
Automatically recovering jobs [page 721]
Manually recovering jobs using status tables [page 728]
Processing data with problems [page 729]

2.18.1 Recovering from unsuccessful job execution

If an SAP Data Services job does not complete properly, you must fix the problems that prevented the successful execution of the job and run the job again.

However, during the failed job execution, some data flows in the job may have completed and some tables may have been loaded, partially loaded, or altered. Therefore, you need to design your data movement jobs so that you can recover—that is, rerun the job and retrieve all the data without duplicate or missing data.

You can use various techniques to recover from unsuccessful job executions. This section discusses two techniques:

- Automatically recovering jobs — A software feature that allows you to run unsuccessful jobs in recovery mode.
- Manually recovering jobs using status tables — A design technique that allows you to rerun jobs without regard to partial results in a previous run.

You might need to use a combination of these techniques depending on the relationships between data flows in your application.

If you do not use these techniques, you might need to roll back changes manually from target tables if interruptions occur during job execution.

Related Information

Automatically recovering jobs [page 721]

Manually recovering jobs using status tables [page 728]

2.18.2 Automatically recovering jobs

With automatic recovery, the software records the result of each successfully completed step in a job. If a job fails, you can choose to run the job again in recovery mode. During recovery mode, the software retrieves the results for successfully completed steps and reruns uncompleted or failed steps under the same conditions as the original job. For recovery purposes, the software considers steps that raise exceptions as failed steps, even if the step is caught in a try/catch block.

2.18.2.1 Enabling automated recovery

To use the automatic recover feature, you must enable the feature during initial execution of a job. The software saves the results from successfully completed steps when the automatic recovery feature is enabled.

2.18.2.1.1 To run a job from Designer with recovery enabled

1. In the project area, select the job name.
2. Right-click and choose *Execute*.

   The software prompts you to save any changes.
3. Make sure that the *Enable Recovery* option is selected in the *Execution Properties* window.

   If this check box is not selected, the software does not record the results from the steps during the job and cannot recover the job if it fails. In that case, you must perform any recovery operations manually.

2.18.2.1.2 To run a job with recovery enabled from the Administrator

When you schedule or execute a job from the Administrator, select the *Enable Recovery* check box.

2.18.2.2 Marking recovery units

In some cases, steps in a work flow depend on each other and must be executed together. Because of the dependency, you should designate the work flow as a "recovery unit." When a work flow is a recovery unit, the entire work flow must complete successfully. If the work flow does not complete successfully, the software executes the entire work flow during recovery, even steps that executed successfully in prior work flow runs.

However, there are some exceptions to recovery unit processing. For example, when you specify that a work flow or a data flow should only execute once, a job will never re-execute that work flow or data flow after it completes successfully, except if that work flow or data flow is contained within a recovery unit work flow that re-executes and has not completed successfully elsewhere outside the recovery unit.

It is recommended that you not mark a work flow or data flow as *Execute only once* when the work flow or a parent work flow is a recovery unit.

Related Information

Reference Guide: Data flow [page 857]
Reference Guide: Work flow [page 1002]

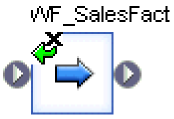
2.18.2.2.1 To specify a work flow as a recovery unit

1. In the project area, select the work flow.
2. Right-click and choose *Properties*.

3. Select the *Recover as a unit* check box, then click *OK*.

   During recovery, the software considers this work flow a unit. If the entire work flow completes successfully—that is, without an error—during a previous execution, then the software retrieves the results from the previous execution. If any step in the work flow did not complete successfully, then the entire work flow re-executes during recovery.

   On the workspace diagram, the black "x" and green arrow symbol indicate that a work flow is a recovery unit.



2.18.2.3 Running in recovery mode

If a job with automated recovery enabled fails during execution, you can re-execute the job in recovery mode.

As with any job execution failure, you need to determine and remove the cause of the failure and rerun the job in recovery mode. If you need to make any changes to the job itself to correct the failure, you cannot use automatic recovery but must run the job as if it is a first run.

In recovery mode, the software executes the steps or recovery units that did not complete successfully in a previous execution—this includes steps that failed and steps that threw an exception but completed successfully such as those in a try/catch block. As in normal job execution, the software executes the steps in parallel if they are not connected in the work flow diagrams and in serial if they are connected.

2.18.2.3.1 To run a job in recovery mode from Designer

1. In the project area, select the (failed) job name.
2. Right-click and choose *Execute*.

   The software prompts you to save any objects that have unsaved changes.
3. Make sure that the *Recover from last failed execution* check box is selected.

   This option is not available when a job has not yet been executed, when the previous run succeeded, or when recovery mode was disabled during previous run.

   When you select Recover from last failed execution, the software retrieves the results from any steps that were previously executed successfully and executes or re-executes any other steps.

   If you clear this option, the software runs this job anew, performing all steps.

When you schedule or execute a (failed) job from the Administrator, select the *Recover from last failed execution* check box.

2.18.2.4 Ensuring proper execution path

The automated recovery system requires that a job in recovery mode runs again exactly as it ran previously.

It is important that the recovery job run exactly as the previous run. If the job was allowed to run under changed conditions—suppose a `<sysdate>` function returns a new date to control what data is extracted—then the new data loaded into the targets will no longer match data successfully loaded into the target during the first execution of the job.

For example, suppose a daily update job running overnight successfully loads dimension tables in a warehouse. However, while the job is running, the database log overflows and stops the job from loading fact tables. The next day, the administrator truncates the log file and runs the job again in recovery mode. The recovery job does not reload the dimension tables because the original, failed run successfully loaded them.

To ensure that the fact tables are loaded with the data that corresponds properly to the data already loaded in the dimension tables, the recovery job must use the same extraction criteria that the original job used when loading the dimension tables. If the recovery job used new extraction criteria—such as basing data extraction on the current system date—the data in the fact tables would not correspond to the data previously extracted into the dimension tables.

In addition, if the recovery job uses new values, then the job execution may follow a completely different path through conditional steps or try/catch blocks.

If any global variable value is changed within a recovery as unit work flow, any downstream global variable reference is not guaranteed to have the updated value in the recovery mode execution. This will happen in the recovery mode execution if the previous execution failure is not in the work flow that contains the variable change.

When recovery is enabled, the software stores results from the following types of steps:

- Work flows
- Batch data flows
- Script statements
- Custom functions (stateless type only)
- SQL function
- exec function
- get_env function
- rand function
- sysdate function
- systime function

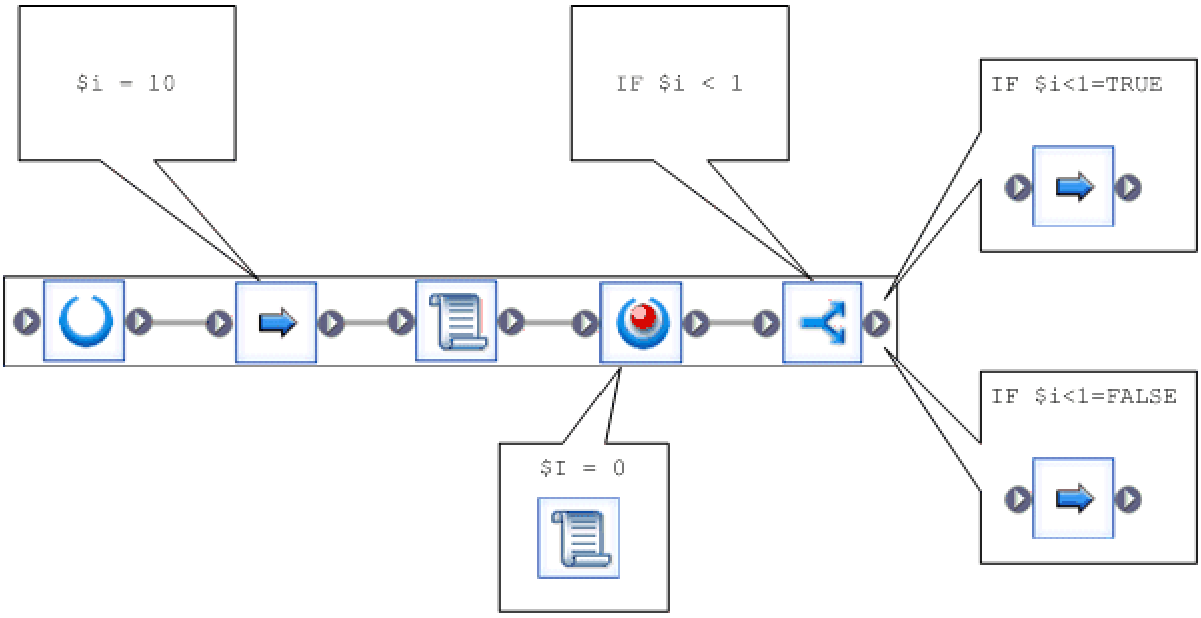
2.18.2.5 Using try/catch blocks with automatic recovery

SAP Data Services does not save the result of a try/catch block for reuse during recovery. If an exception is thrown inside a try/catch block, then during recovery the software executes the step that threw the exception and subsequent steps.

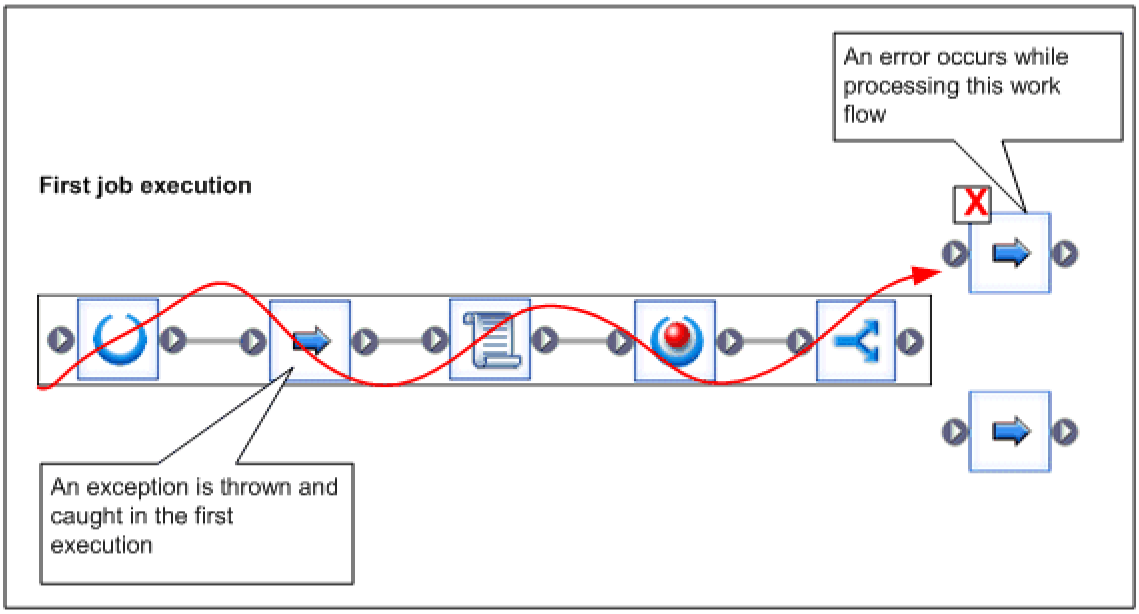
Because the execution path through the try/catch block might be different in the recovered job, using variables set in the try/catch block could alter the results during automatic recovery.

For example, suppose you create a job that defines a variable, `$i,` that you set within a try/catch block. If an exception occurs, you set an alternate value for `$i`. Subsequent steps are based on the value of `$i`.

Job execution logic

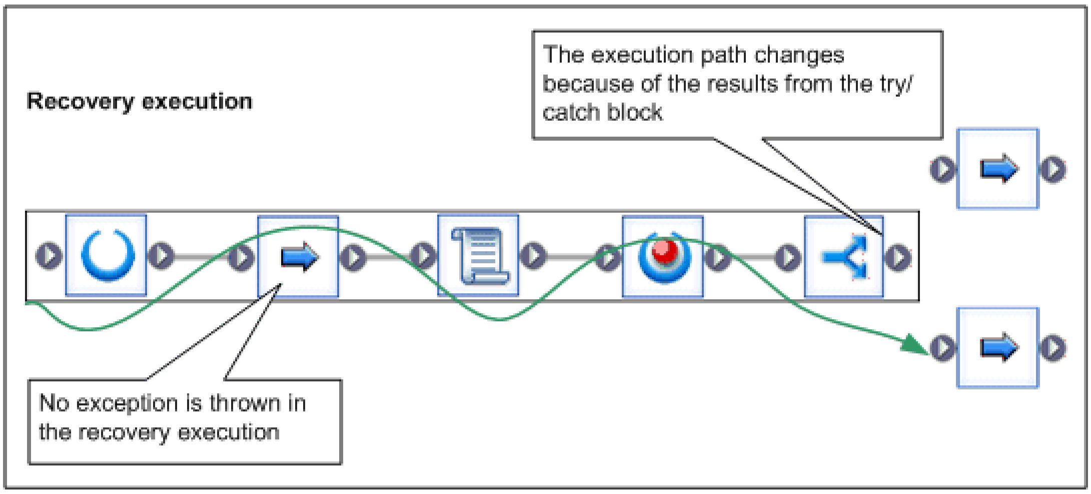


During the first job execution, the first work flow contains an error that throws an exception, which is caught. However, the job fails in the subsequent work flow.



First job execution
An error occurs while processing this work flow
X
An exception is thrown and caught in the first execution

You fix the error and run the job in recovery mode. During the recovery execution, the first work flow no longer throws the exception. Thus the value of the variable, `<$i>` , is different, and the job selects a different subsequent work flow, producing different results.



Recovery execution
The execution path changes because of the results from the try/ catch block
No exception is thrown in the recovery execution

To ensure proper results with automatic recovery when a job contains a try/catch block, do not use values set inside the try/catch block in any subsequent steps.

2.18.2.6 Ensuring that data is not duplicated in targets

Define work flows to allow jobs correct recovery. A data flow might be partially completed during an incomplete run. As a result, only some of the required rows could be inserted in a table. You do not want to insert duplicate rows during recovery when the data flow re-executes.

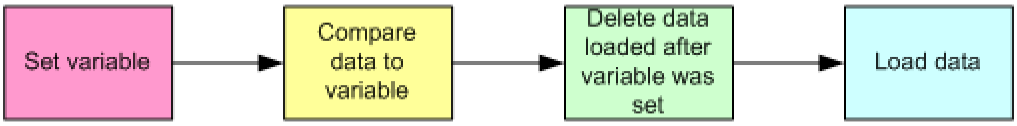
You can use several methods to ensure that you do not insert duplicate rows:

- Design the data flow to completely replace the target table during each execution
  This technique can be optimal when the changes to the target table are numerous compared to the size of the table. You can use tuning techniques such as bulk loading options to improve overall performance.
- Set the auto correct load option for the target table
  The auto correct load option checks the target table for existing rows before adding new rows to the table. Using the auto correct load option, however, can needlessly slow jobs executed in non-recovery mode. Consider this technique when the target table is large and the changes to the table are relatively few.
- Include a SQL command to execute before the table loads
  Preload SQL commands can remove partial database updates that occur during incomplete execution of a step in a job. Typically, the preload SQL command deletes rows based on a variable that is set before the partial insertion step began.

2.18.2.7 Using preload SQL to allow re-executable data flows

To use preload SQL commands to remove partial database updates, tables must contain a field that allows you to tell when a row was inserted. Create a preload SQL command that deletes rows based on the value in that field.

For example, suppose a table contains a column that records the time stamp of any row insertion. You can create a script with a variable that records the current time stamp before any new rows are inserted. In the target table options, add a preload SQL command that deletes any rows with a time-date stamp greater than that recorded by the variable.



During initial execution, no rows match the deletion criteria. During recovery, the variable value is not reset. (The variable value is set in a script, which is executed successfully during the initial run.) The rows inserted during the previous, partial database load would match this criteria, and the preload SQL command would delete them.

To use preload SQL commands properly, you must define variables and pass them to data flows correctly.

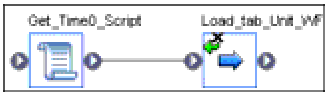
2.18.2.7.1 To use preload SQL commands to ensure proper recovery

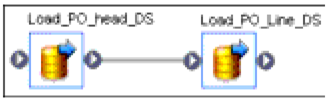
1. Determine appropriate values that you can use to track records inserted in your tables.

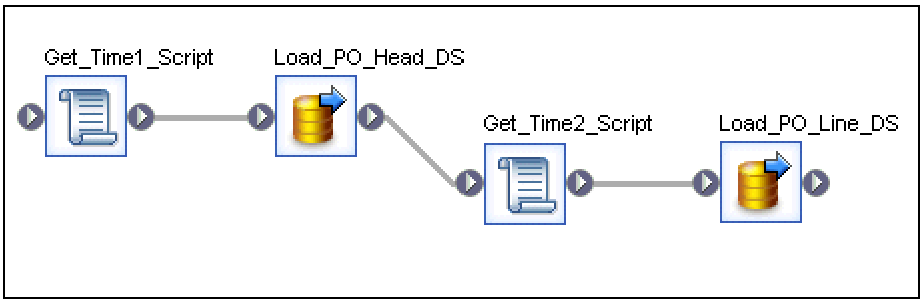
   For example, if each row in a table is marked with the insertion time stamp, then you can use the value from the `sysdate()` function to determine when a row was added to that table.
2. Create variables that can store the "tracking" values.

   Variables are either job or work-flow specific. If a work flow is a recovery unit, create the "tracking" variables for that work flow at the job level; otherwise, create your tracking variables at the work flow level. Generally, you do not want tracking variables reset during recovery because when they reset, the preload SQL command will not work properly.
3. Create scripts that set the variables to the appropriate values.

   Scripts are unique steps in jobs or work flows. You need to create a separate script that sets the required variables before each data flow or work flow that loads a table. If a work flow is a recovery unit, create the scripts for that work flow at the job level; otherwise, create the scripts at the work flow level.
4. Connect the scripts to the corresponding data flows or work flows.







5. Create parameters to pass the variable information from the job or work flow where you created the variable to the data flow that uses the tracking variable in the preload SQL command.
6. Insert appropriate preload SQL commands that remove any records inserted during earlier unsuccessful runs.

   The preload SQL commands reference the parameter containing the tracking variable, deleting rows that were inserted after the variable was set.

   For example, suppose the **`<PO_ITEM>`** table records the date-time stamp in the **`<TIMESTMP>`** column. You created a variable **`<$load_time>`** that records the value from the `sysdate()` function before the load starts, and you passed that variable to the data flow that loads the **`<PO_ITEM>`** table in a parameter named **`<$load_time>`**. Then, your preload SQL command must delete any records in the table where the value in **`<TIMESTMP>`** is larger than the value in **`<$load_time>`**.

   Delete from **`<PO_ITEM>`** where **`<TIMESTMP>`** `> [$`**`<load_time>`**`]`

2.18.3 Manually recovering jobs using status tables

You can design your jobs and work flows so that you can manually recover from an unsuccessful run. A job designed for manual recovery must have certain characteristics:

- You can run the job repeatedly.
- The job implements special steps to recover data when a step did not complete successfully during a previous run.

You can use an execution status table to produce jobs that can be run multiple times without duplicating target rows. The table records a job's execution status. A "failure" value signals SAP Data Services to take a recovery execution path.

To implement a work flow with a recovery execution path:

- Define a flag that indicates when the work flow is running in recovery mode.

- Store the flag value in a status table.
- Check the flag value in the status table before executing a work flow to determine which path to execute in the work flow.
- Update the flag value when the work flow executes successfully.

For example, you could design a work flow that uses the auto correct load option when a previous run does not complete successfully. This work flow would have five steps, as illustrated:

1. Retrieve the flag value, which indicates the success or failure of the previous execution, from the status table. Store this value in a variable such as `<$recovery_needed>` .
2. In a conditional, evaluate the `<$recovery_needed>` variable.
3. If recovery is required, execute the recovery data flow recover_customer. This data flow loads the data using the auto correct load option.
4. If recovery is not required, execute the non-recovery data flow load_customer. This data flow loads the data without the auto correct load option.
5. Update the flag value in the status table to indicate successful execution.

2.18.4 Processing data with problems

Jobs might not produce the results you expect because of problems with data. In some cases, the software is unable to insert a row. In other cases, the software might insert rows with missing information. You can design your data flows to anticipate and process these types of problems. For example, you might have a data flow write rows with missing information to a special file that you can inspect later.

This section describes mechanisms you can use to anticipate and process data problems. In particular, this section discusses three techniques:

- Using overflow files
- Filtering missing or bad values
- Handling facts with missing dimensions

2.18.4.1 Using overflow files

A row that cannot be inserted is a common data problem. Use the overflow file to process this type of data problem. When you specify an overflow file and the SAP Data Services cannot load a row into a table, the software writes the row to the overflow file instead. The trace log indicates the data flow in which the load failed and the location of the file.

For any table used as a target, you can set the option to use an overflow file in the *Options* tab. When you specify an overflow file, give a full path name to ensure that the software creates a unique file when more than one file is created in the same job. By default, the name of the overflow file is the target table name.

When you select the overflow file option, you choose what the software writes to the file about the rows that failed to load: either the data from the row or the SQL commands required to load the row. If you select data, you can use the software to read the data from the overflow file, cleanse it, and load it into the target table. If you select SQL commands, you can use the commands to load the target manually when the target is accessible.

There are many reasons for loading to fail, for example:

- Out of memory for the target
- Overflow column settings
- Duplicate key values

You can use the overflow information to identify invalid data in your source or problems introduced in the data movement. Every new run will overwrite the existing overflow file.

> i Note
>
> You cannot use overflow files when loading to a BW Transfer Structure.

2.18.4.2 Filtering missing or bad values

A missing or invalid value in the source data is another common data problem. Using queries in data flows, you can identify missing or invalid values in source data. You can also choose to include this data in the target or to disregard it.

For example, suppose you are extracting data from a source and you know that some phone numbers and customer names are missing. You can use a data flow to extract data from the source, load the data into a target, and filter the NULL values into a file for your inspection.

The data flow has five steps:

1. Extracts data from the source.
2. Selects the data set to load into the target and applies new keys. (It does this by using the Key_Generation function.)
3. Loads the data set into the target, using the bulk load option for best performance.
4. Uses the same data set for which new keys were generated in step 2, and select rows with missing customer names and phone numbers.
5. Writes the customer IDs for the rows with missing data to a file.

Now, suppose you do not want to load rows with missing customer names into your target. You can insert another query into the data flow to ensure that SAP Data Services does not insert incomplete rows into the target. The new query filters the rows with missing customer names before loading any rows into the target. The missing data query still collects those rows along with the rows containing missing phone numbers. In this version of the example, the Key_Generation transform adds keys for new rows before inserting the filtered data set into the target.

The data flow now has six steps.

1. Extracts data from the source.
2. Selects the data set to load into the target by filtering out rows with no customer name values.
3. Generates keys for rows with customer names.
4. Loads the valid data set (rows with customer names) into the target using the bulk load option for best performance.

5. Uses a separate query transform to select rows from the source that have no names or phones.
   Note that the software does not load rows with missing customer names into the target; however, the software does load rows with missing phone numbers.
6. Writes the customer IDs for the rows with missing data to a file.

You could add more queries into the data flow to select additional missing or invalid values for later inspection.

2.18.4.3 Handling facts with missing dimensions

Another data problem occurs when SAP Data Services searches a dimension table and cannot find the values required to complete a fact table.

You can approach this problem in several ways:

- Leave the problem row out of the fact table.
  Typically, this is not a good idea because analysis done on the facts will be missing the contribution from this row.
- Note the row that generated the error, but load the row into the target table anyway.
  You can mark the row as having an error, or pass the row information to an error file as in the examples from *Filtering missing or bad values* [page 730].
- Fix the problem programmatically.
  Depending on the data missing, you can insert a new row in the dimension table, add information from a secondary source, or use some other method of providing data outside of the normal, high-performance path.

2.18.5 Exchanging metadata

SAP Data Services offers several methods for exchanging metadata:

- Using the Metadata Exchange option, you can export metadata into an XML file. After you create the file, you must manually import it into another tool.
- Using the SAP BusinessObjects Universes option, you can export metadata directly from a repository into a universe using the *Create* or *Update* data mode.

Related Information

Metadata exchange [page 731]

Creating BusinessObjects universes [page 733]

2.18.5.1 Metadata exchange

You can exchange metadata between the software and third-party tools using XML files and the *Metadata Exchange* option.

The software supports two built-in metadata exchange formats:

- CWM 1.0 XML/XMI 1.1
  CWM (the Common Warehouse Metamodel)— is a specification that enables easy interchange of data warehouse metadata between tools, platforms, and repositories in distributed heterogeneous environments.
- ERwin 4.x XML

The software can also use:

- MIMB (the *Meta Integration® Model Bridge*)
  MIMB is a Windows stand-alone utility that converts metadata models among design tool formats. By using MIMB with the software, you can exchange metadata with all formats that MIMB supports. If MIMB is installed, the additional formats it supports are listed in the Metadata Exchange window.
- BusinessObjects Universe Builder
  Converts repository metadata to BusinessObjects universe metadata. See *Creating BusinessObjects universes* [page 733].

2.18.5.1.1 Importing metadata files into the software

You can import metadata from ERwin Data Modeler 4.x XML into a datastore.

2.18.5.1.1.1 To import metadata using Metadata Exchange

1. From the *Tools* menu, select *Metadata Exchange*.
2. In the Metadata Exchange window, select *Import metadata from file*.
3. In the *Metadata format* box, select `ERwin 4.x XML` from the list of available formats.
4. Specify the *Source file name* (enter directly or click *Browse* to search).
5. Select the *Target datastore name* from the list of datastores.
6. Click *OK* to complete the import.

2.18.5.1.2 Exporting metadata files from the software

You can export metadata into a file that other tools can read.

2.18.5.1.2.1 To export metadata using Metadata Exchange

1. From the *Tools* menu, select *Metadata Exchange*.
2. In the Metadata Exchange window, select *Export Data Services metadata to file*.
3. Select a *Metadata format* for the target from the list of available formats.

If you have MIMB installed and you select an MIMB-supported format, select the Visual check box to open the MIMB application when completing the export process.

If you do not select the Visual check box, the metadata is exported without opening the MIMB application. Using the MIMB application provides more configuration options for structuring the metadata in the exported file.

4. Specify the target file name (enter directly or click *Browse* to search).

   When you search for the file, you open a typical browse window, like this:

   Find any of the following file formats/types:

Format	File type
DI CWM 1.0 XML/XMI 1.1	XML
DI ERwin 4.x XML	XML
MIMB format (only if installed)	All

   After you select a file, click Open.
5. Select the *Source datastore name* from the list of datastores.
6. Click *OK* to complete the export.

2.18.5.2 Creating BusinessObjects universes

The software allows you to easily export its metadata to BusinessObjects universes for use with business intelligence tools. A universe is a layer of metadata used to translate physical metadata into logical metadata. For example the physical column name `deptno` might become `Department Number` according to a given universe design.

i Note

To use this export option, first install BusinessObjects Universe Builder on the same computer as SAP BusinessObjects Designer and SAP Data Services Designer. You can install Universe Builder using the installer for Designer or using the separate Universe Builder CD.

You can create usinessObjects universes using the *Tools* menu or the object library.

2.18.5.2.1 To create universes using the Tools menu

1. Select *Tools* > *BusinessObjects Universes* .
2. Select either *Create* or *Update*.

   The *Create Universe* or *Update Universe* window opens.
3. Select the datastore(s) that contain the tables and columns to export and click *OK*.

   The software launches the Universe Builder application and provides repository information for the selected datastores.

For more information, refer to the BusinessObjects Universe Builder Guide.

2.18.5.2.2 To create universes using the object library

1. Select the *Datastores* tab.
2. Right-click a datastore and select *BusinessObjects Universes*.
3. Select either *Create* or *Update*.

   The software launches the Universe Builder application and provides repository information for the selected datastores.

   For more information, refer to the BusinessObjects Universe Builder Guide.

2.18.5.2.3 Mappings between repository and universe metadata

SAP Data Services metadata maps to BusinessObjects Universe metadata as follows:

SAP Data Services	BusinessObjects Universe
Table	Class, table
Column	Object, column
Owner	Schema
Column data type (see next table)	Object data type
Primary key/foreign key relationship	Join expression
Table description	Class description
Table Business Description	Class description
Table Business Name	Class name
Column description	Object description
Column Business description	Object description
Column Business Name	Object name
Column mapping	Object description
Column source information (lineage)	Object description

Data types also map:

Data type	BusinessObjects Type
Date/Datetime/Time	Date
Decimal	Number
Int	Number
Double/Real	Number
Interval	Number
Varchar	Character
Long	Long Text

2.18.5.2.4 Attributes that support metadata exchange

The attributes *Business_Name* and *Business_Description* exist in the software for both tables and columns. These attributes support metadata exchanged between SAP Data Services and SAP BusinessObjects Universe Builder.

- A Business_Name is a logical field. Data Services stores it as a separate and distinct field from physical table or column names. Use this attribute to define and run jobs that extract, transform, and load physical data while the Business Name data remains intact.
- A Business_Description is a business-level description of a table or column. Data Services transfers this information separately and adds it to a BusinessObjects Class description.

The software includes two additional column attributes that support metadata exchanged between SAP Data Services and SAP BusinessObjects Universe Builder:

- Column_Usage
- Associated_Dimension

2.18.6 Loading Big Data file with recovery option

Loading big data file with recovery option is an extension of the existing recovery mechanism in Data Services. In earlier versions of Data Services, the recovery mechanism was only supported until the data flow layer. As a result, if the engine crashed at any data flow, the whole data flow had to be restarted from the beginning in recovery mode.

However, if there is big data inside of the failed dataflow, restarting the process will involve duplicating work of cleaning and restarting. This restarting situation becomes worse if there is a reason that the job needs to be stopped periodically (for example, due to a network disconnect, database timeout or machine reboot).

To avoid this situation, when reading a big source flat file into the database tables, you have the option to turn on the big data loading recovery feature. For example, when you load a large input file into a database, the job may take several days to finish. If the engine crashes or fails in the middle of a job, the job can be resumed from the last failed check point. The last failed check point includes the failed filename and the offset of the file that has been processed so far. The recovery feature avoids restarting of the data flow and ensures that loading progresses forward from where it failed.

2.18.6.1 Turning on the recovery option for Big Data loading

To use the automatic recovery feature for big data loading, you must enable the feature during the initial execution of a job. Consequently, when a job fails, it can resume from the last checked point and run forward instead of restarting.

To run a big data loading job from Designer with recovery enabled:

1. In the project area, select the job name.
2. Right-click and choose *Execute*. The software prompts you to save any changes.
3. Make sure that the *Enable Recovery* option is selected in the *Execution Properties* window.

   > Note
   >
   > The *Enable Recovery* checkbox must be selected for the software to record the steps during the job. If the checkbox isn't selected and the job fails, you cannot recover the job. In this case, you have to perform any recovery operation manually and restart the job.

4. Check for the primary key in the target table of the data flow that contains the big data file source. If there is no primary key, then you have the option to either add the primary key column in the target table or generate the RowID column as the primary key column in the source file, and then pass it into the target tables.
   a) To add the primary key in the target table: If the original schema of the target table does not have a primary key, turn on the *Use Input Keys* in the target table's option and make sure that the input to the target table has a primary key. For example, the row ID column that you enter in the source file can be passed to the target table as a primary key.
   b) To generate Row ID column for the source file: Type a valid column name in the ROW ID input field located in the path *File Reader* > *General*.

      > Note
      >
      > A Row ID is automatically added into the schema as first column on the top. The column name is the name you typed, and the column Data Type is double.

A primary key column is necessary for fast recovery, as the engine uses auto correct loading for the last failed job. If the primary key column is not selected, then the auto correct loading will be very slow. To override this slow auto correct loading, you have the option to add the ROW ID column manually, if the target table does not have a primary key.

Data Services automatically turns on auto-correct loading for the recovery batch regardless of the target setting. Furthermore, for HANA, Netezza and Sybase IQ, the recovery batch auto-correct load uses bulk loading for better performance.

2.18.6.2 Limitations

There are some limitations that need to be met to allow a file to be loaded in recovery mode. The file along with the data flow and job contained in the file, needs to meet the following criteria:

- The file is a delimited file or fixed-width file
- The file has a row delimiter
- The job is running with *Enable recovery*
- The job is not a real-time job
- The job is not running in the Debugger
- The data flow is not within a continuous workflow
- The data flow is not audited
- The data flow is not an ABAP dataflow
- The data flow is not running in sub data flow mode
- The data flow does not contain any loader that does not connect to the file reader
- The data flow does not have the following transforms and functions:
  - Row_Generation
  - Date_Generation
  - gen_row_num
  - gen_row_num_by_group
  - CDC source
  - Target that is included in transaction
- The downstream of the file source does not have the following transforms:
  - Query transform that has an order by clause
  - Query transform that has a group by clause
  - Query transform that selects distinct rows
  - Query transform that has any aggregate function
  - Query transform that has a join in which file is an inner source

    > Note
    >
    > You can use the join rank to control the rank of the source relative to other tables and files, joined in a data flow. Sources with higher join ranks are joined before sources with lower join ranks.

  - Hierarchy_Flattening transform
  - Table_Comparison transform
  - Reverse_Pivot transform

    > Note
    >
    > Reverse_Pivot transform on the downstream of the big file is allowed, only when "input data is grouped" option is checked.

- ○ Validation transform
- ○ Merge

> i Note
>
> Merge transform on the downstream of the big file is allowed, only when all inputs of the Merge transform are directly or indirectly from the file.

- ○ Data Quality transform that uses a break key, such as Match transform
- ○ Either the target table has a primary key or the input to the target table has a primary key and the target’s 'Use input key' option is set to yes.

If any of the above conditions is not satisfied, recovery on the file is not enabled. However, there is no effect on the other source files or dataflows.

If the data flow contains multiple file sources, only one file source is chosen to run in recovery mode.

2.19 Capturing Changed Data

Related Information

Understanding changed-data capture [page 738]
Using CDC with Oracle sources [page 740]
Using CDC with Attunity mainframe sources [page 753]
Using CDC with Microsoft SQL Server databases [page 769]
Using CDC with timestamp-based sources [page 783]
Using CDC for targets [page 797]
Using CDC with SAP Sybase Replication Server [page 759]

2.19.1 Understanding changed-data capture

When you have a large amount of data to update regularly and a small amount of system down time for scheduled maintenance on a data warehouse, update data over time, or delta load. Two commonly used delta load methods are full refresh and changed-data capture (CDC).

2.19.1.1 Full refresh

Full refresh is easy to implement and easy to manage. This method ensures that no data will be overlooked or left out due to technical or programming errors. For an environment with a manageable amount of source data, full refresh is an easy method you can use to perform a delta load to a target system.

2.19.1.2 Capturing only changes

After an initial load is complete, you can choose to extract only new or modified data and update the target system. Identifying and loading only changed data is called changed-data capture (CDC). This includes only incremental data that has changed since the last refresh cycle. SAP Data Services acts as a mechanism to locate and extract only the incremental data that changed since the last refresh.

Improving performance and preserving history are the most important reasons for using changed-data capture.

- Performance improves because with less data to extract, transform, and load, the job typically takes less time.
- If the target system has to track the history of changes so that data can be correctly analyzed over time, the changed-data capture method can provide a record of these changes.
  For example, if a customer moves from one sales region to another, simply updating the customer record to reflect the new region negatively affects any analysis by region over time because the purchases made by that customer before the move are attributed to the new region.

This section discusses both general concepts and specific procedures for performing changed-data capture in the software.

2.19.1.3 Source-based and target-based CDC

Changed-data capture can be either source-based or target-based.

2.19.1.3.1 Source-based CDC

Source-based changed-data capture extracts only the changed rows from the source. It is sometimes called incremental extraction. This method is preferred because it improves performance by extracting the least number of rows.

SAP Data Services offers access to source-based changed data that various software vendors provide. The following table shows the supported data sources, changed-data capture products, and techniques.

Data Source	Products or techniques
Oracle 9i and later	Use Oracle's CDC packages to create and manage CDC tables. These packages make use of a publish and subscribe model. You can create a CDC datastore for Oracle sources using the Designer. You can also use the Designer to create CDC tables in Oracle, then import them for use in jobs.
Mainframe data sources (Adabas, DB2 UDB for z/OS, IMS, SQL/MP, VSAM, flat files) accessed with Attunity Connect	For mainframe data sources that use Attunity to connect to the software, you can use Attunity Streams 4.6.
Microsoft SQL Server databases	Use Microsoft SQL Replication Server to capture changed data from SQL Server databases.

Data Source	Products or techniques
Other sources	Use date and time fields to compare source-based changed-data capture job runs. This technique makes use of a creation and/or modification timestamp on every row. You can compare rows using the time of the last update as a reference. This method is called timestamp-based CDC.
SAP ODP sources i Note SAP extractors interface has been enhanced and replaced with OPD sources. Refer to the What's New Guide for Operational Data Provisioning [ODP] sources	Define CDC filtering criteria when importing an ODP source.
SAP Sybase Replication Server	Use SAP Sybase Replication Server to capture changed data.

Using CDC with Oracle sources [page 740]
Using CDC with Attunity mainframe sources [page 753]
Using CDC with Microsoft SQL Server databases [page 769]
Using CDC with timestamp-based sources [page 783]
Using CDC with SAP Sybase Replication Server [page 759]
Supplement for SAP: Connecting to SAP Applications, Capturing changed data [page 2444]

2.19.1.3.2 Target-based CDC

Target-based changed-data capture extracts all the data from the source, but loads only the changed rows into the target.

Target-based changed-data capture is useful when you want to capture history but do not have the option to use source-based changed-data capture. The software offers table comparison to support this method.

2.19.2 Using CDC with Oracle sources

If your environment must keep large amounts of data current, the Oracle Change Data Capture (CDC) feature is a simple solution to limiting the number or rows that the software reads on a regular basis. A source that reads only the most recent operations (INSERTS, UPDATES, DELETES), allows you to design smaller, faster delta loads.

2.19.2.1 Overview of CDC for Oracle databases

With Oracle 9i or higher, SAP Data Services manages the CDC environment by accessing Oracle's Publish and Subscribe packages. Oracle publishes changed data from the original table to its CDC table.

The Designer allows you to create or import CDC tables and create subscriptions to access the data in the CDC table. Separate subscriptions allow each user to keep track of the last changed row that he or she accessed.

You can also enable check-points for subscriptions so that the software only reads the latest changes in the CDC table.

Oracle uses the following terms for Change Data Capture:

Term	Description
Change (CDC) table	A relational table that contains changed data that results from DML operations performed on a source table.
Change set	A group of CDC tables that are transactionally consistent. For example, SalesOrder and SalesItem tables should be in a change set to ensure that changes to an order and its line items are captured together.
Change source	The database that contains one or more change sets.
Publisher	The person who captures and publishes the changed data. The publisher is usually a database administrator (DBA) who creates and maintains the schema objects that make up the source database and staging database.
Publishing mode	Specifies when and how to capture the changed data. For details, see the following table of publishing modes.
Source database	The production database that contains the data that you extracted for your initial load. The source database contains the source tables.
Staging database	The database where the changed data is published. Depending on the publishing mode, the staging database can be the same as, or different from, the source database.
Subscriber	A user that can access the published data in the CDC tables.
Subscription	Controls access to the change data from one or more source tables within a single change set. A subscription contains one or more subscriber views.
Subscriber view	The changed data that the publisher has granted the subscriber access to use.

Oracle supports the following publishing modes:

Synchronous

- Data is captured using internal triggers on the source tables to store changes in CDC tables.
- Captured data is available in real-time.
- CDC tables must reside in the source database.
- Adds overhead to source database at capture time.
- Available in Oracle 9i and 10G.

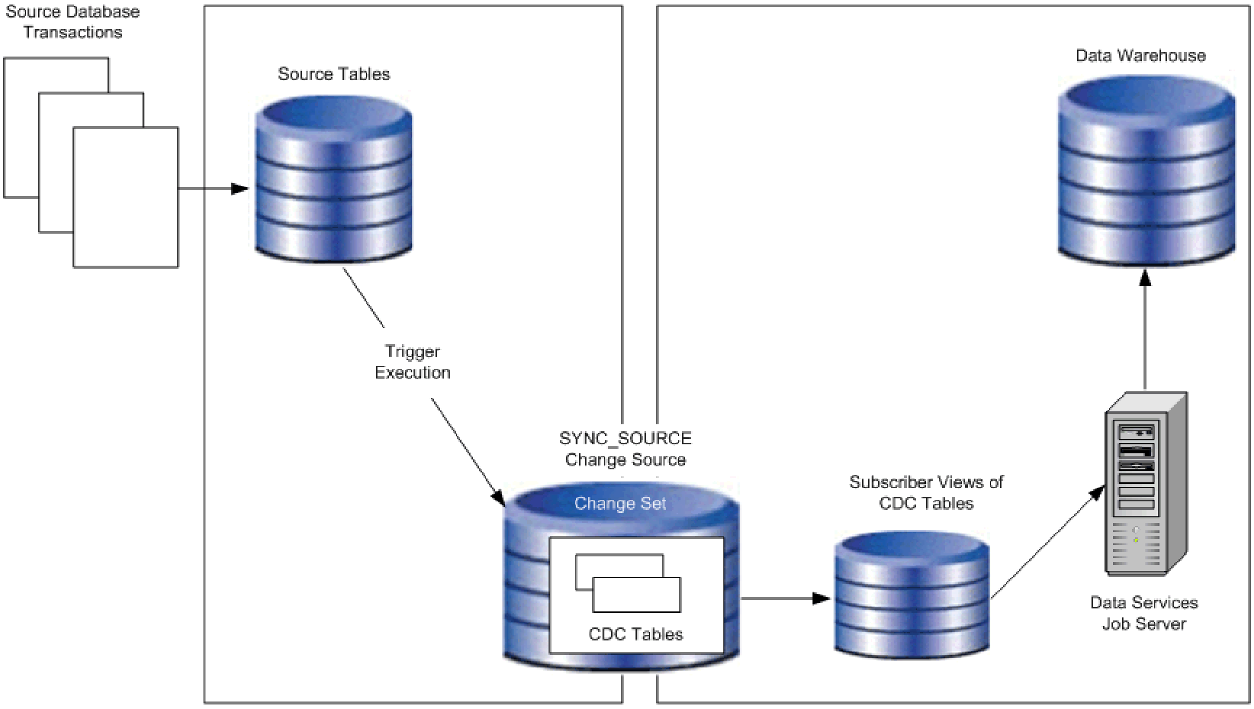
Asynchronous HotLog

- Data is captured using redo or archive logs from the source database.

	• Captured data is available in near real-time. • A change set contains multiple CDC tables and must reside locally in the source database. • Improves performance because data is captured offline. • Available in Oracle 10G only.
Asynchronous AutoLog	• Data is captured using redo logs managed by log transport services that automate transfer from source database to staging database. • Availability of captured data depends on the frequency of redo log switches on the source database. • A change set contains multiple CDC tables and can be remote or local to the source database. • Improves performance because data is captured offline. • Available in Oracle 10G only.

2.19.2.1.1 Oracle CDC in synchronous mode

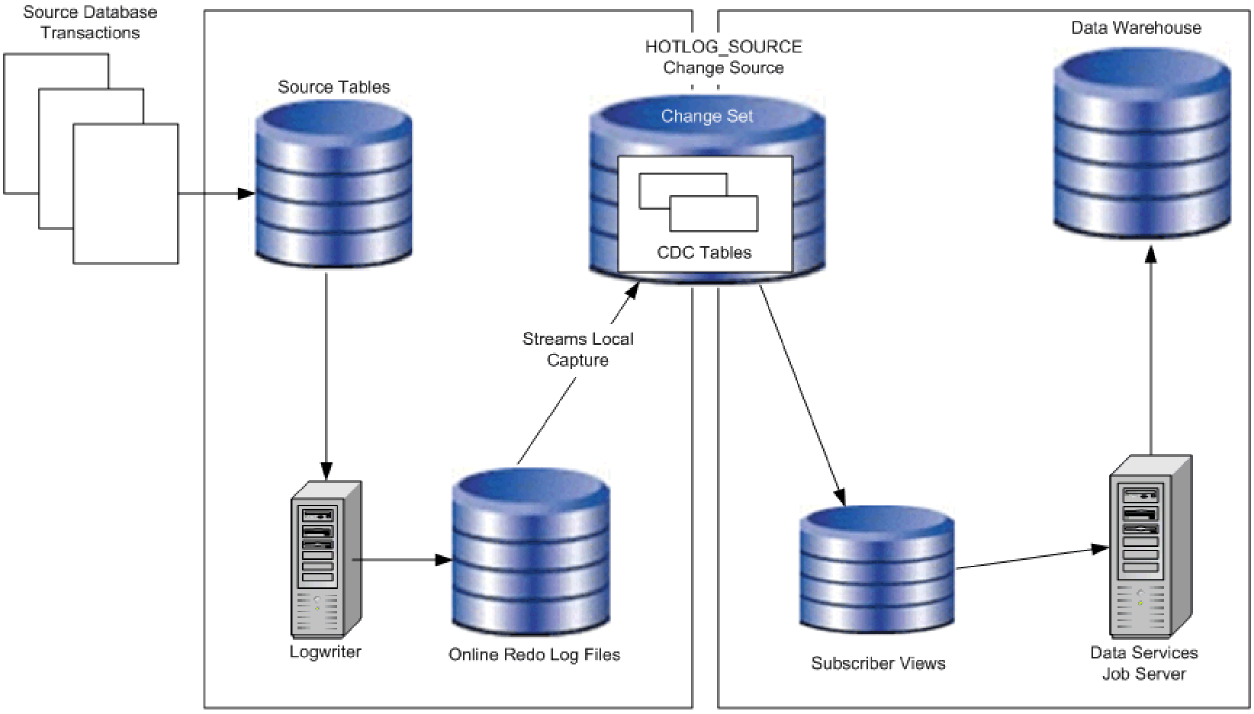
The following diagram shows how the changed data flows from Oracle CDC tables to SAP Data Services in synchronous mode.



When a transaction changes a source table, internal triggers capture the changed data and store it in the corresponding CDC table.

2.19.2.1.2 Oracle CDC in asynchronous HotLog mode

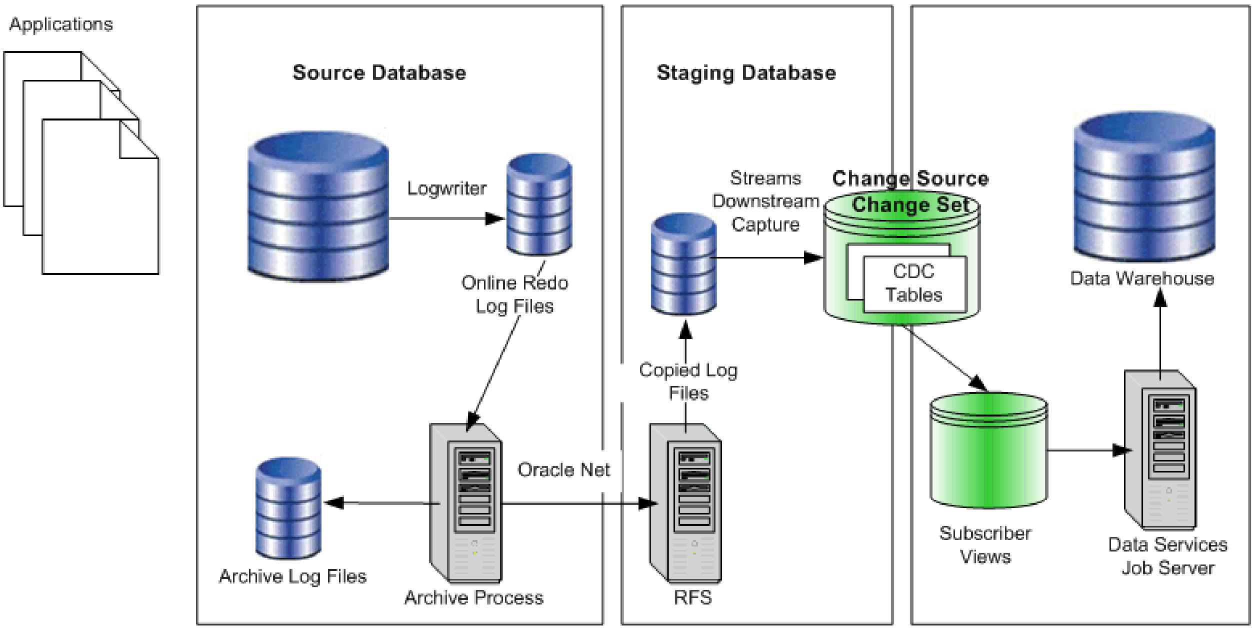
The following diagram shows how the changed data flows from Oracle CDC tables to SAP Data Services in asynchronous HotLog mode.



When a transaction changes a source table, the Logwriter records the changes in the Online Log Redo files. Oracle Streams processes automatically populate the CDC tables when transactions are committed.

2.19.2.1.3 Oracle CDC in asynchronous AutoLog mode

The following diagram shows how the changed data flows from Oracle CDC tables to SAP Data Services in asynchronous AutoLog mode.



When the log switches on the source database, Oracle archives the redo log file and copies the Online Log Redo files to the staging database. Oracle Streams processes populate the CDC tables from the copied log files.

Note

The Oracle archive process requires uninterrupted connectivity through Oracle Net to send the redo log files to the remote file server (RFS).

2.19.2.2 Setting up Oracle CDC

Use the following system requirements on your Oracle source database server to track changes:

- Install Oracle's CDC packages. These packages are installed by default. However, if a CDC package needs to be re-installed, open Oracle's `Admin` directory, then find and run Oracle's SQL script `initcdc.sql`.
  - Synchronous CDC is available with Oracle Standard Edition and Enterprise Edition.
  - Asynchronous CDC is available with Oracle Enterprise Edition only.
- Enable Java.
- Set source table owner privileges so CDC tables can be created, purged, and dropped as needed.
- Give datastore owners the SELECT privilege for CDC tables and the SELECT_CATALOG_ROLE and EXECUTE_CATALOG_ROLE privileges.
- For synchronous CDC, enable Oracle's system triggers.
- For asynchronous AutoLog CDC:
  - The source database DBA must build a LogMiner data dictionary to enable the log transport services to send this data dictionary to the staging database. Oracle automatically updates the data dictionary with any source table DDL operations that occur during CDC to keep the staging tables consistent with the source tables.

- ○ The source database DBA must also obtain the SCN value of the data dictionary build. If you will use the Designer to create CDC tables, you need to specify the SCN in the wizard.
- ○ The publisher (usually the source database DBA) must configure log transport services to copy the redo log files from the source database system to the staging database system and to automatically register the redo log files.

Related Information

To create Oracle CDC tables in the software [page 746]

2.19.2.3 To create a CDC datastore for Oracle

To access CDC tables, create a CDC datastore using the Designer. A CDC datastore is a read-only datastore that can only access tables. Like other datastores, you can create, edit, and access a CDC datastore from the *Datastores* tab of the object library.

1. Create a database datastore with the *Database Type* option set to `Oracle`.
2. Select the *CDC* check box.
3. Select an *Oracle version*.

   The Designer only allows you to select the Oracle versions that support CDC packages.
4. Specify the name of your staging database (the change source database where the changed data is published) in *Connection name*.
5. Enter the *User* and *Password* for your staging database and click *OK*.

   You can use this datastore to browse and import CDC tables.

2.19.2.4 Importing CDC data from Oracle

You must create a CDC table in Oracle for every source table you want to read from before you can import that CDC table using SAP Data Services. Use one of the following ways:

- Use an Oracle utility to create CDC tables
- Use the Designer to create CDC tables

2.19.2.4.1 To use existing Oracle CDC tables

1. Import an Oracle CDC table by right-clicking the CDC datastore name in the object library and selecting *Open*, *Import by Name*, or *Search*.

   If you select Open, you can browse the datastore for existing CDC tables using the Datastore Explorer.

2. When you find the table that you want to import, right-click it and select *Import*.

2.19.2.4.2 To create Oracle CDC tables in the software

The software provides the ability to create Oracle CDC tables for all publishing modes:

- Synchronous CDC
- Asynchronous HotLog CDC
- Asynchronous AutoLog CDC

1. In the object library, right-click a CDC datastore and select *Open*.
2. In the Datastore Explorer, right-click the white space in the *External Metadata* section, and select *New*.

   The New CDC table wizard opens. This wizard allows you to add a CDC table.

   > Note
   >
   > If the Datastore Explorer opens and no CDC tables exist in your datastore, this wizard opens automatically.

3. Select the publishing mode on the first page of the wizard.

   If your source database is Oracle 9i, you can only select the Synchronous mode. The Asynchronous modes are disabled.

   If your source database is Oracle 10G, the wizard selects the Asynchronous HotLog mode by default.

   If your source database uses Asynchronous AutoLog publishing mode, select Asynchronous AutoLog and provide the following source database connection information:

Field	Description
Connection name	The name of the database where the Change Source resides. Use the service name of the Oracle Net service configuration.
User Name	The user name for the source database DBA.
Password	The password for the Change Source user.

4. Click *Next*. The second page of the wizard appears.
5. Specify the source table information in the second page of the wizard.
   a) Click the *Search* button to see a list of non-CDC external tables available in this datastore. To filter a search, enter values for a table Owner and/or Name. You can use a wild-card character (%) to perform pattern matching for Name or Owner values.
   b) (Optional) Select *Generate before-images* if you want to track before- and after-images in the new CDC table.
   c) Click a name in the list of returned tables and click *Next* to create a CDC table using the selected table as a source table.
6. Specify the *CDC table owner* for the new CDC table.

   By default, the owner name of the new CDC table is the owner name of the datastore. The source table owner name is also displayed in the CDC table owner list box. If the owner name you want to use is not in the list, enter a different owner name.

7. Specify the *CDC table name* for the new CDC table.

   By default, the software generates a table name using the following convention: CDC__SourceTableName.
8. By default, all columns are selected. Specify which columns to include or exclude from the CDC table in one of the following ways: Either remove the check mark from the box next to the name of each column that you want to exclude, or click *Unselect All* and place a check mark next to the name of each column that you want to include.
9. For synchronous publishing mode:
   a) Click *Finish*. The Designer connects to the Oracle instance, creates the CDC table on the Oracle server, and imports the table's metadata into the repository. All tables that the software imports through a CDC datastore contain a column that indicates which operation to perform for each row. For an Oracle CDC table, this column is called Operation$. In addition to this column, Oracle adds other columns when it creates a CDC table. These columns all use a dollar sign as a suffix.
   b) Click *OK* on the information dialog. This dialog confirms that Oracle created a new CDC table, then imported it successfully into the software.
10. For asynchronous (HotLog or AutoLog) publishing mode, click *Next*.
11. For asynchronous HotLog publishing mode, specify the change set information in the fourth page of the wizard.
    a) If you would like to add this change table to an existing change set to keep the changes transactionally consistent with the tables in the change set, select a name from the drop-down list for *Change set name*. Alternatively, you can create a new change set by typing in the name.
    b) Select *Stop capture on DDL* if a DDL error occurs and you do not want to capture data.
    c) Select *Define retention period* to enable the *Begin Date* and *End Date* text boxes.
    d) Click *Finish*.
    The Designer connects to the Oracle instance, creates the CDC table on the Oracle server, and imports the table's metadata into the software's repository. All tables that the software imports through a CDC datastore contain a column that indicates which operation to perform for each row. For an Oracle CDC table, this column is called Operation$. In addition to this column, Oracle adds other columns when it creates a CDC table. These columns all use a dollar sign as a suffix.
12. For asynchronous AutoLog publishing mode, specify the change set and change source information in the fourth page of the wizard.
    a) If you would like to add this change table to an existing change set to keep the changes transactionally consistent with the tables in the change set, select a name from the drop-down list for *Change set name*. Alternatively, you can create a new change set by typing in the name.
    b) If you would like to add this change table to an existing change source, select a name from the drop-down list for *Change source name*.
    c) If you want to create a new change source, type the name of the CDC change source and the name of the source database. You can obtain this name from the source database Global_Name table SCN value of the data dictionary build.
    d) Select *Stop capture on DDL* if a DDL error occurs during data capture and you do not want to capture data.
    e) Select *Define retention period* to enable the *Begin Date* and *End Date* text boxes.
    f) Click *Finish*.
    The Designer connects to the Oracle staging database, creates the CDC table on the change source, and imports the table's metadata into the software's repository. All tables that the software imports through a CDC datastore contain a column that indicates which operation to perform for each row. For an Oracle

CDC table, this column is called Operation$. In addition to this column, Oracle adds other columns when it creates a CDC table. These columns all use a dollar sign as a suffix.

Related Information

Using before-images [page 750]

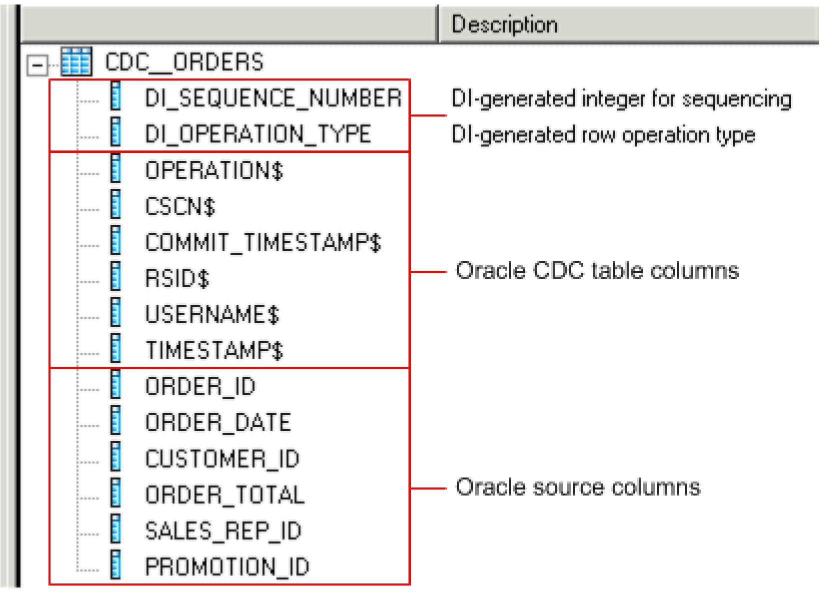
2.19.2.5 Viewing an imported CDC table

To view an imported CDC table:

1. Find your CDC datastore in the object library.
2. Expand the *Tables* folder.
3. Double-click a table name or right-click and select *Open*.

When the software imports a CDC table, it also adds two columns to the table's schema: `DI_SEQUENCE_NUMBER` with the data type integer and `DI_OPERATION_TYPE` with the data type varchar(1).

An imported Oracle CDC table schema looks like the following:



Description

CDC__ORDERS

DI_SEQUENCE_NUMBER — DI-generated integer for sequencing

DI_OPERATION_TYPE — DI-generated row operation type

OPERATION$
CSCN$
COMMIT_TIMESTAMP$
RSID$
USERNAME$
TIMESTAMP$

Oracle CDC table columns

ORDER_ID
ORDER_DATE
CUSTOMER_ID
ORDER_TOTAL
SALES_REP_ID
PROMOTION_ID

Oracle source columns

This example has eight control columns added to the original table:

- Two generated by the software
  - `DI_SEQUENCE_NUMBER` - Contains an integer for sequencing.
  - `DI_OPERATION_TYPE` - Contains the row operation type.
- Six Oracle control columns: OPERATION$, CSCN$, COMMIT_TIMESTAMP$, RSID$, USERNAME$, TIMESTAMP$

ℹ Note

The Oracle control columns vary, depending on the options that were selected when the CDC table is created. All Oracle control columns end with a dollar sign ($).

Related Information

The DI_SEQUENCE_NUMBER column [page 749]
The DI_OPERATION_TYPE column [page 749]

2.19.2.5.1 The DI_SEQUENCE_NUMBER column

The `DI_SEQUENCE_NUMBER` column starts with zero at the beginning of each extraction. This field increments by one each time the software reads a row except when it encounters a pair of before- and after-images for an UPDATE operation. Both the before- and after-images receive the same sequence number. This sequencing column provides a way to collate image pairs if they are separated as a result of the data flow design.

Related Information

Using before-images [page 750]

2.19.2.5.2 The DI_OPERATION_TYPE column

The possible values for the `DI_OPERATION_TYPE` column are:

- `I` for INSERT
- `D` for DELETE
- `B` for before-image of an UPDATE
- `U` for after-image of an UPDATE

When the software reads rows from Oracle, it checks the values in column `Operation$` and translates them to the software values in the `DI_OPERATION_TYPE` column.

Operation$	DI_OPERATION_TYPE
I	I
D	D
UO, UU	B

Operation$	DI_OPERATION_TYPE
UN	U

2.19.2.6 To configure an Oracle CDC source table

When you drag a CDC datastore table into a data flow, it automatically becomes a source object.

1. Drag a CDC datastore table into a data flow.
2. Click the name of this source object to open its Source Table Editor.
3. Click the CDC Options tab.
4. Specify a value for the *CDC subscription name*.

   For more information, see the *Reference Guide*.

2.19.2.6.1 Using check-points

When a job in SAP Data Services runs with check-pointing enabled, software uses the source table's subscription name to read the most recent set of appended rows. If you do not enable check-pointing, then the job reads all the rows in the table and increases processing time.

To use check-points, enter a name in the *CDC Subscription* name box on the Source Table Editor and select the *Enable check-point* option.

> i Note
>
> To avoid data corruption problems, do not reuse data flows that use CDC datastores because each time a source table extracts data it uses the same subscription name. This means that identical jobs, depending upon when they run, can get different results and leave check-points in different locations in the table. When you migrate CDC jobs from test to production, for example, a best practice scenario would be to change the subscription name for the production job so that the test job, if ever runs again, will not affect the production job's results.

2.19.2.6.2 Using before-images

If you want to retrieve the before-images of UPDATE rows, prior to when the update operation is applied to the target, the software can expand the UPDATE row into two rows: one row for the before-image of the update, and one row for the after-image of the update. The before image of an update row is the image of the row before the row is changed, and the after image of an update row refers to the image of the row after the change is applied.

The default behavior is that a CDC reader retrieves after-images only. By not retrieving before-images, fewer rows pass through the engine which allows the job to execute in less time.

You can use before-images to:

- Update primary keys

> ℹ Note
>
> Under most circumstances, when source tables are updated, their primary keys do not need to be updated.

- Calculate change logic between data in columns
  For example, you can calculate the difference between an employee's new and old salary by looking at the difference between the values in salary fields.

2.19.2.6.2.1 To capture before-images for update rows:

1. At CDC table creation time, make sure the Oracle CDC table is also setup to retrieve full before-images.

   If you create an Oracle CDC table using the Designer, you can select the *Generate before-images* to do this.
2. Select *Get before-images for each update row* in the CDC table's source editor.

   If the underlying, CDC table is not set-up properly, enabling the Get before-images for each update row option has no effect.

Once you select the *Get before-images for each update row* option, for every update, the software processes two rows. In addition to the performance impact of this data volume increase, the before- and after-image pairs may be separated or lost depending on the design of your data flow. This would cause data integrity issues.

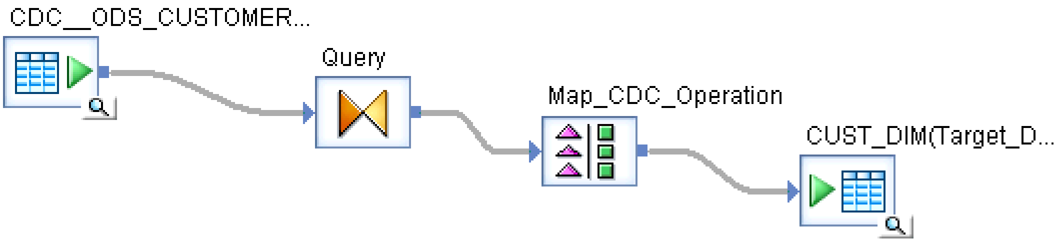
The Map_CDC_Operation transform can resolve problems, but undesirable results may still occur due to programming errors. When using functions and transforms that re-order, re-direct, eliminate, and multiply the number of rows in a data flow (for example, due to the use of the group by or order by clauses in a query) be aware of the possible impact to targets.

2.19.2.7 To create a data flow with an Oracle CDC source

To use an Oracle CDC source, you use a Query transform to remove the Oracle control columns and the Map_CDC_Operation transform to interpret the control columns and take appropriate actions.

1. In the *Designer Object Library* pane, drag the Oracle CDC table, Query, and Map_CDC_Operation transforms to the data flow workspace area.

   > ℹ Note
   >
   > A data flow can contain only one CDC source.
2. Configure the CDC table.
3. Add the appropriate target table and connect the objects.



4. In the *Project Area* pane, double-click a transform.
   The *Query Editor* opens, displaying the transform.
5. Map the *Data Services* control columns and the source table columns that you want in your target table.

   The Map_CDC_Operation transform uses the values in the column in the *Row Operation Column* box to perform the appropriate operation on the source row for the target table. For an Oracle CDC source table, the `DI_OPERATION_TYPE` column is automatically selected as the Row operation column.

   The operations can be `INSERT`, `DELETE`, or `UPDATE`. For example, if the operation is `DELETE`, the corresponding row is deleted from the target table.

Related Information

To configure an Oracle CDC source table [page 750]
Reference Guide: Transforms [page 1067]

2.19.2.8 Maintaining CDC tables and subscriptions

2.19.2.8.1 Purging CDC tables

Periodically purge CDC tables so they do not grow indefinitely.

> Note
>
> The software does not provide this functionality. Refer to your Oracle documentation for how to purge data that is no longer being used by any subscribers.

2.19.2.8.2 To drop Oracle CDC subscriptions or tables

Oracle's purge facility does not purge any data that has not been read by all subscriptions. As a result, it is a good practice to drop any subscriptions that are no longer needed. You can drop Oracle CDC tables and their subscriptions from the *Datastore Explorer* window in the Designer.

1. In the *Local Object Library* pane, right-click a CDC datastore, and click *Open*.
2. In the *Datastore Explorer* window, click *Repository Metadata*.
3. Right-click a table, point to *CDC maintenance*, and do one of the following:
   - Point to *Drop subscription*.
     - *Drop Subscription* opens the list of subscriptions you created in the software for the selected table. Oracle subscriptions are associated with these subscription names. Select each subscription name to drop it from Oracle and delete it from the repository.
   - Click *Drop table*.
     - This option drops the Oracle CDC table and also deletes it from the repository.

2.19.2.9 Limitations

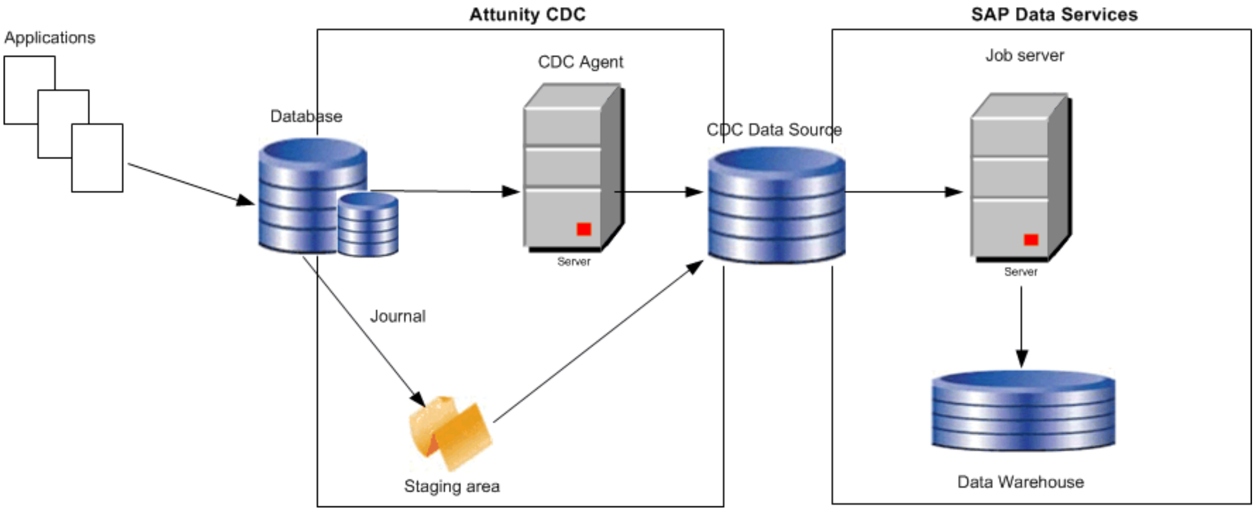
The following limitations exist when using CDC with Oracle sources:

- You cannot use the following transforms and functions with a source table imported with a CDC datastore because of the existence of the SAP Data Services generated columns for CDC tables. The software cannot compare or search these columns.
  - Table_Comparison, Key_Generation, and SQL transforms
  - All database functions, such as `lookup`, `lookup_ext`, key_generation, sql, and total_rows
- You can only create one CDC source in a data flow.
- Oracle CDC captures DML statements, including `INSERT`, `DELETE`, and `UPDATE`. However, Oracle CDC does not support the following operations because they disable all database triggers:
  - Direct-path `INSERT` statements
  - The `multi_table_insert` statement in parallel DML mode
- If you are using check-pointing and running your job in recovery mode, the recovered job will begin to review the job at the start of the CDC table. Check-points are ignored.

2.19.3 Using CDC with Attunity mainframe sources

If your environment must keep large amounts of data current, the mainframe CDC feature is a simple solution to limiting the number of rows that must be read on a regular basis. A source that reads only the most recent operations (INSERTS, UPDATES, DELETES) allows you to design smaller, faster delta loads.

SAP Data Services captures changed data on Attunity mainframe data sources and applies it to a target system. The following diagram shows the path that the data takes from Attunity CDC to SAP Data Services.



- The Attunity CDC Agent monitors the database journal for changes to specific tables. After the first request to capture changes, the CDC agent stores a context that the agent uses as a marker to not recapture changes prior to it.
- The CDC Agent sends the changed data to an optional staging area. The advantages of a staging area are:
  - A single journal scan can extract changes to more than one table. Without a staging area, multiple journal scans, one for each changed table, is required to extract changes.
  - Extracts only committed changes which is less processing than extracting every change. Less processing also occurs during recovery of a failed job because the recovery process does not need to back out the uncommitted changes.

  However, a staging area requires additional storage and processing overhead. Refer to the Attunity CDC documentation for details.
- Attunity Connect CDC sends the changes to the CDC data sources through which the software can access the changes using standard ODBC or JDBC.

2.19.3.1 Setting up Attunity CDC

If you currently use Attunity as the connection to SAP Data Services to extract data from mainframe sources, create an Attunity CDC data source in Attunity Studio. The following steps summarize the procedure for using the Attunity Studio wizard to create a CDC data source.

- Specify your data source.
- Based on your data source, choose one of the following methods to capture changes and specify the location of the journal:
  - VSAM under CICS—By CICS Log stream
  - DB2 on OS/390 and z/OS platforms—By DB2 Journal
  - DB2 on OS/400—By DB400 Journal
  - DISAM on Windows—By Journal

  For a complete list of supported data sources, see the Attunity Connect CDC document.
- Select a name for your CDC agent.

- Specify if you want to capture before images for update operations. If you do not specify this option in Attunity Studio, you will not capture before images even if you specify the option *Get before-image for each update row*.
- Select the tables to monitor for changes.

The Attunity Studio wizard generates the following components that you need to specify on the Datastore Editor when you define an Attunity CDC datastore:

- A CDC data source name that you specify in the option *Data source*. Attunity generates the CDC data source on the same computer as the CDC agent by default. You have the option of placing the CDC data source on the client (same computer as SAP Data Services). Obtain the host name of this computer to specify in the option *Host location*.
- A workspace for the CDC agent to manage the change capture event queue. You specify the workspace name in the option *Attunity workspace*.

For more information, refer to the CDC setup section in the *Attunity Connect: The Change Data Capture Solution*.

2.19.3.2 Setting up the software for CDC on mainframe sources

To use SAP Data Services to read and load changed data from mainframe sources using Attunity, do the following procedures on the Designer:

- Create a CDC datastore for Attunity
- Import metadata for Attunity tables
- Configure a mainframe CDC source
- Build real-time jobs using metadata

2.19.3.2.1 Creating CDC datastores

The CDC datastore option is available for all mainframe interfaces to SAP Data Services.

Related Information

Datastores [page 209]

2.19.3.2.1.1 To create a CDC datastore for Attunity

1. Open the Datastore Editor.
2. Enter a name for the datastore.

3. In the *Datastore type* box, select Database.
4. In the *Database type* box, select Attunity_Connector.
5. Check the *Enable CDC* box to enable the CDC feature. You can enable CDC for the following data sources. For the current list of data sources, refer to the Attunity web site.
   - VSAM under CICS
   - DB2 UDB for z/OS
   - DB2 UDB for OS/400
6. In the *Data source* box, specify the name of the Attunity CDC data source. You can specify more than one data source for one datastore, but you cannot join two CDC tables. You might want to specify multiple data sources in one Attunity datastore for easier management. If you can access all of the CDC tables through one Attunity data source, it is easier to create one datastore, enter the connection information once, and import the tables.

   If you list multiple data source names for one Attunity Connector datastore, ensure that you meet the following requirements:
   - Do not specify regular Attunity data sources with CDC data sources in the same datastore. The software imports data from regular Attunity data sources differently than from CDC data sources.
   - All Attunity data sources must be accessible by the same user name and password.
   - All Attunity data sources must use the same workspace. When you setup access to the data sources in Attunity Studio, use the same workspace name for each data source.
7. In the *Host location* box, specify the name of the host on which the Attunity data source daemon exists.
8. In the *Port* box, specify the Attunity daemon port number. The default value is 2551.
9. Specify the Attunity server workspace name that the CDC agent uses to manage the change capture event queue for the CDC data source.
10. Complete the rest of the dialog and click *OK*.

    You can now use the new datastore connection to import metadata tables into the current repository.

Once saved, this datastore becomes a CDC datastore.

2.19.3.3 Importing mainframe CDC data

After you create a CDC datastore, you can use it to import CDC table metadata. In the object library, right-click the datastore name and select *Open*, *Import by Name*, or *Search*. For mainframe CDC, only the CDC tables that you selected in the procedure *Setting up Attunity CDC* [page 754] are visible when you browse external metadata. Functions and templates are not available because the Attunity CDC datastore is read-only.

The SAP Data Services import operation adds the following columns to the original table:

Column name	Data type	Source of column
DI_SEQUENCE_NUMBER	integer	Generated by SAP Data Services
DI_OPERATION_TYPE	varchar(1)	Generated by SAP Data Services
Context	varchar(128)	Supplied by Attunity Streams

Column name	Data type	Source of column
Timestamp	varchar(26)	Supplied by Attunity Streams
TransactionID	varchar(4)	Supplied by Attunity Streams
Operation	varchar(12)	Supplied by Attunity Streams
tableName	varchar(256)	Supplied by Attunity Streams

2.19.3.3.1 The DI_SEQUENCE_NUMBER column

The DI_SEQUENCE_NUMBER column starts with zero at the beginning of each extraction. This field increments by one each time the software reads a row except when it encounters a pair of before- and after-images. Both the before- and after-images receive the same sequence number. This sequencing column provides a way to collate image pairs if they become separated as a result of the data flow design.

You can configure Attunity Streams to retrieve before- images of UPDATE rows before the software applies the UPDATE operation to the target. Note that if you do not configure Attunity Streams to capture before- images in the database, the software will discard the rows. For information about when to consider using before-images, see *Using before-images* [page 750].

If during the course of a data flow the before- and after-images become separated or get multiplied into many rows (for example, using GROUP BY or ORDER BY clauses in a query), you can lose row order.

The Map_CDC_Operation transform allows you to restore the original ordering of image pairs by using the DI_SEQUENCE_NUMBER column as its *Sequencing column*.

Related Information

Reference Guide: Transforms [page 1067]

2.19.3.3.2 The DI_OPERATION_TYPE column

SAP Data Services generates values in the DI_OPERATION_TYPE column. Valid values for this column are:

- I for INSERT
- D for DELETE
- B for before-image of an UPDATE
- U for after-image of an UPDATE

2.19.3.4 Configuring a mainframe CDC source

When you drag a CDC datastore table into a data flow, it automatically becomes a source object.

2.19.3.4.1 To configure a mainframe CDC table

1. Drag a CDC datastore table into a data flow.

   The table automatically becomes a source object.
2. Click the name of this source object to open its Source Table Editor.
3. Click the CDC Options tab.
4. Specify a value for the *CDC subscription name*.

   For more information, see the *Reference Guide*.

Related Information

Using mainframe check-points [page 758]
Using before-images [page 750]

2.19.3.5 Using mainframe check-points

Attunity CDC agents read mainframe sources and load changed data either into a staging area or directly into the CDC data source. Rows of changed data append to the previous load in the CDC data source.

When you enable check-points, a CDC job in SAP Data Services uses the subscription name to read the most recent set of appended rows and to mark the end of the read. If check-points are not enabled, the CDC job reads all the rows in the Attunity CDC data source and processing time increases.

To use check-points, on the Source Table Editor enter the *CDC Subscription name* and select the *Enable check-point* option.

If you enable check-points and you run your CDC job in recovery mode, the recovered job begins to review the CDC data source at the last check-point.

> Note
>
> To avoid data corruption problems, do not reuse data flows that use CDC datastores because each time a source table extracts data it uses the same subscription name. This means that identical jobs, depending upon when they run, can get different results and leave check-points in different locations in the file. When you migrate CDC jobs from test to production, a best-practice scenario is to change the subscription name for the production job. Therefore, if the test job ever runs again, it does not affect the production job's results.

2.19.3.5.1 Using before-images from mainframe sources

When you must capture before-image update rows.

1. Make sure Attunity Streams is set up to retrieve full before-images.
2. Select the *Get before-images for each update row* option in the CDC table's source editor.

   The underlying, log-based CDC capture software must be set up properly, otherwise enabling the Get before-images for each update row option in the software has no effect.

After you check the *Get before-images for each update row* option, the software processes two rows for every update. In addition to the performance impact of this data volume increase, the before- and after-image pairs could be separated or lost depending on the design of your data flow, which would cause data integrity issues.

The Map_CDC_Operation transform can resolve problems, but undesirable results can still occur due to programming errors. When you use functions and transforms that re-order, re-direct, eliminate, and multiply the number of rows in a data flow, be aware of the possible impact to targets.

Related Information

Using before-images [page 750]
Reference Guide: Transforms [page 1067]

2.19.3.6 Limitations

The following limitations exist for this feature:

- You cannot use the following transforms and functions with a source table imported with a CDC datastore because of the existence of the SAP Data Services generated columns for CDC tables. The software cannot compare or search these columns.
  - Table_Comparison, Key_Generation, and SQL transforms
  - All database functions, such as `lookup`, `lookup_ext`, key_generation, sql, and total_rows
- You can only create one CDC source in a data flow.

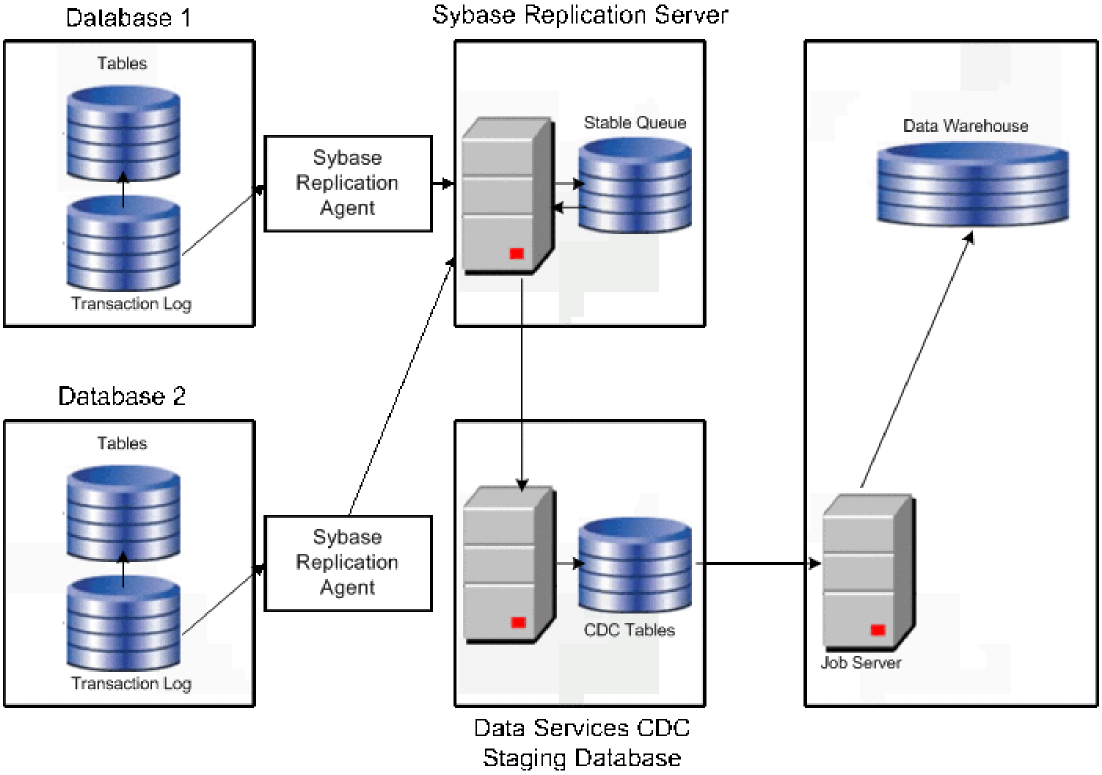
2.19.4 Using CDC with SAP Sybase Replication Server

If your environment must keep large amounts of data current with minimal impact on operational systems, then Data Services CDC feature combined with SAP Sybase Replication Server's replication functionality provides a mechanism to capture, transform, and propagate high volumes of data to data warehouse in real-time. This helps make rapid decisions, thereby keeping pace with the ever-changing environment.

SAP Sybase Replication Server CDC source in data flow reads only the most recent operations (INSERTS, UPDATES, DELETES), allowing you to design smaller, faster delta loads. Data Services

2.19.4.1 Overview of CDC for Sybase Replication Server

Data Services manages the CDC environment by building the CDC staging database and creating SAP Sybase Replication Server's replication definitions and subscriptions, using SAP Sybase Power Designer's Data Movement Model. Upon deployment of the replication definitions and subscriptions and the CDC staging database definitions, SAP Sybase Replication Server publishes changed data from the source table to its corresponding CDC table that resides in the CDC staging database. The CDC Table Source in Data Services' data flow reads the most recent change data from the last check-point from the CDC table and applies it to the target systems, after transformation. The following diagram shows how the changed data flows from the Replication Server to Data Services.



2.19.4.2 Setting up SAP Sybase Replication Server CDC Environment

You need to install the list of prerequisites from the table below for SAP Sybase Replication Server CDC. For more information about SAP Sybase components, see SAP Sybase documentation links.

Design time component	Function	Reference
SAP Sybase Power Designer 16.5	Modelling tool for creating the replication definitions, the subscriptions for Replication Server and the Data Services CDC staging database definitions. You need this tool along with Data Services Designer to model	*http://infocenter.sybase.com/help/index.jsp?topic=/com.sybase.infocen-*

Design time component	Function	Reference
	the source system to the target system CDC data flow.	*ter.help.pd.16.5/doc/html/title.html*
Data Services Designer 4.2	Designing the data flow for transforming change data before applying to the target system.	

Run-time component	Function	Reference
SAP Sybase Replication server 15.7.1	Capturing change data from the source database and publishing to the Data Services CDC staging database.	*http://infocenter.sybase.com/help/topic/com.sybase.infocenter.help.rs.15.7.1/title.htm*
isql tool	Deploying replication definitions and subscriptions in the Replication Server, enabling the source tables in the source databases for replication and creating the Data Services CDC database definitions in staging database.	*Utility Guide of Adaptive Server Enterprise*
SAP Sybase ASE 15.7.1	Staging Data Services CDC change data.	*http://infocenter.sybase.com/help/index.jsp?topic=/com.sybase.infocenter.help.ase.15.7/title.htm*
SAP Sybase ASE 15.7.1 Job Scheduler	Purging the old change data from the CDC staging database (part of CDC environment management).	i Note You need to install Job Scheduler Agent as part of SAP Sybase ASE 15.7.1.
Data Services Job Server 4.2	Transforming the change data and applying to the Target databases.	

2.19.4.3 Modeling of Replication Process for Data Services CDC Staging Database

Power Designer automates the process of configuring SAP Sybase Replication Server, which includes marking the source table as replicated, creating the replication definitions and subscriptions and defining the Data Services CDC staging database.

> Note
>
> Tables in source database that needs to be replicated, must have primary key.

The following steps summarize the procedure to model the replication process for Data Services CDC Staging database in Power Designer:

1. Drop the `SybaseRepServerDataServicesCDC100.xem` file from Data Services install location `%`**`<DS_COMMON_DIR>`**`%/ext/cdc` into Power Designer's *Resource Files* > *Extended Model Definitions* folder.

   > Note
   >
   > Data Services Power Designer Extension is a part of the Data Services Package.

2. Create a new Data Movement Model in the Power Designer by selecting *Model* > *New* > *Data Movement Model*. Enter the *Model name* and in *Extesnions* choose *Replication Server 15.5* from the drop down list.
3. Attach *SAP Data Services CDC 14.2.0 extension* to it. To do this, go to *model* > *extensions* > *List of Extensions*. Click the attach an extension icon and choose *SAP Data Services CDC 14.2.0 extension*.

   > Note
   >
   > This extension works only with Replication Server 15.7 data movement modeling.

4. Run the *Replication Wizard* in the Power Designer by selecting *Tools* > *Replication Wizard*. It creates the replication server process, the source physical data model and the replicated physical data model.

   > Note
   >
   > The Replication Wizard reverse-engineers the source databases to import database objects into the data movement model. Choose only tables and following table properties: Primary Keys, Foreign Keys, Alternate Keys and indexes to create the replicated physical database model.

5. When you are on the *Publication Selection* window, in the *Replication Wizard* dialog box, select *Create or select a single publication to gather replicated tables* and choose replication type as *replication definitions*.

   > Note
   >
   > When the Replication Wizard finishes, Power Designer creates default replication definitions (called Articles) and the Physical Data Model for the Remote database with all selected tables from the source Physical Data Model and corresponding table columns and properties.

6. In the *Replication Wizard*, when you are on the *Remote Physical Data Model Selection* screen, choose the *DBMS* as *Sybase AS Enterprise 15.7*.
7. Save the Data Movement Model and Physical Data Model.
8. Select the Replication Process icon in the Data Movement Model diagram and choose *Add Data Services CDC Definitions* from context menu to run Data Services extension to create the following:
   a) CDC replication definitions
   b) CDC staging tables
   c) CDC system tables (DS_CDC_TABLES_MAP, DS_CHANGE_RETENTION and DS_PURGE_TIMESTAMP)

d) User SAPDS

ℹ Note

Selecting the *Add Data Services CDC Definitions* option automatically changes owner of the replicated tables, the purge stored procedure, the CDC staging table and the CDC system tables to SAPDS. It defines the CDC staging table name same as the Remote Table name of the article with suffix "_SAPCDC". It creates or overrides function strings: rs_delete, rs_insert, rs_update and rs_get_textptr for blob columns. The CDC staging table defines additional columns in addition to the RemoteTable columns to store the Replication Server system variables:

Function string	What it does
DS_SRCDB	stores system variable “rs_origin_db”
DS_SRCDB_SRV	stores system variable “rs_origin_ds”
DS_SRCDB_ID	stores system variable “rs_origin”
DS_SRCDB_COMMIT_TIME	stores system variable “rs_origin_commit_time”
DS_SRCDB_ORIGIN_QID	stores “rs_origin_qid”
DS_SRCDB_OP_TYPE	stores change operation types“I”- insert , “B”- Before image of update,“U”- After image of update, “D”-Delete
DS_CDCDB_PUBLISH_TIME	stores publish datetime of CDC database when record get inserted by the Replication Server

Add Data Services CDC Definitions command also sets “CDC Staging Table” attributes with the CDC staging table name for each article.

Additionally, *SAP Data Services CDC 14.2.0* extension adds two extended attributes, "Retention Period" and "CDC Staging Table" to Article object. Default value "Retention Period" extended attributes is 14 days. You can change this value.

2.19.4.4 Configuring Data Services Sybase Replication Server CDC environment

There are five steps to configure the SAP Data Services Sybase Replication Server CDC environment. These are:

1. Creating Data Services CDC staging database in the SAP Sybase ASE server.
2. Configuring the Replication Server to add the source databases and the CDC staging database.
3. Configuring the Data Services CDC staging database runtime environment in SAP Sybase ASE Server.
4. Deploying the replication definitions and subscriptions into the Replication Server.
5. Configuring the primary databases runtime environment.

2.19.4.4.1 Creating Data Services CDC staging database in SAP Sybase ASE Server

The following procedure describes how to create Data Services CDC staging database in SAP Sybase ASE server

1. Log in as database administrator and create a database that matches the name of Data Services CDC staging database, as defined in Power Designer's data movement model.
2. Create SAPDS log-in user. Lock this user to prevent log-in.

   > **Note**
   >
   > This user is reserved for Data Services CDC and should not be used for any other purpose. All the Data Services staging database objects are owned by user SAPDS.

3. Select the Data Services staging database Physical Data Model, in Power Designer's Data Movement Model and right-click the context to select *Generate Database* to generate the CDC database DDL script.

   > **Note**
   >
   > This automatically generates DDL of all the database objects that are required for Data Services CDC Staging database.

4. Check the CDC database DDL script that is generated as a file.
5. Deploy this DDL script using the isql tool. Enter the code:

   ```
   isql-Usa-Ppwd -Spds -Dpdb -i DS_CDC_staging_DDL_script.sql-
   oDS_CDC_staging_DDL_script.out
   ```

   where:

   - sa is the System Administrator user login on the DS CDC Staging data server.
   - pwd is the password for the System Administrator user login.
   - pds is the name of the DS CDC Staging data server.
   - pdb is the name of the DS CDC staging database.

2.19.4.4.2 Configuring Replication Server to add Source databases and CDC staging database

The following procedure describes how to configure Replication server to add source database and CDC staging database.

1. Add the source database and the CDC staging database to interface file in Replication Server host.
2. Run rs_init to add the source database and the CDC staging database.

The source database and the CDC staging database are added.

2.19.4.4.3 Configuring Data Services CDC staging database in SAP Sybase ASE Server

The following procedure describes how to configure Data Services CDC staging database in SAP Sybase ASE server.

1. Select the Data Services staging database's Physical Data Model in Power Designer's Data Movement Model and right-click the context to select *Generate Script*.
2. Select *SAP Data Services CDC 14.2.0* extension in the dialog box. It generates script file suffixed with "_DataServices_CDC_DB_Runtime_Script.sql". This script file creates Data Services CDC staging database runtime environment and the provides the following functionalities:
   a) Validates the staging database to find out if this database is added to the replication server by replication server's rs_init utility.
   b) Validates if Data Services CDC staging database create script is run.
   c) Creates the Replication Server maintenance user that was defined in Data Movement Model, if it is not created before. You can change the password after creation to protect un-authorized access.
   d) Adds the maintenance user to database.
   e) Adds the TargetTable name and the CDC staging table name to DS_CDC_TABLES_MAP table for each replication definition.
   f) Adds the CDC staging table name and the retention period to DS_CHANGE_RETENTION table for each replication definition.
   g) Grants select, insert, update and delete privileges to the CDC staging tables.
   h) Grants execute privilege to "PURGE_OLD_CHANGE_DATA" stored procedure.
   i) Grants the Replication Server maintenance user, privileges to execute "Purge Old Change Data" scheduled job in SAP Sybase ASE Job Scheduler database.
   j) Creates "Purge Old Change Data" scheduled job in SAP Sybase ASE Job Scheduler database. "Purge Old Change Data" job name is SAPDS_<CDC Staging Database Name>_PURGE_CHANGE_OLD_DATA.
3. Deploy this DDL script using isql tool.

> i Note
>
> Database user who logs in must be a super user.
>
> Enter the code:
>
> ```
> isql -Usa -Ppwd -Spds -Dpdb -i DS_CDC_staging_Runtime script.sql -o
> DS_CDC_staging_Runtime_script.out
> ```
>
> where:
>
> - sa is the System Administrator user login on the CDC Staging database server.
> - pwd is the password for the System Adminstrator user login.
> - pds is the name of the DS CDC Staging database server.
> - pdb is the name of the DS CDC staging database.

2.19.4.4.4 Deploying Replication definitions and subscriptions into the Replication Server

The following procedure describes how to deploy replication definitions and subscriptions into replication server.

1. Select the Replication Process in Power Designer's Data Movement Model and right-click the context to select *Generate Script*.
2. Set *Create Connection* value to false in the dialog box and click *OK* to generate the Replication definitions, CDC Function Strings definitions subscriptions, and the Replication Server's RCL script file.

   > **Note**
   >
   > It is recommended that you create a database connection using rs_init tool.

3. Deploy this RCL script using the isql tool into the Replication Server that you configured for the CDC staging database and the source databases.

   > **Note**
   >
   > The Replication Server user who logs in to deploy must be a super user.
   >
   > Enter the code:
   >
   > `isql -Usa -Ppwd -Spds -Dpbd -i RCL_script.sql -o RCL_script.out` where:
   >
   > ○ sa is the System Administrator user login on the Replication server.
   > ○ pwd is the password for the System Administrator user login.
   > ○ pds is the name of the Replication server.
   > ○ pdb is the name of the Replication database.

2.19.4.4.5 Configuring Primary Database environment

The following procedure describes how to configure the primary database environment.

1. Select the primary database in Power Designer's Data Movement Model and right-click the context to select *Generate Script* and select *Replication Server 15.7*. It generates three script files.
2. Select the script file that contains sp_setreptable stored procedure command.
3. Check the script to make sure that “owner_on” parameter is set for those articles whose primary table name is qualified by owner.

   > **Note**
   >
   > *SAP Data Services CDC 14.2.0* extension turns on multiple-owner attribute for all those primary tables that are qualified by owner.

4. Deploy these scripts using the isql tool and the appropriate source database tool to create user, grants and permissions.

> ℹ Note
>
> The database user who deploys the script must be a super user.
>
> Enter the code:
>
> ```
> isql –Usa -Ppwd -Spdb -Dpdb -i Primary_database_Runtime script.sql -o
> Primary_database_Runtime script.out
> ```
>
> where:
>
> - sa is the System Adminstrator user login on the Primary database server.
> - pwd is the password for the System Adminstrator user login.
> - pds is the name of the Primary database server.
> - pdb is the name of the Primary database.

This marks primary tables as replicable and also change data is captured by SAP Sybase Replication Agent and propagated to Replication Server.

2.19.4.5 Configuring Data Services

To use Data Services to read and load changed data from SAP Sybase Replication Server, do the following procedures in the Designer:

- Create a CDC datastore.
- Import the metadata for SAP Sybase Replication Server tables.
- Create and define a data flow.
- Configure a CDC source.

2.19.4.5.1 Creating a CDC datastore

To access the CDC tables, create a CDC datastore using the Designer. A CDC datastore is a read-only datastore that can only access tables. Like other datastores, you can create, edit, and access a CDC datastore from the *Datastores* tab of the object library.

This procedure describes how to create a CDC datastore using SAP Sybase Replication Server.

1. Open the datastore editor.
2. Enter the name SybCDC for the datastore.
3. In the *Datastore type* box, select *Sybase RepServer CDC.*
4. In the *Database type* box, select *Sybase ASE*.
5. For *Database version*, select *Sybase ASE 15.x*.
6. Enter a *Database server name*.
7. Enter a *Database name*.
8. Enter a database *User name* and *Password*.
9. To create more than one configuration for this datastore, click *Apply* , then click *Edit* and enter the configuration details.

ℹ Note

You cannot change the database type, version, or CDC method.

10. Click *OK*.

You can now use the new datastore connection to import CDC tables in the current repository.

Related Information

Defining a database datastore [page 213]

2.19.4.5.2 Importing CDC tables

After you create a CDC datastore, you can use it to import CDC table metadata.

In the object library, right-click the datastore name and select either *Open*, *Import by Name*, or *Search*

Only the CDC tables that you selected when you set up SAP Sybase replication server for CDC are visible when you browse external metadata. You must create a CDC table in SAP Sybase ASE for every table you want to read from before you can browse and import that CDC table using SAP BusinessObjects Data Services.

Related Information

Configuring the distribution database [page 778]

2.19.4.5.3 Creating and defining the data flow

To use a SAP Sybase CDC source, you use a Query transform to remove the Sybase control columns and the Map_CDC_Operation transform to interpret the control columns and take appropriate actions:

1. In the *Designer Object Library* pane, drag the SAP Sybase CDC table, Query, and Map_CDC_Operation transforms to the data flow workspace area.

ℹ Note

- Multiple Replication Server CDC tables is allowed in same dataflow.
- The Replication Server CDC table stores data records extracted from the source database log. However, these stored data records are not equivalent to the records available in the corresponding source table. Additionally, captured change data records older than the retention period are also deleted from the Replication Server CDC table. Therefore, joining two or more such CDC tables may not produce the same result as joining their corresponding source database tables produces.

2. Configure the CDC table.
3. Add the appropriate target table and connect the objects.
4. In the *Project Area* pane, double-click a transform. The *Query Editor* opens, displaying the transform.
5. Map the Data Services control columns and the source table columns that you want in your target

The Map_CDC_Operation transform uses the values in the column in the *Row Operation Column* box to perform the appropriate operation on the source row for the target table. For the SAP Sybase CDC source table, the DI_OPERATION_TYPE column is automatically selected as the Row operation column.

The operations can be INSERT, DELETE, or UPDATE. For example, if the operation is DELETE, the corresponding row is deleted from the target table.

2.19.4.5.4 Configuring CDC source table

This procedure describes how to configure a CDC source table. Data Services applies check-points across all the tables (in a given datastore configuration) for all the data flows in a job, to provide data consistency. For more information, see the *Reference Guide*.

1. Drag a CDC datastore table into a data flow.
2. Click the name of this source object to open its source table editor.
3. Click the CDC options tab.
4. Optionally select *Enable check-point.*

Once a check-point is placed, the next time the CDC job runs, it reads only the rows inserted into the CDC table since the last check-point.

If check-points are not enabled, the CDC job reads all the rows in the CDC data source (with increased processing time.)

Related Information

Using mainframe check-points [page 758]

2.19.5 Using CDC with Microsoft SQL Server databases

SAP Data Services can capture changed data on Microsoft SQL Server databases and apply it to target systems using the following methods:

- Changed-Data Capture
- Change Tracking
- Replication Server

All three methods use the concept of check-points to read the most recent set of changes and mark the end of the read. If check-points are not enabled, Data Services reads all the changes. In addition, if you enable check-points and you run your CDC job in recovery mode, the recovered job begins to review the CDC data source at the last check-point.

To capture changed data:

- Enable CDC on the Microsoft SQL Server database
- Enable CDC on the source tables
- Configure Data Services datastores, jobs, and sources

Refer to your Microsoft documentation for details on all methods.The following table compares these methods.

Feature	Changed-Data Capture	Change Tracking	Replication Server
Microsoft SQL Server version supported	2008 and later	2008 and later	2000, 2005, 2008
Synchronous (immediate; asynchronous has latency)	No; changes are captured by the SQL Server CDC capture job.	Yes, tracks changes in line with INSERT, UPDATE, and DELETE operations so changes are available immediately.	No; changes are available after the operations are transferred by the log reader agent into the distribution database.
Requires SQL agent	Yes, a capture job populates the CDC tables.	No, the database engine populates the primary keys into change tables during DML operations.	Yes, a replication log reader agent handles the replication.
Automatic cleanup process	Yes, periodically	Yes, periodically	Yes, periodically
Requires separate tables to store tracking data	Yes, stored in a capture table. The storage depends on the number of columns captured for CDC.	Yes. Uses one internal change tracking table per source table. Uses one transaction table per database. The storage depends on number of primary key columns of the source table.	Yes, stored in a distribution database.
Historical data available	Yes	No	Yes
Requires primary key	No	Yes	Yes
Before image available for UPDATE operation in Data Services	Yes. Data Services automatically reads the before-image and makes it available for further use in the data flow.	No	Yes (optional)
Recommendation	Use when historical data or consistency across multiple tables is required.	Use for rapid synchronization.	Supported but deprecated.

2.19.5.1 Limitations

The following limitations apply to all changed-data capture methods in Microsoft SQL Server:

- You cannot use the following transforms and functions with a source table imported with a CDC datastore because of the existence of the Data Services-generated columns for CDC tables. The software cannot compare or search these columns.
  - Table_Comparison, Key_Generation, SQL, and Data_Transfer transforms. The History_Preserving transform is not supported with the Change Tracking method.
  - All database functions including lookup, lookup_ext, lookup_seq, search_replace, pushdown_sql, truncate_table, key_generation, sql, and total_rows.
- You can only create one CDC source table in a data flow.
- CDC tables are not permitted in real-time jobs.
- Profiling is not available for CDC tables.
- Displaying optimized SQL is not available for data flows that read CDC tables.
- Exporting or importing jobs with CDC tables does not retain the check-point information saved in the Data Services repository.

For the Change Tracking and Replication Server methods, do not use the same subscription name to read the same CDC table in parallel data flows because the check-point is identified by a combination of the subscription name and table name. In other words, to avoid data corruption problems, do not reuse data flows that use CDC datastores, because each time a source table extracts data, it uses the same subscription name. This means that identical jobs, depending upon when they run, can get different results and leave check-points in different locations in the file.

For the Change Tracking method, because Microsoft SQL Server cannot track the TRUNCATE operation on a source table, Data Services cannot propagate those results to the target.

2.19.5.2 Data Services columns

When you import metadata into a CDC datastore using any of the methods, Data Services adds the following columns to the original table:

- DI_SEQUENCE_NUMBER
- DI_OPERATION_TYPE

2.19.5.2.1 DI_SEQUENCE_NUMBER column

The DI_SEQUENCE_NUMBER column starts with zero at the beginning of each extraction. This field increments by one each time the software reads a row except when it encounters a pair of before- and after-images. Both the before- and after-images receive the same sequence number. This sequencing column provides a way to collate image pairs if they become separated as a result of the data flow design.

If during the course of a data flow the before- and after-images become separated or get multiplied into many rows (for example, using GROUP BY or ORDER BY clauses in a query), you could lose row order.

The Map_CDC_Operation transform allows you to restore the original ordering of image pairs by using the DI_SEQUENCE_NUMBER column as its *Sequencing column*.

For the Replication Server method, you can configure the server to retrieve before-images of UPDATE rows before Data Services applies the UPDATE operation to the target. Note that if you do not configure the Replication Server to capture before-images in the database, only after-images are captured by default. For information about when to consider using before-images, see *Using before-images* [page 750].

Related Information

Reference Guide: Transforms, Map_CDC_Operation [page 1098]

2.19.5.2.2 DI_OPERATION_TYPE column

Data Services generates values in the DI_OPERATION_TYPE column. Valid values for this column are:

- I for INSERT
- D for DELETE
- B for before-image of an UPDATE (except for the Change Tracking method, which does not use a before-image)
- U for after-image of an UPDATE

2.19.5.3 Changed-data capture (CDC) method

Using the changed-data capture (CDC) method, Data Services applies check-points across all tables (in a given datastore configuration) for all the data flows in a job to provide data consistency. Enable CDC first in the datastore editor, then select the *Enable check-point* option in the data flow source table editor. If *Enable check-point* is not selected, Data Services retrieves all the available data at that time for that table. This CDC method is not available with versions prior to Microsoft SQL Server 2008.

2.19.5.3.1 Adding a CDC datastore

This procedure describes how to create a datastore connection to Microsoft SQL Server and enable the changed-data capture (CDC) method.

1. Open the datastore editor.
2. Enter a name for the datastore.
3. In the *Datastore type* box, select *Database*.
4. In the *Database type* box, select *Microsoft SQL Server*.
5. Check the *Enable CDC* box.

6. For *Database version*, select *Microsoft SQL Server 2008* or later.
7. In the drop-down box below the *Enable CDC* option, select the *CDC* method.
8. Enter a *Database server name*.
9. Enter a *Database name*.
10. Enter a database *User name* and *Password*.
11. To create more than one configuration for this datastore, click *Apply*, then click *Edit* and enter the configuration details. Note that you cannot change the database type, version, or CDC method.
12. Click *OK*.

You can now use the new datastore connection to import the metadata of a capture instance into the current repository.

Related Information

Defining a database datastore [page 213]

2.19.5.3.2 Importing CDC metadata

After you create a CDC datastore, you can use it to import capture instance metadata.

When CDC is enabled on a table, Microsoft SQL Server creates a capture instance. A table can have up to two capture instances with different names. In the object library, right-click the datastore name and select *Open*, *Import by Name,* or *Search*. Data Services displays the capture instance name (instead of the underlying table name). Therefore, when you import by name, the name must be the capture instance name (not the table name).

The import operation adds the following columns to the original table:

Column name	Data type	Source of column
DI_SEQUENCE_NUMBER	integer	Generated by Data Services
DI_OPERATION_TYPE	varchar(1)	Generated by Data Services
MSSQL_TRAN_SEQNO	varchar(256)	Supplied by Microsoft SQL Server
MSSQL_TRAN_TIMESTAMP	timestamp	Supplied by Microsoft SQL Server
MSSQL_COLUMN_UPDATE_MASK	varchar(258)	Supplied by Microsoft SQL Server

2.19.5.3.3 Configuring a source table using CDC

This procedure describes how to configure a CDC source table when employing the Changed Data Capture (CDC) method. For more information, see the *Reference Guide*.

1. Drag a CDC datastore table into a data flow.

   The table automatically becomes a source object.

2. Click the name of this source object to open its source table editor.
3. Click the *CDC Options* tab.
4. Optionally select *Enable check-point*.

   Once a check-point is placed, the next time the CDC job runs, it reads only the rows inserted into the CDC table since the last check-point.
5. Optionally select *Automatically delete rows after reading*.

Related Information

Reference Guide: Objects, CWC table source [page 949]

2.19.5.3.4 Using CDC for data flows in a WHILE loop

For the CDC method, check-points apply at the job level. If you have data flows that run in a WHILE loop to retrieve the changes, then use the function set_cdc_checkpoint() for each iteration of the loop. This function instructs the source reader to set check-points so that the next iteration picks up the latest changes. Call this function for all the datastores used in all the data flows of the job. For more information, see the *Reference Guide*.

```
set_cdc_checkpoint(<datastore>)
```

The function returns 1 if the check-point has been successfully set; otherwise it returns 0. The value **`<datastore>`** is the name of the datastore containing the CDC tables.

Example

set_cdc_checkpoint('MyCdcSource');

2.19.5.4 Change Tracking method

The Change Tracking method identifies that rows in a table have changed but ignores how many times the row has changed or the values of any intermediate changes. Data Services retrieves only the latest data available. Therefore, change tracking is limited in the historical questions it can answer compared to the Changed-Data Capture (CDC) method. However, there is far less storage overhead because the changed data is not being captured. In addition, a synchronous tracking mechanism used to track the changes has minimal overhead to operations.

Change Tracking must first be enabled for the Microsoft SQL Server database and then enabled for the tables that you want to track within that database. Change tracking information is recorded for modified rows. The values of the primary key column from the tracked table are recorded with the change information to identify the rows that have changed. To obtain the latest data for those rows, Data Services uses the primary key column values to join the source table with the tracked table. Information about the changes can include the type of operation that caused the change (INSERT, UPDATE, or DELETE) or the columns that were changed as part of an UPDATE operation, for example.

This method is not available with versions prior to Microsoft SQL Server 2008.

2.19.5.4.1 Adding a Change Tracking datastore

This procedure describes how to create a datastore connection to Microsoft SQL Server and enable the Change Tracking method.

1. Open the datastore editor.
2. Enter a name for the datastore.
3. In the *Datastore type* box, select *Database*.
4. In the *Database type* box, select *Microsoft SQL Server*.
5. Check the *Enable CDC* box.
6. For *Database version*, select *Microsoft SQL Server 2008* or later.
7. In the drop-down box below the *Enable CDC* option, select the *Change tracking* method.
8. Enter a *Database server name*.
9. Enter a *Database name*.
10. Enter a database *User name* and *Password*.
11. To create more than one configuration for this datastore, click *Apply*, then click *Edit* and enter the configuration details. Note that you cannot change the database type, version, or CDC method.
12. Click *OK*.

You can now use the new datastore connection to import table metadata into the current repository.

Related Information

Defining a database datastore [page 213]

2.19.5.4.2 Importing Change Tracking metadata

After you create a Change Tracking datastore, you can use it to import table metadata.

In the object library, right-click the datastore name and select *Open*, *Import by Name*, or *Search*. Only the CDC tables that you select when you set up Microsoft SQL Server for Change Tracking are visible when you browse external metadata.

The import operation adds the following columns to the original table:

Column name	Data type	Source of column
DI_SEQUENCE_NUMBER	integer	Generated by Data Services
DI_OPERATION_TYPE	varchar(1)	Generated by Data Services
MSSQL_SYS_CHANGE_VERSION	decimal(19,0)	Supplied by Microsoft SQL Server

Column name	Data type	Source of column
MSSQL_SYS_CHANGE_CREATION_VERSION	decimal(19,0)	Supplied by Microsoft SQL Server
MSSQL_SYS_CHANGE_CONTEXT _MASK	varchar(256)	Supplied by Microsoft SQL Server

2.19.5.4.3 Configuring a source table to use Change Tracking

This procedure describes how to configure a CDC source table to enable Change Tracking.

1. Drag a CDC datastore table into a data flow.

   The table automatically becomes a source object.
2. Click the name of this source object to open its source table editor.
3. Click the *CDC Options* tab.
4. Specify a value for the *CDC subscription name*.

   Data Services uses this name to track the last check-point internally in the repository.
5. Select *Enable check-point*.

   Once a check-point is placed, the next time the CDC job runs, it reads only the rows inserted into the CDC table since the last check-point.

Related Information

Reference Guide: Objects, CDC table source [page 949]

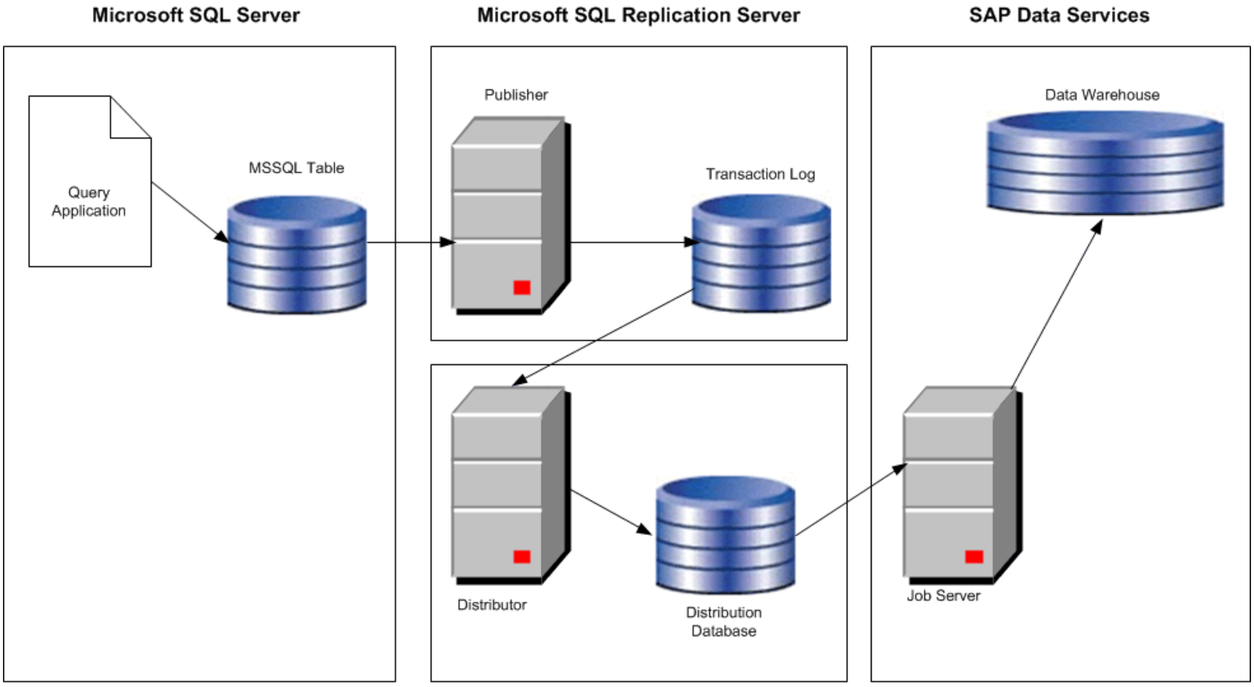
2.19.5.5 Replication Server method

Microsoft uses the following terms for the Microsoft SQL Replication Server:

- Article—An article is a table, a partition, or a database object that the DBA specifies for replication. An article can be any of the following:
  - An entire table
  - Certain columns (using a vertical filter)
  - Certain rows (using a horizontal filter)
  - A stored procedure or view definition
  - The execution of a stored procedure
  - A view
  - An indexed view
  - A user-defined function
- Distributor—The Distributor is a server that stores metadata, history data, and transactions into the distribution database. The software reads the distribution database to obtain changed data.
- Publication—A publication is a collection of one or more articles from one database. A publication makes it easier to specify a logically related set of data and database objects that you want to replicate together.

- Publisher—The Publisher is a server that makes data available for replication to other servers.
- Subscriber—A Subscriber is a server that receives replicated data. Subscribers subscribe to publications, not to individual articles within a publication. They subscribe only to the publications that they need, not to all of the publications available on a Publisher.

The software obtains changed data from the Distribution database in the Microsoft SQL Replication Server. The following diagram shows how the changed data flows from the Replication Server to Data Services.



- An application makes changes to a database and the Publisher within the Replication Server captures these changes within a transaction log.
- The Log Reader Agent in the Distributor reads the Publisher's transaction log and saves the changed data in the Distribution database.
- The software reads the data from the command table within the Distribution database, applies appropriate filters, and creates input rows for a target data warehouse table.

The software accesses the following tables within the Distribution database:

- MSarticles—contains one row for each article that a Publisher replicates.
- MSpublications—contains one row for each publication that a Publisher replicates.
- MSpublisher_databases—contains one row for each Publisher and Publisher database pair that the local Distributor services.
- MSrepl_commands—contains rows of replicated commands (changes to data).

When you enable a database for replication, Replication Server creates tables on the source database. One of these tables is Sysarticles which contains a row for each article defined in this specific database. One of the columns in Sysarticles indicates which columns in a source table are being published.

2.19.5.5.1 Configuring the distribution database

If the software connects to a Microsoft SQL Server to extract data, you need to configure the Distribution database in the Replication Server to capture changes to these tables.

2.19.5.5.1.1 Microsoft SQL Server 2000

The following steps summarize the procedure to configure the Replication Server for Microsoft SQL Server 2000 databases.

1. On the Replication node of the Microsoft SQL Enterprise Manager, select the *Configure publishing, subscribers, and the Distribution* option. Follow the wizard to create the Distributor and Distribution database.

   The following steps summarize the procedure to configure SQL Replication Server for your Microsoft SQL Server 2000 database.

   The wizard generates the following components that you need to specify on the Datastore Editor when you define a Microsoft SQL Server CDC datastore:
   - MSSQL distribution server name
   - MSSQL distribution database name
   - MSSQL distribution user name
   - MSSQL distribution password
2. Select the *New Publications* option on the Replication node of the Microsoft SQL Enterprise Manager to create new publications that specify the tables that you want to publish. The software requires the following settings in the Advanced Options:
   - Select *Transactional publication* on the Select Publication Type window. This type updates data at the Publisher and send changes incrementally to the Subscriber.
   - In the Commands tab of the Table Article Properties window:
     - If you want before images for UPDATE and DELETE commands, select XCALL. Otherwise, select CALL.
     - Clear the options *Create the stored procedures during initial synchronization of subscriptions* and *Send parameters in binary format* options because the software does not use store procedures and has its own internal format.
   - On the Snapshot tab of the Table Article Properties window:
     - Select *Keep the existing table unchanged* because the software treats the table as a log.
     - Clear *Clustered indexes* because the software treats the table as a log and reads sequentially from it.
   - Specify a publication name and description. You specify this publication name on the Datastore Editor when you define an MSSQL CDC datastore.
   - Select option *Yes, allow anonymous subscriptions* to save all transactions in the Distribution database.

For more information, see the Microsoft SQL Enterprise Manager online help.

2.19.5.5.1.2 Microsoft SQL Server 2005 and 2008

The following procedure summarizes how to configure publications for Microsoft SQL Server 2005 and 2008 databases for CDC.

1. Start the Microsoft SQL Server Management Studio.
2. Log in and go to the *Replication* node in the Object Explorer.
3. If this is the first time you are configuring distribution for this server, right-click the *Replication* node and select *Configure Distribution* in the context menu. You can configure the distribution server, snapshot folder, distribution database, and the users for this distributor.
4. Right-click the *Replication* node again and select ▶ *New* ▶ *Publication* ◀. The New Publication Wizard opens.
5. In the New Publication Wizard, click *Next.*
6. Select the database that you want to publish and click *Next.*
7. Under Publication type, select *Transactional publication*, then click *Next*.
8. Click to select tables and columns to publish as articles. Then open *Article Properties*. For each selected table, click *Set Properties of Highlighted Table Article*. The Article Properties window opens:
   a) Set the following to False: *Copy clustered index*; *Copy INSERT, UPDATE and DELETE stored procedures*; *Create schemas at subscriber*.
   b) Set the *Action if name is in use* to *Keep the existing table unchanged*.
   c) Set *Update delivery format* and *Delete delivery format* to *XCALL <stored procedure>*.
   d) Click *OK* to save the article properties.
9. Click *Next*. You can click *Add* to add row filters. Click *Next* if you do not need to filter the data in your publication.
10. Configure Agent Security and specify the account connection setting.
    a) For the Snapshot Agent, click *Security Settings*. Specify the account under which the snapshot agent will run. Configure the account with system administration privileges. Specify the account that connects to the publisher and click *OK.*
    b) For the Log Reader Agent, the *Use the security settings from the Snapshot Agent* option is selected by default. To use different settings, clear this option and click *Security Settings*. Note that it requires a login that grants system administration privileges.
11. In the Wizard Actions window, select *Create the publication* then click *Next*.
12. To complete the wizard, enter a Publication name and click *Finish*.

For more information, see the Microsoft SQL Enterprise Manager documentation.

2.19.5.5.2 Configuring Data Services

To use Data Services to read and load changed data from SQL Server databases using the Replication Server, do the following procedures in the Designer:

- Create a CDC datastore
- Import metadata for Microsoft SQL Server tables
- Configure a CDC source

2.19.5.5.2.1 Adding the CDC datastore

This procedure describes how to create a CDC datastore using the Replication method.

1. Open the Datastore Editor.
2. Enter a name for the datastore.
3. In the *Datastore type* box, select *Database*.
4. In the *Database type* box, select *Microsoft SQL Server*.
5. Check the *Enable CDC* box to enable the CDC feature.
6. Select a *Database version*.
7. Enter a *Database name* (use the name of the Replication server).
8. Enter a database *User name* and *Password*.
9. In the CDC section, enter the names that you created for this datastore when you configured the Distributor and Publisher in the Replication Server:
    - MSSQL distribution server name
    - MSSQL distribution database name
    - MSSQL publication name
    - MSSQL distribution user name
    - MSSQL distribution password
10. If you want to create more than one configuration for this datastore, click *Apply*, then click *Edit* and follow step 9 again for any additional configurations.
11. Click *OK*.

    You can now use the new datastore connection to import table metadata into the current repository.

Related Information

Defining a database datastore [page 213]

2.19.5.5.2.2 Importing CDC metadata

After you create a CDC datastore, you can use it to import CDC table metadata. In the object library, right-click the datastore name and select *Open*, *Import by Name,* or *Search*. Only the CDC tables that you select when you set up Microsoft SQL Server for CDC are visible when you browse external metadata. Data Services uses the MSpublications and MSarticles table in the Distribution database of SQL Replication Server to create a list of published tables.

When you import each CDC table, the software uses the Sysarticles table in the Publisher database of SQL Replication Server to display only published columns.

The import operation adds the following columns to the original table:

Column name	Data type	Source of column
DI_SEQUENCE_NUMBER	integer	Generated by Data Services
DI_OPERATION_TYPE	varchar(1)	Generated by Data Services
MSSQL_TRAN_SEQNO	varchar(256)	Supplied by the Replication Server
MSSQL_TRAN_TIMESTAMP	timestamp	Supplied by the Replication Server

Related Information

Configuring the distribution database [page 778]

2.19.5.5.2.3 Configuring a source table using replication

This procedure describes how to configure a CDC source table using the replication method. For more information, see the *Reference Guide*.

1. Drag a CDC datastore table into a data flow.
   The table automatically becomes a source object.
2. Click the name of this source object to open its source table editor.
3. Click the *CDC Options* tab.
4. Specify a value for the *CDC subscription name*.
   Data Services uses this name to track the last check-point internally in the repository.

Related Information

Using mainframe check-points [page 758]

2.19.5.5.2.3.1 Using check-points with replication servers

A Log Reader Agent in the Microsoft SQL Replication Server reads the transaction log of the Publisher and saves the changed data into the Distribution database, which Data Services uses as the CDC data source. Rows of changed data append to the previous load in the CDC data source.

When you enable check-points, a CDC job uses the subscription name to read the most recent set of appended rows and to mark the end of the read. If check-points are not enabled, the CDC job reads all the rows in the CDC data source (with increased processing time).

To use check-points, on the source table editor enter the *CDC Subscription name* and select the *Enable check-point* option.

2.19.5.5.2.3.2 Using before-images from Microsoft SQL Server sources

When you must capture before-image UPDATE rows:

1. Make sure the Replication Server is set up to retrieve full before-images.
2. When you create a Publication in the Replication Server, specify XCALL for UPDATE commands and DELETE commands to obtain before-images.
3. Select the *Get before-images for each update row* option in the CDC table's source editor.

After you check the *Get before-images for each update row* option, the software processes two rows for every update. In addition to the performance impact of this data volume increase, the before- and after-image pairs could be separated or lost depending on the design of your data flow, which would cause data integrity issues.

> **Note**
>
> The Map_CDC_Operation transform can resolve problems, but undesirable results can still occur due to programming errors. When you use functions and transforms that re-order, re-direct, eliminate, and multiply the number of rows in a data flow, be aware of the possible impact to targets.

Related Information

Using before-images [page 750]

Reference Guide: Transforms [page 1067]

2.19.5.5.2.3.3 Configuring CDC source table

This procedure describes how to configure a CDC source table. Data Services applies check-points across all the tables (in a given datastore configuration) for all the data flows in a job, to provide data consistency. For more information, see the *Reference Guide*.

1. Drag a CDC datastore table into a data flow.
2. Click the name of this source object to open its source table editor.
3. Click the CDC options tab.
4. Optionally select *Enable check-point*.

Once a check-point is placed, the next time the CDC job runs, it reads only the rows inserted into the CDC table since the last check-point.

If check-points are not enabled, the CDC job reads all the rows in the CDC data source (with increased processing time.)

Related Information

Using mainframe check-points [page 758]

2.19.6 Using CDC with timestamp-based sources

Use Timestamp-based CDC to track changes:

- If you are using sources other than Oracle 9i, DB2 8.2, mainframes accessed through IBM II Classic Federation, or mainframes accessed through Attunity and
- If the following conditions are true:
  - There are date and time fields in the tables being updated
  - You are updating a large table that has a small percentage of changes between extracts and an index on the date and time fields
  - You are not concerned about capturing intermediate results of each transaction between extracts (for example, if a customer changes regions twice in the same day).

It is not recommended that you use the Timestamp-based CDC when:

- You have a large table, a large percentage of it changes between extracts, and there is no index on the timestamps.
- You need to capture physical row deletes.
- You need to capture multiple events occurring on the same row between extracts.

The term timestamp refers to date, time, or datetime values. The discussion in this section applies to cases where the source table has either `CREATE` or `UPDATE` timestamps for each row.

Timestamps can indicate whether a row was created or updated. Some tables have both create and update timestamps; some tables have just one. This section assumes that tables contain at least an update timestamp.

Some systems have timestamps with dates and times, some with just the dates, and some with monotonically generated increasing numbers. You can treat dates and generated numbers the same.

It is important to note that for the timestamps based on real time, time zones can become important. If you keep track of timestamps using the nomenclature of the source system (that is, using the source time or source-generated number), you can treat both temporal (specific time) and logical (time relative to another time or event) timestamps the same way.

Related Information

Processing timestamps [page 784]
Overlaps [page 785]
Types of timestamps [page 790]

2.19.6.1 Processing timestamps

The basic technique for using timestamps to determine changes and to save the highest timestamp loaded in a given job and start the next job with that timestamp.

To do this, create a status table that tracks the timestamps of rows loaded in a job. At the end of a job, `UPDATE` this table with the latest loaded timestamp. The next job then reads the timestamp from the status table and selects only the rows in the source for which the timestamp is later than the status table timestamp.

The following example illustrates the technique. Assume that the last load occurred at 2:00 PM on January 1, 1998. At that time, the source table had only one row (key=1) with a timestamp earlier than the previous load. SAP Data Services loads this row into the target table and updates the status table with the highest timestamp loaded: 1:10 PM on January 1, 1998. After 2:00 PM the software adds more rows to the source table:

Source table

Key	Data	Update_Timestamp
1	Alvarez	01/01/98 01:10 PM
2	Tanaka	01/01/98 02:12 PM
3	Lani	01/01/98 02:39 PM

Target table

Key	Data	Update_Timestamp
1	Alvarez	01/01/98 01:10 PM

Status table

Last_Timestamp
01/01/98 01:10 PM

At 3:00 PM on January 1, 1998, the job runs again. This time the job does the following:

1. Reads the Last_Timestamp field from the status table (`01/01/98 01:10 PM`).
2. Selects rows from the source table whose timestamps are later than the value of Last_Timestamp. The SQL command to select these rows is:

   ```
   SELECT * FROM Source
   WHERE 'Update_Timestamp' > '01/01/98 01:10 pm'
   ```

   This operation returns the second and third rows (key=2 and key=3).
3. Loads these new rows into the target table.
4. Updates the status table with the latest timestamp in the target table (`01/01/98 02:39 PM`) with the following SQL statement:

   ```
   UPDATE STATUS SET 'Last_Timestamp' = SELECT MAX('Update_Timestamp') FROM
   target_table
   ```

The target shows the new data:

Table 10: Source table

Key	Data	Update_Timestamp
1	Alvarez	01/01/98 01:10 PM
2	Tanaka	01/01/98 02:12 PM
3	Lani	01/01/98 02:39 PM

Table 11: Target table

Key	Data	Update_Timestamp
2	Tanaka	01/01/98 02:12 PM
3	Lani	01/01/98 02:39 PM
1	Alvarez	01/01/98 01:10 PM

Table 12: Status table

Last_Timestamp
01/01/98 02:39 PM

To specify these operations, a data flow requires the following objects (and assumes all the required metadata for the source and target tables has been imported):

- A data flow to extract the changed data from the source table and load it into the target table, such as Source > Query > Target.
  The query selects rows from SOURCE_TABLE to load to TARGET_TABLE.
  For example:

  ```
  SOURCE.UPDATE_TIMESTAMP > $Last_Update
  ```

  The query includes a where clause to filter rows between timestamps.
- A work flow to perform the following:
  1. Read the status table
  2. Set the value of a variable to the last timestamp
  3. Call the data flow with the variable passed to it as a parameter
  4. Update the status table with the new timestamp
- A job to execute the work flow

2.19.6.2 Overlaps

Unless source data is rigorously isolated during the extraction process (which typically is not practical), there is a window of time when changes can be lost between two extraction runs. This overlap period affects source-based changed-data capture because this kind of data capture relies on a static timestamp to determine changed data.

For example, suppose a table has 1000 rows (ordered 1 to 1000). The job starts with timestamp 3:00 and extracts each row. While the job is executing, it updates two rows (1 and 1000) with timestamps 3:01 and 3:02, respectively. The job extracts row 200 when someone updates row 1. When the job extracts row 300, it updates row 1000. When complete, the job extracts the latest timestamp (3:02) from row 1000 but misses the update to row 1.

Here is the data in the table:

Row Number	Column A
1	...
2	...
3	...
...	...
200	...
...	...
600	...
...	...
1000	...

There are three techniques for handling this situation:

- Overlap avoidance
- Overlap reconciliation
- Presampling

The following sections describe these techniques and their implementations in SAP Data Services. This section continues on the assumption that there is at least an update timestamp.

Related Information

Overlap avoidance [page 786]
Overlap reconciliation [page 787]
Presampling [page 787]
Types of timestamps [page 790]

2.19.6.2.1 Overlap avoidance

In some cases, it is possible to set up a system where there is no possibility of an overlap. You can avoid overlaps if there is a processing interval where no updates are occurring on the target system.

For example, if you can guarantee that the data extraction from the source system does not last more than one hour, you can run a job at 1:00 AM every night that selects only the data updated the previous day until midnight.

While this regular job does not give you up-to-the-minute updates, it guarantees that you never have an overlap and greatly simplifies timestamp management.

2.19.6.2.2 Overlap reconciliation

Overlap reconciliation requires a special extraction process that reapplies changes that could have occurred during the overlap period. This extraction can be executed separately from the regular extraction. For example, if the highest timestamp loaded from the previous job was 01/01/98 10:30 PM and the overlap period is one hour, overlap reconciliation reapplies the data updated between 9:30 PM and 10:30 PM on January 1, 1998.

The overlap period is usually equal to the maximum possible extraction time. If it can take up to **`<n>`** hours to extract the data from the source system, an overlap period of **`<n>`** (or **`<n>`** plus some small increment) hours is recommended. For example, if it takes at most two hours to run the job, an overlap period of at least two hours is recommended.

There is an advantage to creating a separate overlap data flow. A "regular" data flow can assume that all the changes are new and make assumptions to simplify logic and improve performance. For example, rows flagged as INSERT are often loaded into a fact table, but rows flagged as UPDATE rarely are. Thus, the regular data flow selects the new rows from the source, generates new keys for them, and uses the database loader to add the new facts to the target database. Because the overlap data flow is likely to apply the same rows again, it cannot blindly bulk load them or it creates duplicates. Therefore, the overlap data flow must check whether the rows exist in the target and insert only the ones that are missing. This lookup affects performance; therefore, perform it for as few rows as possible.

If the data volume is sufficiently low, you can load the entire new data set using this technique of checking before loading, avoiding the need to create two different data flows.

2.19.6.2.3 Presampling

Presampling eliminates the overlap by first identifying the most recent timestamp in the system, saving it, and then extracting rows up to that timestamp.

The technique is an extension of the simple timestamp processing technique. The main difference is that the status table now contains a start and an end timestamp. The start timestamp is the latest timestamp extracted by the previous job; the end timestamp is the timestamp selected by the current job.

To return to the example: The last extraction job loaded data from the source table to the target table and updated the status table with the latest timestamp loaded:

Source table

Key	Data	Update_Timestamp
1	Alvarez	01/01/98 01:10 PM
2	Tanaka	01/01/98 02:12 PM
3	Lani	01/01/98 02:39 PM

Target table

Key	Data	Update_Timestamp
1	Alvarez	01/01/98 01:10 PM

Status table

Start_Timestamp	End_Timestamp
01/01/98 01:10 PM	NULL

Now it's 3:00 PM on January 1, 1998, and the next job runs; it does the following:

1. Selects the most recent timestamp from the source table and inserts it into the status table as the End Timestamp.
   The SQL command to select one row is:

   ```
   SELECT MAX(Update_Timestamp) FROM source table
   ```

   The status table becomes:

Status table

Start_Timestamp	End_Timestamp
01/01/98 01:10 PM	0 1/01/98 02:39 PM

1. Selects rows from the source table whose timestamps are greater than the start timestamp but less than or equal to the end timestamp. The SQL command to select these rows is:

   ```
   SELECT *
   FROM source table
   WHERE Update_Timestamp > '1/1/98 1:10pm'
   AND Update_Timestamp <= '1/1/98 2:39pm'
   ```

   This operation returns the second and third rows (key=2 and key=3)
2. Loads these new rows into the target table.
3. Updates the status table by setting the start timestamp to the previous end timestamp and setting the end timestamp to NULL.

The table values end up as follows:

Table 13: Source table

Key	Data	Update_Timestamp
1	Alvarez	01/01/98 01:10 PM
2	Tanaka	01/01/98 02:12 PM
3	Lani	01/01/98 02:39 PM

Table 14: Target table

Key	Data	Update_Timestamp
1	Alvarez	01/01/98 01:10 PM
2	Tanaka	01/01/98 02:12 PM
3	Lani	01/01/98 02:39 PM

Table 15: Status table

Start_Timestamp	End_Timestamp
01/01/98 02:39 PM	NULL

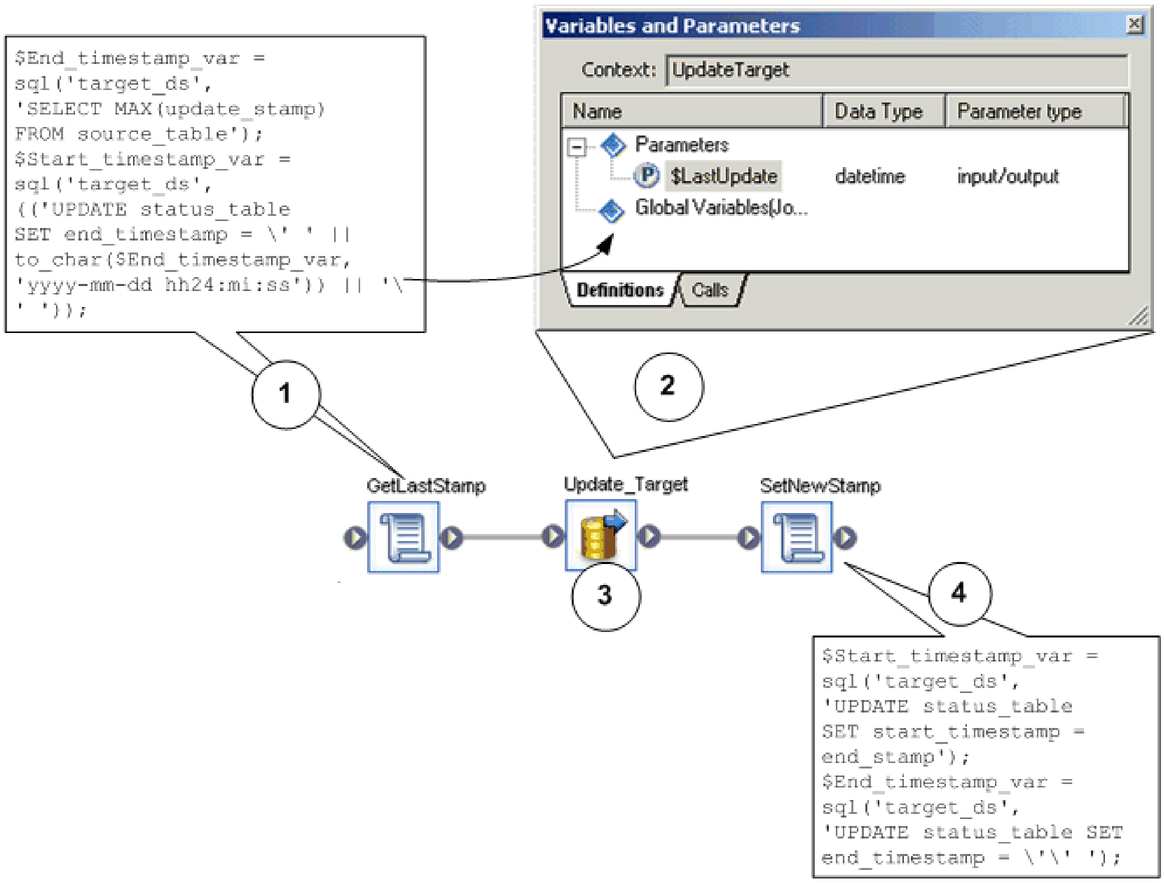
To enhance the previous example to consider the overlap time requires the following changes to the work flow:

- A data flow to extract the changes since the last update and before the most recent timestamp, such as Source > Query > Target.
  The query selects rows from SOURCE_TABLE to load to TARGET_TABLE.
  For example:

  ```
  SOURCE.UPDATE_TIMESTAMP > $start_last_update and
  SOURCE.UPDATE_TIMESTAMP < $end_last_update
  ```

  The query includes a where clause to filter rows between timestamps.
- A work flow to perform the following:
  1. Read the source table to find the most recent timestamp.
  2. Set the value of two variables to the start of the overlap time and to the end of the overlap time, respectively.
  3. Call the data flow with the variables passed to it as parameters.
  4. Update the start timestamp with the value from end timestamp and set the end timestamp to NULL.

Work flow: Changed data with timestamps



```
$End_timestamp_var =
sql('target_ds',
'SELECT MAX(update_stamp)
FROM source_table');
$Start_timestamp_var =
sql('target_ds',
(('UPDATE status_table
SET end_timestamp = \' ' ||
to_char($End_timestamp_var,
'yyyy-mm-dd hh24:mi:ss')) || '\
' '));
```

Variables and Parameters

Context: UpdateTarget

Processing timestamps [page 784]

2.19.6.3 Types of timestamps

Some systems have timestamps that record only when rows are created. Others have timestamps that record only when rows are updated. (Typically, update-only systems set the update timestamp when the row is created or updated.) Finally, there are systems that keep separate timestamps that record when rows are created and when they are updated.

Related Information

Create-only timestamps [page 791]

Update-only timestamps [page 791]

Create and update timestamps [page 791]

2.19.6.3.1 Create-only timestamps

If the source system provides only create timestamps, you have these options:

- If the table is small enough, you can process the entire table to identify the changes. The section *Using CDC for targets* [page 797], describes how to identify changes.
- If the table never gets updated, you can extract only the new rows.
- If the table is large and gets updated, you can combine the following two techniques:
  - Periodically (for example, daily) extract only the new rows.
  - Less frequently (for example, weekly) extract the updated rows by processing the entire table.

2.19.6.3.2 Update-only timestamps

Using only an update timestamp helps minimize the impact on the source systems, but it makes loading the target systems more difficult. If the system provides only an update timestamp and there is no way to tell new rows from updated rows, your job has to reconcile the new data set against the existing data using the techniques described in the section *Using CDC for targets* [page 797].

2.19.6.3.3 Create and update timestamps

Both timestamps allow you to easily separate new data from updates to the existing data. The job extracts all the changed rows and then filters unneeded rows using their timestamps.

Accomplish these extractions in the software by adding the WHERE clause from the following SQL commands into an appropriate query transform:

- Find new rows:

  ```
  SELECT * FROM source_table
  WHERE Create_Timestamp > $Last_Timestamp
  ```

- Find updated rows:

  ```
  SELECT * FROM source_table
  WHERE Create_Timestamp <= $Last_Timestamp AND
  Update_Timestamp > $Last_Timestamp)
  ```

From here, the new rows go through the key-generation process and are inserted into the target, and the updated rows go through the key-lookup process and are updated in the target.

For performance reasons, you might want to separate the extraction of new rows into a separate data flow to take advantage of bulk loading into the target. The updated rows cannot be loaded by bulk into the same target at the same time.

2.19.6.4 Timestamp-based CDC examples

2.19.6.4.1 Preserving generated keys

For performance reasons, many data warehouse dimension tables use generated keys to join with the fact table. For example, customer ABC has a generated key 123 in the customer dimension table. All facts for customer ABC have 123 as the customer key. Even if the customer dimension is small, you cannot simply reload it every time a record changes: unless you assign the generated key of 123 to the customer ABC, the customer dimension table and the fact tables do not correlate.

You can preserve generated keys by either using the lookup function or comparing tables.

Related Information

Using the lookup function [page 792]

Comparing tables [page 794]

2.19.6.4.1.1 Using the lookup function

If history preservation is not an issue and the only goal is to generate the correct keys for the existing rows, the simplest technique is to look up the key for all rows using the `lookup` function in a query. If you do not find the key, generate a new one.

In the following example, the customer dimension table contains generated keys. When you run a job to update this table, the source customer rows must match the existing keys.

Source customer table

Company Name	Customer ID
ABC	001
DEF	002
GHI	003
JKL	004

Target dimension table

Gen_Key	Company Name	Customer ID
123	ABC	001
124	DEF	002

Gen_Key	Company Name	Customer ID
125	GHI	003

This example data flow does the following:

1. Extracts the source rows.
2. Retrieves the existing keys using a `lookup` function in the mapping of a new column in a query.
3. Loads the result into a file (to be able to test this stage of the data flow before adding the next steps).

The `lookup` function compares the source rows with the target. The arguments for the function are as follows:

lookup function arguments	Description
target_ds.owner.customer	Fully qualified name of the target table containing the generated keys.
GKey	The column name in the target table containing the generated keys.
NULL	NULL value to insert in the key column if no existing key is found.
'PRE_LOAD_CACHE'	Caching option to optimize the lookup performance.
Customer_ID	The column in the target table containing the value to use to match rows.
Customer_ID	The column in the source table containing the values to use to match rows.

The resulting data set contains all the rows from the source with generated keys where available:

Result data set

Gen_Key	Company Name	Customer ID
123	ABC	001
124	DEF	002
125	GHI	003
NULL	JKL	004

Adding a new generated key to the new records requires filtering out the new rows from the existing and updated rows. In the data flow, this requires the following steps: A query to select the rows with NULL generated keys. A Key_Generation transform to determine the appropriate key to add. A target to load the new rows into the customer dimension table.

This data flow handles the new rows; however, the rows from the source whose keys were found in the target table might contain updated data. Because this example assumes that preserving history is not a requirement, the software loads all rows from the source into the target.

2.19.6.4.1.1.1 Handling updated rows in the data flow

The data flow requires new steps to handle updated rows, as follows:

1. A new line leaving the query that looked up the existing keys.
2. A query to filter the rows with existing keys from the rows with no keys.
3. A target to load the rows into the customer dimension table.

2.19.6.4.1.2 Comparing tables

The drawback of the generated-keys method is that even if the row has not been changed, it generates an UPDATE and is loaded into the target. If the amount of data is large, a table-comparison transform provides a better alternative by allowing the data flow to load only changed rows.

The table-comparison transform examines all source rows and performs the following operations:

- Generates an INSERT for any new row not in the target table.
- Generates an UPDATE for any row in the target table that has changed.
- Ignores any row that is in the target table and has not changed.
- Fills in the generated key for the updated rows.

You can then run the result through the key-generation transform to assign a new key for every INSERT. This is the data set that the software loads into the target table.

The data flow that accomplishes this transformation includes the following steps:

1. A source to extract the rows from the source table(s).
2. A query to map columns from the source.
3. A table-comparison transform to generate INSERT and UPDATE rows and to fill in existing keys.
4. A key-generation transform to generate new keys.
5. A target to load the rows into the customer dimension table.

2.19.6.4.2 Preserving history

History preserving allows the data warehouse or data mart to maintain the history of data so you can analyze it over time. Most likely, you will perform history preservation on dimension tables.

For example, if a customer moves from one sales region to another, simply updating the customer record to reflect the new region would give you misleading results in an analysis by region over time because all purchases made by a customer before the move would incorrectly be attributed to the new region.

SAP Data Services provides a special transform that preserves data history to prevent this kind of situation. The History_Preserving transform ignores everything but rows flagged as UPDATE. For these rows, it compares the values of specified columns and, if the values have changed, flags the row as INSERT. This produces a second row in the target instead of overwriting the first row.

To expand on how the software would handle the example of the customer who moves between regions:

- If `Region` is a column marked for comparison, the History_Preserving transform generates a new row for that customer.
- A Key_Generation transform gives the new row a new generated key and loads the row into the customer dimension table.
- The original row describing the customer remains in the customer dimension table with a unique generated key.

In the following example, one customer moved from the East region to the West region, and another customer's phone number changed.

Source Customer table

Customer	Region	Phone
Fred's Coffee	East	(212) 123-4567
Jane's Donuts	West	(650) 222-1212
Sandy's Candy	Central	(115) 231-1233

Target Customer table

GKey	Customer	Region	Phone
1	Fred's Coffee	East	(212) 123-4567
2	Jane's Donuts	East	(201) 777-1717
3	Sandy's Candy	Central	(115) 454-8000

In this example, the data flow preserves the history for the `Region` column but does not preserve history for the `Phone` column. The data flow contains the following steps:

1. A source to extract the rows from the source table(s).
2. A query to map columns from the source.
3. A table-comparison transform to generate INSERTs and UPDATEs and to fill in existing keys.
4. A History_Preserving transform to convert certain `UPDATE` rows to INSERT rows.
5. A key-generation transform to generate new keys for the updated rows that are now flagged as INSERT.
6. A target to load the rows into the customer dimension table.

Now that there are two rows for Jane's Donuts, correlations between the dimension table and the fact table must use the highest key value.

Note that updates to non-history preserving columns update all versions of the row if the update is performed on the natural key (for example, `Customer`), and only update the latest version if the update is on the generated key (for example, `GKey`). You can control which key to use for updating by appropriately configuring the loading options in the target editor.

2.19.6.4.2.1 valid_from date and valid_to date

To support temporal queries like "What was the customer's billing address on May 24, 1998," SAP Data Services supports *Valid from* and *Valid to* date columns.

In history-preserving techniques, there are multiple records in the target table with the same source primary key values. A record from the source table is considered valid in the dimension table for all date values `t` such that the *Valid from* date is less than or equal to `t`, which is less than the *Valid to* date. (Valid in this sense means that the record's generated key value is used to load the fact table during this time interval.)

When you specify the *Valid from* and *Valid to* entries, the History_Preserving transform generates an UPDATE record before it generates an INSERT statement for history-preservation reasons (it converts an UPDATE into an INSERT). The UPDATE record will set the *Valid to* date column on the current record (the one with the same primary key as the INSERT) to the value in the *Valid from* date column in the INSERT record.

2.19.6.4.2.2 Update flag

To support slowly changing dimension techniques, Data Services enables you to set an update flag to mark the current record in a dimension table.

Value *Set value* in column *Column* identifies the current valid record in the target table for a given source table primary key.

When you specify *Column*, the History_Preserving transform generates an UPDATE record before it generates an INSERT statement.

This UPDATE record will set the *Column* value to *Reset value* in the target table record with the same source primary key as the INSERT statement.

In the INSERT statement the *Column* will be set to *Set value*.

When you specify entries in both the groups, the History_Preserving transform generates only one extra UPDATE statement for every INSERT statement it produces. This UPDATE statement updates the *Valid to* value.

2.19.6.5 Additional job design tips

When designing a job to implement changed-data capture (CDC), you must consider:

- Synchronizing header and detail
- Capturing physical deletions

2.19.6.5.1 Synchronizing header and detail

Typically, source systems keep track of header and detail information changes in an independent way. For example, if a line-item status changes, its "last modified date" column updates, but the same column at the order header level does not update. Conversely, a change to the default ship-to address in the order header might impact none of the existing line items.

In some instances, however, your source system might not consistently update those tracking columns, or you might not have access to such information (for example, when rows are physically deleted). In these cases, you might choose to extract all header and detail information whenever any changes occur at the header level or in any individual line item.

To extract all header and detail rows when any of these elements have changed, use logic similar to this SQL statement:

SELECT ... FROM HEADER, DETAIL WHERE HEADER.ID = DETAIL.ID AND (HEADER.LAST_MODIFIED BETWEEN $G_SDATE AND $G_EDATE OR DETAIL.LAST_MODIFIED BETWEEN $G_SDATE AND $G_EDATE)

For some databases, this WHERE clause is not well optimized and might cause serious performance degradation. You might opt to relax that clause by removing one of the upper bounds, such as in:

... WHERE HEADER.ID = DETAIL.ID AND (HEADER.LAST_MODIFIED BETWEEN $G_SDATE AND $G_EDATE OR DETAIL.LAST_MODIFIED >= $G_SDATE) ...

This might retrieve a few more rows than originally intended, but it might improve the final performance of your system while not altering the result of your target database.

2.19.6.5.2 Capturing physical deletions

When your source system allows rows to be physically deleted, your job should include logic to update your target database correspondingly. There are several ways to do this:

- Scan a log of operations — If your system logs transactions in a readable format or if you can alter the system to generate such a log, then you can scan that log to identify the rows you need to delete.
- Perform a full refresh — Simply reload all of the data, therefore fully synchronizing the source system and the target database.
- Perform a partial refresh based on a data-driven time-window — For example, suppose that the source system only allows physical deletion of orders that have not been closed. If the first non-closed order in your source table occurred six months ago, then by refreshing the last six months of data you are guaranteed to have achieved synchronization.
- Perform a partial refresh based on a business-driven time-window — For example, suppose that the business that the job supports usually deletes orders shortly after creating them. In this case, refreshing the last month of orders is appropriate to maintain integrity.
- Check every order that could possibly be deleted — You must verify whether any non-closed order has been deleted. To be efficient, this technique requires you to keep a record of the primary keys for every object that is a candidate for deletion.

When physical deletions of detail information in a header-detail relationship are possible (for example, removing line items from an existing order), then you must capture these physical deletions when synchronizing header and detail information.

2.19.7 Using CDC for targets

Source-based changed-data capture is almost always preferable to target-based capture for performance reasons. Some source systems, however, do not provide enough information to make use of the source-based changed-data capture techniques. Target-based changed-data capture allows you to use the technique when source-based change information is limited.

2.20 Monitoring Jobs

2.20.1 Administrator

The Administrator application in the Management Console is the primary monitoring resource for all jobs designed in the Designer. For detailed information, see the “Administrator” section of the *Management Console Guide*.

2.21 Multi-user Development

About multiple users

SAP Data Services supports a multi-user development environment. A team can work together on an application during the development, testing, or production phase. Also, different teams can work on the different phases at the same time.

Each individual developer works on an application in their unique local repository. Each team uses a central repository to store the master copy of its application. The central repository preserves all versions of all objects in the application so you can revert to a previous version if necessary.

Related Information

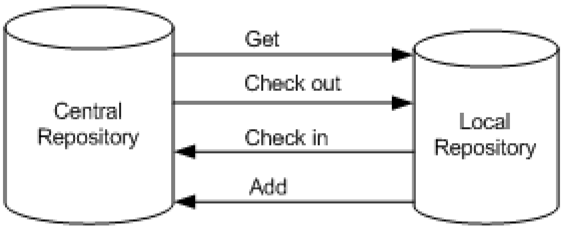
Central versus local repository [page 798]
Multiple users [page 799]

2.21.1 Central versus local repository

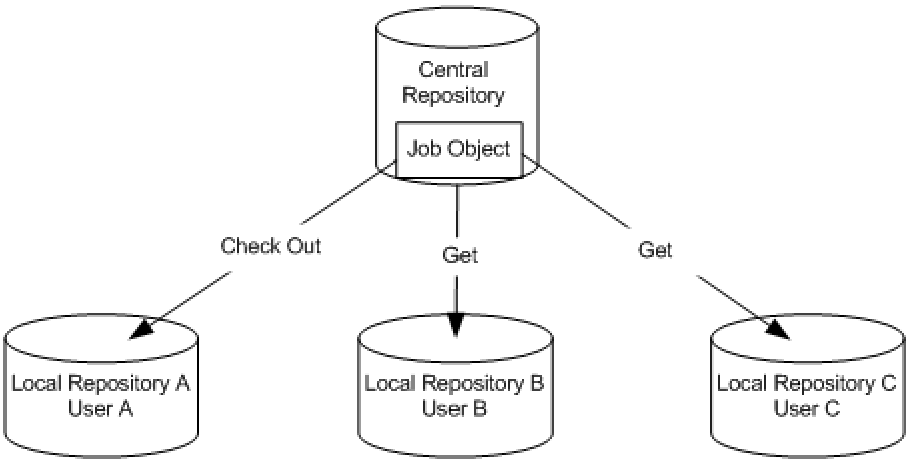
You can create a central repository for storing the team copy of a SAP Data Services application. The central repository contains all information normally found in a local repository such as definitions for each object in an application. However, the central repository is merely a storage location for this information. To change the information, you must work in a local repository.

A local repository provides a view of the central repository. You can "get" (copy) objects from the central repository into your local repository. However, to make changes to an object, you must "check out" that object from the central repository into your local repository. While you have an object checked out from the central repository, other users cannot check out that object, so they cannot change the information.

After completing changes, you "check in" the changed object. When you check in objects, the software saves the new, modified objects in the central repository.



Multiple users working from unique local repositories can connect to the same central repository. These users can work on the same application and share their work. However, at any given time only one user can check out and change a particular object. While an object is checked out to one user, other users can "get" (obtain a copy of) the object but cannot make changes that will update the central repository.



Central Repository
Job Object
Check Out
Get
Get
Local Repository A User A
Local Repository B User B
Local Repository C User C

The central repository retains history for each object. Therefore, if you find you made a change that did not work as planned, you can revert to a previous version of the object.

The local repository and the central repository must use the same software repository version. For example, you can run SAP Data Services Designer X.2 with a central and local repository version X.1. However, you cannot run SAP Data Services X.2 with a central repository X.1 and a local repository X.2

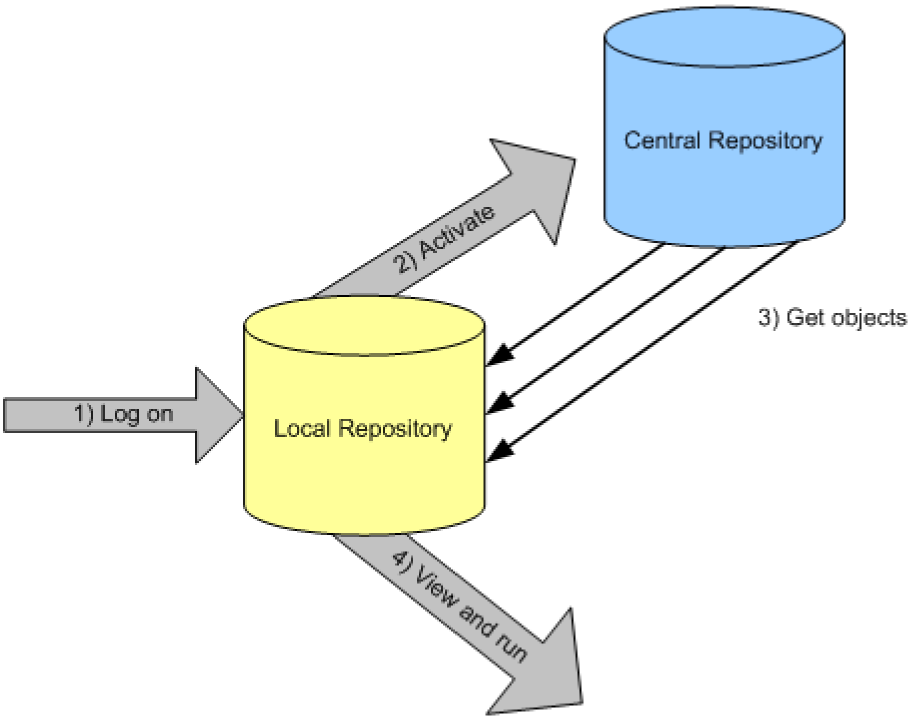
2.21.2 Multiple users

A multi-user environment affects how you use SAP Data Services and how you manage different phases of an application. For success in a multi-user environment, you must maintain consistency between your local repository and the central repository.

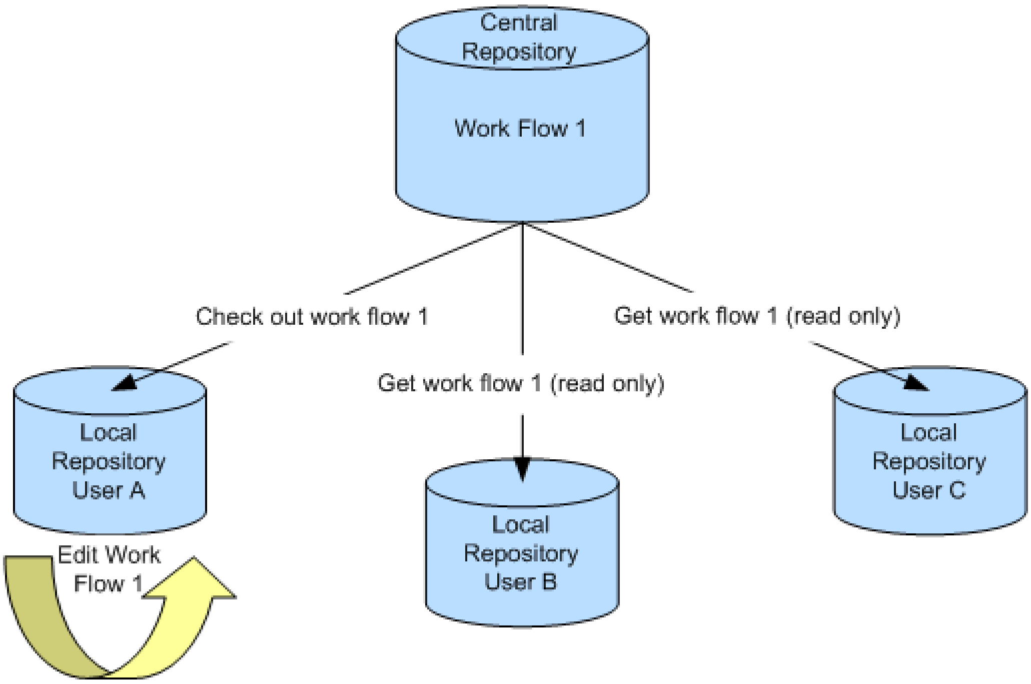
The following terms apply when discussing the software and multi-user environments:

Term	Definition
Highest level object	The highest level object is the object that is not a dependent of any object in the object hierarchy. For example, if Job 1 is comprised of Work Flow 1 and Data Flow 1, then Job 1 is the highest level object.
Object dependents	Object dependents are objects associated beneath the highest level object in the hierarchy. For example, if Job 1 is comprised of Work Flow 1 which contains Data Flow 1, then both Work Flow 1 and Data Flow 1 are dependents of Job 1. Further, Data Flow 1 is a dependent of Work Flow 1.
Object version	An object version is an instance of an object. Each time you add or check in an object to the central repository, the software creates a new version of the object. The latest version of an object is the last or most recent version created.

When working in a multi-user environment, you activate the link between your local repository and the corresponding central repository each time you log in. To ensure that your repository is current, you can get (copy) the latest version of each object in the central repository. Once you get an application in your local repository, you can view and run it from the Designer.



However, if you plan to make changes to objects in the application, you must check out those objects. After you check out an object, no other user can make changes. Essentially, you lock the version in the central repository; only you can change that version. Other users can only get and view the object.



When you are done making changes to an object, save those changes in the local repository and check the object back into the central repository. The software saves the changed object in the central repository and makes the object available for check-out by others. The software maintains all versions of saved objects in the central repository. Thus later, you can copy an old version of a saved object, even after replacing it in your local repository with a new version.

At any time, you can label an object or a group of objects. An object label provides a convenient mechanism for identifying objects later. For example, you may find it helpful to label objects by feature. Later, if you decide you want to eliminate a recently-added feature, you can get all objects that have the label without that feature.

You can also compare two objects—such as two different object versions in the central repository, or an object in your local repository to an object in the central repository. By comparing two objects, you can determine what parts of an object changed and decide whether you want to revert to an older version of an object.

Related Information

Designer Guide: Design and Debug, Comparing Objects [page 714]

2.21.3 Security and the central repository

You also have several options to make your central repository secure. Use these options when you need to control access and provide for object tracking within your central repository. These security options apply only to central repositories and include:

- Authentication — Allows only valid users to log in to a central repository.

- Authorization — Grants various levels of permissions to objects.
- Auditing — Maintains a history of changes made to an object including user names.

Implement security for a central repository by establishing a structure of groups and associated users using the Administrator.

Related Information

Implementing Central Repository Security [page 805]

2.21.4 Multi-user Environment Setup

Overview of multi-user setup

To support multiple developers, configure a multi-user environment and set up several repositories. Specifically, you must:

- Create a local repository for each developer.
- Create a central repository.
- Define a connection to central repository from each local repository.
- Activate the connection to a central repository.

Related Information

Create a nonsecure central repository [page 802]
Define a connection to a nonsecure central repository [page 803]
Activating a central repository [page 803]

2.21.4.1 Create a nonsecure central repository

To support multiple users in a single development environment, it is recommended that you use a central repository. The central repository stores master information for the development environment.

This procedure applies to nonsecure repositories only.

1. Create a database to be used for the central repository using your database management system.
2. Choose *Start* > *Programs* > *SAP Data Services 4.2* > *Data Services Repository Manager*.
3. In the Repository Manager window, click the *Central* button in the *Repository Type* field, and enter the database connection information for the central repository.

4. Click *Create*.

   The repository tables are created in the database you identified.

Related Information

Implementing Central Repository Security [page 805]

2.21.4.2 Define a connection to a nonsecure central repository

A team working on an application only needs one central repository. However, each team member requires a local repository. Furthermore, each local repository requires connection information to any central repository it must access.

This procedure applies to nonsecure repositories only.

> Note
>
> The version of the central repository must match the version of the local repository.

1. Start the Designer and log in to your local repository.
2. Choose *Tools* > *Central Repositories* to open the Options window.

   The Central Repository Connections option is selected in the Designer Options list.
3. Right-click in the *Central Repository Connections* box and select *Add*.

   The *Repository Password* window opens.
4. Enter the password for the central repository.
   The repository appears in the *Central repository connections* box.
5. Click *Activate*.
6. Again, enter the password for the central repository.
7. Click *OK*.

Related Information

Implementing Central Repository Security [page 805]

2.21.4.3 Activating a central repository

To connect to a central repository, you must activate the link between your local repository and a specific central repository.

ℹ Note

When you start the Designer, always log in to a local repository. Never log into a central repository. If you do, then the central repository acts as a local repository. Then you run the risk of corrupting version information. If you attempt to log in to the central repository, you will see a warning message. You should log out immediately and log into a local repository.

Your local repository provides a view of the objects in the active central repository. Whenever you get or check out objects, you copy objects from the active central repository. Whenever you check in objects, you save the version from your local repository into the active central repository.

You must activate the correct central repository each time you log in. When you activate a central repository, the central object library opens and shows all the objects in the central repository and the check-out status of each object.

2.21.4.3.1 To activate a central repository

1. Choose *Tools* > *Central Repositories* to open the Options window.

   The Central Repository Connections option is selected in the Designer Options list.
2. In the *Central repository connections* list, determine a central repository to make active.
3. Check *Reactivate automatically* if you want the active central repository to be reactivated when you next log on to this local repository.
4. Right-click the central repository and select *Activate*.

   The central object library opens. The Options window indicates that the selected central repository is active and closes automatically.

2.21.4.3.2 To open the central object library

Click the *Central Object Library* button on the toolbar.

The central object library looks like the object library—it shows all the objects in the repository, grouped on appropriate tabs.

The window opens in floating mode. Drag the window to dock it. To change the docking state, right-click the Central Object Library tool bar and toggle *Docking*.

You can also change central repository connection information from the central object library.

2.21.4.3.3 To change the active central repository

Select a central repository from the list on the top of the central object library.

SAP Data Services makes the selected central repository active—objects from that repository appear in the central object library. Connection information about that repository appears in the upper right corner of the central object library.

2.21.4.3.4 To change central repository connections

1. Click the *Edit Central Repository Connection* button on the top of the central object library.

   The Options window opens with the Central Repository Connections option selected in the Designer Options list.

   Alternatively, you can open the Options window by selecting *Tools* > *Central Repositories*.
2. Select a central repository in the *Central Repository Connections* box, right-click, and select *Edit*.

   When the Datastore Administrator window opens:

   - To disconnect from the currently active central repository, right-click the central repository in the *Central Repository Datastores* box and select *Deactivate*
   - To delete connection information for a central repository, right-click the central repository in the *Central Repository Datastores* box and select *Delete*.
     After confirming your selection, the connection information from this local repository is deleted. You can no longer connect to that central repository from this local repository.

     > Note
     >
     > You are not deleting the central repository; you are only deleting the connection information between your local repository and this central repository.
   - To make another repository the active central repository, right-click the central repository in the *Central Repository Datastores* box and select *Activate*.

2.21.5 Implementing Central Repository Security

About this section

This section describes how to implement optional security features for central repositories.

2.21.5.1 Overview

SAP Data Services provides options for managing secure access and tracking for objects in central repositories. Mechanisms for managing central repository security include:

- Authentication — Allows only valid users to log in to a central repository.
- Authorization — Grants various levels of permissions to objects.

- Auditing — Maintains a history of changes made to an object including user names.

Note that these security mechanisms and procedures apply only to central repositories.

2.21.5.1.1 Group-based permissions

You implement security for a central repository by establishing a structure of groups and associated users using the Administrator and the Central Management Console (CMC).

Access permissions for objects apply at the group level. More than one group can have the same permissions to the same object at a time. Groups are specific to a repository and are not visible in any other local or central repository.

Therefore, users do not get individual permissions. In the Designer, users select from the group(s) to which they belong, and the selected (current) group dictates their access to that object. Each user must have one default group but can belong to more than one group. When a user adds an object to a secure central repository, the user's current group automatically has Full permissions to that object.

User name and password authentication is required for every logon to a secure central repository. Users can change their passwords at any time in the CMC.

Related Information

Managment Console Guide: Central Repository management, Setting up users and groups [page 1881]
Administrator Guide: User management [page 46]

2.21.5.1.2 Permission levels

Each object in a secure central repository can have one of the following permissions levels:

- Full — This is the highest level of permission. The group can perform all possible actions including checking in, checking out, and deleting the object. You might assign this type of access to developers, for example.
- Read — Users can only get a copy of the object from the central repository or compare objects between their local and central object libraries. You might assign this type of access to QA, for example.
- None — Users cannot get copies of the object but can view it and its properties.

When an authenticated user adds an object to a secure central repository, the user's current group receives Full permissions to the object. All other groups receive Read permissions. Members of the group with Full permissions can change the other groups' permissions for that object.

2.21.5.1.3 Process summary

You implement security for a central repository by:

1. Using the Repository Manager to add a secure central repository or upgrade an existing nonsecure central repository.
2. Using the Central Management Console (CMC) to add users.
3. Using the Administrator to add the users to central repository groups.
4. Defining the connection from the Designer.
5. Adding objects to the central repository as well as view and modify object permissions.

Setting up groups and users [page 808]
Defining a connection to a secure central repository [page 809]
Working with objects in a secure central repository [page 809]

2.21.5.2 Creating a secure central repository

The first step in establishing security measures for multi-user development is to create a secure central repository or upgrade an existing nonsecure central repository.

> ℹ Note
>
> These procedures apply to secure repositories only.

Related Information

Multi-user Environment Setup [page 802]

2.21.5.2.1 To create a secure central repository

1. Create a database to be used for the central repository using your database management system.
2. Choose *Start* › *Programs* › *SAP Data Services 4.2* › *Data Services Repository Manager*.
3. In the Repository Manager window, click the *Central* button in the Repository Type field and enter the database connection information for the central repository.
4. Select the *Enable security* check box.
5. Click *Create*.

   The software creates repository tables in the database you identified.

2.21.5.2.2 To upgrade a central repository from nonsecure to secure

You can modify an existing central repository to make it secure; however, you cannot undo this change.

1. Open the Repository Manager.
2. In the Repository Manager window, click the *Central* button in the Repository Type field and enter the database connection information for the central repository to modify.
3. Select the *Enable security* check box.
4. Click *Upgrade*.

   The software updates the repository tables in the database you identified.

   > Note
   >
   > When you upgrade an existing non-secure central repository to a secure central repository, a new group, DIGroup, is automatically created for you and displayed in *Management Console* > *Administrator* > *Central Repositories*. To access the repository, add existing users to the group in the Administrator.

2.21.5.3 Adding a multi-user administrator (optional)

In the Central Management Console (CMC), you have the option of adding a user with the role of Multi-user Administrator. This role is limited to managing secure central repositories, so it is therefore a subset of the Administrator role. For example, Multi-user Administrators cannot add a local repository or a nonsecure central repository.

Multi-user Administrators can:

- Add and remove secure central repositories.
- Manage users and groups.
- View secure central repository reports.

Related Information

Administrator Guide: User management [page 46]

2.21.5.4 Setting up groups and users

The next step in implementing central repository security is to add and configure groups and users with the Central Management Console (CMC) and the Administrator.

Related Information

Administrator Guide: User management [page 46]
Management Console Guide: Central Repository management, Setting up users and groups [page 1881]

2.21.5.5 Defining a connection to a secure central repository

The next step in implementing central repository security is to define a connection to the repository in the Designer.

This procedure applies to secure central repositories only.

1. Start the Designer and log in to your local repository.
2. From the *Tools* menu, click *Central Repositories* to open the Options window.
   The Central Repository Connections option should be selected in the Designer list.
3. Click *Add*.
4. Enter your CMS connection information and click *Log On*.
5. Select the secure central repository you want to connect.
6. Click *OK*.
   The list of central repository connections now includes the newly connected central repository and it is identified as being secure.
7. With the repository selected, click *Activate*.
8. Click *OK*.

Activating a central repository [page 803]

2.21.5.6 Working with objects in a secure central repository

Related Information

Adding objects to the central repository [page 811]
Viewing and modifying permissions [page 810]

2.21.5.6.1 Viewing and modifying permissions

After completing all configuration tasks and adding objects to the secure central repository, use the central object library to view and modify group permissions for objects.

2.21.5.6.1.1 To view permissions for an object

1. Start the Designer and log in to your local repository.
2. Open the secure central object library.

Your default group appears in the drop-down list at the top of the window and is marked with an asterisk. The Permissions column displays the current group's access level for each object. If you add a new object to the central library, the current group gets FULL permissions and all other groups get READ permission.

2.21.5.6.1.2 To change object permissions to other groups

You must have Full permissions to change object access to other groups.

1. In the central object library, right-click the object and click *Permission* > *CDC Adapter Configuration* > *Object* or *Permission* > *Object and dependants*.
2. The *Permission* dialog box opens, which displays a list of available groups and the group's access level for the object(s).
3. Click in the *Permission* column, and from the drop-down list select a permission level for the group.
4. Click *Apply* or *OK*.

2.21.5.6.1.3 To change the current group or the default group

1. To change the current group, in the central object library select a group from the drop-down box.
2. To change your default group, select the desired group from the drop-down box and click the save icon.

   The software marks the default group with an asterisk.

2.21.6 Working in a Multi-user Environment

To obtain optimal results from development in a multi-user environment, it is recommended certain processes, such as checking in and checking out objects that you change, and establishing a set of conventions that your team follows, such as labeling objects.

2.21.6.1 Filtering

SAP Data Services allows you to customize by filtering (selectively changing) environment-specific information in object definitions. Application objects can contain repository-specific information. For example, datastores and database tables might refer to a particular database connection unique to a user or a phase of development. When multiple users work on an application, they can change repository-specific information.

Specifically, filtering allows you to:

- Change datastore and database connection information
- Change the root directory for files associated with a particular file format
- Select or clear specific dependent objects

The filtering process is available when adding, checking in, checking out, or getting labeled or latest objects in a central repository.

When you select any command that uses the filtering option:

1. The *Version Control Confirmation* window displays your selected object and any dependent objects. You can exclude objects by selecting the object and changing the *Target status* from *create* or *replace* to *exclude*.
2. The *Datastore Options* window shows any datastores used by the object. This window only opens if the objects that you are adding, checking in, or checking out include a datastore.

2.21.6.2 Adding objects to the central repository

After creating a central repository, connecting it to the local repository, and activating the central repository, you can add objects from the local repository to the central repository. Remember that you do all design work—the creation of jobs, work flows, and data flows—in a local repository. Therefore, you use a local repository for the initial creation of any objects in an application. After the initial creation of an object, you add it to the central repository. Once in the central repository, the object is subject to version control and can be shared among users.

You can add a single object to the central repository, or you can add an object with all of its dependents to the central repository. When you add a single object, such as a data flow, you add only that object. No dependent objects are added.

You can add objects to the central repository at any point. However, you cannot add an object that already exists in the central repository.

You cannot add a read-only transform configuration to the repository. You can, however, replicate a transform configuration and add the replica to the repository.

2.21.6.2.1 To add a single object to the central repository

1. Open the local object library.
2. Right-click the object and select *Add to Central Repository* > *Object*.
3. The Comments window opens. Enter any comments in the *Comments* field, and click *OK*.

   The software adds the object to the active central repository.

ℹ Note

The Add to Central Repository command is not available if the object already exists in the central repository.

2.21.6.2.2 To add an object and its dependent objects to the central repository

1. Open the local object library.
2. Right-click the object and select either *Add to Central Repository* > *Object and dependents* or *Add to Central Repository* > *With filtering* (if filtering is required).
3. The Comments window opens. Enter any comments in the *Comments* field, and click *OK*.
4. If you selected *With filtering*, complete the filtering windows.
5. Click *Finish* to add the selected objects.

Alternatively, you can select the object and drag it to the central object library to add the object and its dependents to the central repository. The filtering windows are displayed.

ℹ Note

The *Add to Central Repository* command is not available if the object already exists in the central repository. However, the *Add to Central Repository* command is available if the object's dependents already exist in the central repository but the object itself does not.

ℹ Note

You cannot add a read-only transform configuration to the repository. To do so, you must create a new repository, upgrade the existing repository, or import ATL that contains a new version of read-only transform configurations.

Related Information

Filtering [page 811]

2.21.6.3 Checking out objects

When you might change any of the objects in an application, you should check out the objects that you expect to change. When you check out an object, you make that object unavailable to other users—other users can view the object but cannot make changes to the object. Checking out an object ensures that two users do not make conflicting changes to the object simultaneously.

Data Services changes the object icons in both the local and central object libraries to indicate that the object is checked out.

When an object is checked out, your central object library shows you the local repository that has checked out the object. Based on the repository name, you can determine which user is working with that object.

To see periodic changes, refresh the central object library by clicking on the *Refresh Central Object Library* button in the toolbar of the central object library.

Choose a check-out command based on what you will do to an object.

2.21.6.3.1 Check out single objects or objects with dependents

Dependents are objects used by another object—for example, data flows that are called from within a work flow. You can check out a single object or an object with all of its dependents (as calculated in the central repository). For example, you can simply check out a work flow. In that case, you can change that work flow, such as adding a new script to the work flow; however, you cannot change dependent objects in the work flow, such as data flows, and retain the changes in the central repository. Changes to dependent objects will only be retained in the local repository. Alternatively, you can check out the work flow with all of its dependents. In that case, you can make changes to the work flow or any of its dependents and retain the changes in both central and local repositories.

Generally, it is safest to check out an object with all dependents. When you do this, you prevent others from accidentally changing dependent objects.

2.21.6.3.1.1 To check out a single object

1. Open the central object library.
2. Right-click the object you want to check out.
3. Choose *Check Out* > *Object*.

   Alternatively, you can select the object in the central object library, and click the *Check Out Object* button on the top of the central object library.

   The software copies the most recent version of the selected object from the central repository to your local repository, then marks the object as checked out.

2.21.6.3.1.2 To check out an object and its dependent objects

1. Open the central object library.
2. Right-click the object you want to check out.
3. Choose *Check Out* > *Object and dependents*.

   Alternatively, you can select the object in the central object library, and click the *Check Out Object and dependents* button on the top of the central object library.

SAP Data Services copies the most recent version of the selected object and all of its dependent objects from the central repository and marks these objects as checked out.

If a dependent object is checked out by you or another user, then the software alerts you with a Check Out Alert window, asking to get the latest version of the checked out object.

Related Information

Getting objects [page 820]

2.21.6.3.2 Check out single objects or objects with dependents without replacement

When you check out an object, you can replace the object in your local repository with the latest version from the central repository, or you can leave the current version in your local repository intact.

When you check out an object, SAP Data Services copies the object definition from the central repository and replaces any existing definitions for that object in your local repository.

You can check out objects without replacing the objects in your local repository. For example, suppose you are working in your local repository and you make a change to an object that is not checked out. If you determine that the change improves the design or performance of your application, you will want to include that change in the central repository.

To do this, check out the object without replacing the object in your local repository—the object that you have already improved with a change. Then, check the changed object back into the central repository.

> **Note**
>
> Use caution when checking out objects without replacing the version in your local repository. When you do not replace the version in your local repository, you can lose changes that others have incorporated into those objects.

2.21.6.3.2.1 To check out an object or an object and its dependent objects without replacement

1. Open the central object library.
2. Right-click the object you want to check out and choose *Check Out* > *Object* > *without replacement* to check out the single object or choose *Check Out* > *Object and dependents without replacement* to check out the object and all of its dependent objects.

   SAP Data Services marks all appropriate objects as checked out—in both the object library and in the workspace—but does not copy any objects from the central repository to the local repository.

2.21.6.3.3 Check out objects with filtering

When you check out an object with filtering, the object and all its dependents are checked out.

> **Note**
>
> When you check out objects with filtering, you always replace local versions with the filtered objects from the central repository.

2.21.6.3.3.1 To check out and object and its dependent objects with filtering

1. Open the central object library.
2. Right-click the object you want to check out and choose ▶ *Check Out* ▶ *With filtering* ◀.
3. Complete the filtering windows.
4. Click *Finish* to check out the selected objects.

Related Information

Filtering [page 811]

2.21.6.4 Undoing check out

Occasionally, you may decide that you did not need to check out an object because you made no changes. Or, you may decide that the changes you made to a checked-out object are not useful and you prefer to leave the master copy of the object as is. In these cases, you can undo the check out.

When you undo a check out:

- the object in the central repository remains as it was before the checkout; no changes are made and no additional version is saved in the central repository. Only the object status changes from checked out to available.
- the local version of the object maintains the changes you made. If you want the local object to be an exact copy of the central object, perform a *Get latest* operation on that object.

After you undo a check out, other users can check out and make changes to the object.

2.21.6.4.1 To undo single object check out

1. Open the central object library.
2. Select a checked-out object.
3. Click the *Undo object check out* button. Alternatively, right-click the object and select ▶ *Undo Check Out* ▶ *Object* ◀.

SAP Data Services removes the check-out symbol and makes no changes to the object in the central repository. Any checked-out dependent objects remain checked out.

2.21.6.4.2 To undo check out of an object and its dependents

1. Open the central object library.
2. Select the checked-out object that is the highest level for which you want to undo the check out.
3. Click the *Undo object and dependents check out* button. Alternatively, you can right-click the object in the central object library and select ▶ *Undo Check Out* ▶ *Object and dependents* ◀.

SAP Data Services removes the check-out symbols for the object and any dependent objects that are also checked out. No changes are made to these objects in the central repository.

2.21.6.5 Checking in objects

After you finish making changes to checked out objects, you must check them back into the central repository. Checking in objects creates a new version in the central repository, and allows others to get the changes that you have made. Checking in objects also preserves a copy of the changes for revision control purposes. Later, you can get a particular version of a checked in object and compare it to subsequent changes or even revert to the previous version.

Check in an object when you are done making changes, when others need the object that contains your changes, or when you want to preserve a copy of the object in its present state.

Choose a check-in command based on what you will do to an object.

Related Information

Checking in single objects, objects with dependents [page 817]
Checking in an object with filtering [page 817]

2.21.6.5.1 Checking in single objects, objects with dependents

Just as you can check out a single object or an object with all dependent objects, you can check in a single object or an object with all checked-out dependent objects (as calculated in the local repository).

2.21.6.5.1.1 To check in a single object

1. Open the central object library.
2. Select the object you want to check in.
3. Click *Check in object* button at the top of the central object library.

   Alternatively, you can right-click the object in the central object library and select *Check In* > *Object*.
4. A Check In window opens with a *Comment* box, in which you can enter comments. After entering any comments, click *OK*.

   SAP Data Services copies the object from your local repository to the central repository, and removes the check-out mark.

2.21.6.5.1.2 To check in an object and its dependent objects

1. Open the central object library.
2. Select the highest level object you want to check in.
3. Click *Check in object and dependents* button at the top of the central object library.

   Alternatively, you can right-click the object in the central object library and select *Check In* > *Object* and dependents.
4. A Check In window opens with a *Comment* box, in which you can enter comments. After entering any comments, click *OK*.

   SAP Data Services copies the selected object and all of its dependent objects from your repository to the central repository and removes the check-out mark.

2.21.6.5.2 Checking in an object with filtering

Just as you could check out objects with filtering, you can check in objects with filtering. When you check in an object with filtering, the object and all its dependent objects are checked in.

2.21.6.5.2.1 To check in an object with filtering

1. Open the central object library.
2. Right-click the object you want to check out and choose *Check In* › *With filtering*.
3. A Check In window opens with a *Comment* box, in which you can enter comments. After entering any comments, click *OK*.

   SAP Data Services warns you that you are about to create a new version of the object in the central repository.
4. Click *Yes* to continue with the check in.
5. Complete the filtering windows.
6. Click *Finish* to check in the selected objects.

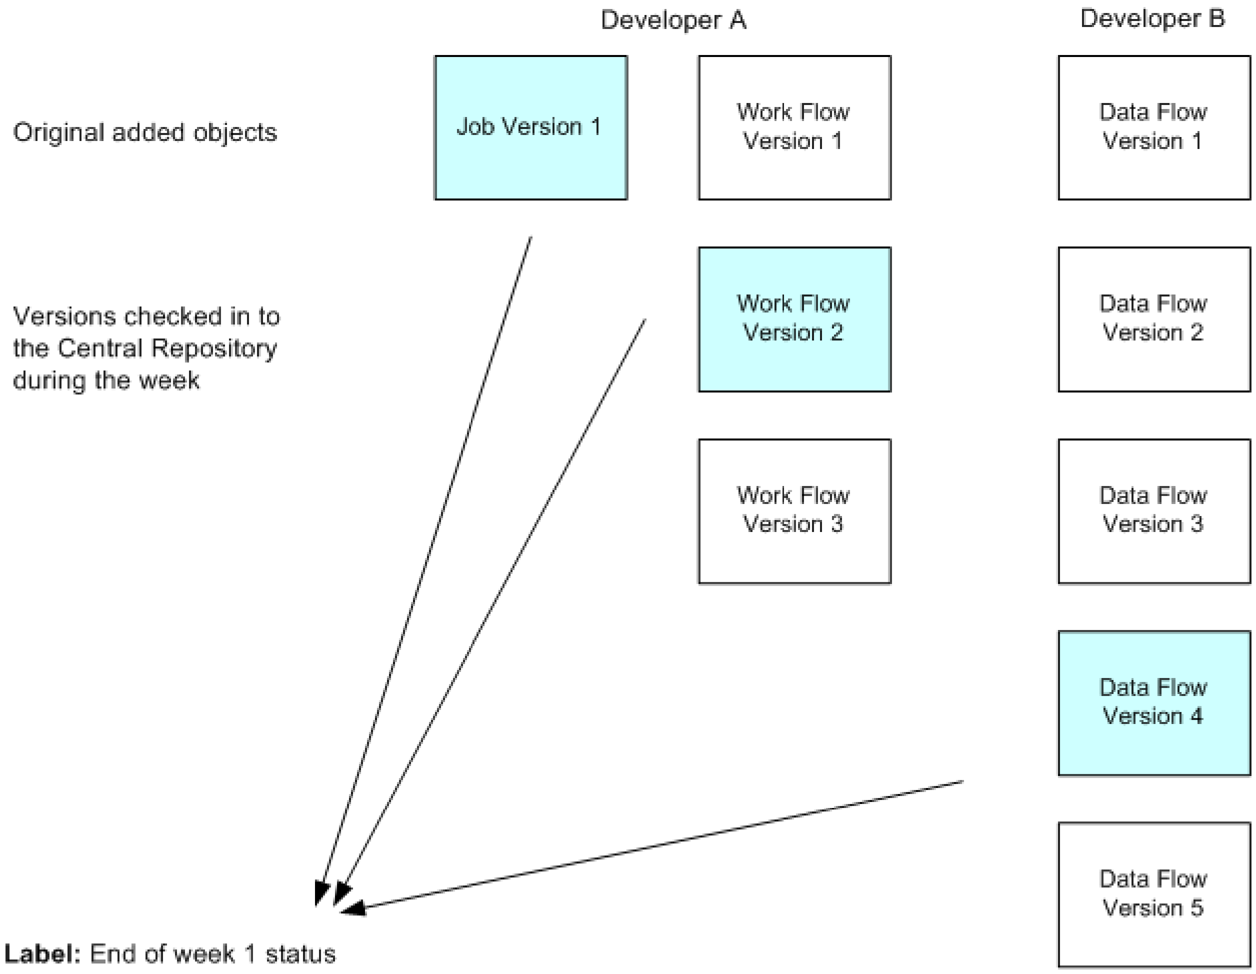
Related Information

Filtering [page 811]

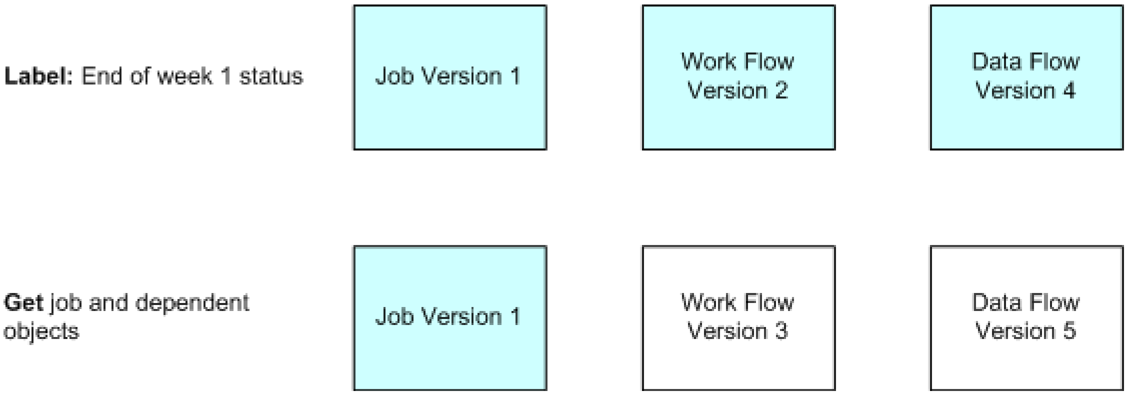
2.21.6.6 Labeling objects

To help organize and track the status of objects in your application, you can label objects. You can choose to either label an object, or label an object and all of its dependent objects. A label not only describes an object, but also allows you to maintain relationships between various versions of objects.

For example, suppose developer A adds a job to the central repository and works on a work flow in that job while developer B works on a data flow in the same job. At the end of the week, after developer A checks in two versions of the work flow and developer B checks in four versions of the data flow to the central repository, the job is labeled "End of week 1 status." This label contains version 1 of the job, version 2 of the work flow, and version 4 of the data flow. Both developers can continue to change their respective work flow and data flow.



At some later point, if you want to get the job with the version of the data flow with this label, getting the job by its label accomplishes this, whereas checking out the job and its dependents does not.



The label "End of week 1 status" serves the purpose of collecting the versions of the work flow and data flow that were checked in at the end of the week. Without this label, you would have to get a particular version of each object in order to reassemble the collection of objects labeled "End of week 1 status."

Related Information

Getting objects [page 820]

2.21.6.6.1 To label an object and its dependents

1. Open the central object library.
2. Right-click the object you want to label and choose *Label Latest Version* > *Object* to label only the highlighted object, or choose *Object and dependents* to label the highlighted object and all its related objects.

   The *Label Latest Version* window opens.
3. In the *Label* box, enter text that describes the current status of the object, then click *OK*.

   The label is inserted in the history of the object and its dependents.

Related Information

Viewing object history [page 822]

2.21.6.6.2 To get a labeled object with filtering

The filtering option for the Get by label operation allows you to filter (selectively change) environment-specific information in object definitions when working in a multi-user environment.

1. Open the central object library.
2. Select the highest level object you want to get.
3. Right-click the object in the central object library and select *Get By Label* > *With filtering* .
4. Complete the filtering window.
5. Click *Finish* to get the selected objects.

Related Information

Filtering [page 811]

2.21.6.7 Getting objects

To make sure that your repository is up-to-date, you "get" objects. When you get an object, you copy the latest version of that object in the central object library and copy it into your local repository, replacing the version in your local repository. When you get an object, you do not check out the object. The object remains free for others to check out and change.

You can get an object with or without dependent objects and filtering.

Related Information

Viewing object history [page 822]

2.21.6.7.1 To get a single object

1. Open the central object library.
2. Select the object you want to get.
3. Click *Get latest version of object* at the top of the central object library.

   Alternatively, right-click the object in the central object library and select ▶ *Get Latest Version* ▶ *Object* ◢.

   The most recent version of the object in the central repository is copied to your local repository.

2.21.6.7.2 To get an object and its dependent objects

1. Open the central object library.
2. Select the highest level object you want to get.
3. Click *Get latest version of objects and dependents* at the top of the central object library.

   Alternatively, right-click the object in the central object library and select ▶ *Get Latest Version* ▶ *Object and dependents* ◢.

   The most recent version of the selected object and all dependent objects from the central repository is copied to your local repository.

2.21.6.7.3 To get an object and its dependent objects with filtering

1. Open the central object library.
2. Select the highest level object you want to get.
3. Right-click the object in the central object library and select ▶ *Get Latest Version* ▶ *With filtering* ◢.
4. Complete the filtering windows.
5. Click *Finish* to get the selected objects.

Related Information

Filtering [page 811]

2.21.6.8 Comparing objects

SAP Data Services allows you to compare two objects from local and central repositories to determine the differences between those objects.

Related Information

Designer Guide: Design and Debug, Comparing Objects [page 714]

2.21.6.9 Viewing object history

The central repository retains a history of all changes made to objects in the central repository. Use this history to help manage and control development of your application.

2.21.6.9.1 To examine the history of an object

1. Open the central object library.
2. Select an object.
3. Click the *Show History* button at the top of the central object library.

   Alternatively, you can right-click the object in the central object library, and choose *Show History*.

   The History window shows several pieces of information about each revision of the object.

Column	Description
Version	The object revision number. Each time a user saves the object, the software creates a new version.
Label	Text that a user enters to describe the status of the object at a given point.
Repository	Information about the local repository from which the software saved this version of the object and the username.
Date	The date and time the software saved this version of the object.

Column	Description
Action	The type of change a user made to the object. This table records actions such as: Checked in — User checked in object
Comment	Comments a user enters when adding an object or checking it into a central repository.

Related Information

Labeling objects [page 818]

2.21.6.9.2 To get a previous version of an object

1. Select an object.
2. Click the *Show History* button at the top of the central object library.
3. Click the version of the object you want.
4. Click the *Get Obj By Version* button.

> i Note
>
> When you get a previous version of an object, you only get the object but not its dependent objects.

2.21.6.9.3 To get an object with a particular label

1. Select an object.
2. Click the *Show History* button at the top of the central object library.
3. Click the version of the object with the particular label you want.
4. Click the *Get By Label* button.

2.21.6.10 Deleting objects

You can delete objects from either the central repository or a local repository. To delete an object from the central repository, right-click the object in the central object library and select *Delete*. To delete an object from the local repository, right-click on the object in the object library and select *Delete*.

When you delete an object from a local repository, you do not automatically delete that object from the active central repository. In fact, you can get the object from the central repository to re-insert it.

Similarly, when you delete an object from a central repository, you do not automatically delete the object from connected local repositories. Until you delete the object from the local repository, you can add the object back to the central repository.

When you delete objects from the central repository, you only delete the selected object and all versions of the selected object; you do not delete any dependent objects.

2.21.7 Migrating Multi-user Jobs

Overview of multi-user job migration

Job migration applies to SAP Data Services on multiple levels: application level, repository management level, and product upgrade level. Application migration is much more flexible in a multi-user environment, allowing you to maintain not only multiple versions of your objects during development, but also during test and production phases if you choose.

Related Information

Application phase management [page 824]
Copying contents between central repositories [page 825]
Central repository migration [page 826]

2.21.7.1 Application phase management

Typically, applications pass through different phases on the way from development to production. For example, an application might pass through three phases:

- Developers creating an application
- Testers validating the application
- Administrators running the application

A single central repository can support your application through all phases. Use job labeling and projects to maintain application components independently for each phase. For example, if development wants to make a certain version of an application ready for testing, they may label it “APPL_V1”. Testers can then get that particular application version using the label and proceed with testing. If testing is successful, an administrator can get the application to run in the production environment. In addition, datastore configurations and file locations allows you to configure the application to run in each local environment.

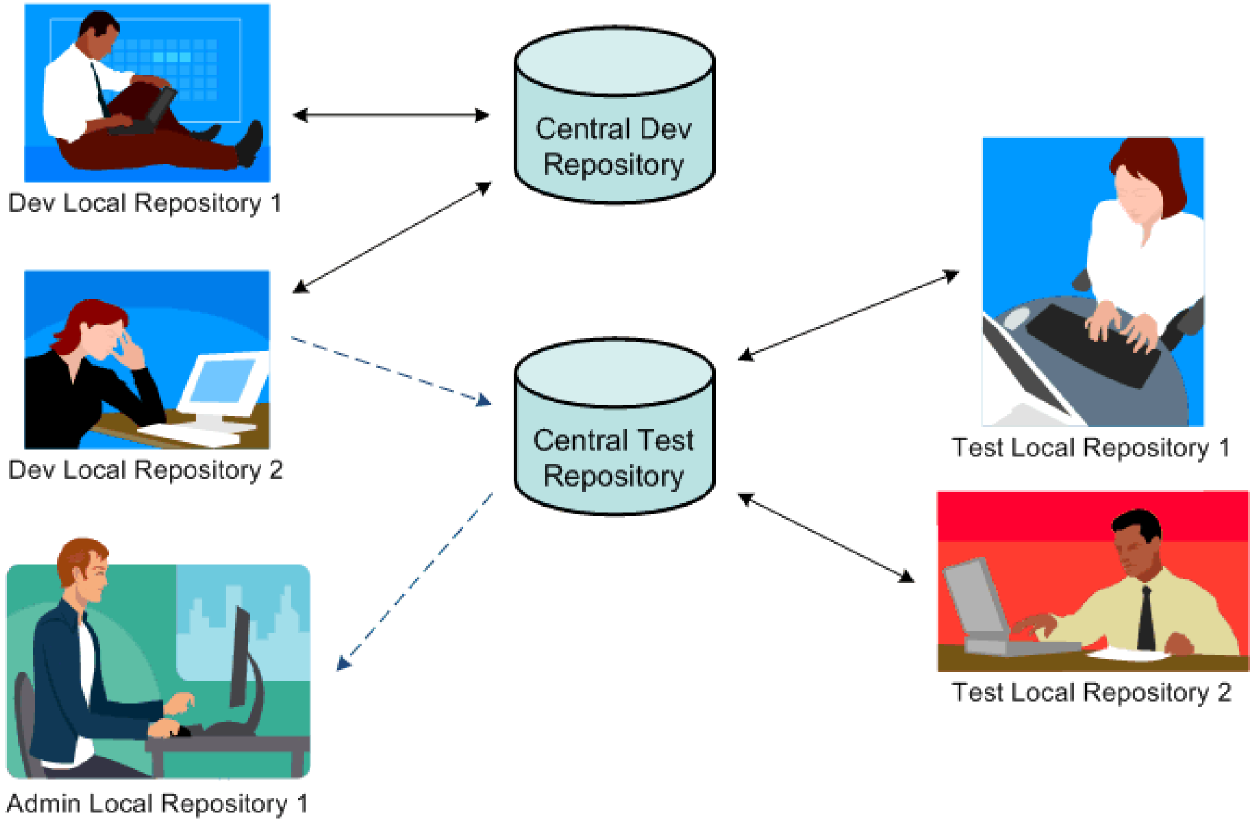
In some situations, you may require more than one central repository for application phase management. If you choose to support multiple central repositories, use a single local repository as a staging location for the transition.

In some situations, you may require more than one central repository for application phase management. Following the example above, once developers create an application version ready for testing by labeling it, a tester would get that version from the development central repository, test it and then check it into a test central repository.

That test central repository will contain all versions tested over time, allowing flexibility for testers to go back to any previous version without relying on the development environment. When an application version passes testing, an administrator can get it from the test repository and make it available in production. Again, if you need to maintain previous versions of an application already in production, you can create another central repository.

With this scheme, a developer will never interfere with the test environment, and a tester will never interfere with a production environment, creating an extremely safe process of migration.

Note that if you choose to support multiple central repositories, use a single local repository as a staging location for file transition.



2.21.7.2 Copying contents between central repositories

You cannot directly copy the contents of one central repository to another central repository. Rather, you must use your local repository as an intermediate repository.

2.21.7.2.1 To copy the contents of one central repository to another central repository

1. Activate the central repository whose contents you will copy.
2. Get the latest version of all objects in this active central repository so they exist in your local repository.
3. Activate the central repository into which you want to copy the contents.
4. The first time you copy the contents, add the objects from your local repository into this central repository.

   However, if you must re-copy the contents of one central repository into another (for example, during your testing phase some part of a job was reassigned to the development phase for redesign), the process is slightly more complex:

   a) First check out specific objects without replacement from the second central repository.
   b) From your local repository, get the latest version of the objects from the first (for example, development) central repository.
   c) Then, instead of adding, check in the updated objects from your local repository to the second (for example, test) central repository.

Activating a central repository [page 803]
Getting objects [page 820]
Adding objects to the central repository [page 811]
Checking out objects [page 812]
Checking in objects [page 816]

2.21.7.3 Central repository migration

When you upgrade your version of SAP Data Services, you should migrate your central repository to the new version. It is recommended that you consider the following guidelines when migrating a central repository to a new release of the software.

1. Back up all central repository (as well as local repository) database tables and associated data before upgrading.
2. Maintain a separate central repository for each version of SAP Data Services to preserve object history.
   To preserve the current version and history of objects in your central repository, create a new central repository of your current version of the software and copy the contents of the original central repository to the newly-created one. This way, the second central repository acts as a backup for your objects and associated history information from the older version of the software.
   When you install the new version of the software, upgrade the newly-created central repository to the latest version of the software.
3. Coordinate efforts to upgrade your central repositories and local repositories at the same time.
   Different versions of your central and local repository may not work together. You cannot perform a multi-user operation between a local and central repository of a different software version.

4. Check in all objects (or undo check-outs if objects were not modified after they were checked out) before migrating the central repositories.
   If you cannot upgrade your central and local repositories at the same time, you should check in all objects (or undo check-outs if objects were not modified during check-out), especially those objects checked out to a local repository you will not be immediately upgrading. After you upgrade your central repository to the new version, you will not be able to check in objects from the local repository of the older version of the software.

3 Reference Guide

3.1 Introduction

3.1.1 Welcome to SAP Data Services

3.1.1.1 Welcome

SAP Data Services delivers a single enterprise-class solution for data integration, data quality, data profiling, and text data processing that allows you to integrate, transform, improve, and deliver trusted data to critical business processes. It provides one development UI, metadata repository, data connectivity layer, run-time environment, and management console—enabling IT organizations to lower total cost of ownership and accelerate time to value. With SAP Data Services, IT organizations can maximize operational efficiency with a single solution to improve data quality and gain access to heterogeneous sources and applications.

3.1.1.2 Documentation set for SAP Data Services

You should become familiar with all the pieces of documentation that relate to your SAP Data Services product. The latest Data Services documentation can be found on the *SAP Help Portal*.

Document	What this document provides
Adapter SDK Guide	Information about installing, configuring, and running the Data Services Adapter SDK
Administrator Guide	Information about administrative tasks such as monitoring, lifecycle management, security, and so on.
Customer Issues Fixed	Information about customer issues fixed in this release. ℹ Note In some releases, this information is displayed the Release Notes.
Designer Guide	Information about how to use Data Services Designer.
Documentation Map	Information about available Data Services books, languages, and locations.
Installation Guide for Windows	Information about and procedures for installing Data Services in a Windows environment.
Installation Guide for UNIX	Information about and procedures for installing Data Services in a UNIX environment.
Integrator Guide	Information for third-party developers to access Data Services functionality using web services and APIs.

Document	What this document provides
Master Guide	Information about the application, its components and scenarios for planning and designing your system landscape. Information about SAP Information Steward is also provided in this guide.
Management Console Guide	Information about how to use Data Services Administrator and Data Services Metadata Reports.
Performance Optimization Guide	Information about how to improve the performance of Data Services.
Reference Guide	Detailed reference material for Data Services Designer.
Release Notes	Important information you need before installing and deploying this version of Data Services.
Technical Manuals	A compiled, searchable, “master” PDF of core Data Services books: ● *Administrator Guide* ● *Designer Guide* ● *Reference Guide* ● *Management Console Guide* ● *Performance Optimization Guide* ● *Integrator Guide* ● *Supplement for J.D. Edwards* ● *Supplement for Oracle Applications* ● *Supplement for PeopleSoft* ● *Supplement for Salesforce.com* ● *Supplement for Siebel* ● *Supplement for SAP* ● *Workbench Guide*
Text Data Processing Extraction Customization Guide	Information about building dictionaries and extraction rules to create your own extraction patterns to use with Text Data Processing transforms.
Text Data Processing Language Reference Guide	Information about the linguistic analysis and extraction processing features that the Text Data Processing component provides, as well as a reference section for each language supported.
Tutorial	A step-by-step introduction to using Data Services.
Upgrade Guide	Information to help you upgrade from previous releases of Data Services and release-specific product behavior changes from earlier versions of Data Services to the latest release.
What's New	Highlights of new key features in this SAP Data Services release. This document is not updated for support package or patch releases.
Workbench Guide	Provides users with information about how to use the Workbench to migrate data and database schema information between different database systems.

In addition, you may need to refer to several Supplemental Guides.

Document	What this document provides
Supplement for SAP	Information about interfaces between Data Services, SAP Applications, SAP Master Data Services, SAP NetWeaver BW, and SAP Master Data Services.
Supplement for SuccessFactors	Information about interfaces between Data Services and SuccessFactors.
Supplement for Salesforce.com	Information about how to install, configure, and use the SAP Data Services Salesforce.com Adapter Interface.
Supplement for J.D. Edwards	Information about interfaces between Data Services and J.D. Edwards World and J.D. Edwards OneWorld.
Supplement for Oracle Applications	Information about the interface between Data Services and Oracle Applications.
Supplement for PeopleSoft	Information about interfaces between Data Servicesand PeopleSoft.
Supplement for Siebel	Information about the interface between Data Services and Siebel.

We also include these manuals for information about SAP BusinessObjects Information platform services.

Document	What this document provides
Information platform services Administrator Guide	Information for administrators who are responsible for configuring, managing, and maintaining an Information platform services installation.
Information platform services Installation Guide for UNIX	Installation procedures for SAP BusinessObjects Information platform services on a UNIX environment.
Information platform services Installation Guide for Windows	Installation procedures for SAP BusinessObjects Information platform services on a Windows environment.

3.1.1.3 Accessing documentation

You can access the complete documentation set for SAP Data Services in several places.

3.1.1.3.1 Accessing documentation on Windows

After you install SAP Data Services, you can access the documentation from the Start menu.

1. Choose *Start* > *Programs* > *SAP Data Services 4.2* > *Data Services Documentation* > *All Guides* .
2. Click the appropriate shortcut for the document that you want to view.

3.1.1.3.2 Accessing documentation on UNIX

After you install SAP Data Services, you can access the documentation by going to the directory where the printable PDF files were installed.

1. Go to **<LINK_DIR>**`/doc/book/en/`.
2. Using Adobe Reader, open the PDF file of the document that you want to view.

3.1.1.3.3 Accessing documentation from the Web

You can access the complete documentation set for SAP Data Services from the SAP Business Users Support site.

To do this, go to *http://help.sap.com/bods*.

You can view the PDFs online or save them to your computer.

3.1.1.4 SAP information resources

A global network of SAP technology experts provides customer support, education, and consulting to ensure maximum information management benefit to your business.

Useful addresses at a glance:

Address	Content
Customer Support, Consulting, and Education services *http://service.sap.com/*	Information about SAP support programs, as well as links to technical articles, downloads, and online forums. Consulting services can provide you with information about how SAP can help maximize your information management investment. Education services can provide information about training options and modules. From traditional classroom learning to targeted e-learning seminars, SAP can offer a training package to suit your learning needs and preferred learning style.
Product documentation *http://help.sap.com/bods/*	SAP product documentation.
Supported Platforms (Product Availability Matrix) *https://service.sap.com/PAM*	Get information about supported platforms for SAP Data Services. Use the search function to search for Data Services. Click the link for the version of Data Services you are searching for.
SAP Data Services Community Network *http://scn.sap.com/community/data-services*	Get online and timely information about SAP Data Services, including forums, tips and tricks, additional downloads, samples, and much more. All content is to and from the community, so feel free to join in and contact us if you have a submission.
Blueprints *http://scn.sap.com/docs/DOC-8820*	Blueprints for you to download and modify to fit your needs. Each blueprint contains the necessary SAP Data Services project, jobs, data flows, file formats, sample data, template

Address	Content
	tables, and custom functions to run the data flows in your environment with only a few modifications.
SAPTerm *https://portal.wdf.sap.corp/go/sapterm*	SAP's terminology database, the central repository for defining and standardizing the use of specialist terms.

3.1.2 Overview of this guide

3.1.2.1 About this guide

The *Data Services Reference Guide* provides detailed information about the objects, data types, transforms, and functions in the Designer.

For source-specific information, such as information pertaining to a particular back-office application, refer to the supplement for that application.

3.1.2.2 Who should read this guide

This and other SAP Data Services software documentation assume the following:

- You are a software developer, consultant, or database administrator working on data extraction, data warehousing, data integration, or data quality.
- You understand your source and target data systems, DBMS, legacy systems, business intelligence, and messaging concepts.
- You understand your organization's data needs.
- You are familiar with SQL (Structured Query Language).
- If you are interested in using this software to design real-time processing, you are familiar with:
  - DTD and XML Schema formats for XML files
  - Publishing Web Services (WSDL, HTTP/S and SOAP protocols, and so on.)
- You are familiar with the installation environments: Microsoft Windows or UNIX.

3.2 Objects

This section provides a reference of detailed information about the objects, data types, transforms, and functions in the Designer.

> Note
>
> For information about source-specific objects, consult the reference section in the supplement document for that source.

Related Information

Characteristics of objects [page 833]
Descriptions of objects [page 835]

3.2.1 Characteristics of objects

This section discusses common characteristics of all the objects.

Related Information

Object classes [page 833]
Object options, properties, and attributes [page 834]

3.2.1.1 Object classes

An object's class determines how you create and retrieve the object. There are two classes of objects:

- Reusable objects
- Single-use objects

3.2.1.1.1 Reusable objects

After you define and save a reusable object, SAP Data Services stores the definition in the repository. You can then reuse the definition as often as necessary by creating calls to the definition.

Most objects created in the software are available for reuse. You access reusable objects through the object library.

A reusable object has a single definition; all calls to the object refer to that definition. If you change the definition of the object in one place, and then save the object, the change is reflected to all other calls to the object.

A data flow, for example, is a reusable object. Multiple jobs, such as a weekly load job and a daily load job, can call the same data flow. If the data flow is changed, both jobs call the new version of the data flow.

When you drag and drop an object from the object library, you are creating a new reference (or **`<call>`**) to the existing object definition.

You can edit reusable objects at any time independent of the current open project. For example, if you open a new project, you can go to the object library, open a data flow, and edit it. The object will remain "dirty" (that is, your edited changes will not be saved) until you explicitly save it.

Functions are reusable objects that are not available in the object library. The software provides access to these objects through the function wizard wherever they can be used.

Some objects in the object library are not reusable in all instances:

- Datastores are in the object library because they are a method for categorizing and accessing external metadata.
- Built-in transforms are "reusable" in that every time you drop a transform, a new instance of the transform is created.

"Saving" a reusable object means storing the language that describes the object to the repository. The description of a reusable object includes these components:

- Properties of the object
- Options for the object
- Calls this object makes to other objects
- Definition of single-use objects called by this object

If an object contains a call to another reusable object, only the call to the second object is saved, not changes to that object's definition.

The description is stored even if the object is not successfully validated.

Objects are saved without prompting you:

- When you import an object into the repository.
- When you finish editing:
  - Datastores
  - Flat file formats
  - XML Schema or DTD formats

You can explicitly save the reusable object currently open in the workspace by choosing *Save* from the *Project* menu. If a single-use object is open in the workspace, the *Save* command is not available.

To save all objects in the repository that have changes, choose *Save All* from the *Project* menu.

You are prompted to save all objects that have changes when you execute a job and when you exit the Designer.

3.2.1.1.2 Single-use objects

Single-use objects appear only as components of other objects. They operate only in the context in which they were created.

"Saving" a single-use object means storing the language that describes the object to the repository. The description of a single-use object can only be saved as part of the reusable object that calls the single-use object.

The description is stored even if the object does not validate.

3.2.1.2 Object options, properties, and attributes

Each object is associated with a set of options, properties, and attributes:

- **Options**: Controls the operation of an object. For example, in a datastore, an option is the name of the database to which the datastore connects.
- **Properties**: Documents an object. For example, properties include the name, description of an object, and the date on which it was created. Properties merely describe an object; they do not affect an object's operation.
  To view properties, right-click an object and select Properties.
- **Attributes**: Provides additional information about an object. Attribute values may also affect an object's behavior.
  To view attributes, double-click an object from an editor and click the Attributes tab.

3.2.2 Descriptions of objects

This section describes each object and tells you how to access that object.

The following table lists the names and descriptions of the objects.

Object	Class	Description
Annotation	Single-use	Describes a flow, part of a flow, or a diagram in the workspace.
Catch	Single-use	Specifies the steps to execute if anerror occurs in a given exception group while a job is running.
COBOL copybook file format	Reusable	Defines the format for a COBOL copybook file source.
Conditional	Single-use	Specifies the steps to execute based on the result of a condition.
Batch Job	Reusable	Defines activities that the software executes at a given time including error, monitor and trace messages. Jobs can be dropped only in the project tree. The object created is a direct reference to the object in the object library. Only one reference to a job can exist in the project tree at one time.
Data flow	Reusable	Specifies the requirements for extracting, transforming, and loading data from sources to targets.
Datastore	Single-use	Specifies the connection information needed to access a database or other data source. Cannot be dropped.
Document	Reusable	Available in certain adapter datastores, documents are data structures that can support complicated nested schemas.
DTD	Reusable	A description of an XML file or message. Indicates the format an XML document reads or writes.
Excel workbook format	Reusable	Defines the format for an Excel workbook source.

Object	Class	Description
File format	Reusable	Indicates how flat file data is arranged in a source or target file.
Function	Reusable	Returns a value.
Log	Single-use	Records information about a particular execution of a single job.
Message function	Reusable	Available in certain adapter datastores, message functions can accommodate XML messages when properly configured.
Outbound message	Reusable	Available in certain adapter datastores, outbound messages are XML-based, hierarchical communications that real-time jobs can publish to adapters.
Project	Single-use	Groups jobs for convenient access.
Query transform	Single-use	Retrieves a data set that satisfies conditions that you specify.
Real-time job	Reusable	Defines activities that the software executes on-demand. Real-time jobs are created in the Designer, then configured and run as services associated with an Access Server in the Administrator. Real-time jobs are designed according to data flow model rules and run as a request-response system.
Script	Single-use	Evaluates expressions, calls functions, and assigns values to variables.
Source	Single-use	An object from which the software reads data in a data flow.
Table	Reusable	Indicates an external DBMS table for which metadata has been imported, or the target table into which data is or has been placed. A table is associated with its datastore; it does not exist independently of a datastore connection. A table retrieves or stores data based on the schema of the table definition from which it was created.
Target	Single-use	An object in which the software loads extracted and transformed data in a data flow.
Template table	Reusable	A new table you want added to a database. All datastores except SAP datastores have a default template that you can use to create any number of tables in the datastore. The software creates the schema for each instance of a template table at runtime. The created schema is based on the data loaded into the template table.
Transform	Reusable	Performs operations on data sets.

Object	Class	Description
		Requires zero or more data sets; produces zero or one data set (which may be split).
Try	Single-use	Introduces a try/catch block.
While loop	Single-use	Repeats a sequence of steps as long as a condition is true.
Work flow	Reusable	Orders data flows and operations supporting data flows.
XML file	Single-use	A batch or real-time source or target. As a source, an XML file translates incoming XML-formatted data into data that the software can process. As a target, an XML file translates the data produced by a data flow, including nested data, into an XML-formatted file.
XML message	Single-use	A real-time source or target. As sources, XML messages translate incoming XML-formatted requests into data that a real-time job can process. As targets, XML messages translate the result of the real-time job, including hierarchical data, into an XML-formatted response and sends the messages to the Access Server.
XML Schema	Reusable	A description of an XML file or message. Indicates the format an XML document reads or writes.
XML template	Single-use	A target that creates an XML file that matches a particular input schema. No DTD or XML Schema is required.

3.2.2.1 Annotation

Class

Single-use

Access

Click the annotation icon in the tool palette, then click in the workspace.

Description

Annotations describe a flow, part of a flow, or a diagram in a workspace. An annotation is associated with the job., work flow, or data flow where it appears. When you import or export that job, work flow, or data flow, you import or export associated annotations.

> **Note**
>
> An annotation has no options or properties.

Related Information

Designer Guide: Creating annotations [page 194]

3.2.2.2 Batch Job

Class

Reusable

Access

- In the object library, click the *Jobs* tab.
- In the project area, select a project and right-click *Batch Job*.

Description

A batch job is a set of objects that you can schedule and execute together. To execute the steps of any object, the object must be part of a job.

A batch job can contain the following objects:

- Data flows

    - Sources
    - Transforms
    - Targets
- Work flows
- Scripts
- Conditionals
- Try/catch blocks
- While Loops

You can run batch jobs such that you can automatically recover from jobs that do not execute successfully. During automatic recovery, SAP Data Services retrieves the results from steps that were successfully completed in the previous run and executes all other steps. Specifically, the software retrieves results from the following types of steps:

- Work flows
- Data flows
- Script statements
- Custom functions (stateless type only)
- SQL function
- EXEC function
- get_env function
- rand function
- sysdate function
- systime function

Batch jobs have the following built-in attributes:

Attribute	Description
Name	The name of the object. This name appears on the object in the object library and in the calls to the object.
Description	Your description of the job.
Date created	The date when the object was created.

Batch and real-time jobs have properties that determine the information collected and logged when running the job. You can set the default properties that apply each time you run the job or you can set execution (run-time) properties that apply for a particular run. Execution properties override default properties.

To set default properties, select the job in the project area or the object library, right-click, and choose *Properties* to open the Properties window.

Execution properties are set as you run a job. To set execution properties, right-click the job in the project area and choose *Execute*. The Designer validates the job and opens the Execution Properties window.

You can set several types of execution properties:

- Execution options
- Trace properties
- Global variables
- Substitution parameters

Related Information

Designer Guide: Setting global variable values [page 408]

3.2.2.2.1 Execution Options

Use execution options to help capture and diagnose errors using log, auditing, statistics collection, or recovery options.

Log information goes to one of three files (in the **`<DS_COMMON_DIR>`**`\log\`**`<Job_Server_Name>`**`\`**`<repository name>`** directory):

- Monitor log file
- Trace log file
- Error log file

When you execute a job, you can also select a system configuration and a Job Server or server group from the *Execution Options* tab of the Execution Properties window.

Select the *Execution Options* tab to set the following options.

Options	Description
Collect statistics for monitoring	Select this check box if you want to display cache statistics in the Performance Monitor in the Administrator. (The default is cleared.) Note Use this option only if you want to look at the cache size. For more information, see the Using Caches section in the *Performance Optimization Guide*.
Collect statistics for optimization	Select this check box if you want to collect statistics that the Data Services optimizer will use to choose an optimal cache type (in-memory or pageable). This option is not selected by default. For more information, see Caching sources in the *Performance Optimization Guide*. For more information, see the Using Caches section in the *Performance Optimization Guide*.
Disable data validation statistics collection	Select this check box if you do not want to collect data validation statistics for any validation transforms in this job. (The default is cleared.) For more information about data validation statistics, see Data Validation dashboards Settings control panel" in the *Management Console Guide*. For more information about data validation statistics, see the Data Validation Dashboard Reports section in the *Management Console Guide*.
Distribution level	Select the level within a job that you want to distribute to multiple job servers for processing:

Options	Description
	- Job - The whole job will execute on an available Job Server. - Data flow - Each data flow within the job can execute on an available Job Server. - Sub data flow - Each sub data flow (can be a separate transform or function) within a data flow can execute on an available Job Server. For more information, see Using grid computing to distribute data flows execution in the *Performance Optimization Guide*. For more information, see the Distributing Data Flow Execution section in the *Performance Optimization Guide*.
Enable auditing	Clear this check box if you do not want to collect audit statistics for this specific job execution. (The default is selected.) For more information about auditing, see Using Auditing in the *Designer Guide*. For more information about auditing, see the Data Assessment section in the *Designer Guide*.
Enable recovery	(Batch jobs only) Select this check box to enable the automatic recovery feature. When enabled, the software saves the results from completed steps and allows you to resume failed jobs. You cannot enable the automatic recovery feature when executing a job in data scan mode. See Automatically recovering jobs in the *Designer Guide* for information about the recovery options. See the Recovery Mechanisms section in the *Designer Guide* for information about the recovery options. See “Loading Big Data file with Recovery option” in the *Designer Guide* for information about big data file recovery options. This property is only available as a run-time property. It is not available as a default property.
Export Data Quality reports	Generates and exports all specified job reports to the location specified in the Report Server Configuration node in the Management Console Administrator. By default, the reports are exported to `<DS_COMMON_DIR>\DataQuality\reports\<repository\job>`.
Job Server or Server group	Select the Job Server or server group to execute this job. A Job Server is defined by a host name and port while a server group is defined by its name. The list contains Job Servers and server groups linked to the job's repository. For an introduction to server groups, see Server group architecture in the *Management Console Guide*. For an introduction to server groups, see the Server Groups section in the *Management Console Guide*. When selecting a Job Server or server group, remember that many objects in the Designer have options set relative to the Job Server's location. For example: - Directory and file names for source and target files - Bulk load directories

Options	Description
Monitor sample rate (# of seconds)	Enter the number of seconds elapsed before the software writes information to the monitor log file and updates job events. The software writes information about the status of each source, target, or transform. For example, if you enter 30, the logs update every 30 seconds. The default is 5 seconds. When setting the value, you must evaluate performance improvements gained by making fewer calls to the operating system against your ability to find errors quickly. With a higher monitor sample rate, more data collects before calling the operating system to open the file: performance improves. However, with a higher monitor rate, more time passes before you are able to see any errors. Setting the rate to 0 disables the monitoring feature. i Note If you use a virus scanner on your files, exclude the log from the virus scan. Otherwise, the virus scan analyzes the log repeated during the job execution, which causes a performance degradation.
Print all trace messages	Select this check box to print all trace messages to the trace log file for the current Job Server. Selecting this option overrides the trace properties set on the *Trace* tab.
Recover from last failed execution	(Batch Job only) Select this check box to resume a failed job. The software retrieves the results from any steps that were previously executed successfully and re-executes any other steps. This option is a run-time property. This option is not available when a job has not yet been executed or when recovery mode was disabled during the previous run.
System configuration	Select the system configuration to use when executing this job. A system configuration defines a set of datastore configurations, which define the datastore connections. For more information, see Creating and managing multiple datastore configurations in the *Designer Guide*. For more information, see the Datastores section in the *Designer Guide*. If a system configuration is not specified, the software uses the default datastore configuration for each datastore. This option is a run-time property. This option is only available if there are system configurations defined in the repository.
Use collected statistics	Select this check box if you want the optimizer to use the cache statistics collected on a previous execution of the job. (The default is selected.) For more information, see Monitoring and tuning caches in the *Performance Optimization Guide*. For more information, see section 6: Using Caches in the *Performance Optimization Guide*.

3.2.2.2.2 Trace properties

Use trace properties to select the information that SAP Data Services monitors and writes to the trace log file during a job. The software writes trace messages to the trace log associated with the current Job Server and writes error messages to the error log associated with the current Job Server.

To set trace properties, click the Trace tab. To turn a trace on, select the trace, click Yes in the Value list, and click OK. To turn a trace off, select the trace, click No in the Value list, and click OK.

You can turn several traces on and off.

Trace	Description
Access Server Communication	Writes messages exchanged between the Access Server and a service provider, including: • The registration message, which tells the Access Server that the service provider is ready • The request the Access Server sends to the service to execute • The response from the service to the Access Server • Any request from the Access Server to shut down
Assemblers	Writes messages for Substitution Parameter and SDK Transforms: • Substitution parameters - Writes trace messages such as substitution configuration used and the actual value substituted for each substitution parameter. • SDK transforms - Writes transform-specific information specified in the form of XML. This information can be hierarchical. At runtime this XML information is extracted or assembled. The trace messages write the assembled XML.
Audit Data	Writes a message when auditing: • Collects a statistic at an audit point • Determines if an audit rule passes or fails
Data Flow	Writes a message when the data flow starts, when the data flow successfully finishes, or when the data flow terminates due to error. This trace also reports when the bulk loader starts, any bulk loader warnings occur, and when the bulk loader successfully completes.
IDoc file reader	Writes a message when reading IDoc files including: • start reading the IDoc file • stop reading the IDoc file • result of the IDoc file validation
Memory Source	Writes a message for every row retrieved from the memory table.
Memory Target	Writes a message for every row inserted into the memory table.
Optimized data flow	For consulting and customer assurance use.

Trace	Description
RFC Function	Writes a message related to RFC calls including: ● start of RFC call ● end of RFC call ● a message for each record received from the software for the RFC call
Row	Writes a message when a transform imports or exports a row.
SAP Table Reader	Writes messages from readers of SAP system tables including: ● start reading from table ● stop reading from table ● start of connection to SAP system where table is present ● end of connection to SAP system
Scripts and Script Functions	Writes a message when the software runs a script or invokes a script function. Specifically, this trace links a message when: ● The script is called. Scripts can be started any level from the job level down to the data flow level. Additional (and separate) notation is made when a script is called from within another script. ● A function is called by the script. ● The script successfully completes.
Session	Writes a message when the job description is read from the repository, when the job is optimized, and when the job runs.
SQL Functions	Writes data retrieved before SQL functions: ● Every row retrieved by the named query before the SQL is submitted in the key_generation function ● Every row retrieved by the named query before the SQL is submitted in the lookup function (but only if PRE_LOAD_CACHE is not specified). ● When mail is sent using the mail_to function.
SQL Loaders	Writes a message when the bulk loader: ● Starts ● Submits a warning message ● Completes successfully ● Completes unsuccessfully, if the *Clean up bulk loader directory after load* option is selected Additionally, for Microsoft SQL Server and SAP SAP Sybase ASE, writes when the SQL Server bulk loader: ● Completes a successful row submission ● Encounters an error This instance reports all SQL that the software submits to the target database, including:

Trace	Description
	- When a `truncate table` command executes if the *Delete data from table before loading* option is selected. - Any parameters included in PRE-LOAD SQL commands - Before a batch of SQL statements is submitted - When a template table is created (and also dropped, if the *Drop/Create* option is turned on) - When a `delete from table` command executes if auto correct is turned on (Informix environment only). This trace also writes all rows that the software loads into the target.
SQL Only	Use in conjunction with Trace the SQL Transforms option, the Trace SQL Readers option, or the Trace SQL Loaders option to stop the writing of trace messages for data sent and received from the database.
SQL Readers	Writes the SQL query block that a script, Query transform, or SQL function submits to the system. Also writes the SQL results.
SQL Transforms	Writes a message (using the Table_Comparison transform) about whether a row exists in the target table that corresponds to an input row from the source table. The trace message occurs before submitting the query against the target and for every row retrieved when the named query is submitted (but only if caching is not turned on).
Stored Procedure	Writes a message when the software invokes a stored procedure. This trace reports: - When the stored procedure starts - The SQL query submitted for the stored procedure call - The value (or values) of the input parameter (or parameters) - The value (or values) of the output parameter (or parameters) - The return value (if the stored procedure is a stored function) - When the stored procedure finishes
Tables	Writes a message when a table is created or dropped. The message indicates the datastore to which the created table belongs and the SQL statement used to create the table.
Trace ABAP	Writes a message when an ABAP data flow starts or stops, and to report the ABAP job status.
Trace Parallel Execution	Writes messages describing how data in a data flow is parallel processed.
Transform	Writes a message when a transform starts, completes, or terminates.
Work Flow	Writes a message when the work flow description is read from the repository, when the work flow is optimized, when the work flow runs, and when the work flow ends.

3.2.2.3 Catch

Class

Single-use

Access

With a work flow in the workspace, click the catch icon in the tool palette.

Description

A catch object is part of a serial sequence called a try/catch block. The try/catch block allows you to specify alternative work flows if one or more errors occur while executing a job. Try/catch blocks "catch" exception groups of errors, apply solutions that you provide, and continue execution.

For each catch object in the try/catch block, specify the following:

- One or more groups of exceptions that the catch object handles.
  If you want to assign different actions to different exception groups, add a catch for each set of actions.
- The actions to execute if an exception in the indicated exception groups occurs.
  It is recommended that you define, test, and save the actions as a separate object rather than constructing them inside the catch editor. The actions can be a single script object, a data flow, a work flow, or a combination of these objects.
- Optional error functions inside the catch block to identify details of the error.

If an exception is thrown during the execution of a try/catch block, and if no catch object is looking for that exception group, then the exception is handled by normal error logic.

For batch jobs only, do not reference output variables from a try/catch block in any subsequent steps if you are using the automatic recovery feature. Referencing such variables could alter the results during automatic recovery.

Also, try/catch blocks can be used within any real-time job component. However, try/catch blocks cannot straddle a real-time processing loop and the initialization or cleanup component of a real-time job.

Catch objects have the following attribute:

Attribute	Description
Name	The name of the object. This name appears on the object in the diagram.

The following table describes exception groups that you can catch in a try/catch block:

Exception group	Group number	Description
Catch All Exceptions	All	All errors
Execution errors	1001	Errors in the job server
Database access errors	1002	Errors from the database server while reading data, writing data, or bulk loading to tables
Database connection errors	1003	Errors connecting to database servers
Flat file processing errors	1004	Errors processing flat files
File access errors	1005	Errors accessing local and FTP files
Repository access errors	1006	Errors accessing the repository
SAP Execution errors	1007	Errors from the SAP system
System resource exception	1008	Errors accessing operating system resources
SAP BW execution errors	1009	Errors from the SAP BW system
XML processing errors	1010	Errors processing XML files and messages
COBOL copybook errors	1011	Errors processing COBOL copybook files
Excel book errors	1012	Errors processing Excel books
Data Quality transform errors	1013	Errors processing Data Quality transforms

3.2.2.3.1 Catch error functions

Syntax

The following table describes error functions that you can use in the script that your catch work flow executes.

i Note

You can only invoke these error functions inside a catch script, a user function, or in an audit script for a data flow. If you call these error functions in any other place, a validation error occurs.

Catch error function	Return data type and size	Description
error_timestamp()	timestamp	Returns the timestamp of the caught exception.

Catch error function	Return data type and size	Description
error_context()	varchar 512	Returns the context of the caught exception. For example, *|Session datapreview_job|Dataflow debug_DataFlow|Transform Debug*
error_message()	varchar 512	Returns the error message of the caught exception.
error_number()	int	Returns the error number of the caught exception.

Related Information

Designer Guide: Work flows, Example: Catching details of an error [page 340]

3.2.2.3.2 Catch scripts

A script is the most common action that a catch executes for a thrown exception. The catch script can contain the following:

- Catch error functions and other function calls
- Nested try/catch blocks
- if statements to perform different actions for different exceptions

Syntax

The syntax for a try/catch block within a script is as follows:

```
try
begin
   <steps>
end
catch(<integer_constants>)
begin
    <steps>
end
```

Where

`<steps>`	Catch error functions, other function calls, if statements, or other statements you want to perform for an error in the specified exception group number.

`<integer_constants >`	One or more exception group numbers that you want to catch.
	Use a comma to separate exception group numbers. For example,
	`catch(1002,1003)`
	Specify `ALL` to catch all exceptions:
	`catch(ALL)`

Related Information

Designer Guide: Work flows, Example: Catching details of an error [page 340]

3.2.2.4 COBOL copybook file format

Class

Reusable

Access

In the object library, click the *Formats* tab.

Description

A COBOL copybook file format describes the structure defined in a COBOL copybook file (usually denoted with a .cpy extension). You store templates for file formats in the object library. You use the templates to define the file format of a particular source in a data flow.

The following tables describe the *Import*, *Edit*, and Source *COBOL copybook* options.

3.2.2.4.1 Import or Edit COBOL copybook format options

The *Import COBOL Copybook* and *Edit COBOL Copybook* format windows include options on the following tabs:

- Format
- Data File
- Data Access

The *Edit COBOL Copybook* format window includes options on the following tabs:

- Field ID
- Record Length Field

Format tab

The Format tab defines the parameters of the COBOL copybook format. Format tab options are not editable in the *Edit COBOL Copybook* window.

Format option	Description
File name	Type or browse to the COBOL copybook file name (usually has a .cpy extension). This file contains the schema definition. For added flexibility, you can enter a variable for this option.
Expand OCCURS	Specifies the way to handle OCCURS groups. These groups can be imported with each field in an OCCURS group in one of the following ways: • Getting a sequential suffix for each repetition: fieldname_1, fieldname_2, etc. (expanded view) • Appearing only once in the copybook's schema (collapsed view). For a collapsed view, the output schema matches the OCCURS group definition, and for each input record there will be several output records. If a copybook contains more than one OCCURS group, you must select this box. The default is selected.
Ignore redefines	Determines whether or not to ignore REDEFINES clauses.
Source format	The format of the copybook source code. Options include: • *Free*—All characters on the line can contain COBOL source code.

Format option	Description
	- *Smart mode*—the softwareattempts to determine whether the source code is in Standard or Free format; if this does not produce the desired result, choose the appropriate source format (Standard or Free) manually for reimporting. - *Standard*—The traditional (IBM mainframe) COBOL source format, where each line of code is divided into the following five areas: sequence number (1-6), indicator area (7), area A (8-11), area B (12-72) and comments (73-80).
Source codes [start]	Defines the start column of the copybook source file to use during the import. Typical value is 7 for IBM mainframe copybooks (standard source format) and 0 for free format.
Source codes [end]	Defines the end column of the copybook source file to use during the import. Typical value is 72 for IBM mainframe copybooks (standard source format) and 9999 for free format.
Generate record number field	If selected, creates a new field at the beginning of the schema that the software populates at run time with the record number.

Data File tab

The Data File tab defines the parameters of the data file.

Data file option	Description
Directory	Specifies the directory that contains the COBOL copybook data file to import. For added flexibility, you can enter a variable for this option. If you include a directory path here, then enter only the file name in the *Name* field. During design, you can specify a file in one of the following ways: - For a file located on the computer where the Designer runs, you can use the Browse button. - For a file located on the computer where the Job Server runs, you must type the path to the file. You can type an absolute path or a relative path, but the Job Server must be able to access it.
File name	Type the name or browse to the COBOL copybook data file. You can use variables or wild cards (* or ?). If you leave *Directory* blank, then type the full path and file name here.
Type	Specifies the record format—fixed or variable: - *Fixed(F)* - *Variable(V)*
Has record length	Specifies whether variable-length records of the data file contain information about the length of each record. The possible values are: - *2-byte* integer - *2-byte followed by 0x0000* (integer followed by two zero bytes)

Data file option	Description
	- *4-byte* integer - *None*—No length information at the beginning of each record
Record size	Defines fixed record length in bytes. All records in the file have this length (padded, if necessary).
Record trailer length	Specifies the length of extra character padding in bytes at the end of each record.
Has record mark	Defines whether there is an extra byte in the beginning of each record's data.
Integer format	Describes how the existing data file stores binary data: - *Big endian*—the most significant byte comes first - *Little endian*—the least significant byte comes first
Code page	Specifies the character encoding of character data in the data file.
Skip first	Defines the number of data records to skip before starting to process the file. For added flexibility, you can enter a variable for this option.
Read total	Defines the number of records to read and process. For added flexibility, you can enter a variable for this option.
Low Value and High Value	Identifies a valid hexadecimal value for a low value, high value, or both from the copybook and applies the associated *Action*. You can also use a variable to define a different value at run time. The Low Value default is 0x40 and the High Value default is 0xFF. For example, if the source field is binary 0x40, enter a Low Value of 0x40 and select the action *Convert to NULL*. The result would be as follows for these data types: - Char—Character represented by 0x40 - Packed decimal—NULL - Binary—0x40
Action	For a Low or High Value, applies one of the following actions: - *No conversion*—Reads the value as an ASCII character (default). - *Convert to NULL*—Converts the given value to NULL. - *Convert to 0*—Converts the given value to 0.

Data Access tab

The Data Access tab specifies how access the data file. If both check boxes are cleared, the software assumes the data file is on the same computer as the Job Server.

Data access option	Description
FTP	Select to use FTP to access the data file.
Host	Type the computer (host) name, fully qualified domain name, or IP address of the computer where the data file resides.

Data access option	Description
User	Type the FTP user name.
Password	Type the FTP user password.
Directory	Type or browse to the directory that contains the COBOL copybook data file to import. If you include a directory path here, then enter only the file name in the *Name* field.
File name	Type or browse to the COBOL copybook data file *Name*. You can use variables or wild cards (* or ?). If you leave *Directory* blank, then type a full path and file name here.
Custom	Select to use a custom executable to access the data file.
Executable	Type the name of the program to read data file.
User	Type the user name.
Password	Type the password.
Arguments	Include any custom program arguments.

Field ID tab

If the imported copybook contains multiple schemas, the Field ID tab is visible on the *Edit COBOL Copybook* window. These options allow you to create rules for identifying which records represent which schemas.

Field ID option	Description
Use field <FIELD NAME> as ID	Select to set a value for the field selected in the top pane. Clear to not set a value for that field.
Edit	Changes the selected value in the Values pane to editable text.
Delete	Deletes the selected value in the Values pane.
Insert above	Inserts a new value in the Values pane above the selected value.
Insert below	Inserts a new value in the Values pane below the selected value.

Record Length Field tab

After you import a copybook, the Record Length Field tab is visible on the *Edit COBOL Copybook* window. It lets you identify the field that contains the length of the schema's record.

Record Length Field column	Description
Schema	The data schemas in the copybook.

Record Length Field column	Description
Record length field	Click to enable a drop-down menu where you select a field (one per schema) that contains the record's length.
Offset	The value that results in the total record length when added to the value in the Record length field. The default value for offset is 4; however, you can change it to any other numeric value.

3.2.2.4.2 COBOL copybook source options

The source editor includes the following COBOL copybook options on the following tabs:

- Source
- Field clauses
- Data File
- Data Access

Source tab

Source option	Description
Make port	Makes the source table an embedded data flow port. For more information, see the Embedded Data Flows section in the *Designer Guide*.

Table 16: Performance

Source option	Description
Join rank	Indicates the rank of the source relative to other tables and files joined in a data flow. The software joins sources with higher join ranks before joining sources with lower join ranks. Join rank specified in the Query transform editor FROM tab overrides any join rank specified in a source. For new jobs, specify the join rank only in the Query transform editor. Must be a non-negative integer. Default value is 0. For more information, see the Other Tuning Techniques section in the *Performance Optimization Guide*.
Cache	Indicates whether the software should read the required data from the source and load it into memory or pageable cache. Because an inner source of a join must be read for each row of an outer source, you might want to cache a source when it is used as an inner source in a join.

Source option	Description
	Options are: - *Yes*: The source is always cached unless it is the outer-most source in a join. - *No*: The source is never cached. The default is *Yes*. Cache specified in the Query transform editor FROM tab overrides any cache specified in a source. For new jobs, specify the cache only in the Query transform editor.

Table 17: Error handling

Source option	Description
Log data conversion warnings	Determines whether to include data-type conversion warnings in the error log. Defaults to *Yes*.
Maximum warnings to log	If Log data conversion warnings is enabled, you can limit how many warnings are loged. Defaults to *{no limit}*.

Table 18: Include file name column

Source option	Description
Include file name column	Determines whether to add a column that contains the source file name in the source output. Defaults to *No*. Change the value to *Yes* when you want to identify the source file in situations such as the following: - You specified a wildcard character to read multiple source COBOL copybooks at one time - You load from different source copybooks on different runs
Modify	If the file name is included, this button enables you to modify *File name column* and *Column size*.
File name column	If the file name is included, the name of the column that holds the source file name. Defaults to *DI_FILENAME*.
Column size	If the file name is included, the size (in characters) of the column that holds the source file name. Defaults to *100*. If the size of the file name column is not large enough to store the file name, truncation occurs from the left.
Include path	If the file name is included, determines whether to include the full path name of the source file. Defaults to *No*.

Field clauses tab

The Field clauses tab displays the attributes for a selected column.

Field clauses option	Description
Possible values	Enter values here to force the software to only process rows that contain the specified value(s). Separate multiple values with the pipe character (|). You can click the ellipses button to open the smart editor; for details on how to use the smart editor, see the Smart Editor section in the *Reference Guide*.
Level	The level number (01-50) assigned to the field in the source record definition.
Original name	The name of the field in the copybook.
Original picture	The PICTURE clause of the field in the copybook.
Original usage	The USAGE clause of the field in the copybook.
Min occurs	Minimum number of occurrences for this field (if this field is a part of an OCCURS group).
Max occurs	Maximum number of occurrences for this field (if this field is a part of an OCCURS group).
Occurs depending on	Specifies the repetition counter field name for the ODO (OCCURS DEPENDING ON).
Redefines	Specifies the name of another field that this one REDEFINES.
Sign separate	Specifies whether the sign is stored separately from the field's value.
Sign position	Specifies whether the sign is LEADING or TRAILING.
Multiply by	Specifies whether the field needs to be scaled (multiplied or divided by a certain number). For example, if the field's PICTURE clause is 9(5)P(3), the value of the field from the data file will be multiplied by 1000.

Related Information

Import or Edit COBOL copybook format options [page 850]

3.2.2.5 Conditional

Class

Single-use

Access

With a work flow diagram in the workspace, click the conditional icon in the tool palette.

Description

A conditional implements if/then/else logic in a work flow.

For each conditional, specify the following:

- *If*: A Boolean expression defining the condition to evaluate.
  The expression evaluates to TRUE or FALSE. You can use constants, functions, variables, parameters, and standard operators to construct the expression. For information about expressions, see Chapter 3: Smart Editor.

  > Note
  >
  > Do not put a semicolon (;) at the end of your expression in the If box.

- *Then*: A work flow to execute if the condition is TRUE.
- *Else*: A work flow to execute if the condition is FALSE.
  This branch is optional.

The *Then* and *Else* branches of the conditional can be any steps valid in a work flow, including a call to an existing work flow.

Conditionals have the following attribute:

Attribute	Description
Name	The name of the object. This name appears on the object in the diagram.

Related Information

Reference Guide: Smart Editor [page 1021]

3.2.2.6 Data flow

Class

Reusable

Access

- In the object library, click the *Data Flows* tab.
- With a work flow diagram in the workspace, click the data flow icon in the tool palette.

Description

A data flow extracts, transforms, and loads data.

You can define parameters to pass values into the data flow. You can also define variables for use inside the data flow.

When SAP Data Services executes data flows, it optimizes the extract, transform, and load requirements into commands to the DBMS and commands executed internally. Where it can, the software runs these operations in parallel.

By definition, a data flow can contain the following objects:

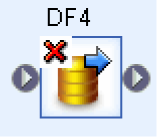
- **Sources**: Files, tables, XMl files, XML messages (real-time jobs only), documents, or pre-defined template tables
- **Targets**: Files, tables, XML files, XML messages (real-time jobs only), outbound messages, documents, XML template, or template tables
- **Transforms**: The Query transform is the most commonly used transform

You can view the SQL code the software generates for table sources in data flows and improve your data flow design accordingly.

Data flows have several built-in properties.

Attribute	Description
Name	The name of the object. This name appears on the object in the object library and in the calls to the object.
Description	Your description of the data flow.

If you delete a data flow from the object library, calls to the object are replaced with an icon indicating that the calls are no longer valid in the workspace.



Related Information

Performance Optimization Guide: Viewing SQL [page 2121]

3.2.2.6.1 Executing jobs only once

You can ensure that a job executes a data flow only one time by selecting the *Execute only once* check box on the data flow Properties window. When you select this check box, SAP Data Services executes only the first occurrence of the data flow and skips subsequent occurrences of it in the job. You might use this feature when developing complex jobs with multiple paths, such as those containing try/catch blocks or conditionals, and you want to ensure that the software executes a particular data flow only once. Before selecting the *Execute only once*, note that:

- If you design a job to execute the same *Execute only once* data flow in parallel flows, the software only executes the first occurrence of that data flow and you cannot control which one is executed first. Subsequent flows wait until the first one is processed. The engine provides a wait message for each subsequent data flow. Since only one Execute only once data flow can execute in a single job, the engine skips subsequent data flows and generates a second trace message for each, "Data flow n did not run more than one time. It is an execute only once flow."
- The *Execute only once* data flow option does not override the *Recover as a unit* work flow option and the *Enable recovery* job option.

3.2.2.6.2 Parallel processing

You can run certain transforms and functions in parallel by entering a number in the *Degree of parallelism* box on your data flow Properties window. When you drop a transform into the data flow and a function into each transform, the number you enter in the *Degree of parallelism* box is the maximum number of instances that can be generated for each transform or function in the data flow.

Related Information

Performance Optimization Guide: Degree of parallelism [page 2142]

3.2.2.6.3 Caching data

You can cache data to improve performance of operations such as joins, groups, sorts, lookups, and table comparisons. You can select one of the following values for the *Cache type* option on your data flow Properties window:

- In-Memory: Choose this value if your data flow processes a small amount of data that can fit in the available memory.
- Pageable: This value is the default.

  > Note
  >
  > For data flows that you created prior to version 11.7, the default cache type is in-memory. If the data retrieved does not fit into available memory, change the cache type to pageable in the data flow Properties window.

> Note
>
> You cannot use pageable cache with nested data or LONG data types.

Related Information

Performance Optimization Guide: Caching sources [page 2130]

3.2.2.7 Datastore

Class

Reusable

Access

In the object library, click the *Datastores* tab.

Description

A datastore provides a connection to a data source such as a database. Through the datastore connection, SAP Data Services can import descriptions of the data source such as its metadata. When you specify tables as sources or targets in a data flow, the software uses the datastore to determine how to read data from or load data to those tables. In addition, some transforms and functions require a datastore name to qualify the tables they access.

Datastores have the following properties:

Property	Description
Name	The name of the object. This name appears on the object in the object library and in the calls to the object. You cannot change the name of a datastore after creation.
Description	Text that you enter to describe and document the datastore.
Date_created	The date that you created the datastore. You cannot change this value.

Note

If you delete a datastore from the object library, you must remove references to the datastore from the following locations:

- Source or target tables using this datastore in your diagrams
- The lookup and key_generation functions and Key_Generation, History_Preserving, Table_Comparison, and SQL transform references

3.2.2.7.1 Datastore editor

To open the Datastore Editor, go to the Datastores tab in the object library, right-click the white space, and select *New*. Alternatively, you can right-click the name of an existing datastore and select *Edit*. The Datastore Editor consists of several windows.

- *New* opens the *Create New Datastore* window
- *Edit* opens the Edit Datastore **<DatastoreName>** window

Creating a new Datastore—Basic Configuration Options

Initially only two options appear on this resizable window: *Datastore Name* and *Datastore type*. When you select a datastore type, the window automatically updates to display other options relevant to that type. The combination of *Datastore type* and *Database type* determine the rest of your available options for that datastore.

There are three general categories of datastores:

- Database datastores allow you to connect to supported databases.
- Adapter datastores allow you to connect to adapters.

- Application datastores, such as PeopleSoft and JDE One World allow you to connect to applications that run on databases. You can select these applications by name from the *Datastore type* list.

SAP Data Services supports changed-data capture (CDC) and transfer tables with Oracle databases. So in this case, the Designer displays the *Enable CDC* and *Enable automatic data transfer* check boxes.

- The *Enable CDC* option is available only when you create a new datastore. After you save a datastore, or when editing a datastore, the software disables the *Enable CDC* check box. Note that although a database datastore may have multiple configurations of different database types, if you enable CDC for a datastore then all configurations must use the same database type.
- The *Enable automatic data transfer* check box is selected by default when you create a new datastore and you chose `Database` for *Datastore type*. This check box is available when you edit an existing datastore. This check box displays for all databases except Attunity Connector, Memory, and Persistent Cache.

  > i Note
  >
  > The Enable automatic data transfer check box is not available for application datastores such as SAP and Oracle Applications.

  Keep Enable automatic data transfer selected to enable transfer tables in this datastore that the Data_Transfer transform can use to push down subsequent database operations.
- The *Force UTF-16 codepage* check box is available only when you select Persistent Cache as the database type. Selecting this option caches the data in a Unicode multi-byte format. Deselecting this option runs the data flow based on the engine runtime locale. You may want to use this option if you have several data flows that are dependent on each other and also have a mix of single-and multi-byte data. Setting this option ensures that the dependent data flows are compatible. However, if you have single-byte data and you select this option, you may see performance degradation in the data flow that uses this persistent cache.

Click *Advanced* to expand the datastore editor. The expanded window displays a grid of additional datastore options.

Creating a new Datastore—Advanced Configuration Options

You can toggle the *Advanced* button to hide and show the grid of additional datastore editor options.

The grid displays datastore configurations as column headings and lists datastore options in the left column. Each row represents a configuration option. Different options appear depending upon datastore type and (if applicable) database type and version. Specific options appear under group headings such as *Connection, General*, and *Locale*.

To improve readability, you can expand and collapse the datastore option groups. Each cell in the grid represents the value for a configuration option. If the value for a cell comes from a closed set, the cell becomes a drop-down list when you click it. If you are required to manually enter the value for an option, the cell becomes an text box when you click it.

If the *Database type* supports multiple configurations, the window also enables the *Edit...* button.

The Configurations Editor

Click the *Edit...* button to open the configurations editor which contains the grid of configuration options as well as an editing toolbar. The configurations editor is a subset of the datastore editor functionality. Use the configurations editor to add, edit, and remove datastore configurations.

The configurations editor always contains at least one configuration (initially that configuration reflects the first values set for the datastore). This first configuration is the default. When a datastore contains only one configuration (the default), you cannot remove it from the datastore. All subsequent configurations appear as additional columns in the grid.

The configurations editor provides a tool bar which includes commands to add, edit, and remove configurations.

From left to right, the toolbar buttons are:

Button	Button name	Description
	Create New Configuration	Adds a new configuration with no values.
	Duplicate Configuration	Creates a new configuration with identical settings as the selected configuration. The new configuration name must be unique, so the software uses the following naming convention: OldConfigurationName _Copy_CopyNumber. For example, if you duplicate a configuration called TestConfiguration, the software would name the duplicate TestConfiguration_Copy_1. If you do not rename the original or duplicate configuration and duplicate the original configuration again, the copy number appends by 1. So, the software would name the second duplicate TestConfiguration_Copy_2, and so forth.
	Rename Configuration	Shifts input focus to the name of the selected configuration so you can edit it.
	Delete Configuration	Removes the configuration from the datastore and its column from the grid.
AZ	Sort Configurations (Ascending)	Arranges the configurations by their names in ascending order. The arrangement is sensitive to the computer's system locale.
ZA	Sort Configurations (Descending)	Arranges the configurations by their names in descending order. The arrangement is sensitive to the computer's system locale.
	Move Default to First	Moves the default configuration to the first column in the list. Does not change the order of other columns.
	Create New Alias	Adds a new alias name for the datastore. To map individual configurations to an alias, enter the real owner name of the configuration in the grid.

Button	Button name	Description
	Delete Alias	Removes the selected alias name for the datastore.
	Expand All Categories	Opens all the nodes so that every configuration property is visible.
	Collapse All Categories	Closes all the nodes so that every configuration property is hidden.
	Show/Hide Details	This is a toggle to show additional datastore options on the dialog box: Database type, Number of Configurations, and CDC status.
Go to: Oracle1 ▾	Navigation box	This list contains the names of all configurations. Selecting a name from this list will (if necessary) scroll the configuration into view and highlight the configuration name in the grid.

These commands (except for the Navigation box) also appear on a shortcut menu when you right-click any active cell on the grid.

To save a newly-defined configuration and keep working in the configurations editor, click *Apply*. To save configuration changes and exit the configurations editor, click *OK*. Your configurations are saved in the same sequence shown in the configurations editor. To exit the configurations editor without saving changes, click *Cancel*.

You can also manage configurations by directly manipulating the grid.

- When a datastore contains more than one configuration, you can rearrange the order of configuration columns by clicking a configuration name and dragging it left or right.
- Double-click a configuration name to edit it.
- Right-click a configuration name or any active cell on the grid to select any of the following options from the shortcut menu:
  - *Create New Configuration* (see toolbar description)
  - *Duplicate Configuration* (see toolbar description)
  - *Rename Configuration* (see toolbar description)
  - *Delete Configuration* (see toolbar description)
  - *Sort Configurations in Ascending Order* (see toolbar description)
  - *Sort Configurations in Descending Order* (see toolbar description)
  - *Move Default Configuration to First Column* (see toolbar description)
  - *Expand All Categories* (see toolbar description)
  - *Collapse All Categories* (see toolbar description)
  - *Add Linked Datastore*
  - *Delete Linked Datastore*
  - *Create New Alias*
  - *Delete Alias*

Using multiple configurations with database datastores can minimize your efforts to port existing jobs from one database type and version to another. The datastore editor supports quick creation of multiple configurations by allowing you to duplicate and rename configurations. Duplicating a configuration copies its options to create another configuration.

Because each datastore must have only one Default configuration (used to browse, search, and import metadata), when you select *Yes* as the default for any one configuration, the grid automatically sets the Default configuration value for the others to *No*.

> Note
>
> While you can change the Default configuration value from *No* to *Yes*, you cannot change the value from *Yes* to *No*. If you attempt to do so, the Designer displays an error message instructing you to select *Yes* for another configuration instead.

Adding New Configurations

When you add new configurations, the software modifies the language of data flows in the datastore if the data flows contain any of the following objects:

- Table targets
- Table transfer type used in Data_Transfer transform as a target
- SQL transforms

The software adds the target options and SQL transform text to additional datastore configurations based their definitions in an existing configuration.

This functionality operates in the following ways:

- If a new configuration has the same database type and the same or newer version as an old configuration, then the software automatically uses the existing SQL transform, target table editor, and Data_Transfer transform editor values (including bulk loader options).
- If the database type and version are not already associated with (or if the version is older than) any existing configuration, you can use the values from an existing database type and version by selecting that option from the *Use values from* list.
  The Use values from list always contains the following options:
  - Default values
  - Database type and version for each configuration currently associated with the datastore

  So if your datastore contains two configurations, for example one for Oracle 9i and one for Microsoft SQL Server 2000, when you create a third configuration, (in this example, for DB2) you will see Default values, Oracle 9i and Microsoft SQL Server 2000 as the options in the Use values from list.
  Default values are the same defaults that appear for all database targets, Data_Transfer target tables, and SQL transforms. Default SQL text is always blank. Some target option default values are:
  Row commit size = 1000
  Column comparison = Compare by name
  Delete data from table before loading = not selected
  Drop and re-create table = not selected for regular tables (Selected for template tables)
- If you select the *Restore values if they already exist* check box (pre-selected as default), the software creates the new configuration then determines whether SQL transform, target table editor, or Data_Transfer transform editor values already exist for the new database. If the database values already exist, the software

restores the bulk load option. However, if no values exist for the database, the software sets the bulk load option to *None*, the default value.
Also, if you deselect Restore values if they already exist, the software sets the bulk load option to None, the default value.

Example: Suppose you are working in a multi-user environment and have a local datastore with configurations for Oracle 9i and SQL Server 2000. You also have existing data flows that use target tables, Data_Transfer target tables, or SQL transforms from this datastore. You then delete Oracle 9i (perhaps because you checked out a different version of the datastore from the central repository). Later, you want to add an Oracle 9i configuration to this datastore.

Deleting a version causes the software to remove the configuration, but not the target table, Data_Transfer target table, and SQL transform values. If you select *Restore values if they already exist* when you create a new configuration, the software determines whether values already exist for the database. If the software cannot find these values, the Designer uses values specified in the *Use values from* box.

After you click *Apply* to save a new configuration, the software:

- Copies any existing SQL transform, target table editor, and Data_Transfer target table editor values, and
- Displays a report of the modified objects in a popup window as well as in the Designer Output window.

The report shows the following information:

Report column	Description
data flow	Names of the data flows where language was modified
Modified Object	Objects in the data flows that were affected
Object Type	Types of the objects affected (table target or SQL transform)
Usage	Usage of the objects (source or target)
Has Bulk Loader	Whether the objects have a bulk loader
Bulk Loader Copied	Whether the bulk loader option was copied
Values Existed	Whether there were previous values
Values Restored	Whether the previous values were restored

You can use this report as a guide to manually change the values for options of targets, Data_Transfer target tables, and SQL transforms, as needed. In the pop-up window, you can sort results by clicking on column headers. You can also save the output to a file. The popup appears after each newly-added configuration.

SAP Data Services also clears and displays the results in the Output window after each newly-added configuration. Because the datastore editor windows are modal, you cannot see the entire Output window or manipulate it. However, you can double-click one of the objects on the report and to view the data flow.

Configurations with Different Database Types

When a datastore contains multiple configurations of different database types, the rows show the options for all configurations.

When an option does not apply to a configuration, the cell displays N/A in gray and does not accept input. Cells that correspond to a group header such as Connection and Locale display hashed gray lines and also do not accept input.

Importing database links

Use this datastore option to import and configure a database link in the Designer.

Performance Optimization Guide: Maximizing Push-Down Operations, DataTransfer transform for push-down operations [page 2122]
Working with Aliases [page 868]
Designer Guide: Datastores, Adapter datastores [page 233]
Designer Guide: Datastores, Linked datastores [page 231]

3.2.2.7.1.1 To link a target datastore to a source datastore using a database link

1. From the *Datastores* tab in the object library, right-click a target datastore and select *Edit*.

   If the database type supports database links, the list of configuration options includes the *Linked Datastores* option, in the *Advanced* section.

   > i Note
   >
   > The datastore editor allows you to edit database links on target datastores for the default configuration only. So, if your target datastore contains multiple configurations (for example: Config1, Config2, and Config3), change your default configuration before you attempt to import or edit links that apply to it (for example, make Config2 the default if you want to edit it).

2. Click the *Linked Datastores* label.

   The *Add Linked Datastore* window opens.
3. From the *Add Linked Datastore* window, select a datastore that your target datastore will be linked to based on the settings in the database link you want to import.

   For example if your target datastore is DS_Emp (employee information) and the database link you want to import will associate employee information with sales information, select DS_Sales (sales information).

   The datastores in the list box have database types supported for linked datastores.

   > i Note
   >
   > The datastore editor allows only one database link between a target datastore and a source datastore pair. Therefore, if target datastore B already has a link to source datastore A, you cannot import another database link that associates datastore B with datastore A.

4. Click *OK*.

   The *Datastore Editor* window displays the datastore that you selected.

5. Select the list button to the right of `Not Linked` or double-click the cell.

   The *Database Link* window opens.
6. To link to a datastore or to change the existing link, select *Use the database link*.

   > **Note**
   >
   > To remove an existing link, select Do not link.
7. Select a database link from the list read from the default configuration connection of the target datastore you are editing.

   This list box contains links that you previously defined on the DBMS.
8. Select the source datastore configuration that you want to use with this database link.
9. (Optional) Select *Details* to view additional information about the links or to test them.

   The check mark indicates the link to use. If you use the *Details* window, click OK when you are finished.
10. From the *Database Link* dialog, click *OK*.

3.2.2.7.1.2 Working with Aliases

Use this option to define aliases for your datastore. After you create an alias (for example, ALIAS1, ALIAS2), navigate horizontally to each configuration and define the owner name to which that alias name maps.

Note that SAP Data Services does not label alias owner names in the configurations grid.

When you delete an alias name, the delete operation applies to the entire datastore (all configurations). the software removes the selected row which includes the alias and all assigned owner names.

3.2.2.7.2 Database datastores

You can define datastores so that SAP Data Services can read from and write to the following types of databases:

- Attunity Connector (use for mainframe systems)
- Data Federator (read only)
- DB2
- HP Neoview
- Informix
- Memory
- Microsoft SQL Server
- MySQL
- Netezza
- ODBC
- Oracle
- Persistent Cache
- SAP HANA (ODBC)
- SQL Anywhere

- SAP SAP Sybase ASE
- SAP SAP Sybase IQ
- Teradata

Each database requires its own connection information in the datastore definition.

For a description of the datastore connection information and options specific to each database, see the tables in this section.

i Note

The *Enable CDC* option is available with a subset of the databases. When the *Enable CDC* option is checked, the following Advanced option groups do not display because a CDC datastore is read-only and you can only use it as a source: *General*, *Bulk Loader*, and *FTP*.

3.2.2.7.2.1 Attunity

Table 19: Main window

Attunity option	Possible values	Description
Data source	Refer to the requirements of your database	Type the Attunity data source name(s) as defined in Attunity Studio. Separate multiple data source names with semicolons.
Host location	Computer name, fully qualified domain name, or IP address	Type the name of the Attunity server computer (host).
Port	Positive integer	Type the port number for the Attunity server.
Attunity workspace	Refer to the requirements of your database	Type the workspace name under which the data sources are defined in Attunity Studio.
User name	Alphanumeric characters and underscores	Type the user name of the account through which SAP Data Services accesses the database.
Password	Alphanumeric characters, underscores, and punctuation	Type the user's password.
Enable CDC	-	Select to enable changed data capture for this datastore.

Table 20: General (these options do not appear for CDC datastores)

Attunity option	Possible values	Description
Rows per commit	Positive integer	Enter the maximum number of rows loaded to a target table before saving the data. This value is the default commit size for target tables in this datastore. You can overwrite this value for individual target tables.
Overflow file directory	Directory path or click *Browse*	Enter the location of overflow files written by target tables in this datastore. A variable can also be used.

Table 21: Locale

Attunity option	Possible values	Description
Language	-	See the section "Locales and Multi-Byte Functionality."
Code page	-	See the section "Locales and Multi-Byte Functionality."
Server code page	-	See the section "Locales and Multi-Byte Functionality."

Table 22: Session

Attunity option	Possible values	Description
Additional session parameters	A valid SQL statement or multiple SQL statements delimited by semicolon	Additional session parameters specified as valid SQL statement(s)

Table 23: Aliases

Attunity option	Possible values	Description
Aliases	-	Enter the alias name and the owner name to which the alias name maps.

3.2.2.7.2.2 Data Federator

Any decimal column imported to SAP Data Services from an SAP Data Federator data source is converted to the decimal precision and scale(28,6).

Any varchar column imported to the software from a SAP Data Federator data source is varchar(1024).

You may change the decimal precision or scale and varchar size within the software after importing form the SAP Data Federator data source.

3.2.2.7.2.3 DB2

Table 24: Main window

DB2 option	Possible values	Description
Database version	DB2 UDB `<version number>`	Select the version of your DB2 client. This is the version of DB2 that this datastore accesses.
Use data source name (DSN)	Check box selected or not selected	Select to use DSN to connect to the database. By default, this option is not selected and a server name (also known as DSN-less) connection will be used. For a DSN-less connection, you must fill in *Database server name*, *Database name*, and *Port*. If you select this checkbox, you must fill in *Data source name*
Database server name	Refer to the requirements of your database	Type the DB2 database server name. This option is required if you did not select *Use data source name (DSN)*.
Database name	Refer to the requirements of your database	Type the name of the database defined in DB2. This option is required if you did not select *Use data source name (DSN)*.
Port	Five digit integer Default: 50000	Enter the number of the database port. This option is required if you did not select *Use data source name (DSN)*.
Data source name	Refer to the requirements of your database	Type the data source name defined in DB2 for connecting to your database. This option is required when you select *Use data source name (DSN)*. If you are going to use the Auto correct load feature for DB2 targets, be sure that your data source allows your user name to create or replace stored procedures.
User name	Alphanumeric characters and underscores	Enter the user name of the account through which SAP Data Services accesses the database.
Password	Alphanumeric characters, underscores, and punctuation	Enter the user's password.

Table 25: General

DB2 option	Possible values	Description
Rows per commit	Positive integer	Enter the maximum number of rows loaded to a target table before saving the data. This value is the default commit size for target tables in this da-

DB2 option	Possible values	Description
		tastore. You can overwrite this value for individual target tables.
Bulk loader directory	Directory path or click *Browse*	Enter the location where command and data files are written for bulk loading. For Solaris systems, the path name must be less than 80 characters. You can enter a variable for this option.
Overflow file directory	Directory path or click *Browse*	Enter the location of overflow files written by target tables in this datastore. A variable can also be used.

Table 26: Locale

DB2 option	Possible values	Description
Language	-	See the section "Locales and Multi-Byte Functionality."
Code page	-	See the section "Locales and Multi-Byte Functionality."
Server code page	-	See the section "Locales and Multi-Byte Functionality."

Table 27: Bulk loader

DB2 option	Possible values	Description
Bulk loader user name	Alphanumeric characters and underscores or blank	The name used when loading data with the bulk loader option. For bulk loading, you might specify a different user name. For example, specify a user who has import and load permissions.
Bulk loader password	Alphanumeric characters, underscores, and punctuation, or blank	The password used when loading with the bulk loader option.
DB2 server working directory	Directory path or click *Browse*	The working directory for the load utility on the computer that runs the DB2 server. You must complete this field whenever the DB2 server and the Job Server run on separate machines.

Table 28: FTP

DB2 option	Possible values	Description
FTP host name	Computer name, fully qualified domain name, or IP address	If this field is left blank or contains the name of the computer (host) where the Job Server resides, the software assumes that DB2 and and the software share the same computer and that FTP is unnecessary. When FTP is unnecessary, all other FTP-related fields can remain blank.

DB2 option	Possible values	Description
FTP login user name	Alphanumeric characters and underscores, or blank	Must be defined to use FTP.
FTP login password	Alphanumeric characters, underscores, and punctuation, or blank	Must be defined to use FTP.
Session		
Additional session parameters	A valid SQL statement or multiple SQL statements delimited by semicolon.	Additional session parameters specified as valid SQL statement(s)
Aliases (Click here to create)		
Aliases	-	Enter the alias name and the owner name to which the alias name maps.
Linked Datastores (Click here to create)		
Datastore name	Alphanumeric characters and underscores or blank	The name of a datastore to which you linked the current datastore configuration in preparation to import a database link

3.2.2.7.2.4 HP Neoview

Table 29: Main window

HP Neoview option	Possible values	Description
Database version	Currently supported versions `<version number>`	Select the version of your HP Neoview client. This is the version of HP Neoview that this datastore accesses.
User name	Alphanumeric characters and underscores	Enter the user name of the account through which the software accesses the database.
Password	Alphanumeric characters, underscores, and punctuation	Enter the user's password.
Enable automatic data transfer		The Enable automatic data transfer check box is selected by default when you create a new datastore and you chose Database for Datastore type. Keep Enable automatic data transfer selected to enable transfer tables in this datastore that the Data_Transfer transform can use to push down subsequent database operations.

Table 30: General

HP Neoview option	Possible values	Description
Rows per commit	Positive integer	Enter the maximum number of rows loaded to a target table before saving the data. This value is the default commit size for target tables in this datastore. You can overwrite this value for individual target tables.
Bulk loader directory	Directory path or click *Browse*	Enter the location where command and data files are written for bulk loading. For Solaris systems, the path name must be less than 80 characters. You can enter a variable for this option.
Overflow file directory	Directory path or click *Browse*	Enter the location of overflow files written by target tables in this datastore. A variable can also be used.

Table 31: Neoview Transporter

HP Neoview option	Possible values	Description
Data source	Alphanumeric characters and underscores	Type the data source name of the ODBC and JDBC connection to the HP Neoview system. The name must be unique.
System	Alphanumeric characters and underscores	Type the name of the primary segment, for example, the HP Neoview system named neo0101.domain.com has the system name of neo0101.
Access point URL	Alphanumeric characters and underscores	Enter the URL for internal database connections. For example, the HP Neoview system named neo0101.domain.com would have a JDBC connection URL as `jdbc:hpt4jdbc://eno0101.domain.com:18650`.
User name	Alphanumeric characters and underscores	Type the username for connecting to the data source.
Password	Alphanumeric characters, underscores, and punctuation	Type the password for connecting to the data source.

Table 32: Session

HP Neoview option	Possible values	Description
Additional session parameters	A valid SQL statement or multiple SQL statements delimited by semicolon	Additional session parameters specified as valid SQL statement(s).

Table 33: Aliases (Click here to create)

HP Neoview option	Possible values	Description
Aliases	-	Enter the alias name and the owner name to which the alias name maps.

3.2.2.7.2.5 Informix

Table 34: Main window

Informix option	Possible values	Description
Database version	Informix IDS `<version number>`	Select the version of your Informix client. This is the version of Informix that this datastore accesses.
Use data source name (DSN)	Check box selected or not selected	Select to use DSN to connect to the database. By default, this option is not selected and a server name (also known as DSN-less) connection will be used. For a DSN-less connection, you must fill in *Database server name*, *Database name*, and *Port*. If you select this checkbox, you must fill in *Data source name*.
Database server name	Refer to the requirements of your database	Type the Informix database server name. This name is the Informix server instance name, not the host name. This option is required if you did not select *Use data source name (DSN)*.
Database name	Refer to the requirements of your database	Type the name of the database defined in Informix . This option is required if you did not select *Use data source name (DSN)*.
Port	Four digit integer Default: 1526	Type the port number to connect to this database. This option is required if you did not select *Use data source name (DSN)*.
Data source name	Refer to the requirements of your database	Type the Data Source Name defined in the ODBC. This option is required when you select *Use data source name (DSN)*.
User name	Alphanumeric characters and underscores	Enter the user name of the account through which SAP Data Services accesses the database.
Password	Alphanumeric characters, underscores, and punctuation	Enter the user's password.

Table 35: General

Informix option	Possible values	Description
Rows per commit	Positive integer	Enter the maximum number of rows loaded to a target table before saving the data. This value is

Informix option	Possible values	Description
		the default commit size for target tables in this datastore. You can overwrite this value for individual target tables.
Bulk loader directory	Directory path or click *Browse*	Enter the directory where the software writes sql, control, command, and data files for bulk loading. For Solaris systems, the path name must be less than 80 characters. You can enter a variable for this option.
Overflow file directory	Directory path or click *Browse*	Enter the location of overflow files written by target tables in this datastore.

Table 36: Locale

Informix option	Possible values	Description
Language	-	See the section "Locales and Multi-Byte Functionality."
Code page	-	See the section "Locales and Multi-Byte Functionality."
Server code page	-	See the section "Locales and Multi-Byte Functionality."

Table 37: Session

Informix option	Possible values	Description
Additional session parameters	A valid SQL statement or multiple SQL statements delimited by semicolon.	Additional session parameters specified as valid SQL statement(s).
Aliases (Click here to create)		
Aliases	-	Enter the alias name and the owner name to which the alias name maps.

i Note

To use large object types with Informix, you must first enable large object support within the Informix ODBC driver options.

For Windows, in the *Informix ODBC Driver Setup* screen used for configuration of the Informix ODBC driver, check *Report Standard ODBC Types Only* and click *OK* to save the change.

For UNIX platforms, edit the `odbc.ini` file to set the option `NEEDODBCTYPESONLY=1`.

For more information about Informix ODBC driver configuration, see your Informix ODBC driver configuration documentation.

3.2.2.7.2.6 Memory

Table 38: Bulk Loader

Memory option	Possible values	Description
JS and DB on same machine	Yes, No	Indicate whether the Job Server and database are on the same computer.

Related Information

Locales and Multi-byte Functionality [page 1793]

3.2.2.7.2.7 Microsoft SQL Server

i Note

If there is a problem when processing Microsoft SQL Server data using a UNIX Job Server, Data Services will issue an error message that might contain a DataDirect internal error message. DataDirect's error-message syntax resembles the following structure: `<vendor-ODBCcomponent: message>`

For more information about message text or codes that DataDirect issues, consult DataDirect documentation or web site.

Table 39: Main window

Microsoft SQL Server option	Possible values	Description
Database version	Microsoft SQL Server `<version number>`	Select the version of your SQL Server client. This is the version of SQL Server that this datastore accesses.
Database server name	Computer name, fully qualified domain name, or IP address	Enter the name of machine where the SQL Server instance is located.
Database name	Refer to the requirements of your database	Enter the name of the database to which the datastore connects.
User name	Alphanumeric characters and underscores	Enter the user name of the account through which Data Services accesses the database.
Password	Alphanumeric characters, underscores, and punctuation	Enter the user's password.
Enable CDC	-	Select to enable changed data capture for this datastore.

Microsoft SQL Server option	Possible values	Description
Connection		
Use Windows Authentication	No, Yes	Select whether to use Windows authentication or Microsoft SQL Server authentication to connect to this datastore. Defaults to No. For more information on how to use Windows authentication with Microsoft SQL Server, refer to the Microsoft SQL Server documentation. i Note Windows authentication is not supported on UNIX.

Table 40: General

Microsoft SQL Server option	Possible values	Description
Rows per commit	Positive integer	Enter the maximum number of rows loaded to a target table before saving the data. This value is the default commit size for target tables in this datastore. You can overwrite this value for individual target tables.
Overflow file directory	Directory path or click *Browse*	Enter the location of overflow files written by target tables in this datastore. You can enter a variable for this option.

Table 41: Locale

Microsoft SQL Server option	Possible values	Description
Language	-	See the section "Locales and Multi-Byte Functionality."
Code page	-	See the section "Locales and Multi-Byte Functionality."
Server code page	-	See the section "Locales and Multi-Byte Functionality."

Table 42: Session

Microsoft SQL Server option	Possible values	Description
Additional session parameters	A valid SQL statement or multiple SQL statements delimited by semicolon	Additional session parameters specified as valid SQL statement(s)

Table 43: Aliases (Click here to create)

Microsoft SQL Server option	Possible values	Description
Aliases	-	Enter the alias name and the owner name to which the alias name maps.

Table 44: Linked Datastores (Click here to create)

Microsoft SQL Server option	Possible values	Description
Datastore Name	Alphanumeric characters and underscores or blank	The name of a datastore to which you linked the current datastore configuration in preparation to import a database link

3.2.2.7.2.8 MySQL

Table 45: Main window

MySQL option	Possible values	Description
Database version	Currently supported versions `<version number>`	Select the version of your MySQL client. This is the version of MySQL that this datastore accesses.
Use data source name (DSN)	Check box selected or not selected	Select to use DSN to connect to the database. By default, this option is not selected and a server name (also known as DSN-less) connection will be used. For a DSN-less connection, you must fill in *Database server name*, *Database name*, and *Port*. If you select this checkbox, you must fill in *Data source name*
Database server name	Refer to the requirements of your database	Type the MySQL database server name. This option is required if you did not select *Use data source name (DSN)*.
Database name	Refer to the requirements of your database	Type the name of the database defined in MySQL. This option is required if you did not select *Use data source name (DSN)*.
Port	Refer to the requirements of your database	Enter the number of the database port. This option is required if you did not select *Use data source name (DSN)*.
Data source name	Refer to the requirements of your database	Type the data source name defined in MySQL for connecting to your database. This option is required when you select *Use data source name (DSN)*. If you are going to use the Auto correct load feature for MySQL targets, be sure that your data source allows your user name to create or replace stored procedures.
User name	Alphanumeric characters and underscores	Enter the user name of the account through which SAP Data Services accesses the database.

MySQL option	Possible values	Description
Password	Alphanumeric characters, underscores, and punctuation	Enter the user's password.
Enable automatic data transfer		The Enable automatic data transfer check box is selected by default when you create a new datastore and you chose Database for Datastore type. Keep *Enable automatic data transfer* selected to enable transfer tables in this datastore that the Data_Transfer transform can use to push down subsequent database operations.

Table 46: Connection

MySQL option	Possible values	Description
Additional connection parameters	Alphanumeric characters and underscores, or blank	Enter information for any additional parameters that the data source supports (parameters that the data source's ODBC driver and database support). Use the format: `<parameter1=value1; parameter2=value2>`

Table 47: General

MySQL option	Possible values	Description
Rows per commit	Positive integer	Enter the maximum number of rows loaded to a target table before saving the data. This value is the default commit size for target tables in this datastore. You can overwrite this value for individual target tables.
Bulk loader directory	Directory path or click *Browse*	Enter the location where command and data files are written for bulk loading. For Solaris systems, the path name must be less than 80 characters. You can enter a variable for this option.
Overflow file directory	Directory path or click *Browse*	Enter the location of overflow files written by target tables in this datastore. A variable can also be used.
Database Server working directory	Directory path or click *Browse*	The working directory for the load utility on the computer that runs the MySQL server. You must complete this field whenever the MySQL server and the Job Server run on separate machines.

Table 48: Locale

MySQL option	Possible values	Description
Language	-	See the section "Locales and Multi-Byte Functionality."

MySQL option	Possible values	Description
Code page	-	See the section "Locales and Multi-Byte Functionality."
Server code page	-	See the section "Locales and Multi-Byte Functionality."

Table 49: FTP

MySQL option	Possible values	Description
FTP host name	Computer name, fully qualified domain name, or IP address	If this field is left blank or contains the name of the computer (host) where the Job Server resides, the software assumes that MySQL and and the software share the same computer and that FTP is unnecessary. When FTP is unnecessary, all other FTP-related fields can remain blank.
FTP login user name	Alphanumeric characters and underscores, or blank	Must be defined to use FTP.
FTP login password	Alphanumeric characters, underscores, and punctuation, or blank	Must be defined to use FTP.
FTP host working directory	Absolute file path Virtual file path (Windows servers only)	The location on the database server where Data Services transfers the data file between the Job Server and the MySQL server. For Windows servers only, you can configure a path to a virtual directory.

Table 50: ODBC Miscellaneous

MySQL option	Values	Description
Date format	`yyyy.mm.dd` or other combinations	Enter a date format supported by the data source (a date format that the data source's ODBC driver and database supports).
Time format	`hh24:mi:ss` or other combinations	Enter a time format supported by the data source (a time format that the data source's ODBC driver and database supports).
Date-time format	`yyyy.mm.dd hh24:mi:ss` or other combinations	Enter a date-time format supported by the data source (a date-time format supported by the data source's ODBC driver and database).
Decimal separator	.(peroid) or , (comma)	Enter the character that the data source uses to separate the decimal portion of a number.
Data type conversion support	Automatic, ODBC syntax, No, SQL-92 syntax	When there's a data type mismatch in an expression, the software automatically generates an explicit convert function call.
NVL support	Automatic, ODBC syntax, No, custom	If the input value is NULL, replace with the specified value.

MySQL option	Values	Description
Ifthenelse support	Yes, No	Allows conditional logic in mapping and selection operations.

Table 51: Session

MySQL option	Possible values	Description
Additional session parameters	A valid SQL statement or multiple SQL statements delimited by semicolon	Additional session parameters specified as valid SQL statement(s).

Table 52: Aliases (Click here to create)

MySQL option	Possible values	Description
Aliases	-	Enter the alias name and the owner name to which the alias name maps.

3.2.2.7.2.9 Netezza

Table 53: Main window

Netezza option	Possible values	Description
Database version	Currently supported versions `<version number>`	Select the version of your Netezza client. This is the version of Netezza that this datastore accesses.
Use data source name (DSN)	Check box selected or not selected	Select to use DSN to connect to the database. By default, this option is not selected and a server name (also known as DSN-less) connection will be used. For a DSN-less connection, you must fill in *Database server name*, *Database name*, and *Port*. If you select this checkbox, you must fill in *Data source name*
Database server name	Refer to the requirements of your database	Type the Netezza database server name. This option is required if you did not select *Use data source name (DSN)*.
Database name	Refer to the requirements of your database	Type the name of the database defined in Netezza. This option is required if you did not select *Use data source name (DSN)*.
Port	Refer to the requirements of your database	Enter the number of the database port. This option is required if you did not select *Use data source name (DSN)*.

Netezza option	Possible values	Description
Data source name	Refer to the requirements of your database	Type the data source name defined in Netezza for connecting to your database. This option is required when you select *Use data source name (DSN)*. If you are going to use the Auto correct load feature for Netezza targets, be sure that your data source allows your user name to create or replace stored procedures.
User name	Alphanumeric characters and underscores	Enter the user name of the account through which SAP Data Services accesses the database.
Password	Alphanumeric characters, underscores, and punctuation	Enter the user's password.
Enable automatic data transfer		The Enable automatic data transfer check box is selected by default when you create a new datastore and you chose Database for Datastore type. Keep *Enable automatic data transfer* selected to enable transfer tables in this datastore that the Data_Transfer transform can use to push down subsequent database operations.

Table 54: Connection

Netezza option	Possible values	Description
Additional connection parameters	Alphanumeric characters and underscores, or blank	Enter information for any additional parameters that the data source supports (parameters that the data source's ODBC driver and database support). Use the format: `<parameter1=value1; parameter2=value2>`

Table 55: General

Netezza option	Possible values	Description
Rows per commit	Positive integer	Enter the maximum number of rows loaded to a target table before saving the data. This value is the default commit size for target tables in this datastore. You can overwrite this value for individual target tables.
Bulk loader directory	Directory path or click *Browse*	Enter the location where command and data files are written for bulk loading. For Solaris systems, the path name must be less than 80 characters. You can enter a variable for this option.

Netezza option	Possible values	Description
Overflow file directory	Directory path or click *Browse*	Enter the location of overflow files written by target tables in this datastore. A variable can also be used.
Database Server working directory	Directory path or click *Browse*	The working directory for the load utility on the computer that runs the Netezza server. You must complete this field whenever the Netezza server and the Job Server run on separate machines.

Table 56: Locale

Netezza option	Possible values	Description
Language	-	See the section "Locales and Multi-Byte Functionality."
Code page	-	See the section "Locales and Multi-Byte Functionality."
Server code page	-	See the section "Locales and Multi-Byte Functionality."

Table 57: FTP

Netezza option	Possible values	Description
FTP host name	Computer name, fully qualified domain name, or IP address	If this field is left blank or contains the name of the computer (host) where the Job Server resides, the software assumes that Netezza and and the software share the same computer and that FTP is unnecessary. When FTP is unnecessary, all other FTP-related fields can remain blank.
FTP login user name	Alphanumeric characters and underscores, or blank	Must be defined to use FTP.
FTP login password	Alphanumeric characters, underscores, and punctuation, or blank	Must be defined to use FTP.
FTP host working directory	Absolute file path Virtual file path (Windows servers only)	The location on the database server where Data Services transfers the data file between the Job Server and the Netezza server. For Windows servers only, you can configure a path to a virtual directory.

Table 58: ODBC Miscellaneous

Netezza option	Possible values	Description
Date format	`yyyy.mm.dd` or other combinations	Enter a date format supported by the data source (a date format that the data source's ODBC driver and database supports).

Netezza option	Possible values	Description
Time format	`hh24:mi:ss` or other combinations	Enter a time format supported by the data source (a time format that the data source's ODBC driver and database supports).
Date-time format	`yyyy.mm.dd hh24:mi:ss` or other combinations	Enter a date-time format supported by the data source (a date-time format supported by the data source's ODBC driver and database).
Decimal separator	.(peroid) or , (comma)	Enter the character that the data source uses to separate the decimal portion of a number.
Data type conversion support	Automatic, ODBC syntax, No, SQL-92 syntax	When there's a data type mismatch in an expression, the software automatically generates an explicit convert function call.
NVL support	Automatic, ODBC syntax, No, custom	If the input value is NULL, replace with the specified value.
Ifthenelse support	Yes, No	Allows conditional logic in mapping and selection operations.

Table 59: Session

Netezza option	Possible values	Description
Additional session parameters	A valid SQL statement or multiple SQL statements delimited by semicolon	Additional session parameters specified as valid SQL statement(s).

Table 60: Aliases (Click here to create)

Netezza option	Possible values	Description
Aliases	-	Enter the alias name and the owner name to which the alias name maps.

3.2.2.7.2.10 ODBC

To define an ODBC datastore connection, you need to define a data source, a user name, a password if applicable, and optionally a set of advanced options.

Selecting an ODBC data source

You can select a data source in one of the following ways. In the *Data source* field of the ODBC datastore editor:

- From the drop-down list, click an existing data source
- Type the name of a data source
- Click *ODBC Admin* to launch the Windows ODBC Data Source Administrator where you create or configure data sources. After closing the ODBC Data Source Administrator, you can select a newly created data source from the datastore editor's drop-down list.

Defining ODBC datastore options

To define options for an ODBC datastore, click *Advanced*. For each option to configure, you can select a value from its drop-down list, or many options allow you to type a custom value.

Most ODBC datastore options include the following values.

Automatic

When you create a new ODBC datastore, most options default to *Automatic*. With this setting, if you do not know if the ODBC driver supports an option, SAP Data Services queries the driver to determine its capabilities. If the driver supports that option, the software pushes down the operation to the ODBC database. If the ODBC driver does not support that option, the software executes the operation internally.

To circumvent possible inconsistencies with the ODBC driver, you might need to specify an option other than *Automatic*. If you select anything other than *Automatic*, the software does not query the driver for that particular capability. Most options in the ODBC datastore editor provide some or all of the following choices.

ODBC syntax

The software assumes the ODBC driver supports the function/capability and uses ODBC syntax.

For example, for the ABSOLUTE function, the syntax is:

```
{fn abs (TAB1.COL1)}
```

SQL-92

The software assumes the ODBC driver supports the function/capability and uses SQL-92 syntax.

For example, when the software generates an explicit CONVERT function, the syntax is:

```
CAST (TAB1.VC_COL AS SQL_INTEGER)
```

No

The software assumes the ODBC driver does not support the function/capability and executes it internally.

Custom

Many functions allow you to type in the specific function call to use for that option. The software assumes the ODBC driver supports the function/capability.

> **Note**
>
> You cannot specify the signature of the function; it will be the same as in the ODBC signature.

For example, for the string function *Upper case*, instead of using `{fn ucase(...)}`, you can type in the *Upper case* option field `upper`. The software generates:

```
upper(TAB1.VC_COL)
```

The following tables describes the fields and options in the ODBC datastore editor.

Table 61: Main window

ODBC option	Values	Description
Data source	Refer to the requirements of your database.	Select or type the Data Source Name defined in the ODBC Administrator for connecting to your database.
User name	Alphanumeric characters and underscores	Enter the user name of the account through which the software accesses the database. **Note** If you use the Neoview utility Nvtencrsrv for storing the encrypted words in the security file when using Neoview Transporter, enter the encrypted user name
Password	Alphanumeric characters, underscores, and punctuation	Enter the user's password. **Note** If you use the Neoview utility Nvtencrsrv for storing the encrypted words in the security file when using Neoview Transporter, enter the encrypted password.
ODBC Admin button		Click to launch the Windows ODBC Data Source Administrator where you create or configure data sources. After closing the ODBC Data Source Administrator, you can select a newly created data source from the datastore editor's drop-down list.

Table 62: Connection

ODBC option	Values	Description
Additional connection information	Alphanumeric characters and underscores, or blank	Enter information for any additional parameters that the data source supports (parameters that the data source's ODBC driver and database support). Use the format: `<parameter1=value1; parameter2=value2>`

Table 63: General

ODBC option	Values	Description
Rows per commit	Positive integer	Enter the maximum number of rows loaded to a target table before saving the data. This value is the default commit size for target tables in this datastore. You can overwrite this value for individual target tables.
Bulk loader directory	Directory path or click *Browse*	Enter the directory where the software writes sql, control, command, and data files for bulk loading. For Solaris systems, the path name must be less than 80 characters. You can enter a variable for this option.
Overflow file directory	Directory path or click *Browse*	Enter the location of overflow files written by target tables in this datastore. You can enter a variable for this option.
Database server working directory	Directory path or click *Browse*	A working directory on the database server that stores files such as logs. Must be defined to use FTP.

Table 64: Locale

ODBC option	Values	Description
Language		See the section "Locales and Multi-Byte Functionality"
Code page		See the section "Locales and Multi-Byte Functionality"
Server code page		See the section "Locales and Multi-Byte Functionality"

Table 65: Neoview Transporter

ODBC option	Values	Description
Data source	Alphanumeric characters and underscores	Type the data source name of the ODBC and JDBC connection to the HP Neoview system. The name must be unique.
System	Alphanumeric characters and underscores	Type the name of the primary segment, for example, the HP Neoview system named neo0101.domain.com has the system name of **`neo0101`**.
Access point URL	Alphanumeric characters and underscores	Enter the URL for internal database connections. For example, the HP Neoview system named neo0101.domain.com would have a JDBC connection URL as `jdbc:hpt4jdbc://eno0101.domain.com:18650`.
User name	Alphanumeric characters and underscores	Type the username for connecting to the data source.
Password	Alphanumeric characters, underscores, and punctuation	Type the password for connecting to the data source.

Table 66: FTP

Note

If this datastore is not being used specifically for Netezza bulk loading, the software ignores any FTP option entries.

ODBC option	Values	Description
FTP host name	Computer name, fully qualified domain name, or IP address	For a Netezza server, type the name of the Netezza server computer (host). Must be defined to use FTP.
FTP login user name	Alphanumeric characters and underscores, or blank	Must be defined to use FTP.
FTP login password	Alphanumeric characters, underscores, and punctuation, or blank	Must be defined to use FTP.
FTP host working directory	Absolute file path	The location on the database server from where the software retrieves diagnostic files generated by the database's bulk loader. It must be accessible from the FTP server. It is usually the same as the database's working directory. If unsure, contact your system administrator. Note Configure the FTP server to accept an absolute path.

Table 67: ODBC Capability Support

ODBC option	Values	Description
Array fetch	Automatic, No	If you encounter errors when reading from an ODBC datastore, especially if the error message involves the ODBC call SQLFetchScroll, it is safe to assume that your ODBC driver does not support array fetch. In this case, select the *No* value to turn off the array fetch capability. The software fetches one row at a time from the ODBC data source. The *No* value causes all Source Table Editors and SQL Transform Editors that use this ODBC datastore to not display the *Array fetch size* performance option.
Parameterized SQL	Automatic, No	By using parameterized SQL, the software generates SQL statements with parameters instead of literal values, which can significantly improve performance.
Outer join	Automatic, ODBC syntax, SQL-92 syntax, No	Determines whether the ODBC driver supports outer join syntax.
Auto commit	Automatic, Yes, No	Determines whether the ODBC driver supports auto commit.
Server sorts in binary	Yes, No	Determines whether the server performs binary sort.

Table 68: ODBC Math Function Support

ODBC option	Values	Description
Absolute	Automatic, ODBC syntax, No, custom	Returns the absolute value of an input number.
Ceiling	Automatic, ODBC syntax, No, custom	Returns the smallest integer value greater than or equal to an input number.
Floor	Automatic, ODBC syntax, No, custom	Returns the largest integer value less than or equal to an input number.
Round	Automatic, ODBC syntax, No, custom	Rounds a given number to the specified precision.
Truncate	Automatic, ODBC syntax, No, custom	Truncates a given number to the specified precision.
Sqrt	Automatic, ODBC syntax, No, custom	Returns the square root of the input number.
Log	Automatic, ODBC syntax, No, custom	Returns the base-10 logarithm of the given numeric expression.
Ln	Automatic, ODBC syntax, No, custom	Returns the natural logarithm of the given numeric expression.
Power	Automatic, ODBC syntax, No, custom	Returns the value of the given expression to the specified power.
Mod	Automatic, ODBC syntax, No, custom	Returns the remainder when one number is divided by another.

Table 69: ODBC String Function Support

ODBC option	Values	Description
Lower case	Automatic, ODBC syntax, No, custom	Changes the characters in a string to lowercase.
Upper case	Automatic, ODBC syntax, No, custom	Changes the characters in a string to uppercase.
Rtrim blanks	Automatic, ODBC syntax, No, custom	Removes blank characters from the end of a string.
Ltrim blanks	Automatic, ODBC syntax, No, custom	Removes blank characters from the start of a string.
Length	Automatic, ODBC syntax, No, custom	Returns the number of characters in a given string.
Substring	Automatic, ODBC syntax, No, custom	Returns a specific portion of a string starting at a given point in the string.
Soundex	Automatic, ODBC syntax, No, custom	Returns the soundex encoding of the input string.

Table 70: ODBC Date Function Support

ODBC option	Values	Description
System date	Automatic, ODBC syntax, No, custom	Returns the current date as listed by the Job Server's operating system.
System time	Automatic, ODBC syntax, No, custom	Returns the current time as listed by the operating system.
Week	Automatic, ODBC syntax, No, custom	Determines the week in the year in which the given date falls.
Month	Automatic, ODBC syntax, No, custom	Determines the month in which the given date falls.
Quarter	Automatic, ODBC syntax, No, custom	Determines the quarter in which the given date falls.
Year	Automatic, ODBC syntax, No, custom	Determines the year in which the given date falls.
Day of month	Automatic, ODBC syntax, No, custom	Determines the day in the month on which the given date falls.
Day of year	Automatic, ODBC syntax, No, custom	Determines the day in the year on which the given date falls.

Table 71: ODBC Aggregate Function Support

ODBC option	Values	Description
Average	Automatic, SQL-92 syntax, No	Calculates the average of a given set of values.
Count	Automatic, SQL-92 syntax, No	Counts the number of values in a table column.
Count Distinct	Automatic, SQL-92 syntax, No	Counts the number of distinct non-NULL values in a table column.
Max	Automatic, SQL-92 syntax, No	Returns the maximum value from a list.
Min	Automatic, SQL-92 syntax, No	Returns the minimum value from a list.
Sum	Automatic, SQL-92 syntax, No	Calculates the sum of a given set of values.

Table 72: Miscellaneous

ODBC option	Values	Description
Date format	`yyyy.mm.dd` or other combinations	Enter a date format supported by the data source (a date format that the data source's ODBC driver and database supports).

ODBC option	Values	Description
Time format	`hh24:mi:ss` or other combinations	Enter a time format supported by the data source (a time format that the data source's ODBC driver and database supports).
Date-time format	`yyyy.mm.dd hh24:mi:ss` or other combinations	Enter a date-time format supported by the data source (a date-time format supported by the data source's ODBC driver and database).
Decimal separator	.(peroid) or , (comma)	Enter the character that the data source uses to separate the decimal portion of a number.
Data type conversion support	Automatic, ODBC syntax, No, SQL-92 syntax	When there's a data type mismatch in an expression, the software automatically generates an explicit convert function call.
NVL support	Automatic, ODBC syntax, No, custom	If the input value is NULL, replace with the specified value.
Ifthenelse support	Yes, No	Allows conditional logic in mapping and selection operations.
NVARCHAR type name	<Unknown> NVARCHAR NVARCHAR2	For loading multibyte data to template tables, select the option depending on the database type: *NVARCHAR*: All supported databases except Oracle *NVARCHAR2*: Oracle databases only In the template table target editor, setting the option *Use NVARCHAR for VARCHAR columns in supported databases* to Yes enables this data type conversion. See also *Template table* [page 996].

Table 73: Session

ODBC option	Values	Description
Additional session parameters	A valid SQL statement or multiple SQL statements delimited by a semicolon	Additional session parameters specified as valid SQL statement.

Table 74: Aliases

ODBC option	Values	Description
Aliases		Enter the alias name and the owner name to which the alias name maps.

3.2.2.7.2.11 Oracle

Table 75: Main window

Oracle option	Possible values	Description
Database version	Oracle `<version number>`	Select the version of your Oracle client. This is the version of Oracle that this datastore accesses.
Use TNS name	Check box selected or not selected	Select to use TNS to connect to the database. By default, this option is not selected and a server name (also known as TNS-less) connection will be used. For a TNS-less connection, you must fill in *Hostname*, *SID*, and *Port*. If you select this checkbox, you must fill in *TNS name*
Hostname	Computer name, fully qualified domain name, or IP address	Enter the name of machine where the Oracle Server instance is located. This option is required if you did not select *Use TNS name*.
SID	Refer to the requirements of your database	Enter the System ID for the Oracle database. This option is required if you did not select *Use TNS name*.
Port	Four digit integer Default: 1521	Enter the port number to connect to this Oracle Server. This option is required if you did not select *Use TNS name*.
TNS name	Refer to the requirements of your database	Enter an existing Oracle Transparent Network Substrate (TNS) name through which the software accesses sources and targets defined in this datastore. This option is required when you select *Use TNS name*.
User name	Alphanumeric characters and underscores	Enter the user name of the account through which the software accesses the database.
Password	Alphanumeric characters, underscores, and punctuation	Enter the user's password.
Enable CDC	-	Select to enable changed data capture for this datastore.

Table 76: General

Oracle option	Possible values	Description
Rows per commit	Positive integer	Enter the maximum number of rows loaded to a target table before saving the data. This value is the default

Oracle option	Possible values	Description
		commit size for target tables in this datastore. You can overwrite this value for individual target tables.
Bulk loader directory	Directory path or click *Browse*	Enter the location where command and data files are written for bulk loading. For Solaris systems, the path name must be less than 80 characters. You can enter a variable for this option.
Overflow file directory	Directory path or click *Browse*	Enter the location of overflow files written by target tables in this datastore. You can enter a variable for this option.

Table 77: Locale

Oracle option	Possible values	Description
Language	-	See the section "Locales and Multi-Byte Functionality."
Code page	-	See the section "Locales and Multi-Byte Functionality."
Server code page	-	See the section "Locales and Multi-Byte Functionality."

Table 78: Session

Oracle option	Possible values	Description
Additional session parameters	A valid SQL statement or multiple SQL statements delimited by semicolon	Additional session parameters specified as valid SQL statement(s)

Table 79: Oracle Miscellaneous

Oracle option	Possible values	Description
Default precision for number	1 <= precision <= 96	Enter the total number of digits in the value.
Default scale for number	0 <= scale <= precision	Enter the number of digits to the right of the decimal point.

Table 80: Aliases (Click here to create)

Oracle option	Possible values	Description
Aliases	-	Enter the alias name and the owner name to which the alias name maps.

Table 81: Linked Datastores (Click here to create)

Oracle option	Possible values	Description
Datastore Name	Alphanumeric characters and underscores or blank	The name of a datastore to which you linked the current datastore configuration in preparation to import a database link

3.2.2.7.2.12 Persistent Cache

Table 82: Locale

Persistent Cache option	Possible values	Description
Server code page	-	See the section "Locales and Multi-Byte Functionality."

Table 83: Session

Persistent Cache option	Possible values	Description
Additional session parameters	A valid SQL statement or multiple SQL statements delimited by semicolon	Additional session parameters specified as valid SQL statement(s)

3.2.2.7.2.13 SAP HANA

Option	Possible values	Description
Database version	SAP HANA database `<version number>`	Select the version of your SAP HANA database client. This is the version of the SAP HANA database that this datastore accesses.
Use data source name (DSN)	Check box selected or not selected	Select to use DSN to connect to the database. By default, this option is not selected and a server name (also known as DSN-less) connection will be used. For a DSN-less connection, you must fill in *Database server name* and *Port*. If you select this checkbox, you must fill in *Data source name*.
Database server name	Computer name	Enter the name of the computer where the SAP HANA server is located. This option is required if you did not select *Use data source name (DSN)*.
Port	Five digit integer Default: 30015	Enter the port number to connect to this SAP HANA Server. This option is required if you did not select *Use data source name (DSN)*.
Data source name	Refer to the requirements of your database	Select or type the Data Source Name defined in the ODBC Administrator for connecting to your database. This option is required when you select *Use data source name (DSN)*.

Option	Possible values	Description
User name	Alphanumeric characters and underscores	Enter the user name of the account through which the software accesses the database.
Password	Alphanumeric characters, underscores, and punctuation	Enter the user's password.
Enable automatic data transfer		The *Enable automatic data transfer* check box is selected by default when you create a new datastore and you choose Database for *Datastore type*. Keep *Enable automatic data transfer* selected to enable transfer tables in this datastore that the Data_Transfer transform can use to push down subsequent database operations.
Additional connection information	Alphanumeric characters and underscores, or blank	Enter information for any additional parameters that the data source supports (parameters that the data source's ODBC driver and database support). Use the format: `<parameter1=value1; parameter2=value2>`
Rows per commit	Positive integer	Enter the maximum number of rows loaded to a target table before saving the data. This value is the default commit size for target tables in this datastore. You can overwrite this value for individual target tables.
Overflow file directory	Directory path or click Browse.	Enter the location of overflow files written by target tables in this datastore. A variable can also be used.
Aliases (Click here to create)	-	Enter the alias name and the owner name to which the alias name maps.

3.2.2.7.2.14 SAP Sybase ASE

Table 84: Main window

SAP Sybase ASE option	Possible values	Description
Database version	SAP Sybase ASE **`<version number>`**	Select the version of your SAP Sybase ASE client. This is the version of SAP Sybase that this datastore accesses.
Database server name	Computer name	Enter the name of the computer where the SAP Sybase ASE instance is located.

SAP Sybase ASE option	Possible values	Description
		Note For UNIX Job Servers, when logging in to a SAP Sybase repository in the Designer, the case you type for the database server name must match the associated case in the SYBASE_Home\interfaces file. If the case does not match, you might receive an error because the Job Server cannot communicate with the repository.
Database name	Refer to the requirements of your database	Enter the name of the database to which the datastore connects.
User name	Alphanumeric characters and underscores	Enter the user name of the account through which the software accesses the database.
Password	Alphanumeric characters, underscores, and punctuation	Enter the user's password.

Table 85: General

SAP Sybase ASE option	Possible values	Description
Rows per commit	Positive integer	Enter the maximum number of rows loaded to a target table before saving the data. This value is the default commit size for target tables in this datastore. You can overwrite this value for individual target tables.
Overflow file directory	Directory path or click *Browse*	Enter the location of overflow files written by target tables in this datastore. A variable can also be used.

Table 86: Locale

SAP Sybase ASE option	Possible values	Description
Language	-	See the section "Locales and Multi-Byte Functionality."
Code page	-	See the section "Locales and Multi-Byte Functionality."
Server code page	-	See the section "Locales and Multi-Byte Functionality."

Table 87: Session

SAP Sybase ASE option	Possible values	Description
Additional session parameters	A valid SQL statement or multiple SQL statements delimited by semicolon	A valid SQL statement or multiple SQL statements delimitated by semicolon.

Table 88: Aliases (Click here to create)

SAP Sybase ASE option	Possible values	Description
Aliases	-	Enter the alias name and the owner name to which the alias name maps.

3.2.2.7.2.15 SAP Sybase IQ

Displayed options vary depending on the version of SAP Sybase IQ you select in the datastore editor.

Table 89: Main window

SAP Sybase IQ option	Possible values	Description
Database version	Currently supported versions	Select the version of SAP Sybase IQ that this datastore accesses. Displayed options in the rest of the datastore editor vary depending on the version selected.
Use data source name (DSN)	Check box selected or not selected	Select to use DSN to connect to the database. By default, this option is not selected and a server name (also known as DSN-less) connection will be used. For a DSN-less connection, you must fill in *Hostname*, *Database name*, and *Port*, and *Server name*. If you select this checkbox, you must fill in *Data source name*
Hostname	Computer name or IP address	Type the computer name or IP address. This option is required if you did not select *Use data source name (DSN)*.
Database name	Refer to the requirements of your database	Type the name of the database defined in SAP Sybase IQ. This option is required if you did not select *Use data source name (DSN)*.
Port	Four digit integer Default: 2638	Type the number of the database port. This option is required if you did not select *Use data source name (DSN)*.
Server name	Refer to the requirements of your database	Type the SAP Sybase IQ database server name. This option is required if you did not select *Use data source name (DSN)*.
Database server name	Refer to the requirements of your database	Type the SAP Sybase IQ database server name.

SAP Sybase IQ option	Possible values	Description
		This option is required if you did not select *Use data source name (DSN)*.
Data source name	Refer to the requirements of your database	Select or type the Data Source Name defined in the ODBC Administrator for connecting to your database. This option is required when you select *Use data source name (DSN)*.
User name	Alphanumeric characters and underscores	Enter the user name of the account through which the software accesses the database.
Password	Alphanumeric characters, underscores, and punctuation	Enter the user's password.

Table 90: General

SAP Sybase IQ option	Possible values	Description
Rows per commit	Positive integer	Enter the maximum number of rows loaded to a target table before saving the data. This value is the default commit size for target tables in this datastore. You can overwrite this value for individual target tables.
Bulk loader directory	Directory path or click *Browse*	Enter the location where command and data files are written for bulk loading. For Solaris systems, the path name must be fewer than 80 characters. You can enter a variable for this option. If you do not enter a name here, Data Services by default writes the files to the directory **`<DS_COMMON_DIR>`**`\log\bulkloader`.
Overflow file directory	Directory path or click *Browse*	Enter the location of overflow files written by target tables in this datastore. You can enter a variable for this option.

Table 91: Locale

SAP Sybase IQ option	Possible values	Description
Language		See the section "Locales and Multi-Byte Functionality."
Code page		See the section "Locales and Multi-Byte Functionality."
Server code page		See the section "Locales and Multi-Byte Functionality."

Table 92: Bulk loader

SAP Sybase IQ option	Possible values	Description
JS and DB on same machine	Yes, No	For some versions of SAP Sybase IQ, you must configure Data Services to transfer via FTP the data file generated on the Job Server (JS) to the database server (DB). Refer to the following table for how to use this option together with the *Use named pipe* option and FTP depending on the version of SAP Sybase IQ you are using.
Server working directory	Absolute file path	Type the path to the working directory for the load utility on the computer that runs the SAP Sybase IQ server. If an absolute file path is specified for the *FTP host working directory* box, then the Server working directory is optional. If the box is left blank, then the software uses the file path to the *FTP host working directory*. If a virtual file path is specified for the *FTP host working directory*, then you must enter an absolute file path in the *Server working directory* box.
Use named pipe	Yes, No	Select Yes to eliminate the need to write a data file to disk, which can improve performance. If a data file is required for SAP Sybase IQ database recovery, select No. Defaults to No. Refer to the following table for how to use this option together with the *JS and DB on same machine* option and FTP depending on the version of SAP Sybase IQ you are using.

Table 93: Supported bulk loader options and methods

JS and DB on same machine	Use named pipe	For SAP Sybase IQ versions earlier than 15.x	For SAP Sybase IQ versions 15.x and later
Yes	Yes	Named pipe	Named pipe
Yes	No	File	File
No	Yes	FTP	Named pipe
No	No	FTP	File

Table 94: FTP

SAP Sybase IQ option	Possible values	Description
FTP host name	Computer name, fully qualified domain name, or IP address	For some versions of SAP Sybase IQ, Data Services generates a data file and transfers it via FTP to the database for loading.

SAP Sybase IQ option	Possible values	Description
		Type the name of the SAP Sybase IQ server computer (host). If the FTP host name is left blank and Data Services needs this FTP information for bulk loading, it generates a validation error.
FTP login user name	Alphanumeric characters and underscores, or blank	Must be defined to use FTP.
FTP login password	Alphanumeric characters, underscores, and punctuation, or blank	Must be defined to use FTP.
FTP host working directory	Absolute file path Virtual file path (Windows servers only)	The location on the database server where Data Services transfers the data file between the Job Server and the SAP Sybase IQ server. For Windows servers only, you can configure a path to a virtual directory.

Table 95: Session

SAP Sybase IQ option	Possible values	Description
Additional session parameters	A valid SQL statement or multiple SQL statements delimited by semicolon	Additional session parameters specified as valid SQL statement(s).

Table 96: SAP Sybase Miscellaneous

SAP Sybase IQ option	Possible values	Description
Use linked remote servers	Yes, No	This option lets you use the INSERT...LOCATION SQL statement for a data flow that uses SAP Sybase IQ as the loader and SAP Sybase ASE or SAP Sybase IQ as the reader. The Data Services engine pushes down the SQL statement for the SAP Sybase IQ server location. Select Yes to use remote servers that have already been linked. To define a remote server, use the CREATE SERVER SQL statement in SAP Sybase IQ. To set up the remote login for users, use the CREATE EXTERNLOGIN SQL statement. For detailed information about the SQL statements, see the relevant SAP Sybase IQ product documentation.

Table 97: Aliases (Click here to create)

SAP Sybase IQ option	Possible values	Description
Aliases		Enter the alias name and the owner name to which the alias name maps.

3.2.2.7.2.16 Teradata

Table 98: Main window

Teradata option	Possible values	Description
Database version	Teradata `<version number>`	Select the version of your Teradata client. This is the version of Teradata that this datastore accesses.
Use data source name (DSN)	Check box selected or not selected	Select to use DSN to connect to the database. By default, this option is not selected and a server name (also known as DSN-less) connection will be used. For a DSN-less connection, you must fill in *Database server name*, *Database name*, and *Port*. If you select this checkbox, you must fill in *Data source name*
Database server name	Refer to the requirements of your database	Type the Teradata database server name. This option is required if you did not select *Use data source name (DSN)*.
Database name	Refer to the requirements of your database	Type the name of the database defined in Teradata. This option is required if you did not select *Use data source name (DSN)*.
Port	Four digit integer Default: 8888	Type the port number to connect to this database. This option is required if you did not select *Use data source name (DSN)*.
Data source name	Refer to the requirements of your database	Type the Data Source Name defined in the ODBC Administrator for connecting to your database. This option is required when you select *Use data source name (DSN)*.
User name	Alphanumeric characters and underscores	Enter the user name of the account through which the software accesses the database.
Password	Alphanumeric characters, underscores, and punctuation	Enter the user's password.

Table 99: General

Teradata option	Possible values	Description
Bulk loader directory	Directory path or click *Browse*	Enter the location where command and data files are written for bulk loading. For Solaris systems, the path name must be less than 80 characters. You can enter a variable for this option.
Bulk reader directory	Directory path or click *Browse*	Specify the directory on the Job Server where Teradata Parallel Transporter-specific files (con-

Teradata option	Possible values	Description
		trol and error files) are stored. If this option is left empty, the default location is `$LINK_DIR\log\BulkReader`.
Overflow file directory	Directory path or click *Browse*	Enter the location of overflow files written by target tables in this datastore. You can enter a variable for this option.

Table 100: Locale

Teradata option	Possible values	Description
Language		See the section "Locales and Multi-Byte Functionality."
Code page		See the section "Locales and Multi-Byte Functionality."
Server code page		See the section "Locales and Multi-Byte Functionality."
Teradata		
Log directory	Directory path or click *Browse*	The directory in which to write log files.
TdpId	Alphanumeric characters, underscores, and punctuation	Teradata Director Program Identifier which identifies the name of the Teradata database to load. If you use bulk loading, this identifier is mandatory.

Table 101: Session

Teradata option	Possible values	Description
Additional session parameters	A valid SQL statement or multiple SQL statements delimited by semicolons.	Additional session parameters specified as valid SQL statement(s). For example, to use the Table_Comparison transform with Teradata 13 and later tables as the comparison table and target table, you must do the following: ● On the Teradata server, set the *General* parameter *DBSControl* to TRUE to allow uncommitted data to be read. ● In the Data Services Teradata datastore, add the following statement in the "Additional session parameters" field: `SET SESSION CHARACTERISTICS AS TRANSACTION ISOLATION LEVEL READ UNCOMMIT-TED;`

Table 102: Aliases (Click here to create)

Teradata option	Possible values	Description
Aliases	-	Enter the alias name and the owner name to which the alias name maps.

3.2.2.7.3 Application datastores

The information you enter for a datastore depends on the type of datastore to which you are connecting. Application datastore types include:

Datastore type	More information
JDE OneWorld	Datastore configuration options for this datastore type vary depending on which database type you select. The JDE OneWorld datastore type works with the following database types: ● DB2 ● Microsoft SQL Server ● ODBC ● Oracle For details on configuring the datastore options for JD Edwards applications, refer to the *Supplement for J.D. Edwards*.
JDE World	For JDE World, Data Services supports the database type ODBC. For details on configuring the datastore options for JD Edwards , applications refer to the *Supplement for J.D. Edwards*.
Oracle Applications	For details on configuring the datastore options for Oracle applications, refer to the *Supplement for Oracle Applications*.
PeopleSoft	Datastore configuration options for this datastore type vary depending on which database type you select. The PeopleSoft datastore type works with the following database types: ● Microsoft SQL Server ● Oracle For more information about PeopleSoft applications, refer to the *Supplement for PeopleSoft*.
SAP Applications	The options for all SAP datastore types (SAP Applications, SAP BW Source, SAP BW Target, and SAP Master Data Services) are documented in the *Supplement for SAP*.
SAP BW Source	
SAP BW Target	
SAP Master Data Services	
Siebel	The Siebel datastore type works with the following database types:

Datastore type	More information
	• DB2 • Microsoft SQL Server • Oracle For more information about Siebel applications, refer to the *Supplement for Siebel*.
Web Service	The options for the Web Service datastore type are documented in the *Integrator Guide*.

After you create a datastore, you can import metadata about the objects, such as tables and functions, into that datastore.

3.2.2.8 Document

Class

Reusable

Access

In the object library, click the *Datastores* tab.

Description

Available in some adapter datastores, documents describe a data schema. Documents can support complicated nested schemas. You can use documents as sources or targets.

See your adapter's documentation for more specific information about the options available for documents.

3.2.2.9 DTD

Class

Reusable

Access

In the object library, click the *Formats* tab, then open the DTD category.

Description

A DTD (document type definition) describes the data schema of an XML message or file.

> **Note**
>
> XML Schemas can be used for the same purpose.

Data flows can read and write data to messages or files based on a specified DTD format.You can use the same DTD to describe multiple XML sources or targets.

To use DTDs, import metadata into SAP Data Services. You can import a DTD directly, or you can import an XML document that contains or references a DTD. During import, the software converts the structure defined in the DTD into the nested-relational data model (NRDM).

Related Information

XML schema [page 1008]
Rules for importing DTDs [page 911]

3.2.2.9.1 Editor

Open the DTD editor by double-clicking a DTD name in the object library.

Related Information

Designer Guide: Using Document Type Definitions (DTDs) [page 353]

3.2.2.9.2 Properties

DTDs have the following properties.

Property	Description
Name	The name of the format. This name appears in the object library under the Formats tab and is used for sources and targets (XML files or messages) that reference this format in data flows.
Description	Text that you enter to describe and document the DTD.
Imported from	The full path to the format. For example, `C:\data\test.dtd.` A variable can also be used.
DTD file	(Read-only) If the check box is selected, the DTD format was originally imported from a DTD file. Otherwise, it was imported from an XML file with an associated DTD.
Root element name	The name of the primary node of the XML that the DTD is defining. SAP Data Services only imports elements of the format that belong to this node or any sub nodes.

3.2.2.9.3 Attributes for DTDs

The following DTD attributes are supported.

Supported column attribute	Description
Enumeration	Contains a list of all possible values separated by vertical bars. For example: "Red | White | Blue Green | Magenta". A string display is cut off at 256 characters.
Fixed Value	The only value the column can have.
Native Type	String. The original data type of the of the element or attribute in the DTD.
Required	Indicates whether this column always has to be mapped (YES/NO). If a column is optional (required =no), then validation will allow mapping expressions to be missing for these columns and at runtime the engine will substitute NULLs for the missing values.
XML Type	Allows you to track whether the column was an element or attributes in the original DTD.

Supported nested table attribute	Description
Any One Column	If choice (for example, "white | black | almond"), then SAP Data Services sets the value of Any One Column to YES. If sequence (for example, "first, last, street, city, state") then the software sets the value to NO. If both are present in the DTD, the value is set to NO.
Minimum Occurrence	If ()* then minimum occurrence is set to zero. If ()+, then minimum occurrence is set to 1. Indicates minimum number of rows that can be in the table.

3.2.2.9.4 Supported DTD components

SAP Data Services reads the following DTD components. To process the data read in an XML file or message, the software translates the DTD into its internal nested-relational database model.

Each component in the DTD is defined by its `<content model>`. The software supports the declarations in XML content models as follows:

DTD declaration		Supported
DOCTYPE	SYSTEM	Supported.
	PUBLIC	No support.
Declarations	ELEMENT	Supported. The XML Type attribute of the corresponding column is set to Element.
	ATTRIBUTE	Supported. The XML Type attribute of the corresponding column is set to Attribute.
	ENTITY	Supported. All entity references that can be expanded are expanded. Any that cannot be expanded cause an error at the time that you import the DTD.
	NOTATION	No support. Elements defined with NOTATION cause an error at the time that you import the DTD.
Content model	ANY	No support. Elements defined with ANY cause an error at the time that you import the DTD.
	EMPTY	Supported.
	#PCDATA	Supported. Converts to varchar(1024).
	MIXED	Supported.
Attribute declarations	CDATA	Supported. Converts to varchar(1024).
	ID	Supported. Converts to varchar(1024). When producing XML output, the software cannot ensure that ID values are unique throughout the schema.
	IDREF	Supported. Converts to varchar(1024).
	IDREFS	Supported. Converts to varchar(1024).
	NMTOKEN	Supported. Converts to varchar(1024).
	NMTOKENS	Supported. The software treats multiple tokens as a single token with more than one space-separated values.
	Enumerated value	Supported. The software saves the enumerated values in the Enumeration attribute of the column. When producing XML output, the software checks to ensure that the value generated by the real-time job for the corresponding column is from the list; if no value is generated, the software uses the provided default value. If you validate XML messages against the DTD in a real-time job and the message includes a value that is not allowed based on the DTD, the XML source produces an error.
Attribute declaration defaults	#REQUIRED	Supported. The software saves this as the Required attribute with a value of `YES` and as data type `varchar(1024)`. When pro-

DTD declaration		Supported
		ducing XML output, the software always provides a value. If there is no value supplied, the output value is NULL (`''`).
	#IMPLIED	Supported. The software saves this as the Required attribute with a value of `NO` and as the data type `varchar(1024)`. When producing XML output, the software provides whatever value is generated in the data flow for the corresponding column, including a NULL value (`''`).
	#FIXED (default value)	Supported. The software saves this as the Fixed Value attribute and the data type `varchar(1024)`. When producing XML output, the software checks to ensure that the value generated by the real-time job for the corresponding column is from the list; if no value is generated, the software uses the provided default value.
	Default values	Supported. Converts to data type `varchar(1024)`. When producing XML output, the software uses the default value if the value generated in the real-time job for the corresponding column is NULL.

To produce a data model that can include all possible configurations of an element, the software can simplify some of the content model operations:

Operator	Description	Supported
No operator	One and only one	One and only one.
Comma (,)	Sequence	Supported. The software uses the ordering given in the DTD as the column ordering in the internal data set. Also the Any One Column attribute is set to a value of `NO`.
Vertical bar (|)	Choice (either/or)	Supported. The software uses the ordering given in the DTD as the column ordering in the internal data set. Also the Any One Column attribute is set to a value of `YES`. The internal data set must include both options.
Plus (+)	One or more	Supported. Saved as nested table attribute Minimum Occurrence with a value of "1". The internal data set must include options for one or more elements.
Asterisk (*)	Zero or more	Supported.

Operator	Description	Supported
		Saved as nested table attribute Minimum Occurrence with a value of "0". The software translates an item or grouping including zero or more items into a nested table.
Question mark (?)	Optional	Supported. The internal data set includes the Required attribute set to a value of NO for the corresponding column or nested table.
Parentheses ()	Group	Dropped. The internal data set does not maintain groupings unless the group is operated on by the * operator. If the group can allow more than one item, the software makes a new nested table into which it places the elements in the group.

After these simplifications, the software needs only work with two DTD operators: sequence (strict ordering) and the combined operators of the group operator with the zero or more item operator. For the purpose of representing the data internally in the software, all DTDs can now be written using only , or ()*.

3.2.2.9.5 Rules for importing DTDs

SAP Data Services applies the following rules to convert a DTD to an internal schema:

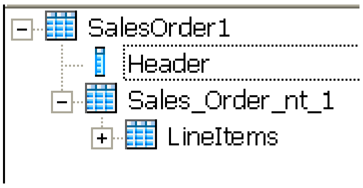
- Any element that contains an PCDATA only and no attributes becomes a column.
- Any element with attributes or other elements (or in mixed format) becomes a table.
- An attribute becomes a column in the table corresponding to the element it supports.
- Any occurrence of choice (,)or sequence (|) operators uses the ordering given in the DTD as the column ordering in the internal data set.
- Any occurrence of a multiple entities, such as ()* or ()$^{+}$, becomes a table with an internally generated name (an implicit table).
- The internally generated name is the name of the parent followed by an underscore, then the string "nt" followed by a sequence number. The sequence number starts at 1 and increments by 1.

After applying these rules, the software uses two additional rules, except where doing so would allow more than one row for a root element:

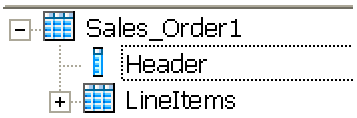
- If an implicit table contains one and only one nested table, then the implicit table can be eliminated and the nested table can be attached directly to the parent of the implicit table.
  For example, the SalesOrder element might be defined as follows in a DTD:

  ```
  <!ELEMENT SalesOrder (Header, LineItems*)>
  ```

  When converted into the software, the LineItems element with the zero or more operator would become an implicit table under the SalesOrder table. The LineItems element itself would be a nested table under the implicit table.



Because the implicit table contains one and only one nested table, the format would remove the implicit table.

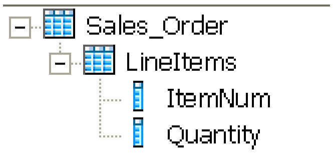


- If a nested table contains one and only one implicit table, then the implicit table can be eliminated and its columns placed directly under the nested table.
  For example, the nested table LineItems might be defined as follows in a DTD:

  ```
  <!ELEMENT LineItems (ItemNum, Quantity)*>
  ```

  When converted into the software , the grouping with the zero or more operator would become an implicit table under the LineItems table. The ItemNum and Quantity elements would become columns under the implicit table.

  
  Because the LineItems nested table contained one and only one implicit table, the format would remove the implicit table.

3.2.2.9.6 Design considerations

The following areas provide opportunities for you to improve performance and tune the nested-relational data model results for a given DTD:

- Recursion
  If the DTD contains an element that uses an ancestor element in its definition, SAP Data Services expands the definition of the ancestor for a fixed number of levels. For example, given the following definition of element "A":
  A: B, C
  B: E, F
  F: A, H

The software produces a table for the element "F" that includes an expansion of "A." In this second expansion of "A," "F" appears again, and so on until the fixed number of levels. In the final expansion of "A," the element "F" appears with only the element "H" in its definition.

- Repeated column names
  The software does not allow more than one column with the same name at the same level in a table. If the internal schema that the software produces from a DTD contains duplicate names, the software adds a suffix to each instance of the duplicated name to ensure unique column names. The suffix is an underscore followed by a sequence number, starting at 1 and incrementing by 1.
  A DTD can produce duplicate names when the DTD contains a repeated element at one level or an element with a scalar value with an attribute of the same name.
- Ambiguous DTDs
  You can create a DTD such that the software does not have enough information to make a unique decision when generating the internal data set. The software reacts to an ambiguous DTD by throwing an error for the XML message source at run time. An example of an ambiguous definition is as follows:

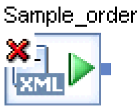
DTD	`A: ((B, (C)*) | (B, (D)*))+`
Schema in Data Services	`A: (B, (C)*, B, (D)*)*`

XML input	`A: <B>text</B>`
	`<D>1</D> <D>2</D>`

The software will use the B element data to populate the first B column, then use the D element data to populate the D element. If this data is then translated back into XML, it would be invalid relative to the DTD.

Metadata

If you delete a DTD from the object library, XML file and message sources or targets that are based on this format are invalid. The software marks the source or target objects with an icon that indicates the calls are no longer valid.



To restore the invalid objects, you must delete the source or target and replace it with a source or target based on an existing DTD.

3.2.2.9.7 Error checking

You can control whether SAP Data Services checks each incoming XML file or message for validity. If you choose to check each XML file or message, the software uses the DTD imported and stored in the repository rather than a DTD specified by a given XML file or message. If a file or message is invalid relative to the DTD, the real-time job produces an error and shuts down.

During development, you might validate all files and messages to test for error conditions. During production, you might choose to accept rare invalid files or messages and risk ambiguous or incorrect data.

All files or messages that the software produces for an XML file or message target are validated against the imported DTD.

You can enable or disable validation for an XML file or message source or target in that object's editor.

3.2.2.10 Excel workbook format

Class

Reusable

Access

In the object library, click the *Formats* tab.

Description

An Excel workbook format describes the structure defined in an Excel workbook (denoted with a .xls extension). You store format templates for Excel data ranges in the object library. You use the template to define the format of a particular source in a data flow. SAP Data Services accesses Excel workbooks as sources only (not as targets).

You can define the format schema by:

- Import the Excel metadata from a sample Excel workbook and create the schema automatically. You can opt to import the schema from:
    - A named range defined in an Excel workbook.
    - A custom range in a worksheet (for example A1:C10).
    - All fields. Note that the field range does not necessarily begin on row 1, column 1; it starts at the upper left-most cell in the worksheet that contains data.

  After you select an access method, import the schema by clicking Import schema.

  > i Note
  >
  > Importing overwrites the existing schema.

After you import, you can edit column names, data types, and content types in the schema pane at the top of the window. You can optionally add descriptions for each column.

- You can manually define (enter) column names, data types, content types and descriptions in the schema pane at the top of the window.

You will see Blank if the content type cannot be automatically determined for a column.

3.2.2.10.1 Notes

- If SAP Data Services cannot determine the data type for a column, for example if your column selection doesn't contain any data, it imports the column as varchar(255).
- If the worksheet is empty and you select the *All fields* option, the software creates a single field, F1 varchar(255).
- For workbook-specific (global) named ranges, the software would name a range called *range* as *range*. However for worksheet-specific (local) named ranges, the software would name a range called *range* that belongs to the worksheet *Sheet1* as *range!Sheet1*.
  In UNIX, you must also include the worksheet name when defining a workbook-specific (global) named range.
- Because the software reads stored formula values, incorrect values could result if Excel does not exit properly. Close and reopen the file in Excel to refresh the values.
- If an invalid Excel formula displays an error such as #DIV/0, #VALUE or #REF!, the software processes the cell as NULL.
- You cannot import or process a password-protected workbook.
- The software might not be able to import or process blank worksheet names or those that contain special characters such as /?:!*[]`.

3.2.2.10.2 Import or Edit Excel workbook format options

The top panel of the *Import* or *Edit Excel Workbook* window displays:

- *Format name:* The name of the Excel workbook format template in the object library. In the *Import Excel Workbook* window, you can define the name of the format.
- *Schema pane*: This pane lets you manually define (or edit) the schema of the Excel workbook template.

The Import (and Edit) Excel workbook format dialog boxes include options on the *Format* and *Data Access* tabs.

Format tab

The *Format* tab defines the parameters of the Excel workbook format.

Format option	Description
Directory	Specify the directory that contains the Excel workbook. You can specify variables or wild cards, but the *Import schema* button will then be disabled.
File name	Specify the file name for the Excel workbook file. This file contains the schema definition. You can specify variables or wild cards, but the *Import schema* button will then be disabled.
Access method	Specifies whether to import a named range (as defined in Excel) or a range from a worksheet: *Named range*—The drop-down box displays named ranges defined in the Excel workbook (provided that the directory/file name combination refers to a valid file). You can also type the name manually. Note The drop-down does not display non-contiguous named ranges, even if they exist in the Excel workbook. *Worksheet*—You can select a specific worksheet by either name or ordinal number (select the *Number* check box to designate the worksheet name as a number). The drop-down box displays all worksheets in the Excel workbook (provided that the directory/filename combination refers to a valid file). You can also type the name manually. Note If the worksheet name starts with a dollar sign ($), Data Services treats it as a variable; to use a worksheet name that starts with a dollar sign, prefix (escape) it with a backslash (\). The Worksheet method includes the following *Range* options: ● *All fields*—Includes everything from the uppermost left-hand populated cell to the lowest, right-hand cell. ● *Custom range*—Uses Excel notation, for example A1:B3. Click the button to the right of the field to launch a new instance of Excel (if installed) to select the cell range directly in the worksheet. Note Subsequently making the software the active window closes this Excel instance. *Extend range*—If you are using a custom range, select this check box to extend the custom range selection to the end of the worksheet.

Format option	Description
Code page	Specifies the character encoding (code page) of the character data in the Excel workbook. For more information, see the Locales and Multi-Byte Functionality section in the *Reference Guide*.
Use first row values as column names	Select to use the first-row values as column names. If this check box is cleared, then the software names the fields for you (F1 represents the first field, F2 represents the second field, and so on).

Data Access tab

The Data Access tab specifies how the software accesses the data file. If both the *FTP* and *Custom* check boxes are cleared, the software assumes the data file is on the same computer as the Job Server.

Data access option	Description
FTP	Select to use FTP to access the data file.
Host	Type the computer (host) name, fully qualified domain name, or IP address of the computer where the data file resides.
User	Type the FTP user name.
Password	Type the FTP user password.
Directory	Type or browse to the directory that contains the Excel workbook data file to import. If you include a directory path here, then enter only the file name in the *Name* field.
File name	Type or browse to the Excel workbook data file *Name*. You can use variables or wild cards (* or ?). If you leave *Directory* blank, then type a full path and file name here.
Custom	Select to use a custom executable to access the data file.
Executable	Type the name of the program to read data file.
User	Type the user name.
Password	Type the password.
Arguments	Include any custom program arguments.

3.2.2.10.3 Excel workbook source options

The source editor includes the following Excel workbook options on the following tabs. Note that many fields in the source editor allow you to select from a list of variables.

- Source tab
- Format tab
- Data Access tab

Source tab

Source option	Description
Make port	Makes the source table an embedded data flow port.

Table 103: Performance

Source option	Description
Join rank	Indicates the rank of the source relative to other tables and files joined in a data flow. The software joins sources with higher join ranks before joining sources with lower join ranks. Join rank specified in the Query transform editor FROM tab overrides any join rank specified in a source. For new jobs, specify the join rank only in the Query transform editor. Must be a non-negative integer. Default value is 0. For more information, see the Other Tuning Techniques section in the *Performance Optimization Guide*.
Cache	Indicates whether the software should read the required data from the source and load it into memory or pageable cache. Because an inner source of a join must be read for each row of an outer source, you might want to cache a source when it is used as an inner source in a join. Options are: • *Yes*: The source is always cached unless it is the outer-most source in a join. • *No*: The source is never cached. The default is *Yes*. Cache specified in the Query transform editor FROM tab overrides any cache specified in a source. For new jobs, specify the cache only in the Query transform editor.
Skip all empty rows	Select to skip any rows that are empty in the workbook. Clear to also import empty rows, which will display as NULLs.

Table 104: Error handling

Source option	Description
Log errors to file	Specifies whether to produce an error report. Defaults to unchecked. Columns with run-time conversion errors will contain NULLs.
Maximum errors to log	If *Log data conversion warnings* is enabled, you can limit how many warnings the software logs. Defaults to *{no limit}*.
Error file directory	Type or browse to the directory in which to store the error file.
Error file name	Type or browse to the error file name.

Table 105: Include file name column

Source option	Description
Include file name column	Determines whether to add a column that contains the source Excel workbook file name in the source output. Defaults to *No*. Change the value to *Yes* when you want to identify the source Excel workbook file in situations such as the following: ● You specified a wildcard character to read multiple source Excel workbook files at one time ● You load from different source workbook files on different runs
Modify	If the file name is included, this button enables you to modify *File name column* and *Column size*.
File name column	If the file name is included, the name of the column that holds the source Excel workbook file name. Defaults to *DI_FILENAME*.
Column size	If the file name is included, the size (in characters) of the column that holds the source Excel workbook file name. Defaults to *100*. If the size of the file name column is not large enough to store the file name, truncation occurs from the left.
Include path	If the file name is included, determines whether to include the full path name of the source Excel workbook file. Defaults to *No*.

Table 106: Other options

Source option	Description
Skip first	Optionally enter the number of rows to skip (not read) starting at the top of the worksheet. Defaults to *{none}*.
Read total	Optionally enter the number of total rows to read starting at the top of the worksheet or after the *Skip first* value. Defaults to *{no limit}*.

Related Information

Designer Guide: Embedded Data Flows [page 391]

3.2.2.11 File format

Class

Reusable

Access

In the object library, click the *Formats* tab.

Description

A file format describes the structure of an ASCII file. You store templates for file formats in the object library. You use the templates to define the file format of a particular source or target file in a data flow.

A file format consists of multiple properties. You set the properties in the *File Format Editor*. Available properties vary by the mode of the *File Format Editor*. The modes are as follows:

Mode	Description
New	Use to create a new file format template. To open in new mode, go to the *Formats* tab in the object library, right-click *Flat Files*, and select *New*. The *File Format Editor* appears.
Edit	Use to edit an existing file format template. To open in edit mode, go the *Formats* tab in the object library, select an existing flat file format, double-click, or right-click and select *Edit*. The *File Format Editor* appears.
Source	Use to edit the file format of a particular source file. To open in source mode, click the name of the source file in the workspace. The *File Format Editor* appears below the file's schema.

Mode	Description
Target	Use to edit the file format of a particular target file. To open in target mode, click the name of the target file in the workspace. The *File Format Editor* appears below the file's schema.

The work area on the left, in the *File Format Editor* lists file format properties that are not field specific. The following table lists all of the options. These options are filtered by the mode you are using.

Option	Possible values	Description	Mode
General			
Type	Delimited, Fixed width, SAP transport, Unstructured text, Unstructured binary	The format of the data in the text file. Available properties change based on the selected file format type. For information about the SAP transport file format, see the *Supplement for SAP*.	New, Edit
Name	Any alphanumeric character and underscores	A descriptive name for the file format. This name appears in the object library.	New
Join rank	Integer greater than or equal to 0	Indicates the rank of the source relative to other tables and files joined in a data flow. The software joins sources with higher join ranks before joining sources with lower join ranks. Join rank specified in the Query transform editor FROM tab overrides any join rank specified in a source. For new jobs, specify the join rank only in the Query transform editor. Must be a non-negative integer. Default value is 0. For more information, see the “Other Tuning Techniques” section in the *Performance Optimization Guide*.	Source
Cache	Yes, No	Indicates whether the software should read the required data from the source and load it into memory or pageable cache. Because an inner source of a join must be read for each row of an outer source, you might want to cache a source when it is used as an inner source in a join. Options are: ● *Yes*: The source is always cached unless it is the outer-most source in a join. ● *No*: The source is never cached. The default is *Yes*.	Source

Option	Possible values	Description	Mode
		Cache specified in the Query transform editor FROM tab overrides any cache specified in a source. For new jobs, specify the cache only in the Query transform editor.	
Adaptable schema	Yes, No	Indicates whether the schema of a delimited file format is adaptable or fixed. ● *Yes*: Indicates that the schema is adaptable. The actual file can contain fewer or more columns than indicated by the file format. If a row contains fewer columns than expected, the software loads null values into the columns missing data. If a row contains more columns than expected, the software ignores the additional data. ● *No*: Indicates that the schema is fixed. The software requires the number of columns in each row to match the number of columns specified in the file format. The default is *No*. If you select *Yes*, you must ensure that the selected column and row delimiters do not appear inside the actual data.	New, Edit, Source
Data Alignment	Character, Byte	Indicates how the software will process fixed-width file formats. The default setting is *Character*. *Character* indicates that fields in your data are measured as character. All processing will be in character semantics. *Byte* indicates that fields in your data are measured as bytes. All processing will be in byte semantics. For example, in character semantic, if you define a column as varchar(30), it means that the column has 30 characters regardless of the number of bytes for each character. In byte semantic, varchar(30) means 30 bytes. Byte semantic recognizes bytes only, it does not recognize characters. Note The reader reads as many bytes in a column based on the length of the column. For multibyte code pages, a character can be more than one byte. There could be times when trailing bytes of the last character of a column exceeds the length of the column. When this happens the reader continues reading until it gets to the total length of the character. Also in this situation, the loader writes as many bytes as what is specified for the length of the column. The loader then truncates trailing bytes if they exceed the length of the column and the code page is multibyte. Therefore there is a potential for partial characters in the file. When this happens, errors are only logged in the reader. You can specify the error logging options in the *File Format Editor*.	New, Edit

Option	Possible values	Description	Mode
Make port	Yes, No	Indicates whether the file is an embedded data flow port. Choose *Yes* to make a source or target file an embedded data flow port. The default is *No*. For more information, see "Creating embedded data flows" in the *Designer Guide*.	Source, Target
Rows to read	Integer or blank	Indicates the maximum number of rows that the software reads. The default is blank. If the value is zero or negative, the software reads all rows.	Source
Custom transfer program	Yes, No	Enables the software to use a third-party file transfer program. Displays additional Custom transfer program options in the *File Format Editor* below the Input/Output properties.	All
Skip error handling	Yes, No	Selecting *Yes* disables the Error Handling section in the Format editor. The default is *No.*	New, Edit, Source
Parallel process threads	Integer greater than 0, {none}, {default}	Specifies the number of threads for parallel processing, which can improve performance by maximizing CPU usage on the Job Server computer. For example, if you have four CPUs, enter 4 for this option. For more information, see "File multi-threading" in the *Performance Optimization Guide*. For jobs that process USPS certification tests, the value should be set to *{none}*.	All
Data File(s)			
Location	Local, Job Server	During design, indicates whether files are located on the local machine that runs the Designer or on the machine that runs the Job Server. If you select Job Server, you must enter the absolute path to files. Remember that UNIX systems are case-sensitive. During execution, all files must be located on the Job Server machine that executes the job. If you use different files to design your job, change the file specified (through the Root directory and File properties) before execution.	All
Root directory	Path name for the file or blank	The directory where the file is located. For added flexibility, you can enter a variable for this option. If you enter a directory name, then enter only the file name for the *File* property. If you leave the root directory blank, then enter a file name that includes the full path name in the *File* property.	New, Edit
File name(s)	File name(s), file name(s) including full	In new and edit modes, specifies an existing file on which you base the file format description. Data from this file appears in the Col-	All

Option	Possible values	Description	Mode
	path name, or blank	umn Attributes area. In these modes, you can leave this property blank. In source and target modes, specify the location of the actual file for this source or target. In these modes, you cannot leave this property blank. For added flexibility, you can enter: ● A variable that is set to a particular file with full path name. Use variables to specify file names that you cannot otherwise enter, such as file names that contain multi-byte characters. ● A list of files, separated by commas, or a file name containing a wild card. In this case, the software reads all these files as a single source. See “Reading multiple files at one time” in the *Designer Guide*.	
Read subfolders	Yes, No	For unstructured file formats, specifies whether to read the files in any and all nested subfolders.	New, Edit, Source
Skip empty files	Yes, No	For unstructured file formats, specifies whether to ignore empty files. ● *Yes*: Skips empty files. ● *No*: Creates a row with NULL data.	New, Edit, Source
Number of files to read	Integer or {none}	For unstructured file formats, indicates the maximum number of files to read. A zero or negative value reads all files. The default is {none}.	Source
Delete file	Yes, No	Specifies whether the software should delete the file before loading. ● *Yes*: Indicates that the software should delete the file before loading. ● *No*: Indicates that the software should append to the existing file.	Target
Delimiters			
Column	Tab, Semicolon, Comma, Space, or any character sequence	For delimited file formats, this is the character sequence that indicates the end of one column and the beginning of the next.	New, Edit
Row	{new line}, {Windows new line}, {Unix new line}, or any character sequence	A character sequence that indicates where one row of data ends and the next begins.	New, Edit

Option	Possible values	Description	Mode
Row within text string	Character, Row delimiter	Defines how the row delimiter is interpreted within a text string. • *Character*: The specified row delimiter is treated as characters within the text string. • *Row delimiter*: The specified row delimiter is interpreted and defines rows within the text string.	New, Edit
Text	Single quotation marks ('), double quotation marks ("), or {none}	Denotes the start and end of a text string. All characters (including those specified as column delimiters) between the first and second occurrence of this character is a single text string. The treatment of the row characters is defined by the *Row within text string* setting.	New, Edit
Note Data in columns cannot include the column or row delimiter, unless you also specify a text delimiter. For example, if you specify a comma as your column delimiter, none of the data in the file can contain commas. However, if you specify a comma as the column delimiter and a single quote as the text delimiter, commas are allowed in strings in the data. You can use any ASCII characters (including non-printing characters) for column and row delimiters. You can specify an ASCII character by entering a forward slash (/) followed by the decimal representation of the character. For example, to use Y umlaut (Ÿ) as a delimiter, enter /255 in the delimiter property box.			
Default Format			
Escape char	Any character sequence, or {none}	A special character sequence that causes the software to ignore the normal column delimiter. Characters following the escape character sequence are never used as column delimiters. For example, suppose you specify a forward slash as the escape character and a comma as the column delimiter. Then, you must have a forward slash to have a comma appear inside a field.	New, Edit
NULL indicator	{none} or any other character sequence	Special character sequence that the software interprets as NULL data. The software ignores any NULL indicator specified in the file format for blob columns.	New, Edit
Ignore row marker(s)	{none} or any other character sequence	Character sequence, which when found at the beginning of rows, cause the software to ignore the row when reading the file or automatically creating metadata. To enter multiple character sequences, separate each with a semi-colon. To include a semi-colon or backslash as a marking character, precede with a backslash.	New, Edit, Source
Blank padding	leading, trailing	For fixed-width file format targets, pads extra blank spaces before or after the fields. • *Leading*: Adds blanks to the left of (before) the data.	New, Edit

Option	Possible values	Description	Mode
		- *Trailing*: Adds blanks to the right of (after) the data.	
Blank trimming	leading, trailing, both, or none	For fixed-width file format sources, trims extra blank spaces before or after the fields. - *Leading*: Trims blanks from the left of (before) the data. - *Trailing*: Trims blanks from the right of (after) the data.	New, Edit
Date	yyyy.mm.dd or other combinations	The date format for reading or writing date values to and from the file.	New, Edit
Time	hh24:mi:ss or other combinations	The time format for reading or writing time values to and from the file.	New, Edit
Date-Time	yyyy.mm.dd hh24:mi:ss or other combinations	The datetime format for reading or writing datetime values to and from the file.	New, Edit
Validate decimal data	Yes, No	For file targets, by default, the software converts data in delimited files to the decimal data type (even if it is in string form due to lazy decimal conversion) to make sure that the decimal format is valid. Note Lazy decimal conversion is an optimization whereby the data for columns of type DECIMAL is stored as STRING data type in rows and is converted to internal DECIMAL format only when they are used in an operation. To improve performance, you can manually deselect this conversion and validation operation. In the Target File Editor, set *Validate decimal data* to No.	Target
Input/Output			
Style	Headers or BOF/EOF	The format of the start and end of the file. Available properties in the Input/Output property group may change, based on this selection.	New, Edit
Skipped rows	Integer	For file formats using Headers style, the number of rows skipped when reading the file. Specify a non-zero value when the file includes comments or other non-data information.	New, Edit

Option	Possible values	Description	Mode
Skip row header	Yes, No	For file formats using Headers style, indicates whether the first row of data in the file contains the column names and should be skipped when reading the file. The software uses this property in addition to the *Skipped rows* property. When you select *Yes*, the software does not read data from the first row, and uses data in the first row to determine the file's column names.	New, Edit
Write row header	Yes, No	For file formats using Headers style, indicates whether to write column names in first row of output file.	New, Edit
Write BOM	Yes, No	For file formats using UTF-8 and UTF-16, determines the writing of BOM characters into the file. Choose Yes if you want to include BOM characters into a UTF-8 or UTF-16 file in which byte order is not otherwise defined. For a UTF-16 file, the software assumes the file to be UTF-16be, unless BOM characters are added by this property.	New, Edit
BOF Marker	Any character sequence, including a blank space, an empty string, or {none}	For file formats using BOF/EOF style, the string that marks the start of data in the file.	New, Edit
EOF Marker	Any character sequence, including a blank space, an empty string or {none}	For file formats using BOF/EOF style, the string that marks the end of data in the file.	New, Edit
Custom Transfer			
Program executable	File name	(Required) The name of the custom transfer program or its initialization script. For example: MyProgram.exe or MyProgram.cmd.	New, Edit
User name	Any character sequence, including a blank space, an empty string or {none}	(Optional) Log in ID for the server to which the custom transfer program connects. You may want to allow a custom program user to enter their user name when they enter their password in the software.	New, Edit
Password	Any character sequence, including a blank space,	(optional) Password for the server to which the custom transfer program connects. Passwords entered into this option are encrypted.	New, Edit

Option	Possible values	Description	Mode
	an empty string or {none}		
Arguments	Any character sequence, including a blank space, an empty string or {none}	(optional) You can create arguments in your custom transfer program and then specifically flag them from within the software using this box. For example, you might have security or compression mechanisms in your program. You can also link connection data to your transfer program's flags.	New, Edit
Locale	For more information about locales for sources, targets, and the software's internal processing, see *Locales and Multi-byte Functionality* [page 1793].		
Language	The three-letter language abbreviations specified in the ISO 639-2/T standard	Specifies the human language (for example, Korean, Japanese, or English) in which data is stored or processed. Select from the displayed list.	New, Edit
Territory	The two-letter territory abbreviations specified in the ISO 3166-1 standard.	Represents the geographical location (usually the country) where the language is used. The paring of a language and a territory determines factors such as date format, time format, decimal separator, and so on. For example, English is used differently in the United States and the United Kingdom.	New, Edit
Code Page	Shows the list of supported code pages. See Supported Locales and Encodings.	Specifies the sequence of bits that defines a character. For example, the Japanese code page contains ASCII, Greek, Cyrillic, and Japanese characters, thereby supporting the English, Greek, Russian, and Japanese languages.	New, Edit
Error Handling			
Log data conversion warnings	Yes, No	Determines whether to include data-type conversion warnings in the error log. Defaults to *Yes*.	New, Edit, Source
Log row format warnings	Yes, No	Determines whether to include row-format warnings in the error log. Defaults to *Yes*.	New, Edit, Source

Option	Possible values	Description	Mode
Log warnings	Yes, No	For unstructured file formats, determines whether to log warnings including: - When there are no files in the specified directory. - When no files match the specified filter. - When skipping an irregular file on UNIX (for example, a FIFO, symbolic link, character or block device, or UNIX socket). - When encountering an empty file with *Skip empty files* set to *Yes*.	New, Edit, Source
Maximum warnings to log	Integer greater than 0 or {no limit}	If *Log data conversion warnings* or *Log row format warnings* is enabled, you can limit how many warnings the software logs. Defaults to *{no limit}*.	New, Edit, Source
Capture data conversion errors	Yes, No	Determines whether to capture data-type conversion errors when processing a flat-file source. Defaults to *No*.	New, Edit, Source
Capture row format errors	Yes, No	Determines whether to capture row-format errors when processing a flat-file source. Defaults to *Yes*.	New, Edit, Source
Capture file access errors	Yes, No	For unstructured file formats, determines whether to log file-access errors when processing a flat-file source. Defaults to *Yes*.	New, Edit, Source
Capture string truncation error	Yes, No	Determines whether to capture string truncation errors when processing a flat-file source. Defaults to *No*.	New, Edit, Source
Maximum errors to stop job	Integer greater than 0 or {no limit}	If *Capture data conversion errors* or *Capture row format errors* is enabled, you can limit how many invalid rows the software processes before stopping the job. Defaults to *{no limit}*.	New, Edit, Source
Write error rows to file	Yes, No	Determines whether to write invalid rows to an error file. Defaults to *No*.	New, Edit, Source
Error file root directory	Directory path or blank	If *Write error rows to file* is enabled, type the root directory in which to save the error file. For added flexibility, you can enter a variable for this option. If you type a directory path here, then only enter the file name in the *Error file name* property. If you leave *Error file root directory* blank, then type a full path and file name in the *Error file name* property.	New, Edit, Source
Error file name	File name, file name including full path name, or blank	If *Write error rows to file* is enabled, type the name of the file in which to record the invalid rows. For added flexibility, you can enter a variable that is set to a particular file with full path name. Use variables to specify file names	New, Edit, Source

Option	Possible values	Description	Mode
		that you cannot otherwise enter such as file names that contain multi-byte characters.	
Source Information			
Include file name column	Yes, No	Determines whether to add a column that contains the source file name in the source output. Defaults to *No*. Change the value to *Yes* when you want to identify the source file in situations such as the following: ● You specified a wildcard character to read multiple source files at one time. ● You load from different source files on different runs.	Source
Column name		If the file name is included, the name of the column that holds the source file name. Defaults to *DI_FILENAME*.	Source
Column size		If the file name is included, the size (in characters) of the column that holds the source file name. Defaults to *100*. If the size of the file name column is not large enough to store the file name, truncation occurs from the left.	Source
Include path		If the file name is included, determines whether to include the full path name of the source file. Defaults to *No*.	Source

The Column Attributes work area in the *File Format Editor* contains properties about the fields in the file format.

Property	Possible values	Description
Field name	Any sequence of letters or numbers, not including blank spaces	A name that identifies data in this column. If your file format uses the Headers style and you select *Yes* for the *Write row header* property, the software writes the field names in the target file.
Data type	blob, date, datetime, decimal, double, int, long, numeric, real, time, timestamp, varchar	The data type of values in this column. The long data type is not available in fixed-width formats.
Field size	Positive integer	If the data type is blob or varchar, specifies the number of characters in the field. For a blob column, the minimum field size is 1 and the maximum field size is 32768.
Precision	Positive integer	If the data type is decimal or numeric, specifies the total number of digits in the field.
Scale	Positive integer	If the data type is decimal or numeric, specifies the number of digits to the right of the decimal point.

Property	Possible values	Description
Format	{none}	For all data types other than varchar, specifies the format for this particular field. You can use this property to overwrite the default format. For example, if one date field is different than others, you can specify the different format here.
Content Type	{blank}, Address, Address_Primary_Name, Address_Primary_Number, Address_Primary_Postfix, Address_Primary_Prefix, Address_Primary_Type, Address_Secondary_Number, Country, Date, Delivery Point, DPV Status, Email, Family_Name1, Family_Name_Match_Std, Family_Name2, Family_Name2_Match_Std, Firm, Firm_Location, Firm_Location_Match_Std, Firm_Match_Std, Given_Name1, Given_Name1_Match_Std, Given_Name2, Given_Name2_Match_Std, Group_Number, Locality, Lot, Lot_Order, Name, Names_And_Firms, Phone, Postcode, Postcode1, Postcode2, Postname, Postname_Match_Std, Prename, Prename_Match_Std, Region, Sortcode_Rte, SSN, Title, Title_Match_Std	The name that specifies the type of data in a column. Typically use the field name, or a name similar to the field name. For example, if your field name is LastName, you may want to name the content type Family_Name.

If you delete a file format template from the object library, you must also delete all file sources and targets that are based on that file format template.

3.2.2.12 Function

ƒ

Class

Reusable

Access

- For existing functions, click the *Functions* button in object editors.
- For imported functions, in the object library, click the *Datastores* tab, expand a datastore, and expand the *Functions* node.
- For custom or validation functions, click the *Custom Functions* tab in the object library or select *Tools* > *Custom Functions*.

Description

Use functions to process values. There are several types of functions:

- Built-in functions
- DBMS and application functions or stored procedures imported into SAP Data Services
- Custom functions you create
- Validation functions that you can import from SAP Information Steward or create locally

Functions have the following common attributes:

Attribute	Description
Name	The name of the function. This name appears in the function wizard and smart editor. It is also used when the function appears in a script or expression.
Description	Descriptive text entered when the function is created or imported into the software.
Function type	Each imported or custom function has a type. For imported and custom functions, right-click the function from the object library and select *Properties* to view the type. Descriptions and syntax for built-in functions is listed in the function wizard and the smart editor. Some funcitons also include a Category designation on the *Function* tab of the Properties dialog box.
Enable Parallel Execution	Check box on the Properties dialog box. Enables the software to run stored procedures and custom functions in parallel. This option must be selected in addition to entering a positive number for the parent data flow's degree of parallelism. For more information, see "Degree of parallelism" in the *Performance Optimization Guide*.
Validation function	Check box on the Properties dialog box indicating if the function is a validation function.

Related Information

Functions and Procedures [page 1511]

3.2.2.13 HDFS file format

Class

Reusable

Access

In the object library, click the *Formats* tab.

Description

An HDFS file format describes the structure of a Hadoop distributed file system. You can store templates for HDFS file formats in the object library. The format consists of multiple properties that you set in the editor. Available properties vary by the mode of the editor.

The HDFS file format editor includes most of the regular file format editor options plus the following options that are particular to HDFS. For a description of the modes and additional file format options, see *File format* [page 920].

After you add an HDFS file format to a data flow as a source or target, these options are also available in the source and target file editors.

Option	Possible values	Description	Mode
Data File(s)			
NameNode host	Computer name, fully qualified domain name, IP address, or variable	Name of the NameNode computer. If you use the default settings of *default* for NameNode host and *0* for NameNode port, the local Hadoop system uses what is set as the default file system in the Hadoop configuration files.	All
NameNode port	Positive integer or variable	Port on which the NameNode listens.	All
Hadoop user	Alphanumeric characters and underscores or variable	Hadoop user name.	All

Option	Possible values	Description	Mode
Pig			
Working directory	Directory path or variable	The pig script uses this directory to store intermediate data. If left blank, Data Services creates and uses the directory `/user/sapds_temp`, which is within HDFS.	All
Clean up working directory	Yes, No	Select *Yes* to delete the Pig output file and other intermediate files such as scripts and log files (including the `$LINK_DIR/log/hadoop` directory) after job execution. If *No* is selected, intermediate files remain in both the Pig Working Directory and the Data Services directory `$LINK_DIR/log/hadoop`.	All
Custom Pig script	Directory path or variable	Specify the location of a custom Pig script to run and use as an input for your job. A custom Pig script can contain any valid Pig Latin command, including calls to any MapReduce jobs that you want to use with Data Services. See the Pig documentation for information about Pig Latin commands. Custom Pig scripts must reside on and be runnable from the local file system of the machine that contains the Data Services Job Server configured for Hadoop (not on HDFS). Any external references or dependencies in the script should be available on the machine. To test your custom Pig script, you need to execute the script from the command prompt and check that it finishes without errors. For example, you could use the following: `$ pig -f myscript` In the Designer, you also need to do the following: 1. In the Format tab, right-click on HDFS Files and select *New*. The HDFS File Format Editor opens. 2. In the General section, set the *Type* option to Delimited. 3. In the Data File(s) section, set *Root directory* to the output location of the custom Pig script and *File name(s)* to the name of the files created (usually part*). 4. In the Pig section, set *Custom Pig script* to the path of the custom Pig script on the machine that contains the Data Services Job Server. 5. Define the schema of the output for the custom Pig script. 6. Set the delimiters to match the output. At this point, the file format can be used as a source. When you run the job, the custom Pig script also runs and you can then use the results for the rest of the job.	All

Option	Possible values	Description	Mode
Locale			
Code page	<default> us-ascii	For better performance, select *<default>* (UTF-8) or *us-ascii*, which are supported by Pig. For other code pages, Data Services uses HDFS API-based file reading.	All

Related Information

File format [page 920]
Hadoop [page 1841]

3.2.2.14 Log

Class

Single-use

Access

- To see the logs for jobs run on a particular Job Server, log in to the repository associated with the Job Server when you open the Designer. In the project area of the Designer, click the *Log* tab, and expand the job tree.
- To see the logs for jobs run on a particular Job Server, in the Administrator, select *Batch Jobs* > *Repository* (selecting the repository associated with the Job Server). Then, in the *Job Information* column for a job execution, click the type of log you want to view.

Description

A log records information about a particular execution of a single job.

- The *Log* tab in the Designer displays all logs for each execution. When you are finished with the logs for a given job or project, delete them from the *Log* tab. Right-click the log and select *Delete Log*.
- The *Job Information* column, of the Batch Job Status page in the Administrator also displays all logs for each execution.

There are three types of logs:

- Trace logs

- Monitor logs
- Error logs

Related Information

Trace logs [page 936]
Monitor logs [page 937]
Error logs [page 938]

3.2.2.14.1 Trace logs

The tracelog shows the execution progress through each component (object) of the job. It lists the process ID, thread ID, the object type being executed, the time each event began, and a description of the event.

For unsuccessful jobs, use the trace log to see which components of a partially executed job completed or where an error occurred.

Trace logs have the following information:

Entry	Description
Pid	Indicates the process identification number of the thread executing.
Tid	Indicates the thread identification number of the thread executing.
Type	Indicates the object being executed, such as a data flow or a transform. The generic job events are labeled TRACE. Possible types are listed and described in the following table.
TimeStamp	Indicates the date and time when the thread generated the message.
Message	Gives a description of the event that occurred as the thread was executing.

There are several types of traces.

Error number prefix	Description
ABAP	Traces the ABAP query execution.
ADMIN	Prints administrative information like "server not responding" or "power failure."
BLKLOAD	Traces bulk loading.
DATAFLOW	Traces the data flow execution.

Error number prefix	Description
EMAIL	Traces e-mail messages.
FTP	Traces FTP transport.
JOB	Traces the job execution.
OPTIMIZE	Records optimized details.
REPO	Traces objects in the repository.
ROW	Traces the row as it passes from one transform to another. It prints the row that is input to the transform and the output row it generates.
SQLFUNC	Traces function execution.
SQLLOAD	Traces loader execution, including the SQL sent to the target database.
SQLREAD	Traces reader execution, including the SQL sent to the source database.
SQLTRAN	Traces SQL transforms such as Table_Comparison and Key_Generation. The trace includes the SQL query sent to the underlying database and SQL results returned.
TRAN	Traces the transform execution.
USERFUNC	Traces user functions.

Related Information

Performance Optimization Guide: Checking system utilization [page 2108]

3.2.2.14.2 Monitor logs

The monitor log quantifies the activities of the components of the job. It lists the time spent in a given component of a job and the number of data rows which streamed through the component.

Use the monitor log to help tune the performance of a job.

Monitor logs have the following information:

Entry	Description
Path Name	Indicates which object is executing. The path name has the following format: `<dfname[_subdataflownumber]/objectname >`

Entry	Description

	where
	• **`<dfname>`** is the name of the data flow
	• **`<_subdataflownumber>`** is the number of the sub data flow if SAP Data Services split the data flow into multiple sub data flows
	• **`<objectname >`** is the name of the source, transform, or target that the data flow is processing
	For example, the following path name is for the first sub data flow of a data flow named Orders_DF, and the object being processed is a source named Order Details:
	`/Orders_DF_1/ORDER DETAILS`
	The next example is a path name for the first sub data flow of the Orders_DF data flow, and the object being processed is temporary storage for data from Order Details. The '`TS`' indicates that this object is temporary storage, and '`ORDERTEMP`' is the name of the temporary storage specified in the Data_Transfer transform.
	`/Orders_DF_1/TS_ORDER DETAILS_ORDERTEMP`
	The next example is a path name for the second sub data flow of the Orders_DF data flow, and the object being processed is a query transform:
	`/Orders_DF_2/Query`

State	Indicates the current status of the execution of the object. If you view the log while the job is running, this value changes as the status changes. The possible values are START, PROCEED, and STOP. In a successfully run job, all of these values are STOP to indicate that they finished successfully.
Row Count	Indicates the number of rows processed through this object. This value is updated based on the *Monitor sample rate (# of seconds)* set as a debug property.
Elapsed Time	Indicates the time (in seconds) since this object received its first row of data.
Absolute Time	Indicates the time (in seconds) since the execution of this entire data flow (including all of the transforms) began.

3.2.2.14.3 Error logs

The *error log* lists errors generated by SAP Data Services, by the source or target DBMS, or the operating system. If the error log is empty (that is, the button is dimmed), the job completed successfully.

Error logs have the following information:

Entry	Description
Pid	The process thread identification number of the thread executing.

Entry	Description
Tid	The thread identification number of the thread executing.
Number	An error number prefix (explained in the following table) and a number.
TimeStamp	The date and time when the thread generated the message.
Message	A description of the error that occurred as the thread was executing.

The error number prefixes are as follows:

Error number prefix	Description
ADM	Administration errors.
BAP	BAPI errors.
BIW	SAP BW errors.
CON	Connection errors. The connection indicated could not be initialized or failed during execution.
DBS	Database management system errors.
EML	Email errors.
FIL	Filespec errors.
OPT	Optimization errors.
PAR	Parser errors.
R3C	SAP connectivity errors.
R3S	SAP syntax errors.
REP	Repository errors.
RES	Resolver errors.
RUN	Runtime errors.
SCH	Job launcher errors.
SRV	Job Server errors.
SYS	System exceptions.
USR	User function errors.
VAL	Validator errors.
XRN	Transform errors.

3.2.2.15 Message function

ƒ

Class

Reusable

Access

In the object library, click the *Datastores* tab.

Description

Available in certain adapter datastores, message functions can accommodate XML messages when properly configured.

See your adapter's documentation for more specific information about the options available for a message function.

3.2.2.16 Outbound message

Class

Reusable

Access

In the object library, click the *Datastores* tab.

Description

Available in some adapter datastores, outbound messages are XML-based, hierarchical communications that SAP Data Services can publish to adapters. Outbound messages only wait for an acknowledgement from an external system; they do not wait for a reply. You can use outbound messages as targets only. You cannot use outbound messages as sources.

See your adapter's documentation for more specific information about the options available for outbound messages.

3.2.2.17 Project

Class

Single-use

Access

- Choose *Project* > *New*.
- In the object library, click the *Projects* tab.

Description

A project allows you to group jobs. It is the highest level of organization offered by SAP Data Services. Opening a project makes one group of jobs easily accessible in the user interface.

Projects have the following attribute:

Attribute	Description
Name	The name of the object. This name appears on the object in the project area.

3.2.2.18 Query transform

Class

Single-use

Access

With a data flow diagram in the work space, click the Query transform icon in the tool palette, then click in the work space.

Description

A Query transform, like a SQL SELECT statement, retrieves a data set that satisfies the conditions you specify. With a Query transform, you can:

- Map columns from input to output schema
- Add new columns, nested schemas, and functions to the output schema
- Choose the data to extract
- Perform operations on the data
- Join data from multiple sources

A Query transform can operate on nested data. Using a Query transform, you can nest data or unnest nested data.

Query transforms have one attribute:

Attribute	Description
Name	The name of the object. This name appears on the object in the diagram.

Related Information

Designer Guide: Query [page 310]

Designer Guide: Nested Data [page 342]

3.2.2.19 Real-time job

Class

Reusable

Access

- In the object library, click the *Jobs* tab.
- In the project area, right-click a project and select *Real-time Job*.

Description

A real-time job is a set of objects that you can execute together to process messages.

A real-time job is made up of three logical components:

- Initialization (optional)
- Real-time processing loop
- Clean-up (optional)

Each component can include the same objects as a batch job.

A real-time job is created in the Designer and then configured in the Administrator as a real-time service associated with an Access Server.

Start real-time services in the Administrator. If you have included any objects in the initialization component of a a real-time job, they run when the service starts. When a real-time service starts, a real-time processing loop registers itself and its message type with the Access Server and waits for the Access Server to send requests. The real-time processing loop continues to run until it encounters an error or you shut it down using the Administrator. The objects you placed inside the clean-up component of a real-time job run only when a service is shut down.

The message type that a given real-time job processes is determined (when it is designed) by the real-time source you include in the real-time processing loop; the format of the response is determined by the real-time target you include.

A real-time job has the same built-in attributes as a batch job:

Attribute	Description
Name	The name of the object. This name appears on the object in the object library and in the calls to the object.
Description	Your description of the job.
Date created	The date when the object was created.

Like batch jobs, real-time jobs use the debug and trace properties to determine what information the software collects and logs when running the job. However, real-time jobs do not support the Enable Recovery debug options.

Related Information

Log [page 935]

3.2.2.19.1 Content of real-time job

A real-time processing loop can contain the following objects:

- A single data flow which can contain:
  - A single real-time source — XML message (required)
  - Sources — Files, XML files, and tables, including SAP tables
  - A single real-time target — XML message (required)
  - Targets — Files, XML files, tables, and template tables
  - Transforms, including queries
- Multiple data flows which can contain:
  - A single real-time source in the first data flow — XML message (required)
  - Sources — Files, XML files, and tables, including SAP tables
  - A single real-time target in the last data flow — XML message (required)
  - Targets — Files, XML files, tables, and template tables
  - Transforms, including queries
  - Memory tables — used to as staging tables to move data sets to the next data flow in the job.
- Multiple work flows, scripts, conditionals, while loops, etc.

Real-time jobs can also be built using IDocs. See the *Supplement for SAP* for more information.

> Note
>
> Real-time jobs can not use the following features: Data_Transfer transform, run as a separate process, or run at a job distribution level lower than a job level.

3.2.2.19.2 Arranging metadata

If you delete an object used in a real-time job from the object library, calls to the object are replaced with an icon indicating that the calls are no longer valid.

You can insert any number of work flows and data flows into a real-time job as long as the data flow models for a real-time processing loop are followed.

- A single data flow in a loop — Must have both a message source and target
- Multiple data flows in a loop — Must have a message source in the first data flow and a message target in the last data flow

At the job level, work flows and data flows cannot be designed to run in parallel. Inside a job level work flow, they can.

The messages in a data flow are significant. The following table indicates how data flows can be used.

If a data flow has:	It can be used as the:
One XML message source	First data flow in a real-time processing loop.
One XML message target	Last data flow in a real-time processing loop.
One XML message source and one XML message target.	Only data flow in a real-time processing loop.
No message source or target	Not the first, last, or only data flow in a real-time processing loop. Data flow in a batch job.

Data flows that do not contain messages can be used in batch jobs or in real-time processing loops (between its first and last data flows).

3.2.2.19.3 Message processing

Unlike batch jobs, real-time jobs are designed to process multiple messages rather than just files or tables of data.

For transforms that require all of the message's data at one time, such as queries that include aggregation functions, data is cached temporarily. The transform performs the specified operation, then clears caches in preparation for the next message.

To test a real-time job using the Designer, the recommended procedure is to test one message and create a target test file to receive the data. A real-time job will clear data after processing each message if system defaults are used. Therefore, deselect:

- *Delete data from table before loading* for a table target
- *Delete file* for a flat file target
- *Delete and re-create file* for an XML target

3.2.2.19.4 Loading targets as a single transaction

In a real-time job, you can load more than one table from a single datastore in a single transaction. When transactional loading is turned on for table targets, SAP Data Services sends `INSERT` statements for any of the tables included in the transaction to the database to process. You can also control which tables are loaded first by specifying the transaction order for the tables.

If the data flow includes a real-time target, it is always loaded in parallel with other targets to ensure load time is as short as possible.

3.2.2.19.5 Starting and stopping real-time services

For development and testing, you can manually execute a real-time job from the Designer. The Designer runs a real-time job in test mode.

When testing a real-time service or when running in production, the Access Server triggers the Job Server to process a request using the logic you built inside a real-time processing loop. The Access Server can also trigger the Job Server to shut down real-time processing loops. In a production environment, you control the operation of real-time services using the Administrator.

3.2.2.20 Script

Class

Single-use

Access

With a work flow or job diagram in the workspace, click the script icon in the tool palette.

Description

A script is a single-use object that assigns values to local, global or environment variables in a job or work flow. Define the script using the SAP Data Services scripting language.

Scripts have the following attribute:

Attribute	Description
Name	The name of the object. This name appears on the object in the diagram.

Related Information

Scripting Language [page 1709]

3.2.2.21 Source

Class

Single-use

Access

- To insert a document, table, or template table as a source, open the object library, go to the *Datastores* tab, select the object, drag it into the workspace, and select *Make Source*.
- To insert a flat file as a source, open the object library, go to the *Formats* tab, select the file format template for the file, drag it into the workspace, and select *Make Source*. Use the file format editor to specify the file's location.
- To insert an XML message or file as a source, open the object library, go to the *Formats* tab, select the an XML Schema or DTD format template, drag it into the workspace, and select *Make XML message source* or *Make XML file source*. Use the source editor to specify the test file name for the message or the source XML name for the file.
- To view options of a particular source, click the name of the source in the workspace or in the project area. This opens the appropriate editor, such as the table editor, or the XML file, XML message, or flat file format editors.

Description

A source is an object from which SAP Data Services reads data.

In a batch job, a source can be a document, a file, a table, a previously defined template table, an XML file, or a source-specific data flow (see your source-specific supplement for more options).

In a real-time job, a source can be a table, a previously defined template table, a flat file, an XML message, or an XML file. Each real-time job must have exactly one real-time data source.

You can make an embedded data flow a source.

Options available for sources from adapter datastores depend on the adapter implementation. Thus, options vary by data source and adapter version. See your adapter documentation for more information.

Related Information

Designer Guide: Embedded Data Flows [page 391]

3.2.2.21.1 Table source

You can tune performance by configuring the following common source options.

Option	Description
Make Port	Makes the source table an embedded data flow port.
Enable partitioning	Enables SAP Data Services to use the partition information in this table. If this option is selected, the software reads table data using the number of partitions in the table as the maximum number of parallel instances.
Join rank	Indicates the rank of the source relative to other tables and files joined in a data flow. The software joins sources with higher join ranks before it joins sources with lower join ranks. Join rank specified in the Query transform editor FROM tab overrides any join rank specified in a source. Best practice is to specify the join rank only in the Query transform editor. Must be a non-negative integer. Default value is 0. For more information, see the Other Tuning Techniques section in the *Performance Optimization Guide*.
Cache	Indicates whether the software should read the required data from the source and load it into memory or pageable cache. Because an inner source of a join must be read for each row of an outer source, you might want to cache a source when it is used as an inner source in a join. Options are: ● *Yes*: The source is always cached unless it is the outer-most source in a join. ● *No*: The source is never cached. The default is *Yes*. Cache specified in the Query transform editor FROM tab overrides any cache specified in a source. Best practice is to specify the cache only in the Query transform editor.
Array fetch size	Indicates the number of rows retrieved in a single request to a source database. The default value is 1000. Higher numbers reduce requests, lowering network traffic, and possibly improve performance. Maximum value is 5000. This option is available for source tables from DB2, Informix, ODBC, Oracle, and SQL Server datastores. When retrieving a column with an Oracle LONG data type, the software automatically sets *Array Fetch Size* to 1. If a column has an Oracle LONG data type, the software can only retrieve one row at a time.

For Oracle source tables you can use an overflow file for error handling. Select Yes for *Use overflow file* and enter a name for the file. Errors that occur while reading data are logged into the overflow file and the job execution proceeds while ignoring the rows that cause the error. To set the location of the overflow file directory use the table's Datastore Editor.

Related Information

Designer Guide: Creating embedded data flows [page 393]

Performance Guide: Using parallel execution [page 2137]

Performance Optimization Guide: Other tuning techniques, Join ordering [page 2197]

3.2.2.21.2 CDC table source

If a table comes from a CDC datastore, click the *CDC Options* tab and complete the following to set the Oracle, Attunity, SAP Sybase Replication Server and Microsoft SQL Server changed-data capture options. Options vary by source type.

Option	Description
CDC subscription name	The name used to mark sets of changed data read from the continuously growing CDC table. The subscription name marks the last row read so that the next job starts reading the CDC table from that position. You can use multiple subscription names to identify different users who read from the same imported CDC table. The subscription saves the position of each user. Select from the list or type a new name to create a new subscription. A subscription name must be unique within a datastore, owner, and table name. For example, you can use the same subscription name without conflict with different tables that have the same name in the same datastore if they have different owner names. This value is required for the Microsoft SQL server Change Tracking and Replication Server methods.
Enable check-point	Enables the software to restrict CDC reads using check-points. Once a check-point is placed, the next time the CDC job runs, it reads only the rows inserted into the CDC table since the last check-point. By default, check-points are not enabled.
Automatically delete rows after reading	For Microsoft SQL Server only. If the option is cleared, no rows are deleted from the CDC table. If the option is selected, the behavior is different depending on the CDC method used: ● Replication Server method: If more than one data flow uses the same CDC table as a source, only the rows that have been read by all readers are deleted. If any of those readers have the option cleared, no rows are deleted. ● Changed-data capture (CDC) method: All rows of the CDC table are deleted regardless of whether other readers have finished reading from the table. Therefore, if more than one data flow uses the same CDC table as a source, only select this option for the data flow that executes last.

Option	Description
Get before-image for each update row	Some databases allow two images to be associated with an UPDATE row: a before-image and an after-image. If your source can use before-images and you want to read them during change-data capture jobs, enable this option. By default, only after-images are retrieved.

Related Information

Designer Guide: Capturing Changed Data [page 738]

3.2.2.21.3 Flat file source

A flat file source has the *Join rank* and *Cache* options in addition to the file format options. For these two options, SAP Data Services uses the same interpretation for both files and tables.

The flat file source options are the same in the source editor as in the new object editor with the following exception. For the Unstructured text and Unstructured binary file format types, there is an additional option:

Number of files to read: Indicates the maximum number of files to read. A value of zero reads all files. The default is blank.

Related Information

Table source [page 948]
File format [page 920]

3.2.2.21.4 Hadoop Hive Adapter Source

You can set the following options on the *Adapter Source* tab of the source table editor.

Option	Possible values	Description
Clean up working directory	True, False	Select *True* to delete the working directory after the job completes successfully.
Parallel process threads	Positive integers	Specify the number of threads for parallel processing, which can improve performance by maximizing CPU usage on the Job Server computer. For

Option	Possible values	Description
		example, if you have four CPUs, enter 4 for this option.

Related Information

Performance Optimization Guide: Using Parallel Execution, File multi-threading [page 2150]

3.2.2.21.5 Persistent cache source

A persistent cache source has the following options:

Option	Description
Make Port	Makes the persistent cache source an embedded data flow port.
Join rank	For this option, SAP Data Services uses the same interpretation for both persistent cache tables and database tables.
Cache	For this option, the software uses the same interpretation for both persistent cache tables and database tables.
Table name	The *Table name* box displays the name that you entered when you created the persistent cache table. You cannot change this name.
Table owner	The *Table owner* box displays the owner that you entered when you created the persistent cache table. You cannot change this name.
Datastore name	The *Datastore name* box displays the name that you entered when you created the persistent cache. You cannot change this name.
Database type	The *Database type* box displays the *Persistent Cache* option, which you cannot change.

Related Information

Table source [page 948]
Designer Guide: Creating embedded data flows [page 393]

3.2.2.21.6 SAP sources

SAP sources include Open Hub tables and SAP ODP sources.

For details on SAP sources, refer to the *SAP Data Services Supplement for SAP*.

Related Information

Supplement for SAP: Open Hub Table source [page 2565]
Supplement for SAP: ODP source [page 2557]

3.2.2.21.7 Teradata source

The *Teradata options* tab for a Teradata source includes the following modes.

- Parallel transporter API
- Parallel Transporter Export Operator
- None

The availablity of *Advanced* options differs between modes. If an option is empty in the *Advanced* section, Data Services uses the default value specified at the database level.

For details on the following options, refer to your Teradata documentation.

Option	Description
General	
Clean up bulk reader directory after export	Select *Yes* to delete all files in the bulk reader directory after successfully exporting. Select *No* to leave the files in the directory.
Minimum number of sessions	Specifies the minimum number of sessions required for the Export driver job to continue. Default is one session.
Maximum number of sessions	Specifies the maximum number of connections to Teradata. Must be greater than zero. Defaults to one session per available AMP. Use this parameter in conjunction with *Number of export operator instances* and *Parallel process threads* for performance tuning when reading from a Teradata source. For large volumes of data, more sessions allows more data to be read in parallel. Ideally this number should equal the number of AMPs.
Number of export operator instances	Specifies the number of instances for export operators. Use this parameter in conjunction with *Maximum number of sessions* and *Parallel process threads* for performance tuning when reading from a Teradata source. Multiple export instances can improve performance. Ideally this value should equal the number of CPUs.
Tenacity hours	Specifies the number of hours the Export driver attempts to log on when the maximum number of load and export operations are already running on the Teradata database. Default is 4 hours.

Option	Description
Tenacity sleep	Specifies the number of minutes the Export driver pauses before attempting to log on when the maximum number of load and export operations are already running on the Teradata database. Default is 6 minutes.
Data handling	
Block size	Specifies the block size (in bytes) when returning data to the client.
Data encryption	Select *Yes* to enable full security encryption of SQL requests, responses, and data. Select *No* to disable encryption.
Query band session	Specifies a user-defined query band expression to be set for every SQL session.
Notification	
Level	Indicates the level at which certain events are reported: ● Off: No notifications. Default. ● Low: Notifications occur for Initialize, CLIv2/DBS Error, Exit. ● Medium: Notifications occur for all events except File or OUTMODE Open and Statement Fetch Begin and End. ● High: Notifications occur for all events.
Method	Specifies the method for reporting events: ● None: No event logging. Default. ● Message: Send events to a log (for example the EventLog on Windows). ● Exit: Send the events to a user-defined notify exit routine and to the system log.
User-defined string	Specifies a user-defined string that precedes all messages sent to the system log.
User-defined exit routine	Specifies the name of a user-defined notify exit routine.
Trace	
Level	Specifies the type(s) of diagnostic messages each instance of the driver wirtes to a log file. API mode writes to external log files and Export Operator mode writes to public or private logs. ● CLI: Activates the tracing function for CLIv2-related activities. ● PX: Activates the tracing function for activities involving the common library. ● Oper: Activates the tracing function for driver-specific activities. ● Notify: Activates the tracing function for activities related to the Notify feature.
Tracing file	For API mode, specifies the name of the external log file used for trace messages.

Option	Description
Miscellaneous	
Parallel process threads	Specifies the number of threads for parallel processing, which can improve performance by maximizing CPU usage on the Job Server computer. Use this parameter in conjunction with *Maximum number of sessions* and *Number of export operator instances* performance tuning when reading from a Teradata source. The data loads into buffers in Data Services, and the parallel process threads break these buffers into rows and columns. Ideally this number should equal to the number of CPUs.
Logon mechanism	Specifies which logon mechanism to use: ● Kerberos 5 ● NT Lan Manager ● Lightweight Directory Access Protocol ● Simple and Protected GSSAPI Negotiation Mechanism
Logon mechanism data	Specifies additional optional logon mechanism data.
AccountId	An optional attribute that specifies the account associated with the user name (the user specified in the datastore).
Private log name	Specify the name of a log that is maintained by the Teradata Parallel Transporter Logger inside the public log. The private log contains all of the output provided by the Export operator.

Teradata [page 902]
Teradata target table options [page 989]

3.2.2.21.8 XML file source

An XML file source has the same *Join rank* and *Make port* options as tables.

An XML file source has the following options in addition to its read-only XML Schema or DTD format information:

Option	Description
XML file	The location relative to the Job Server of an XML-formatted file to use as the source. You can enter a variable for this option.

Option	Description
	Note If your Job Server is on a different computer that the Designer, you cannot use Browse to specify the file path. You must type the path. You can type an absolute path or a relative path, but the Job Server must be able to access it.
Enable validation	A check box to turn on the comparison of the incoming data to the stored XML Schema or DTD format. When this option is enabled, the data flow throws an exception if the incoming source is not valid.
Include file name column	Determines whether to include a column in the source output that contains the source XML file name. Defaults to *No*. Change the value to *Yes* when you want to identify the source XML file in situations such as the following: ● You specified a wildcard character to read multiple source XML files at one time ● You load from different source XML files on different runs
Modify	If the file name is included, this button enables you to modify *File name column* and *Column size*.
File name column	If the file name is included, the name of the column that holds the source file name. Defaults to *DI_FILENAME*.
Column size	If the file name is included, the size (in characters) of the column that holds the source file name. Defaults to *100*. If the size of the file name column is not large enough to store the file name, truncation occurs from the left.
Include path	If the file name is included, determines whether to include the full path name of the source file. Defaults to *No*.

Related Information

Table source [page 948]

3.2.2.21.9 XML message source

An XML message source has the same *Make port* option as tables.

The XML message source has these options in addition to its read-only XML Schema or DTD format information:

Option	Description
XML test file	The location relative to the Job Server of an XML-formatted file to use as the message source when you execute the job in test mode. Note If your Job Server is on a different computer that the Designer, you cannot use Browse to specify the file path. You must type the path. You can type an absolute path or a relative path, but the Job Server must be able to access it. A variable can also be used.
Enable validation	A check box to turn on the comparison of the incoming message to the stored XML Schema or DTD format. When this option is selected, the real-time job throws an exception if the incoming message is not valid. When you are developing a real-time job, this validation helps you to make sure sample data is both valid and well-formed. If you select this option in production, make sure to include appropriate error handling either in the SAP Data Services job or the client application to process an error caused if a data flow in the real-time job receives data that does not validate against the imported format.
`<implied>` : Join rank	The XML message source is always the outer table in a join. You cannot change its join rank. This option is implied and does not appear in the editor.

Related Information

Table source [page 948]

3.2.2.22 Table

Class

Reusable

Access

In the object library, click the *Datastores* tab. Expand a datastore to find the tables node. Expand this node to view the list of imported tables. Right-click and select *Properties* to view and edit table properties.

Description

You can use a table as a source or target in a data flow.

The *Indexes* tab on the Properties window for a table shows information about the table's indices. Under *Index*, the window lists the primary index followed by any secondary index. Select an index and the window lists the columns in that index under *Column*.

The *Partition* tab on the Properties window displays how table metadata is partitioned. Partitions can be imported with a table or you can create metadata for them within SAP Data Services.

The *Attributes* tab on the Properties window displays built-in table attributes:

Table Attribute	Description
Name	The name of the object. This name appears on the object in the object library and in the calls to the object.
Description	A configurable description field.
Business_Name	Supports metadata exchanged between Data Services and SAP BusinessObjects Universe Builder (UB) 1.1. A configurable field for the logical Business_Name used in SAP BusinessObjects Universe Builder. Data Services can extract, transform and load data while transferring this information intact.
Business_Description	Supports metadata exchanged between Data Services and SAP BusinessObjects Universe Builder (UB) 1.1. A configurable, business-level description of the table. Data Services transfers this information separately and adds it to any SAP BusinessObjects Universe Builder Class description.
Table_Usage	A configurable label field. Use it to mark a table as `fact` or `dimension` for example.
Total_Number_Of_ Rows_Processed	The number of rows loaded into the table in the last successful load.
Date_last_loaded	The time the table was last successfully loaded.
Number_Of_Rows_ Rejected	The number of rows rejected in the last successful load.
Number_Of_Inserts	The number of rows inserted in the last successful load.
Number_Of_Updates	The number of rows updated in the last successful load.

Table Attribute	Description
Date_Created	The date that the object was created.
Estimated_Row_ Count	A configurable estimate of the table size used in calculating the order in which tables are read to perform join operations. Used for SAP tables only.
Number_Of_Deletes	The number of rows deleted in the last successful load.
Elapsed_Time_For_ Load	The time it took to load this table in the last successful load.
Table_Type	The type of datastore object for tables and hierarchies. Most often the value `TABLE` is displayed. However, the software might display the following values for SAP sources: BW master data transfer, BW transaction data transfer, BW hierarchy data transfer, SAP hierarchy.
SAP_Table_Class_ Name	Imported with SAP table metadata.
Loader_Is_Template_Table	If `YES`, indicates that the table is an internal, template table created in the software. Before running production jobs, execute the job to load the target table then right-click the template table in the object library or in a data flow and the software creates the table in your database and imports it.
SavedAfterCheckOut	If `YES`, indicates you saved the table after it was checked out of the central repository. The software uses this information to determine whether to save the table in the central repository when it is checked in.
PartitionModified	If `YES`, indicates that you modified the partitions in this table using the software after you imported the table's metadata.

Related Information

Performance Optimization Guide: Overview of parallel execution [page 2137]
Template table [page 996]

3.2.2.22.1 Column attributes for tables

SAP Data Services also supports column attributes for tables.

3.2.2.22.2 To view column attributes for a table

1. In the *Datastores* tab of the object library, double-click a table.

   The Table Metadata window opens.
2. Right-click a column name and select *Properties*.

   The Column Attributes window opens.
3. Click the *Attributes* tab.

Column Attribute	Description
Business Name	A configurable logical name.
Business_ Description	A configurable business-level description of the column.
Column_Usage	Supports metadata exchanged between SAP Data Services and SAP BusinessObjects Universe Builder (UB) 1.1. Enter `Dimension`, `Measure`, or `Detail` as a value for a corresponding object in SAP BusinessObjects Universe Builder. ● If set to `Dimension`, the corresponding object created in SAP BusinessObjects Universe Builder is of qualification type *Dimension*. ● If set to `Measure`, the corresponding object is of qualification type *Measure*. ● If set to `Detail`, the corresponding object is of qualification type *Detail* and requires you to set a value for *Associated_Dimension*.
Associated_ Dimension	Set this value only if *Column_Usage* is set to `Detail`. The value must be in the format: `table.column`. The Detail column is created under the Dimension column you specify.
Acta_autojoin	Generated by SAP Data Services. Not configurable.
Associated_ domain	Use for databases that use domains such as PeopleSoft.
Physical_Name	Use for applications that allow logical names for a column such as Oracle Applications.

The attributes listed above are available for all tables.

Related Information

Designer Guide: Attributes that support metadata exchange [page 735]
Attributes for DTDs [page 908]
Attributes supported for XML schemas [page 1010]

3.2.2.23 Target

Class

Single-use

Access

- To display target options, click the name of the target in the workspace or in the project area. This opens the object editor.
- To display target properties, right-click a target and choose *Properties*.

Description

A target is an object to which SAP Data Services loads extracted and transformed data in a data flow.

In a data flow, a target can be one of the objects that the following table shows.

Icon for target object	Target object description
	Document
	Flat file
	Outbound message
	Table
	Template table
	XML file
	XML message
	XML template

You can make a target an embedded data flow port: set the *Make port* option to *Yes* for flat files; select the *Make port* check box for other targets.

This section describes:

- Target files
- Target persistent cache tables
- Target tables
- Target Data_Transfer files and tables
- Target XML files, messages, and templates

Documents and outbound messages are only available from adapter datastores. Options available for these targets depend on the adapter implementation. Thus, options vary by data source and adapter version. See your adapter documentation for more information

Related Information

Designer Guide: Embedded Data Flows [page 391]

Designer Guide: Creating embedded data flows [page 393]

3.2.2.23.1 Target files

You can use any flat file format as a target in a data flow. To add a target file, select a file format in the object library, drag the file format into the data flow workspace, and select *Make Target*.

If the schema defined in the file format does not match the schema that is input to the target, SAP Data Services provides validation errors to identify the mismatch.

Use the file format editor in target mode to edit the file format of a target file. You cannot edit all properties of a particular target file. You can change some properties of the file format.

You can also change the name of the target file object using the object's properties. Right-click the object and choose *Properties*.

Related Information

File format [page 920]

3.2.2.23.2 Target persistent cache tables

To create a new persistent cache target table, take one of the following actions:

- Select a template table under a persistent cache datastore in the object library, drag the table into the workspace, and type a name for the table.
- Click the template table icon in the tool palette, click the workspace, choose a persistent cache datastore, and type a name for the table.

i Note

You cannot update a persistent cache table. If the data within it changes, you must recreate it and load it.

Table 107: Target

Option	Description
Make port	Select this check box to make the target table an embedded data flow port.
Table name	The *Table name* box displays the name that you entered when you created the persistent cache table. You cannot change this name.
Table owner	The *Table owner* box displays the owner that you entered when you created the persistent cache table. You cannot change this name.
Datastore name	The *Datastore name* box displays the name that you entered when you created the persistent cache. You cannot change this name.
Database type	The *Database type* box displays `Persistent_Cache` which you cannot change.

Table 108: Options

Option	Description
Column comparison	Specifies how the input columns are mapped to persistent cache table columns. There are two options: ● *compare_by_position*: SAP Data Services disregards the column names and maps source columns to target columns by position ● *compare_by_name*: the software maps source columns to target columns by name
Include duplicate keys	Specifies whether or not to include duplicate keys in the persistent cache. Defaults to selected.

Table 109: Keys

Option	Description
Key column	Specify one or more columns to use as the key for the persistent cache. Click the arrow to view a drop-down list of column names. To change the order of the columns in the key, use one of the following options: ● Right-click the column and select *Move Up* or *Move Down*. ● Select the column and click the down or up arrow in the top right corner of the *Keys* tab. To remove a column, use one of the following options: ● Right-click the column and select *Delete*. ● Select the column and click the delete icon in the top right corner of the *Keys* tab.

Related Information

Designer Guide: Embedded Data Flows [page 391]

3.2.2.23.3 Target tables

You can add a table to a data flow diagram as a target if SAP Data Services can write to the application or database containing the table. To add a target table, select the table in the object library, drag the table into the workspace, and select *Make Target*.

If the schema defined in the table does not match the schema that is input to the target, the software provides validation errors to identify the mismatch.

When loading DB2, ODBC, or Oracle tables, the software parameterizes the SQL. Parameterized SQL statements result in quicker load times. To parameterize SQL, the software must be able to generate, parse, and compile the statement. For example, the software is unable to parameterize SQL when using transactional loading or triggers.

You configure a target table by setting options in the target editor. Available options depend on the database in which the table is defined.

3.2.2.23.3.1 Common target table options

This table describes the options common to all supported database types.

Table 110: Target tab

Option	Description
Make port	Select this check box to make the target table an embedded data flow port.
Database type	Select an item in the *Database type* box to set the content of additional tabs on the target table editor to match the specific options for that database type. This option allows you to quickly set target option values in data flows. If your target datastore has multiple configurations, all database types and their version numbers, which you specified in these configurations, are listed. To add or remove items in this list, edit the datastore configuration information in the datastore editor. The software allows you to use target table editor option values from any datastore configuration: ● If the datastore has only one configuration, then the initial values for the target table editor are defaults set by Designer for that database type or version. ● If the datastore has more than one configuration and there are different database types/versions, then the software determines the initial values for the additional database types/versions from the *Use values from* box in the Create New Configuration dialog (a sub-dialog of the datastore editor). ● If you also select the *Restore values if they already exist* check box (in the Create New Configuration dialog), SAP Data Services looks for previously defined values that once existed for that database type or version. It is possible for a data flow to contain target table editor values for a database type or version, even if its datastore configuration was deleted. The software retains all target table editor values saved with every datastore configuration. If such values exist, then it restores those values. Otherwise, it gets the values from the configu-

Option	Description
	ration you select from the *Use values from* option. For example, suppose you set a configuration for Oracle 8i. When you edit the target table editor options, you change the *Rows Per Commit* default value of 1000 to 500. Later you add a new datastore configuration for a Microsoft SQL Server 2000 database to your original datastore and set the *Use values from* option to Oracle 8i. In this case, the target table editor settings for SQL Server inherit the value 500 for *Rows per Commit* because this was the value set in the Oracle 8i configuration. The values you set for the options in the target table editor are specific to the instance and database type/version of that object in the data flow. If you set values for one target table, any other target table in the same data flow is not affected.

Table 111: Options tab

Option	Description
Rows per commit	Specifies the transaction size in number of rows. For example, if set to 1000, the software sends a commit to the underlying database every 1000 rows. Load triggers are never split across transaction boundaries, so if the load trigger crosses transaction boundaries, then the size of the transaction is automatically extended to accommodate the entire trigger requirement. For example, suppose you set *Rows per commit* to 3 and specified an insert trigger, where an incoming insert statement is converted into 5 statements. *Rows per commit* would automatically be extended to 5 to accommodate each insert trigger statement in a single transaction. This option is not available for targets in real time jobs.
Delete data from table before loading	For batch jobs, to clear the contents of the table before loading it, sends a TRUNCATE statement to databases that support it (Oracle, Microsoft SQL Server, SAP Sybase) or sends a DELETE statement to databases that do not support TRUNCATE. Default setting is not selected. For real-time jobs, clears data after processing each message. For real-time jobs you may want to deselect this option during development and testing.
Drop and re-create table	Drops the existing table and creates a new one with the same name before loading. This option displays only for template tables. Template tables are used in design or test environments.
General	
Column comparison	Specifies how the input columns are mapped to output columns. There are two options: *Compare by position*: The software disregards the column names and maps source columns to target columns by position. *Compare by name*: The software maps source columns to target columns by name. Validation errors occur if the data types of the columns do not match.

Option	Description
Number of loaders	Loading with one loader is known as “single loader loading”. Loading when the number of loaders is greater than one is known as “parallel loading”. The default number of loaders is 1. You can specify any number of loaders. When parallel loading, each loader receives the number of rows indicated in the Rows per commit option, in turn, and applies the rows in parallel with the other loaders. For example, if you choose a *Rows per commit* of 1000 and set the *Number of Loaders* to 3, the first 1000 rows are sent to the first loader. The second 1000 rows are sent to the second loader, the third 1000 rows to the third loader, and the next 1000 rows back to the first loader.
Enable Partitioning	(Displayed only if the target table data is partitioned) Loads data using the number of partitions in the table as the maximum number of parallel instances. You can only select one of the following loader options: ● Number of Loaders ● Enable Partitioning ● Transactional Loading Note If you set *Enable Partitioning* to Yes and *Include in transaction* to Yes, the *Include in transaction* setting overrides the *Enable Partitioning* option.
Error handling	
Use overflow file	This option is used for recovery purposes. If a row cannot be loaded it is written to a file. When this option is set to Yes, options are enabled for the file name and file format. The default setting is No.
File name *File format*	These options are available only when you select Yes for the *Use overflow* file option. Specifies the file name and file format for the overflow file. The overflow format can include the data rejected and the operation being performed (write_data) or the SQL command used to produce the rejected operation (write_sql). You can enter a variable for the file name.
Update control	
Use input keys	If the target table contains no primary key, this option enables the software to use the primary keys from the input. The default setting is No.
Update key columns	This option is set to No by default. If you select Yes for this option, the software updates key column values when it loads data to the target.
Auto correct load	Select Yes to use auto correct loading. Auto correct loading ensures that the same row is not duplicated in a target table. This is particularly useful for data recovery operations. The default setting is No.

Option	Description
	Note This option is not available for targets in real time jobs or target tables that contain LONG column(s). When you select Yes for this option, the software reads a row from the source, then checks if the row exists in the target table with the same values in the primary key. If *Use input keys* is set to Yes, the software uses the primary key of the source table. Otherwise, the software uses the primary key of the target table; if the target table has no primary key, the software considers the primary key to be all the columns in the target. If a matching row does not exist, a new row is inserted, regardless of other options. If a matching row exists, the row is updated depending on the values of *Ignore columns with value*, and *Ignore columns with null*: ● When the column data from the source matches the value in *Ignore columns with value*, the corresponding column in the target table is not updated. The value may be spaces. Otherwise, the corresponding column in the target is updated with the source data. ● When the *Ignore columns with null* option is set to Yes and the column data from the source is NULL, then the corresponding column in the target table is not updated. Otherwise, the corresponding target column is updated as NULL since the source column is NULL. For supported databases, when the *Allow merge or upsert* option is enabled, the software can optimize data flows such that the database completes the auto correct load operation. When all other operations in the data flow can be pushed down to the source database, the auto-correct loading operation is also pushed down. The generated SQL implements the *Ignore columns with value* value if completed in the target editor, and the *Ignore columns with null* Yes/No setting.
Allow merge or upsert (This is available for Microsoft SQL Server 2008 and higher only)	Specifies whether the Optimizer may use a MERGE statement to improve the performance of auto correct load functionality. *Yes:* Allows the Optimizer to consider using a MERGE statement during an auto correct load operation. If the Optimizer does not use a MERGE statement, it uses a T-SQL block to identify, insert, and update rows. *No:* The Optimizer will not use a MERGE statement to improve auto correct load performance. The default is Yes. **Note** When the data flow contains a Query transform with an Order by clause, the Optimizer always uses a T-SQL block to identify, insert, and update rows.

Option	Description
Ignore columns with value	Enter a value that might appear in a source column and that you do not want updated in the target table. When this value appears in the source column, the corresponding target column is not updated during auto correct loading. You can enter spaces.
Ignore columns with null	Select Yes if you do not want NULL source columns updated in the target table during auto correct loading. This option is only available when you select Yes for the *Auto correct load* option.
Transaction control	
Include in transaction	Indicates that this target is included in the transaction processed by a batch or real-time job. This option allows you to commit data to multiple tables as part of the same transaction. If loading fails for any one of the tables, no data is committed to any of the tables. Transactional loading can require rows to be buffered to ensure the correct load order. If the data being buffered is larger than the virtual memory available, the software reports a memory error. The tables must be from the same datastore. If you choose to enable transactional loading, other options are not available: ● Rows per commit ● Use overflow file, and overflow file specification ● Number of loaders ● Enable partitioning ● Bulk loader options ● Pre load commands ● Post load commands ● Delete data from table before loading The software does not push down a complete operation to the database if transactional loading is enabled.
Transaction order	Transaction order indicates where this table falls in the loading order of the tables being loaded. By default, there is no ordering. All loaders have a transaction order of zero. If you specify orders among the tables, the loading operations are applied according to the order. Tables with the same transaction order are loaded together. Tables with a transaction order of zero are loaded at the discretion of the data flow process. In Data flow view, the specified transaction order number appears nearer to the corresponding target.
Commit at end of INSERT... SELECT	When set to Yes (default), the software commits a single transaction log statement per load. When set to No, transaction size is limited to the value specified in *Rows per commit* to create a smaller transaction size than the single commit per job default behavior.

Option	Description
	If your transaction log size is too small for a single transaction of this type, set a commit size when the following applies: • the job has a source and target that use the same datastore • the job has an Oracle target table • the software is optimizing and executing the job by pushing down the read operation to the Oracle target table host. This type of operation requires that the software generate an INSERT...SELECT SQL statement. The software commits a transaction for an INSERT...SELECT by default at the end of the job. • the job failed with an Oracle transaction log full error. Troubleshooting: 1. View the SQL that the software generates to see if an INSERT...SELECT statement is in use. (In the Designer, open a data flow and select ▸ *Validate* ▸ *Display Optimized SQL* ◂.) 2. If so, set the Commit at end of INSERT...SELECT to No and enter a value for *Rows per commit*. If you use this option, expect to see a decrease in performance.
Use NVARCHAR for VARCHAR columns in supported databases	The software creates **`<nvarchar>`** columns in the template table for all **`<varchar>`** columns in the input schema of the data flow. The data type displays as varchar in the Designer, and, when supported by the DBMS, as nvarchar in the database table. The following database management systems do not support the **`<nvarchar>`** data type: • DB2 (non-UTF-8) • Oracle 8.x • Informix • SAP Sybase ASE • SAP Sybase IQ For these DBMSs, the software creates columns with varchar data types and increases the column size using a codepage conversion factor based on the client code page defined in the datastore. ⚠ Caution Data loss may occur when transcoding from one national language to a different national language. Data loss will not occur when transcoding from a national language to Unicode. ⚠ Caution Data truncation occurs when the column size of the source exceeds the maximum size allowed by the target DBMS.

Load triggers tab

Specifies SQL commands performed by the database on an INSERT, UPDATE, or DELETE operation.

You can specify a **`<load trigger >`** (a template SQL statement) that has placeholders for column and variable values. The software sets the placeholders at execution time based on the fields in the transform's input schema. For each row, the template is filled out and applied against the target.

The special operations you specify in a load trigger can occur before, after, or instead of normal operations.

Use load triggers in situations such as archiving updates to a warehouse or incremental updates of aggregation value.

The software does not parse load triggers. Thus, when you specify a load trigger, the software does not parameterize SQL statements. As a result, load times might be higher when you use load triggers.

The software does not validate load triggers.

> Note
>
> If you use an override, you cannot specify auto correct load.

For example, instead of applying an insert of a new sales order rows, you use a load trigger that applies inserts and updates of aggregated values of sales_per_customer and sales_per_region.

The templates give you a row with customer_id, order_amount, region_id, and so forth.

The INSERT and UPDATE statements are:

```
INSERT into order_fact
values ([customer_id], [order_amount]);
UPDATE region_fact
SET order_amount =
order_amount + [order_amount]
WHERE region_id = [region_id];
```

Enter your load triggers manually or drag column names from the input schema. Column names must be enclosed in curly braces or square brackets. For example, `{SalesOffice} or [SalesOffice]`.

With curly braces, the software encloses the value in quotation marks, if needed. With square brackets, it will not. To avoid unintended results, use curly braces for varchar or char column names.

If you insert column names into the SQL statement by dragging the column names, the software inserts square brackets for you. If you require curly braces, you must make the change from square brackets to curly braces.

`[#insert]`, `[#update]`, and `[#delete]` represent the default operations.

To delimit a SQL statement, use `[#new]`. For example:

```
[#insert] [#new]
insert into foo values ([col1], {col2}, ...)
```

For UPDATE operations you must specify both the "before" and the "after" image values. You can specify both images for INSERT and DELETE operations, also, but it is not required.

To specify "before" images, add the suffix `.before` to the column name. To specify "after" images, add the suffix `.after` to the column name.

The default suffix for UPDATE and INSERT operations is `.after`. The default suffix for DELETE operations is `.before`.

You can include variables in the SQL statements, but not expressions.

You can map a batch of SQL statements. Each SQL statement is separated by a new separator (`[#new]`).

The following statement is an example for mapping insert SQL:

```
INSERT into log_table values ({col1}, {col2})
[#new]
[#insert] [#new]
delete from alt_junk where . . .
```

Pre Load Commands tab and *Post Load Commands tab*

Specify SQL commands that the software executes before starting a load or after finishing a load.

When a data flow is called, the software opens all the objects (queries, transforms, sources, and targets) in the data flow. Next, the software runs the target's preload script. Therefore, the software executes any preload SQL commands before processing any transform.

> i Note
>
> Because the software executes the SQL commands as a unit of transaction, you should not include transaction commands in preload or postload SQL statements.

Both the *Pre Load Commands* tab and the *Post Load Commands* tab contain a *SQL Commands* box and a *Value* box. The *SQL Commands* box contains command lines. When you first open the tab, an empty line appears.

To edit a line, select the line in the *SQL Commands* box. The text for the SQL command appears in the *Value* box. Edit the text in that box.

To add a new line, determine the desired position for the new line, select the existing line immediately before or after the desired position, right-click, and choose *Insert Before* to insert a new line before the selected line, or choose *Insert After* to insert a new line after the selected line. Finally, type the SQL command in the *Value* box.

To delete a line, select the line in the *SQL Commands* box, right click, and choose *Delete*.

You can include variables and parameters in preload or postload SQL statements. Put the variables and parameters in either brackets, braces, or quotes. The software translates each statement differently, writing a statement that depends on the variable or parameter type.

Entered statement	Variable value	Written statement
`[$X]`	5	`5`
`[$X]`	John Smith	`John Smith`
`{$X}`	5	`5`
`{$X}`	John Smith	`'John Smith'`
`'$X'`	5	`'$X'`
`'$X'`	John Smith	`'John Smith'`

You cannot use Pre Load and Post Load SQL commands in a real-time job.

Message processing [page 945]

3.2.2.23.3.2 DB2 target table options

The following table contains option and description information specific to DB2 target tables.

Table 112: Target tab

Option	Description
Make port	Specifies the table as an embedded data flow port.

Table 113: Options tab

Option	Description
Allow Merge or upsert	Specifies whether the Optimizer may use a MERGE statement to improve the performance of auto correct load functionality. *Yes*: Allows the Optimizer to consider using a MERGE statement during an auto correct load operation. If the Optimizer does not use a MERGE statement, it uses a stored procedure to identify, insert, and update rows. *No*: The Optimizer will not use a MERGE statement to improve auto correct load performance. The default is Yes.

Table 114: Bulk loader tab

Option	Description
Bulk load	Indicate the bulk load method. Choose one of the following options: *CLI load*: Use the DB2 CLI load utility. The CLI load utility performs better than the load utility because it writes data directly from memory to the DB2 target table or view. You must use DB2 version 8.x or later. *Import*: Use the DB2 import utility to bulk load data. The import utility uses a SQL INSERT statement to write data from an input file into a table or view. *Load*: Use the DB2 bulk load utility. The load utility improves performance over the import utility by writing data directly into the data file. *No*: Do not bulk load data.
Generate files only	This option is available only when *Bulk load* is set to *import* or *load*. Select this check box to generate a data and control file. Rather than loading data into the target shown in the data flow, SAP Data Services generates a control file

Option	Description
	and a data file that you can later load using DB2 bulk loading. This option is useful when the DB2 server is located on a system running a different operating system than the Job Server. The software writes the data and control files in the bulk loader directory specified in the datastore definition. If you have not specified a bulk loader directory, the software writes the files in the **<DS_COMMON_DIR>**`\log\bulkloader` directory. To load the data, you must manually copy the files to the remote system and start the bulk load execution. When you select this check box, only the *Text delimiter* and *Column delimiter* options are available.
Clean up bulk loader directory after load	Select this check box to delete all files in the bulk loader directory after the load completes successfully. If you have not specified a bulk loader directory in the *Connections* tab in the datastore definition, the software writes the files in the **<DS_COMMON_DIR>**`\log\bulkloader` directory. When this option is selected, the software deletes the following files after each bulk load unless an error has occurred: ● Message file (`.log` file name) that DB2 creates for the import, load, or CLI load ● Control file (`.ctl`) that the software generates only when *Bulk load* is set to *import* or *load* ● Data file (`.dat`) that the software generates only when *Bulk load* is set to *import* or *load* ● Bad file (`.bad`) that DB2 generates only when *Bulk load* is set to *load* and the *Data file on client machine* option is not checked. If the *Data file on client machine* option is checked, DB2 creates the `.bad` file on the DB2 server working directory (specified in the *DB2 Properties* tab of the datastore definition). In this case, the software does not delete the .bad file when the bulk load completes.
Mode	Specify the mode for loading data in the target table. Available modes depend on the bulk load method. Available modes when *Bulk load* is set to *import*: *Insert*: Adds new records to the table. Use when loading data into an empty table or when appending data to an existing table that contains data that you want to maintain. *Insert-update*: If a record with matching primary keys exists in the table, updates that record; otherwise, adds new record to the table. This method requires that the target table has primary keys. *Replace*: Deletes all existing records in the table, then adds new records. *Truncate*: Deletes all existing records in the table, then adds new records. Available modes when *Bulk load* is set to *CLI load* or *load*:

Option	Description
	Insert: Appends the new records into the target table. *Replace*: Deletes the existing records, and then inserts the loaded data.
Rows per commit	Enter the number of rows that will be loaded before a commit takes place. If no value is entered, the load utility uses the default value at run time. This option is available only when *Bulk load* is set to *import*.
Save count	Enter the minimum number of rows loaded before the load utility establishes a consistency point. This is the point when DB2 saves the data. DB2 converts this value to a page count, and rounds up to intervals of the extent size. If you enter zero, the load utility establishes no consistency points. This option is available only when *Bulk load* is set to *load*.
Warning row count	Enter the number of warnings allowed for each load operation. This option is available only when *Bulk load* is set to *CLI load* or *load*.
Text delimiter	Enter a single character string delimiter. The default value is a double quote ("). The specified character is used in place of double quotation marks to enclose a character string. The specified character can be any printable or non-printable ASCII character, escaped with a double slash "\\". This option is available only when *Bulk load* is set to *import* or *load*.
Column delimiter	Enter a single-character column delimiter. The default value is a comma (,). This option is available only when *Bulk load* is set to *import* or *load*.
Maximum bind array	Enter the maximum number of rows extracted or transformed before the software sends the data to the DB2 table or view. If you do not enter a value, the software uses the default DB2 CLI Loader value which is 10000. This option is available only when *Bulk load* is set to *CLI load*.
Exception table name	Enter the table into which the DB2 server loads rows that violate a table constraint. Rows that violate constraints are deleted from the target table and inserted into the exception table. This option is available only when *Bulk load* is set to *CLI load* or *load*.
Recoverable	Select this check box to support data recovery through the DB2 roll-forward recovery feature. When this option is not selected, you cannot recover from failure using DB2 roll-forward. When this option is selected, DB2 writes a backup copy of the loaded data. You can use DB2 roll-forward recovery after failure. You must specify the directory for writing the backup file (*Copy target directory*). Select this option only if your DB2 target database is roll-forward enabled. This option is available only when *Bulk load* is set to *CLI load* or *load*.

Option	Description
Copy target directory	Enter the directory where copy files are stored when the *Recoverable* option is enabled. Only local media is supported. This option is available only when *Bulk load* is set to *CLI load* or *load*.
Data file on client machine	Select this check box to have the load utility process the local file directly rather than using FTP to send the data file to the DB2 server. To use this option: ● You must use DB2 version 7.x or later. ● The target DB2 cannot be a DB2 enterprise (extended edition environment). ● The target table and database must not be partitioned. This option is applicable only if the software and DB2 are on different servers. This option is available only when *Bulk load* is set to *load*.

Related Information

Common target table options [page 963]

3.2.2.23.3.3 Hadoop Hive Adapter Target

You can set the following options on the *Adapter Target* tab of the target table editor.

Option	Possible values	Description
Append	True, False	Select *True* to append new data to the table or partition. Select *False* to delete all existing data, then add new data.
Clean up working directory	True, False	Select *True* to delete the working directory after the job completes successfully.
Dynamic partition	True, False	Select *True* for dynamic partitions. Hive evaluates the partitions when scanning the input data. Select *False* for static partitions. Only all-dynamic or all-static partitions are supported.
Number of loaders	Positive integers	Enter a positive integer for the number of loaders (threads). Loading with one loader is known as *single loader loading*. Loading when the

Option	Possible values	Description
		number of loaders is greater than one is known as *parallel loading*. You can specify any number of loaders. The default is 1.

3.2.2.23.3.4 HP Neoview target table options

The following table contains option and description information specific to HP Neoview target tables.

> Note
>
> You can use substitution parameters for all of the options listed below with the exceptions of *Clean up bulk loader directory after load*, *File options*, *Use the control file and Generate files only*, *Mode*, and *Operation*.

Table 115: Bulk Loader Options

Option	Description
Bulk load	Select to use HP Neoview bulk loading options to write the data.

Table 116: Options

Option	Description
Clean up bulk loader directory after load	Deletes all bulk loader-related files (script, data files, temporary file, control file, error file, data files, log file) after the load is complete. If an error occurs during bulk load, SAP Data Services does not delete script and data files. Errors usually occur when: ● There is a syntax error in the script. ● Error tables are not empty. Error tables contain rows that cannot be inserted into the target table due to data conversion or constraint violation.
Column delimiter	Specify a single-character to delimit (enclose) the columns. Default value is /127 (non-printable character). You may also have a comma, semicolon or any decimal character (for example /38 is the decimal value for &), except for the following: any alphabetic characters a-z, A-Z, decimal numbers 0-9, carriage return (/10) or line feed (/13). Note The software uses decimal numbers, and HP Neoview uses octal numbers for delimiter values.
File option	Specify the staging type before loading data into the target: ● Data file ● Named pipe

Option	Description
Generates files only	When this option selected, the software generates a data file and a script file, and ignores the *Number of loaders* option (in the Options tab). You can load the file using HP Neoview bulk loading later. This option is often useful when the target database is located on a system running a different operating system than the Job Server. The software writes the data and control files in the bulk loader directory (default value is <**`<DS_COMMON_DIR>`**\log\bulkloader) specified in the datastore definition. The naming conventions for these files is: **`<DatastoreName_OwnerName_TableName_PID_n>`**`.ctl` and **`<DatastoreName_OwnerName_TableName_PID_n>`**`.dat` where: ● **`<OwnerName>`** is the table owner ● **`<TableName>`** is the target table ● **`<PID>`** is the process ID ● **`<n>`** is a positive integer, optionally used to guarantee that pre-existing files are not overwritten
Mode	Specify the mode for loading data in the target table: ● *Append*: Adds new records to the table ● *Truncate*: Deletes all existing records in the table, then inserts the loaded data as new records
SQL Operation	Specify the type of SQL operation to perform: ● *Insert*: Places data into a Neoview table. ● *Update*: Updates data in a Neoview table. ● *Upsert*: Updates the data in a Neoview table if the data exists, otherwise it inserts the data.
Text delimiter	Specify a character used to delimit (enclose) char or varchar data. Valid values are single quotes, double quotes, or blank (default).

Table 117: Neoview options

Option	Description
Bad data file name	Specify a name and location for source records that fail internal processing before being written to the database. For example, a record that contains 6 fields when 8 fields are expected will fail internal processing and be placed in this file. If this option is left blank during runtime, the software places the file **`<datastore_schema_tablename_PID_n>`**`_badrecord.dat` in the directory listed in **`<DS_COMMON_DIR>`**`\log\bulkloader`.
Enable triggers	Allows triggers (a template SQL statement) to run on a table while loading jobs. When this option is set to true, one of the following situations must also be true: ● update trigger on a table with primary key, enable triggers is before update, and operation must be set to update.

Option	Description
	- update trigger on a table with multiple column primary key, enable triggers is before update, and operation must be set to update.
Failed data file name	Specify a name and location for source records that have a valid format, but could not be written to the database. For example, a record that fails a data conversion step or violates a uniqueness setting is placed in this file. If this option is left blank during runtime, the software places the file `<datastore_schema_tablename_PID_n>_failedrecord.dat` in the directory listed in `<DS_COMMON_DIR>\log\bulkloader`.
Force staging	Specify whether to write rows to an internal staging table before populating the target tables. i Note Using staging tables increases the performance for load operations. However, if the load fails, it may be more difficult to recover.
Maximum number of discarded rows	Specify the maximum number of rows that do not match the expected format or information specified for the table being loaded. When the value is exceeded, the bulk loader stops. Set this option to 0 to ignore rejected rows, continue processing, and log warnings.
Maximum number of failed rows	Specify the maximum number of rows that fail to load into the database. When the value is exceeded, the bulk loader stops. Set this option to 0 to ignore rejected rows, continue processing, and log warnings.
NoAudit	Specify whether to use non-transactional database operations to improve performance. If you set this option to true, you must also set the *sorted by primary key* option and the *truncate* option to true, and the *force staging* option to false.
Number of data connections	Specify the number of data connections to access the database. By default, there is one data connection for every four partitions of the table. i Note The maximum value is limited to the number of partitions for the table.
Retry attempts	Specify the number of times to connect to a database or open a named pipe on behalf of a job.
Retry duration	Specify the amount of time, in seconds, between attempts to connect to the database or to open the named pipe.
Row set size	Specify the number of records in each batch of rows that Neoview Transporter exchanges with the HP Neoview database. If this option is not set, Neoview Transporter selects an optimized value based on the HP Neoview SQL table or query.

Option	Description
Rows per commit	Specify the maximum number of rows to process during a single transaction. When this number is reached, Neoview Transporter will stop processing the job.
Server processes on a connection	Specify the number of Neoview server processes on a single connection. In most instances, set this number to the number of Neoview segments.
Sorted by primary key	Specify whether to sort the source files by the table's primary key. Neoview Transporter can improve performance and parallelism of certain database operations when the data is sorted by the primary key.
Time out	Specify the amount of time, in seconds, for Neoview Transporter to wait for the load operation to complete before timing out and returning an error. The duration starts after a named pipe has successfully opened. The default value is 1000.

3.2.2.23.3.5 Informix target table options

The following table contains option and description information specific to Informix target tables. All other option information for target tables can be found in the *Common target table options* [page 963].

i Note

Commit at the end of INSERT..SELECT option is not applicable.

Table 118: Options

Option	Description
Drop and re-create table	Drops the existing table and creates a new one with the same name before loading.

Table 119: Bulk Loader Options

Option	Description
Bulk load	Select this check box to use Informix bulk loading options to write the data.
Generate files only	Select this check box to generate a data and control file. Rather than loading data into the target shown in the data flow, SAP Data Services generates a control file and a data file that you can later load using Informix bulk loading. This option is often useful when the Informix server is located on a system running a different operating system than the Job Server.

Option	Description
	The software writes the data and control files in the bulk loader directory specified in the datastore definition. If you have not specified a bulk loader directory, the software writes the files in the `<DS_COMMON_DIR>\log\bulkloader` directory. You need to copy the files to the remote system manually. The files names are `<tablename>.ctl` and `<tablename>.dat`, where `<tablename>` is the name of the target table.
Lock table	Select this check box to lock the table for the duration of the load.
Clean up bulk loader directory after load	Select this check box to delete all bulk load-oriented files after the load is complete, unless an error occurs. When you select this option, the software deletes these files after a successful bulk load: ● Control file ● Log file ● Bad file
Mode	Select the mode for loading data in the target table: ● *Append*: Adds new records to the table. ● *Replace*: Deletes all existing records in the table and then adds new records.
Bulk loader server name	Enter the name of the Informix database server.
Bulk loader database name	Enter the name of the target information warehouse database.
Rows per commit	Enter the number of rows that must be loaded before a commit takes place.
Field delimiter	Enter the character that separates columns. Make sure the character you designate is not used in any of the data columns.
Maximum rejects	Enter the maximum number of acceptable warnings. Bulk load stops after this many warnings. Set this parameter when you expect no warnings, but want to verify that the correct file and table are used. If you enter 0, or do not specify a value, the load continues regardless of the number of warnings issued. The default value is 10.
Begin/end column character	Enter the character that designates the beginning or ending of the column.

Related Information

Common target table options [page 963]

3.2.2.23.3.6 Microsoft SQL Server target table options

The following table contains option and description information specific to Microsoft SQL Server target tables. All other option information for target tables can be found in the *Common target table options* [page 963].

Table 120: Options

Option	Description
Allow merge or upsert (This is available for Microsoft SQL Server 2008 and higher only)	Specifies whether the Optimizer may use a MERGE statement to improve the performance of auto correct load functionality. *Yes*: Allows the Optimizer to consider using a MERGE statement during an auto correct load operation. If the Optimizer does not use a MERGE statement, it uses a T-SQL block to identify, insert, and update rows. *No*: The Optimizer will not use a MERGE statement to improve auto correct load performance. The default is Yes. Note When the data flow contains a Query transform with an *Order by* clause, the Optimizer always uses a T-SQL block to identify, insert, and update rows.

Table 121: Bulk loader options

Option	Description
Bulk load	Select this check box to use Microsoft SQL Server bulk loading options to write the data.
Rows per commit	Select this option to load a specified number of rows per commit.
Mode	Specify the mode for loading data in the target table: ● *Append*: Adds new records to the table. ● *Truncate*: Deletes all existing records in the table, and then adds new records.
Maximum rejects	When the value for *Maximum rejects* is exceeded, the bulk loader stops. Set this parameter when you expect no warnings about rejected rows, but want to verify that the correct file and table are being loaded. If you enter `0` or do not specify a value, the load continues regardless of the number of warnings issued. A rejected row contains data that does not match the expected format or information specified for the table being loaded.
Network packet size	Specify the network packet size in KB. Default is 4 KB. When loading, the client caches rows until it either fills a network packet or reaches the commit size (regardless of whether the packet is full). Then the client sends the packet to the server. You can affect performance by tuning commit size and network packet size.

3.2.2.23.3.7 Netezza target table options

The following table contains option and description information specific to Netezza target tables. All other option information for target tables can be found in the common table options (see related links below).

i Note

All options under the Transaction Control category are not available for Netezza (Include in Transaction, Transaction ID, Commit at the end of INSERT...SELECT).

Table 122: Bulk Loader options tab

Option	Description
Bulk load	Select a bulk-loading method: *File*: Writes all data to a file before loading through the external table to the staging table. For files that are smaller than 4 GB in size, select this option for faster performance. *Named pipe*: Streams data as it is written to the named pipe through the external table to the staging table. For files that are larger than 4 GB in size, select this option for faster performance. *None*: Does not use bulk loading (default).
Mode	Specify the mode for loading data to the target table: *Append*: Adds new records to table (default). *Truncate*: Deletes all existing records in table then adds new records.
Update method	Specify how to apply UPDATE SQL. *Delete-insert*: Issues a DELETE to the target table for data that matches the old data in the staging table, and then issues an INSERT with the new data (default). Select this option for faster performance. i Note Do not use this option if the update rows do not contain data for all columns in the target table because SAP Data Services will replace missing data with NULLs. *Update*: Issues an UPDATE to the target table.
Maximum rejects	Enter the maximum number of error records allowed before the software terminates the job. Default is 10.
Commit size	Enter the maximum number of rows loaded to the staging and target tables before saving the data. A value of 0 means the software loads and saves all rows automatically (default). This option overrides the *Rows per commit* setting.
Text delimiter	Enter the character used to delimit (enclose) char or varchar data. Valid values are single quotes, double quotes, or blank (default). If you expect the data to contain single or double quotes, use an Escape character.
Field delimiter	Enter the character that separates the columns in a row. Valid values are all printable characters except the single quote. The default is pipe (|). If you expect the field delimiter character to be present in the varchar or char data, use a Text delimiter.

Option	Description
Generate files only	Select this check box to generate data into a file on the Job Server. This option is useful when you want to manually load data using the SQL statements generated in the .sql script. Default is cleared.
Escape character	If you expect the Text delimiter character or a row delimiter (the ASCII character line feed, LF) to be present in any varchar or char data, enter a backslash (the only valid value) to escape the text or row delimiter before writing to the file or named pipe. (The software also escapes back slashes in the data with a back slash.) If you expect a NULL string as part of varchar data, then you should set the escape character. The NULL string is used as null indicator to identify null values while bulk loading. Note The null indicator string is not case sensitive so if you have varchar data as NULL (case insensitive) the escape character should be set. Default is cleared because this option can degrade job execution performance significantly.
Clean up bulk loader directory after load	Select this check box to delete all bulk-loader-related files (for example dat, sql, nzlog, nzbad, etc.) after the load completes successfully. If an error occurs during the bulk load, the Netezza server creates an nzbad file in the Database server working directory defined in the datastore editor. If you have enabled FTP by configuring the FTP options in the datastore editor, the software transfers the nzbad and nzlog files from the Database server working directory to the Bulk loader directory on the Job Server computer. Default is checked.

Common target table options [page 963]

3.2.2.23.3.8 ODBC target table options

The following table contains option and description information specific to ODBC target tables. All other option information for target tables can be found in the *Common target table options* [page 963].

Table 123: Bulk loader options tab

Note

Bulk loader options are only visible if you are loading to a Netezza target.

Option	Description
Rows per commit	Enter the number of rows that will be loaded before a commit takes place. If no value is entered, the load utility uses the default value at run time. This option is available only when *Bulk load* is set to *import*.

Related Information

Netezza target table options [page 980]

3.2.2.23.3.9 Oracle target table options

The following table contains option and description information specific to Oracle target tables. All other option information for target tables can be found in the *Common target table options* [page 963].

Table 124: Options

Option	Description
Allow merge	Specifies whether the Optimizer may use a MERGE statement to improve the performance of auto correct load functionality. *Yes*: Allows the Optimizer to consider using a MERGE statement during an auto correct load operation. If the Optimizer does not use a MERGE statement, it uses a PL/SQL block to identify, insert, and update rows. *No*: The Optimizer will not use a MERGE statement to improve auto correct load performance. The default is Yes.

Table 125: Bulk loader options tab

Option	Description
Bulk load	Select a bulk loading method. Use database tools to load data in bulk instead of using SQL statements. *API*: Allows you to use an Oracle direct-path load API to load table data directly to database files. The target database must be Oracle 8.1 or later. *File*: Allows you to use a staging file and the Oracle SQL*Loader to load table data. To use this feature, the version of the Oracle SQL*Loader (specified on this tab) and the database (specified in the datastore for the target) must match. If you also want to use the direct-path load method, manually select it from the File Options section. Otherwise, a convention load is performed. Conventional loads generally are slower than direct-path loads because data is loaded to tables rather than directly to database files associated with tables

Option	Description
	None: Allows you to use normal load functionality. See the Options tab.
Mode	Specify the mode for loading data in the target table. Available modes when Bulk load is set to File: *Append*: Adds new records containing the loaded data. *Insert*: Adds new records containing the loaded data. Requires that the table is empty before loading. SQL loader terminates with an error if the table is not empty. *Replace*: Deletes all existing records in the table, and then adds new records containing the loaded data. *Truncate*: Deletes all existing records in the table, and then adds new records containing the loaded data. This mode does not execute any delete triggers. Available modes when Bulk load is set to API: *Append*: Adds new records containing the loaded data. *Truncate*: Deletes all existing records in the table, and then adds new records containing the loaded data.
Rows per commit	Specifies the transaction size in number of rows or bulk loading. If Rows per commit is set to 1000, a commit is sent to the underlying database every 1000 rows. If you do not enter a value, the default (1000) is used. Bulk loading is not available for targets in a real-time jobs.
Maximum rejects	Enter the maximum number of error records allowed before the job is terminated. If you do not enter a value, the default (10) is used.
Recoverable	Select this check box to log direct-path information about the loaded data in the Oracle redo log. Note All conventional loads are automatically specified as recoverable.
Use local index to rebuild primary key	(API method only) Select this option to ensure that the primary key uses the partitioned index (if the table has local partitioned indexes on primary key) instead of any other indexes that are available on primary key.
*SQL *Loader version*	(File method only) The version used to load data into the table. The version of the Oracle SQL*Loader and the database (specified in the datastore for the target) must match.
Text delimiter	(File method only) Enter the character used to delimit char or varchar columns. The default character is a double quotation mark (“). Make sure the character you enter is not used in any of the data columns.

Option	Description
Field delimiter	(File method only) Enter the character used to separate columns. The default character is a comma (,). Make sure the character you enter is not used in any of the data columns. You can specify a non-printable character by entering the ASCII equivalent, such as: **`/ASCII_number`**
Maximum bind array	(File method only) Enter the maximum bind array. The bind array needs to be large enough to contain a single row. For good performance, make this large enough to hold 100 rows. If you do not enter a value, the default Oracle Bulk Loader value is used.
Use the control file	(File method only) Select this check box to load data from a specific bulk loading control file and data file. Rather than loading data from the source shown in the data flow, Data Services directs Oracle to load data from the data file associated with the named control file. Enter the name of the control file. Do not include the `.ctl` extension in the file name. If you do not specify a complete path, Data Services searches for the file in: ● The path you have specified as the bulk loader directory in the datastore definition ● `\$LINK_DIR\log\bulkloader` Both a control file and an associated data file must be in the same directory. If you select this option, you can also select these options or specify these values: ● Direct path ● Clean up bulk loader directory after load ● Rows per commit ● Maximum rejects ● Maximum bind array A variable can also be used.
Generate files only	(File method only) Select this check box to have Data Services generate a data and control file. Rather than loading data into the target shown in the data flow, Data Services generates a control file and a data file that you can later load using Oracle bulk loading. This option is often useful when the target database is located on a system running a different operating system than the Data Services Job Server. Data Services writes the data and control files in the bulk loader directory specified in the datastore definition. You need to copy the files to the remote system manually. Data Services names these files **`<tablename>`** `.ctl` and **`<tablename>`** `.dat`, where **`<tablename>`** is the name of the target table.
Direct path	(File method only) Select this check box to specify a direct-path load.

Option	Description
	To use direct-path load, the version of SQL*Loader available to the Job Server executing the job must be the same as the target database version. For example, you cannot perform a SQL*Loader Version 7.1.2 direct path load to load into a Oracle Version 7.1.3 database. For more information, see the Oracle server documentation.
Clean up bulk loader directory after load	(File method only) Select this check box to have Data Services delete all bulk loader-related files (control file, datafile, log file) after the load is complete. If an error occurs during the bulk load, Data Services creates a `.bad` file and does not delete any files. Errors occur when: ● Log file was not created ● Log file contains “ORA-” or “SQL*Loader-”
Trailing nullcols	(File method only) Select this check box to indicate that columns not represented in the data being loaded should be treated as null columns. Use when a data record is not complete but the existing data needs to be loaded. If this option is not selected, the system generates an error.

3.2.2.23.3.10 SAP HANA target table options

The following table contains option and description information specific to SAP HANA target tables.

Table 126: Options

Option	Description
Table type	For template tables, select the appropriate table type for your SAP HANA target: *Column Store* (default) *Row Store*

Table 127: Bulk loading

Option	Description
Bulk load	Select to enable bulk loading.
Mode	Specify the mode for loading data to the target table: *Append*: Adds new records to the table (default). *Truncate*: Deletes all existing records in the table and then adds new records.
Commit size	The value *default* means Data Services identifies the SAP HANA target table type and applies a default commit size for the maximum number of rows loaded to the staging and target tables before saving the data (committing): *Column Store*: commit size is 10,000 *Row Store*: commit size is 1,000 You can also type a custom value in the field (any value greater than 1).

Option	Description
Update method	Specify how the input rows are applied to the target table: *Default*: Select to let Data Services apply the default value for this option based on the SAP HANA target table type: ● *Column Store* tables use UPDATE. ● *Row Store* tables use DELETE-INSERT. *UPDATE*: Issues an UPDATE to the target table. *DELETE-INSERT*: Issues a DELETE to the target table for data that matches the old data in the staging table, and then issues an INSERT with the new data. Note Do not use DELETE-INSERT if the update rows do not contain data for all columns in the target table, because Data Services will replace missing data with NULLs.

3.2.2.23.3.11 SAP Sybase ASE target table options

The following table contains option and description information specific to SAP Sybase ASE target tables. All other option information for target tables can be found in the common table options (see related links below).

Table 128: Bulk loader options

Option	Description
Mode	Specify the mode for loading data in the target table: *Append*: Adds new records to the table. *Truncate*: Deletes all existing records in the table and then adds new records.
Bulk load	Select this check box to use SAP Sybase ASE bulk loading options to write the data.
Rows per commit	Select this option to load a specified number of rows per commit.
Maximum rejects	When the value for Maximum rejects is exceeded, the bulk loader stops. Set this parameter when you expect no warnings about rejected rows, but want to verify that the correct file and table are being loaded. If you enter `0` or do not specify a value, the load continues regardless of the number of warnings issued.

Option	Description
	A rejected row contains data that does not match the expected format or information specified for the table being loaded.
Network packet size	Specify the network packet size in KB. Default is 4 KB. When loading, the client caches rows until it either fills a network packet or reaches the commit size (regardless of whether the packet is full). Then the client sends the packet to the server. You can affect performance by tuning commit size and network packet size.

Related Information

Common target table options [page 963]

3.2.2.23.3.12 SAP Sybase IQ target table options

The following table contains option and description information specific to SAP Sybase IQ target tables.

Table 129: Bulk loader options

Option	Description
Bulk load	Select this check box to use SAP Sybase IQ bulk loading options to write the data.
SAP Sybase IQ checkpoint	If selected, Data Services enables the SAP Sybase IQ checkpoint as part of the LOAD TABLE SQL statement used to execute the bulk load. If cleared (the default), the checkpoint is not enabled.
Binary format	Select the check box to load the staging and target tables in binary format. This format generally provides faster performance. Clear the check box to load the staging and target tables in delimited format. This format is useful if you want to be able to view the data.
Ignore conversion error	Select to set the SAP Sybase IQ database option CONVERSION_ERROR to OFF. If cleared, Data Services executes with the current database value for the option. For more information, see the SAP Sybase IQ documentation. Conversion errors are reported as warnings in Data Services.
Mode	Specify the mode for loading data into the target table: *Append*: Adds new records to the table. *Truncate*: Deletes all existing records in the table and then adds new records.
Block size (bytes)	The number of bytes read per block. Inappropriate adjustments to this option can dramatically affect performance. Defaults to 500,000 bytes.

Option	Description
File Options	
Field delimiter	This is the delimiter that separates the columns in a row. It can only be a single character (including a non-printable character) and can be represented by a string of ASCII numbers preceded by a forward slash (for instance /95 results in an underscore character while /09 represents a tab). Default value is /127.
Row delimiter	A character sequence that indicates where one row of data ends and the next begins. It can only be a single character; however, you can represent it with a string of up to 4 hexadecimal ASCII characters. Defaults to \n. Field and row delimiters cannot be the same value.
Generate files only	If checked, the software generates the data files in the bulk loader directory specified in the datastore editor and does not execute the bulk load. If cleared (the default), the software generates the data files and executes the bulk load.
Clean up bulk loader directory after load	If checked (the default), the software deletes the data file and auxiliary files after successfully completing the load. If cleared or if the load does not complete successfully, the data file and auxiliary files remain in the bulk loader directory.
Error Handling	
Constraints	The error handling table lets you select which types of constraint violations to ignore and whether to log the errors for each type. Constraint types include *Unique*, *Null*, *Data value*, *Foreign key*, and *All*. For *All*, type the maximum number of constraint violations the software ignores before stopping the job.
Ignore errors	Type the maximum number of violations the software encounters for any given constraint before stopping the job. Typing 0 means tolerate all errors of that constraint (allows unlimited errors).
Log errors	Select the type(s) of constraint violations to log in the message and row log files.

Related Information

Common target table options [page 963]

3.2.2.23.3.13 Teradata target table options

The following table contains option and description information specific to the *Bulk Loader Options* for Teradata target tables. For information on other target table options, see *Common target table options* [page 963].

On the *Bulk Loader Options* tab, the *Bulk loader* choices are:

- FastLoad
- MultiLoad
- TPump
- Parallel Transporter
- Load Utility
- None

The options on the *Bulk Loader Options* tab vary depending on the *Bulk loader* selected. However some options are common to all methods.

FastLoad, MultiLoad, TPump, and Parallel Transporter bulk loaders include several *Attributes*. A different set of attributes displays depending on the bulk loader (and operator) selected. Attribute names in bold indicate that a value is required. You can accept the default values or modify them.

For details on all Teradata options and attributes, consult your Teradata documentation.

Table 130: Common Teradata bulk loader options

Option	Description
File option	Choose the type of file that will contain the data to bulk load: • Data File • Generic Named Pipe • Named Pipes Access Module
Data Services options	
Generate files only	When selected, the software generates a data file and a script file and ignores the *Number of loaders* option (on the *Options* tab). Rather than loading data into the target shown in the data flow, the software generates a control file and a data file that you can later load using Teradata bulk loading. This option is often useful when the target database is located on a system running a different operating system than that of the Job Server. The software writes the data and control files in the bulk loader directory (default value is **`<DS_COMMON_DIR>`**`\log\bulkloader`) specified in the datastore definition. You must copy the files to the remote system manually. The naming conventions for these files is: <**`<DatastoreName_OwnerName_TableName_n>`**.ctl and **`<DatastoreName_OwnerName_TableName_n>`**`.dat` where: • **`<OwnerName>`** is the table owner • **`<TableName>`** is the target table • **`<n>`** is a positive integer, optionally used to guarantee that the software does not overwrite a pre-existing file
Clean up bulk loader directory after load	Select to delete all bulk loader-related files (script, data files, temporary file) after the load is complete. If an error occurs during bulk loading, the software does not delete script and data files. Errors usually occur when: • There is a syntax error in the script. • Error tables are not empty. Error tables contain rows that cannot be inserted into the target table due to data conversion or constraint violation.
Mode	Specifies the mode for loading data into the target table:

Option	Description
	Append: Adds new records to the table. *Replace*: Deletes all existing records in the table, and then inserts the loaded data as new records.
Field delimiter	Specifies a single-character field delimiter. Default value is /127 (non-printable character).
Bulk operation	For MultiLoad and TPump and for the Parallel Transporter bulk loader Update and Stream operators, specify the bulk operation to use: *Insert*: Insert rows. *Upsert* : If the row exists, update it; if not, insert it.
Named pipes access module	For bulk loaders FastLoad, MultiLoad, TPump, and Parallel Transporter with the *File Option Named pipes access module* selected, the following *Named pipe parameters* are available.
Named pipe parameters	You can override the default settings for the following Teradata Access Module parameters: ● Logdirectory ● Loglevel ● Blocksize ● FallbackFilename ● FallbackDirectory ● SignatureChecking The Teradata Access Module creates a log file to record the load status. The Access Module log file differs from the tbuild log that you specify in the *Log directory* option. The Teradata Access Module writes information to fallback data files. If the job fails, the Teradata Access Module uses its log file and fallback data files to restart the load. The bulk loader directory is the default value for both Logdirectory and Fallback-Directory. For more information about these Access Module parameters, see your Teradata tools and utilities documentation.

Table 131: FastLoad bulk loader

FastLoad paramaters	Description
Data encryption	Select to encrypt requests.
Print all requests	Allows printing of every request sent to the Teradata database.
Buffer size	Output buffer size, in kilobyte,s used for Teradata FastLoad messages to the Teradata database. The output buffer size and the size of the rows in the Teradata FastLoad table determine the maximum

FastLoad paramaters	Description
	number of rows that can be included in each message to the database. A larger buffer size reduces processing overhead by including more data in each message. The default buffer size is also the maximum size allowed: 63 kb. If a value greater than 63 kb is specified, Teradata FastLoad: ● Responds with a warning message ● Resets the buffer size back to the default value ● Continues with the Teradata FastLoad job
Character set	Character set specification for the target.

Table 132: MultiLoad bulk loader

MultiLoad parameters	Description
Reduced print output	Select to limit the print output to the minimal information required to determine the success of the job.
Data encryption	Select to encrypt requests.
Character set	Character set specification for the target.

Table 133: TPump bulk loader

TPump parameters	Description
Reduced print output	Select to limit the print output to the minimal information required to determine the success of the job.
Retain macros	Select to keep macro(s) that TPump generates between jobs.
Data encryption	Select to encrypt requests.
Print all requests	Select to allow printing of every request sent to the Teradata database.
Number of buffers	Optionally increase the number of buffers per session from the default of 2 to a maximum of 10.
Periodicity value	This parameter is in effect whenever the Teradata BEGIN LOAD command uses the RATE parameter to control the rate at which statements are sent to the database. The default periodicity value is four 15-second periods per minute. To improve TPump work flow, adjust to a value from 1 to 30.
Character set	Character set specification for the target.
Configuration file	A file that contains various configuration and tuning parameters for TPump.

Table 134: Parallel Transporter bulk loader

Option	Description
Operator	Parallel Transporter operator values include: - Load - Update - Stream - SQL Inserter Note that the *Attributes* vary depending on the *Operator* selected. Refer to your Teradata documentation for information on attributes.
Number of instances	Specify the number of instances for the load operator. This information is included in the Parallel Transporter script that Data Services generates.
Number of DataConnector instances	For the File Option *Data File*, specify the number of DataConnector instances for the read operator to read data files generated by Data Services. This information is included in the Parallel Transporter script that Data Services generates. The value should be less than or equal to the number of data files.
tbuild parameters	
Debug all tasks	Enables debug trace functions for all tasks. Using this option outputs termination return codes that help with script debugging. Corresponds to the tbuild -d option.
Trace all tasks	Enables the trace option for all tasks. If not specified, trace is disabled. Corresponds to the tbuild -t option.
Latency interval (sec)	Latency is the interval value, in seconds, between the flushing of stale buffers. Corresponds to tbuild -l option.
Checkpoint interval (sec)	Specifies a time interval, in seconds, between checkpoints. Defaults to10 seconds. Corresponds to tbuild -z option.

Table 135: Load Utilities

Option	Description
Command line	Use this field to call a custom script. Load utilities include FastLoad, MultiLoad, and TPump. For example for FastLoad, you could enter: `fastload < C:\Teradata\FLScripts\myScript.ctl` Data Services does not parse or modify these scripts.
Named pipe name	For a Load Utility, if you choose either *Named Pipes Access Module* or *Generic Named Pipes* file option, enter the pipe name. On UNIX, the pipe is a FIFO (first in, first out) file that has name of this format: `/temp/`**`<filename>`**`.dat` On Windows, the pipe name has this format: `\\.\pipe\`**`<datastorename_ownername_tablename_loadernum>`**`.dat`

Related Information

Common target table options [page 963]
Teradata [page 902]
Teradata source [page 952]
Performance Optimization Guide: Bulk Loading and Reading, Bulk loading and reading in Teradata [page 2178]

3.2.2.23.4 Target Data_Transfer files and tables

When you add a Data_Transfer transform to a data flow, you create a target for the temporary storage that SAP Data Services uses to process large amounts of data.

3.2.2.23.5 Target XML files, messages, and templates

An XML Schema or DTD format can be added to a job as a target. Choose *Make XML File Target* or *Make XML Message Target* from the context menu that opens when you drop either format into the workspace.

You can also create an XML file target without creating a format by using an XML template.

Option	Description
Make port	Select this check box to make the target file an embedded data flow port.
XML file	(File targets only) The location relative to the Job Server of a file to use as the target. If the file does not exist, SAP Data Services creates it. If the file exists, the software clears the content of the file before writing the output to it. i Note If your Job Server is on a different computer that the Designer, you cannot use Browse to specify the file path. You must type the path. You can type an absolute path or a relative path, but the Job Server must be able to access it. A variable can also be used.
XML test file	(Message targets only) The location relative to the Job Server of a file to use as the message target when you run the job in test mode. If the file does not exist, the software creates it. If the file exists, the software clears the content of the file before writing the output to it. i Note If your Job Server is on a different computer that the Designer, you cannot use Browse to specify the file path. You must type the path. You can type an absolute

Option	Description
	path or a relative path, but the Job Server must be able to access it. A variable can also be used.
Delete and recreate file	Allows you to override the default behavior which is to append new data sets to the file. If selected, the software deletes the old file and creates a new one containing only the current data set.
Print comment	Allows you to include or exclude a comment in the target file data that identifies the data as having been processed by the software.
Replace NULL or blank	Allows you to specify a value that will replace NULL or blank values in element data. Select the check box, then enter a value in the *With* field.
Enable validation	Enable a comparison of the outgoing data to the stored XML Schema or DTD from which this XML file was created. When this option is enabled, the data flow throws an exception if the outgoing data is not valid. When you are developing real-time jobs, this validation helps you ensure sample data is both valid and well-formed. If you turn on this option in production, make sure to include appropriate error handling either in the job or the client application to process an error caused if the real-time job receives data that does not validate against the imported XML Schema or DTD.
Include schema location	Allows you to include or exclude the schema location in the target file data. This check box is selected by default. If you do not want to include the schema location in the XML output, clear this check box.
Include DTD	(For targets created from DTD formats only) The content of an XML target does not normally include the DTD format (which the software uses internally). If you want to add the DTD format to the target file or message, select this check box.
XML encoding	Select an XML encoding for the XML target file. If you do not select a value, the encoding in the XML header field is used. If that field is empty, UTF-8 is used. XML file targets can be saved with a different encoding/code page than the software's system locale. XML message source and target encodings default to UTF-8 and cannot be changed.
XML header	You can use a unique header for each file target. To use this option, you must first enter the header information you want to use for the target. Thereafter, you can edit it from this field. For example, if your header includes more information than the XML Schema version and the encoding, you may want to view and edit this information in the Designer. If you only need to change the XML encoding for this file target, use the XML encoding option instead of editing the header.
DTD file in DOCTYPE	(For targets created from DTD formats only) The content of an XML target does not normally include the DTD format (which the software uses internally). If you want to add a DOCTYPE element to the target file or message, that specifies a path to a DTD format enter the path here or use the Browse button to select one.
Format Name	(Read only) The name of the DTD or XML Schema format used in the Designer.

Option	Description
Root element name	(Read only) The name of the root element used in the DTD or XML Schema.
Namespace	(Read only) The name space used in the XML Schema.

The validation for an XML target allows columns and nested tables marked as optional in the output schema to not be present in the input schema. At run-time the XML target will handle missing columns appropriately.

Locales and Multi-byte Functionality [page 1793]

3.2.2.24 Target Writer migrated from Data Quality

If you migrate a Data Quality repository to SAP Data Services and you have projects that contain database Writer transforms, the resulting SAP Data Services jobs will contain migrated Writer targets. A migrated Writer target contains the SQL statements from the Data Quality Writer transform options *Write_SQL_Statement*, *Pre_Write_SQL_Statement*, and *Post_Write_SQL_Statement*.

For more information, see the *Data Services Upgrade Guide*.

3.2.2.25 Template table

Class

Reusable

Access

- To insert as a target, open a data flow diagram in the work space, click the template table icon in the tool palette, and click anywhere in the data flow.
- To insert as a source, open the object library, click the *Datastores* tab, select the desired template table, and drag into the data flow.
- To view options, click the name of the template table in the workspace or in the project area. This opens the object editor.

Description

Template tables are new tables you want to add to a database. You can use a template table one time as a target and multiple times as a source. You cannot use a template table in an ABAP data flow.

A template table provides a quick way to add a new target table to a data flow. When you use a template table, you do not have to specify the table's schema or import the table's metadata. Instead, during job execution, SAP Data Services has the DBMS create the table with the schema defined by the data flow. After you create a template table as a target in one data flow, you can use the same template table as a source in any other data flow.

Use template tables in the design and testing phases of your projects. You can modify the schema of the template table in the data flow where the table is used as a target. Any changes are automatically applied to any other instances of the template table. During the validation process, the software warns you of any errors, such as errors that result from changing the schema.

Before you can use a template table as a source in a data flow design, the data flow where the template table was created as a target has to be valid and you have to save the data flow.

Before executing any job where a template table is used as a source, you must execute the job where the template table is used as a target at least one time. If the template table is used as a target and a source in the same job, then the data flow where it is used as a target must be executed first.

When running a job where a template table is used as a target, use care if the table already exists. If the *Drop and re-create table* option is selected in the template table editor (this is the default option), the software drops the existing table and creates a new one. If the *Drop and re-create table* option is not selected, the software attempts to load data in the existing table. In this case, the software generates run-time errors if the existing table schema does not match the schema generated in the data flow.

When used as a target, the options available from the target editor for template tables are the same as those available for target tables with some exceptions.

Table 136: Target tab

Option	Description
Table name	The name of the table. Can contain alpha, numeric, and underscores; cannot include blank spaces.

Table 137: Options tab

Option	Description
Column comparison	Drops the existing table and creates a new one with the same name before loading.

Option	Description
Drop and re-create table	Drops an existing table with the same name before creating the table specified by the template table. When using template tables in real-time jobs, deselect this and the *Delete data from table before loading* option. These options are selected by default when you create a template table.
Use NVARCHAR for VARCHAR columns in supported databases	Creates nvarchar columns in the template table for all varchar columns in the input schema of the data flow. The data type displays as varchar in the Designer, and, when supported by the DBMS, as nvarchar in the database table. If you are using an ODBC datastore to connect to Oracle, in the datastore editor for *ODBC Miscellaneous* ▸ *NVARCHAR type name*, select *NVARCHAR2*. See also *ODBC* [page 885]. The following database management systems do not support the nvarchar data type: ● DB2 (non-UTF-8) ● Oracle 8.x ● Informix ● SAP Sybase SQL Anywhere ● SAP Sybase ASE ● SAP Sybase IQ For these DBMSs, the software creates columns with varchar data types and increases the column size using a codepage conversion factor based on the client code page defined in the datastore. ⚠ Caution Data loss may occur when transcoding from one national language to a different national language. Data loss will not occur when transcoding from a national language to Unicode. ⚠ Caution Data truncation occurs when the column size of the source exceeds the maximum size allowed by the target DBMS.

Table 138: Bulk Loader Options tab

Option	Description
Bulk load	Not available for template tables.

Table 139: Load Triggers tab

Option	Description
On operation	Not available for template tables.

Before running production jobs, execute the job to load the target table if you have not already done so, then right-click the template table in the object library or in a data flow and select Import Table. The software creates the table in your database and imports it. All information about the table is marked as part of the database and you can make no further changes to the schema. You can now use the new table in expressions, functions, transform options, or for bulk loading. Other features, such as exporting an object, are available for template tables.

Related Information

Target [page 960]

Message processing [page 945]

3.2.2.26 Transform

Class

Reusable

Access

In the object library, click the *Transforms* tab.

Description

Transforms define your data transformation requirements. Transforms use the operation codes associated with each row of data read from a source. The descriptions of individual transforms indicate which operation codes the transforms ignore or use.

Transforms have the following built-in attributes:

Attribute	Description
Name	The name of the object. This name appears on the object in the object library and in the calls to the object.

Attribute	Description
Description	Your description of the transform. Description is not available for query transforms.

If you delete a user-defined transform from the object library, calls to the object are replaced with an icon indicating that the calls are no longer valid, and it is deleted from the project area.

Related Information

Descriptions of transforms [page 1068]

3.2.2.27 Try

Class

Single-use

Access

With a work flow diagram in the workspace, click the try icon in the tool palette.

Description

A try is part of a serial sequence called a try/catch block. Use a single try with each try/catch block; there can be more than one catch with a single try. The try/catch block allows you to specify alternative work flows if errors occur while SAP Data Services is executing a job. Try/catch blocks "catch" classes of errors, apply solutions that you provide, and continue execution.

Do not reference output variables from a try/catch block in any subsequent steps if you plan on using the automatic recovery feature. Referencing such variables could alter the results during automatic recovery.

Tries have the following attribute:

Attribute	Description
Name	The name of the object. This name appears on the object in the diagram.

Related Information

Catch [page 846]

3.2.2.28 While loop

Class

Reusable

Access

With a work flow diagram in the workspace, click the while loop icon in the tool palette.

Description

A while loop repeats a sequence of steps as long as a condition is true.

For each while loop, specify:

- Condition: In the *While* box enter a Boolean expression that the job evaluates.
  The expression must evaluate to TRUE or FALSE. You can use constants, functions, variables, parameters, and standard operators to construct the expression.
- Set of steps: In the while loop workspace, enter the steps you want completed when the condition is true.
  You can add any objects valid in a work flow, including scripts, work flows, and data flows. Connect these objects to represent the order that you want the steps completed.

  > Note
  >
  > Though you can include the parent work flow in the while loop, recursive calls can create an infinite loop.

Related Information

Designer Guide: While loops [page 335]
Smart editor [page 1021]

3.2.2.29 Work flow

Class

Reusable

Access

- In the object library, click the *Work Flows* tab.
- With a job or work flow diagram in the workspace, click the work flow icon in the tool palette.

Description

A work flow contains data flows and the operations that support data flows. The work flow defines the execution order of the data flows and supporting operations. A job is also a work flow.

You can define parameters to pass values into the work flow. You can also define variables for use inside the work flow.

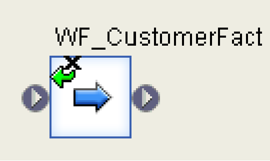
The definition of a work flow can contain the following objects:

- Other work flows
- Data flows
- Scripts
- Try/catch blocks
- Conditionals
- While loops

In some cases, steps in a work flow depend on each other and should always be executed together. You can designate such a work flow (batch jobs only) as a "recovery unit." When designated as a recovery unit, the entire work flow must complete successfully during execution. If any step in such a work flow does not complete successfully, SAP Data Services re-executes all steps in the work flow during automatic recovery, except for ABAP data flows, the software re-executes data flows that executed successfully earlier. The software may or may not re-execute ABAP data flows.

To designate a work flow as a recovery unit, Access work flow Properties, select *Regular* from the *Execution type* dropdown list and select the *Recover as a unit* check box.

On the workspace diagram, a symbol indicates when a work flow is a recovery unit.



3.2.2.29.1 Executing jobs only once

You can ensure that a job executes a work flow only one time by selecting *Regular* from the *Execution type* dropdown list and selecting the *Execute only once* check box on the data flow Properties window. When you select this check box, SAP Data Services executes only the first occurrence of the work flow and skips subsequent occurrences in the job. You might use this feature when developing complex jobs with multiple paths, such as those containing try/catch blocks or conditionals, and you want to ensure that the software executes a particular work flow only once.

Before selecting the *Execute only once* option, note that:

- If you design a job to execute the same *Execute only once* work flow in parallel flows, the software only executes the first occurrence of the work flow, and you cannot control which one the software executes first. Subsequent flows wait until the software processes the first one. The engine provides a wait message for each subsequent work flow. Since only one Execute only once work flow can execute in a single job, the engine skips subsequent work flows and generates a second trace message for each, "Work flow n did not run more than one time. It is an execute only once flow."
- If you design a job to execute more than one instance of the same *Execute only once* work flow, you must manage the values of output variables. The software only processes one such work flow per job. Subsequent instances of the work flow do not run and do not affect the values of variables in the job.
- The *Execute only once* work flow option does not override the *Enable recovery* job option.

Work flows have several built-in attributes.

Attribute	Description
Name	The name of the object. This name appears on the object in the object library and in the calls to the object.
Description	Your description of the work flow.
Date_created	The date that the object was created.

If you delete a work flow from the object library, calls to the object are replaced with an icon indicating that the calls are no longer valid.

3.2.2.30 XML file

Class

Single-use

Access

In the object library, click the *Formats* tab.

Description

An XML file object allows you to indicate a source or target in a batch or real-time job. When used as a source, an XML file object translates incoming XML-formatted data into an internal SAP Data Services data set. When used as a target, an XML file object translates the data produced by a data flow, including nested data, into an XML-formatted file.

The data read into or written out of an XML file must have a single row at the top-level table. When writing out an empty nested table, the software includes a single row of the nested table, with null values in each column of the table.

To produce the metadata that describes the data that an XML file object handles, the software reads an XML Schema or DTD. The metadata is stored in the repository as either an XML Schema or DTD object.

3.2.2.30.1 Source or target

You can insert an XML file into a data flow by dragging either an XML Schema or DTD format from the *Formats* tab of the object library into the workspace of a data flow. When you drop the format in the workspace, SAP Data Services prompts you to specify that the resulting object is a source or target file or a source or target message.

3.2.2.30.2 Parsing input and producing output

Mapping rules govern how SAP Data Services translates an XML Schema or DTD into its internal schema definition and produces XML formatted data from an internal data set.

Related Information

Designer Guide: Formatting XML documents [page 345]

3.2.2.30.3 Properties

XML file properties are the same as those of its format.

Related Information

DTD [page 906]
XML schema [page 1008]

3.2.2.31 XML message

Class

Single-use

Access

In the object library, click the *Formats* tab.

Description

An XML message object allows you to indicate a real-time source or target in a job.

When used as a source, an XML message object translates incoming XML-formatted messages into an internal SAP Data Services data set. When used as a target, an XML message object translates the data produced by a job, including nested data, into an XML-formatted message and sends the message to the Access Server.

When a real-time job contains an XML message source, it must also contain an XML message target.

The data read into or written out of an XML message must have a single row at the top-level table. When writing out an empty nested table, the software includes a single row of the nested table, with null values in each column of the table.

To produce the metadata that describes the data that an XML message handles, the software reads the format for the XML message. The metadata is stored in the repository as an XML Schema or DTD.

Related Information

DTD [page 906]
XML schema [page 1008]

3.2.2.31.1 Source or target

You can insert an XML message into a real-time job by dragging a XML Schema or DTD format from the *Formats* tab of the object library into the workspace of a data flow. When you drop the format in the workspace, you are prompted to specify that the resulting XML message as a source or target.

3.2.2.31.2 Source and Target editors

You can find information about source and target options elswhere in the *Reference Guide*.

Related Information

XML message source [page 955]
Target XML files, messages, and templates [page 994]

3.2.2.31.3 XML test files

During the design phase of your application, you can execute a real-time job in "test mode." In test mode, the real-time job reads messages from an XML test file specified in the source editor, and writes XML-formatted messages to an XML test file specified in the target editor.

3.2.2.31.4 Parsing input and producing output

Mapping rules govern how SAP Data Services translates an XML Schema or DTD into its internal schema definition and produces XML from an internal data set.

See the Nested Data section of the *Designer Guide* for an introduction to the nested relational data model which the software uses to generate an internal hierarchical schema.

Related Information

DTD [page 906]
XML schema [page 1008]

3.2.2.31.5 Properties

XML file properties are the same as those of its format.

Related Information

DTD [page 906]
XML schema [page 1008]

3.2.2.32 XML schema

Class

Reusable

Access

In the object library, click the *Formats* tab, then double-click the XML Schema category.

Description

SAP Data Services supports W3C XML Schemas Specification 1.0. This XML Schema version is documented on the following web site: *www.w3.org/TR/2001/REC-xmlschema-1-20010502/* .

XML Schemas describe the data structure of an XML file or message. Data flows can read and write data to messages or files based on a specified XML Schema format. You can use the same XML Schema to describe multiple XML sources or targets.

To use XML Schemas, import XML Schema metadata into the software. During import, the software converts the structure defined in the XML Schema into the the software internal schema based on the nested relationship data model.

Related Information

Rules for importing XML Schemas [page 1014]

3.2.2.32.1 Editor

Open the XML Schema editor by double-clicking an XML Schema name in the object library.

```
<?xml version="1.0"?>
<xs:schema targetNamespace="http://my-company.com/namespace"
    xmlns:xs="http://www.w3.org/2001/XMLSchema">
```

```
  <xs:element name="Order">
   <xs:complexType>
    <xs:sequence>
        <xs:element name="OrderNo" type="xs:string" />
     <xs:element name="CustID" type="xs:string" />
     <xs:element name="ShipTo1" type="xs:string" />
     <xs:element maxOccurs="unbounded" name="LineItems">
       <xs:completType>
       <xs:sequence>
       <xs:element name="Item"    type="xs:string" />
       <xs:element name="ItemQty"   type="xs:string" />
       <xs:element name="ItemPrice" type="xs:string" />
         </xs:sequence>
       </xs:complexType>
     </xs:element>
    </xs:sequence>
   <xs:complexType>
  <xs:element>
</xs:schema>
```

The XML Schema editor displays:

- The nested schema. This example shows:
  - The object name is Simple_Order.
  - Columns at the top level are OrderNo, CustID, ShipTo1, and ShipTo2.
  - LineItems is a nested table.
  - Item, ItemQty, and ItemPrice are columns nested one level.
- The XML Format tab shows:
  - Full path to the XML Schema format file in the *Imported from* text box.
  - Root element in XML Schema format in the *Root element name* text box.
  - Namespace of XML Schema format in the *Namespace* text box.

Related Information

Designer Guide: Formatting XML documents [page 345]

3.2.2.32.2 Properties

XML schema property	Description
Name	The name of the format. This name appears in the object library under the Formats tab and is used for sources and targets (XML files or messages) that reference this format in data flows.
Description	Text that you enter to describe and document the XML Schema.
Imported from	The full path to the format. For example, `D:\data\test.xsd`.

XML schema property	Description
Root element name	The name of the primary node you want to import. SAP Data Services only imports elements of the format that belong to this node or any sub nodes.
Namespace	(Optional) The Namespace URL of the root element.

3.2.2.32.3 Attributes supported for XML schemas

Column attribute	Description
Required	Indicates whether this column always has to be mapped (YES/NO)
Native Type	Original data type of the column. Saved as a string during import.
Default Value	Default value for this column.
Fixed Value	The only value the column can have.
Max Value Inclusive Of Min Value Inclusive Of Max Value Exclusive Of Min Value Exclusive Of	Mapped from the following data type constraining facets: MaxInclusive, MinInclusive, MaxExclusive, and MinExclusive.
Pattern	For a string: the pattern to which its value should match.
Enumeration	Contains a list of all possible values separated by vertical bars. For example: "Red | White | Blue Green | Magenta". A string is cut off at 256 characters.
XML Type	Allows you to track whether the column wasan element or attribute in the original XML Schema.
Length	Number of characters in this column.
Max Length	Maximum number of characters allowed in this column.
Min Length	Minimum number of characters allowed in this column.
Namespace	Column namespace.

Nested table attribute	Description
Any One Column	If choice (for example, "white | black | almond"), then SAP Data Services sets the value of Any One Column to YES. If sequence (for example, "first, last, street, city, state") then the value is set to NO. If both are present in the XML Schema, the value is set to NO.
Maximum Occurrence	Indicates maximum number of rows in the table.

Nested table attribute	Description
	If maximum occurrence equals zero, the software indicates that your XML Schema structure is not valid.
Minimum Occurrence	Indicates minimum number of rows that can be in the table.
Optional Table	Indicates that an instance document might not contain this table, but the software still accepts the document as input.

Related Information

Column attributes for tables [page 958]

3.2.2.32.4 Supported XML Schema components

SAP BusinessObejcts Data Services supports nearly all valid XML Schemas.

The software supports features such as abstract types and blocking in that the software will import and accept these features without error. Except for abstract types, this document does not discuss such features in depth as they do not have a direct impact on the ability of the software to support XML Schemas.

The software imports XML Schema data types as well as element and attribute names and their structure. Once imported, double-click an XML Schema format from the object library to view table and column names and structure. From the XML Format editor, right-click a column name and select edit properties, attributes, and data types.

Related Information

Unsupported XML schemas [page 1016]

3.2.2.32.5 Abstract datatypes

When you build an XML file or message target using an XML schema that contains elements with abstract datatypes you must set the correct value for the "xsi:type" attribute to generate valid XML output. As data flow designer, you must know which of the many derived types is correct for any given element.

i Note

By default, all elements with abstract datatypes have an attribute called xsi:type.

When using XML Schemas with namespaces, you must include the right namespace in the type name. Obtain the right namespace tag by reviewing the namespace tags generated by SAP Data Services (typically ns1, ns2, ...) then using the tag that represents the right namespace in which the type exists.

Example:

Assume you have an element called Publication which has an abstract type called PublicationType. When the software imports this element, it will add an extra column called "xsi:type" as a child of Publication. You must then set the expression for this column to be equal to the expected type of the result (for instance, it could be BookType). To add the correct tag, first execute your job and note the generated tag names. For this example, it is ns1 for a namespace called <http://www.bookworld.com/>. So, for this example, the expression of xsi:type would be "ns1:BookType".

3.2.2.32.6 XML Schema elements

The following XML Schema elements are mapped to attributes when they are imported as metadata.

XML Schema Element	Attribute (nested table or column)
All	All. Elements should occur but they can occur in any order. See Choice.
Choice	Any One Column. If the complex type for an element has been specified as choice then an attribute called Any One Column is created and set to YES. If the complex type has been defined with sequence or several nesting levels containing a mix of choice and sequence then the Any One Column table attribute is created and set to NO. `<Sequence>` , `<choice>` , and `<all>` are handled as follows: ● Sequence becomes "Any One Column = NO". Attributes A, B, and C become columns A, B, and C. ● Choice becomes "Any One Column = YES": Attributes A, B, and C become columns A or B or C. ● All becomes "All": B, C, and A or any combination of the three.
Default	Default Value
Enumeration	Enumeration. The value for this attribute is cut off after 256 characters. As a result, all the enumerated values may not be visible.
Fixed	Fixed Value
Length MinLength MaxLength	Length, Min Length, and Max Length.
MaxInclusive MinInclusive MinExclusive MaxExclusive	Max Value Inclusive Of, Min Value Inclusive Of, Min Value Exclusive Of, Max Value Exclusive Of.
MaxOccurs	Maximum Occurrence (only applies to tables).
MinOccurs	Minimum Occurrence (only applies to tables).
Name	Column name

XML Schema Element	Attribute (nested table or column)
Pattern	Pattern
TotalDigits and FractionDigits	None. Digits are handled as decimal data types. .
Type	Saved as the Native Type attribute (string). The Type element is also translated into a data type (usually `varchar`).
Sequence	See Choice.

Related Information

Unsupported XML schemas [page 1016]

3.2.2.32.7 XML Schema attributes

The following XML Schema **`<attributes>`** are mapped to Data Services column attributes when they are imported as metadata.

XML Schema Attribute	Column Attributes
Default	Default Value
Fixed	Fixed Value The only value the column can have.
Name	Column name
Type	Saved as the Native Type attribute (string). The Type element is also translated into a data type (usually `varchar`).
Use	An XML Schema **`<Use>`** attribute with a value of OPTIONAL becomes the **`<Required>`** attribute with a value of NO. An XML Schema **`<Use>`** attribute with a value of REQUIRED becomes the **`<Required>`** attribute with a value of YES.

Related Information

Unsupported XML schemas [page 1016]

3.2.2.32.8 Included XML Schemas

An XML Schema can be extended by including pointers to other XML Schema files. This is done by using `<import>`, `<include>` and `<redefine>` . These elements are defined at the schema level.

The difference between `<include>` and `<import>` is that for `<include>` the name spaces must be identical in both XML Schemas. `<Redefine>` is similar to `<include>` except the caller can redefine one or more components in the related XML Schema.

When you import an XML Schema, SAP Data Services follows the links to included files to define additional metadata. The included schema information is saved in the repository so that at run time there is no need to access these files again. Inclusions can be files or URLs.

3.2.2.32.9 Groups

XML Schemas allow you to group elements and then refer to the group. A similar concept is available for attributes (called an attribute group). In SAP Data Services any reference to a group will be replaced by the contents of that group.

3.2.2.32.10 Rules for importing XML Schemas

SAP Data Services applies the following rules to convert an XML Schema to the software's internal schema:

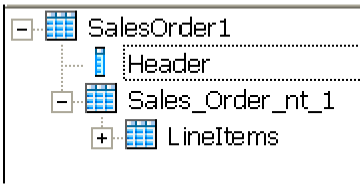
1. Any element that contains an element only and no attributes becomes a column.
2. Any element with attributes or other elements becomes a table.
3. An attribute becomes a column in the table corresponding to the element it supports.
4. Any occurrence of `<choice>` , `<sequence>` or `<all>` uses the ordering given in the XML Schema as the column ordering in the internal data set.
5. Any occurrence of `<maxOccurs ,>` from greater than 1 to “unbounded”, becomes a table with an internally generated name (an implicit table).
   The internally generated name is the name of the parent followed by an underscore, then the string "nt" followed by a sequence number. The sequence number starts at 1 and increments by 1.

After applying these rules, the software uses two additional rules, except where doing so would allow more than one row for a root element:

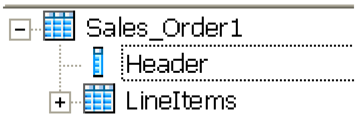
1. If an implicit table contains one and only one nested table, then the implicit table can be eliminated and the nested table can be attached directly to the parent of the implicit table.
   For example, the SalesOrder element might be defined as follows in an XML Schema:

```
<xs:element name="SalesOrder">
<xs:complexType>
<xs:sequence>
<xs:element name="Header"/>
<xs:element name="LineItems" minOccurs="0"
maxOccurs="unbounded"/>
</xs:sequence>
</xs:complexType>
</xs:element>
```

When converted in the software, the LineItems element with MaxOccurs ="unbounded" would become an implicit table under the SalesOrder table. The LineItems element itself would be a nested table under the implicit table.



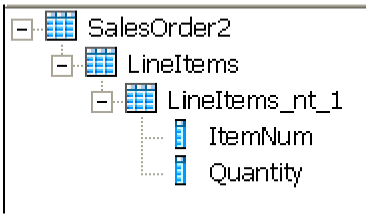
Because the implicit table contains one and only one nested table, the format would remove the implicit table.



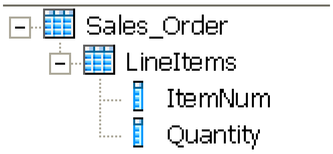
2. If a nested table contains one and only one implicit table, then the implicit table can be eliminated and its columns placed directly under the nested table.
For example, the nested table LineItems might be defined as follows in an XML Schema:

```
<xs:element name="SalesOrder">
<xs:element name="LineItems"  minOccurs="0"
maxOccurs="unbounded">
<xs:complexType>
<xs:sequence>
<xs:element ref="ItemNum"/>
<xs:element ref="Quantity"/>
</xs:sequence>
</xs:complexType>
</xs:element>
```

When converted into the software, the grouping with MaxOccurs ="unbounded" would become an implicit table under the LineItems table. The ItemNum and Quantity elements would become columns under the implicit table.



Because the LineItems nested table contained one and only one implicit table, the format would remove the implicit table.



3.2.2.32.11 Unsupported XML schemas

The following XML Schema elements and attributes are not supported in SAP Data Services. They are ignored and not imported.

Component	Description
Annotation	The softwares ignores both documentation and appinfo annotation components.
Non-native attributes	Non-native attributes are attributes that come from a name space other than the one your XML Schema uses. The W3C XML Schema standard enables users to add non-native attributes to attributes and elements. However, the software ignores all such attributes.
XDR files	The software does not support XML Data Reduced (XDR) files. XDR files were used as a format in some products before XML Schema became the standard. There are third-party tools on the market which can automatically convert XDR to XML Schema.

3.2.2.32.12 Limitations

If an XML schema definition contains the following elements or attributes, SAP Data Services imports it with the following limitations:

- Any element or anyAttribute
  You can import an XML schema that contains an Any element or anyAttribute or both, but the format that the software creates does not show the Any element or anyAttribute.
  Consequently, the software ignores the content of the Any element or anyAttribute when it reads an XML instance document. When an element has type anyType, the software treats everything within it as a string and does not recognize the subelements within it.
- Mixed content
  The structure of an XML schema usually consists of elements that contain subelements, and the subelements at the lowest level contain character data. However, an XML schema definition allows character data to appear next to subelements, and the character data is not confined to the lowest level. For instance documents that contain mixed content, the software ignores the character data between any two subcolumns, but captures the values of the subcolumns.

3.2.2.32.13 Data type mappings

SAP Data Services imports data types for XML Schema elements and attributes.

There are two types of built-in data types, the Primitive data types and the Derived data types (derived from primitive). Each data type has the following values defined: space, lexical space, and constraining facet.

If the constraining facet **`<length>`** is missing when metadata is imported into the software, the default varchar(1024) is applied. Similarly, for a decimal the default values 28 and 2 are applied for **`<precision>`** and **`<scale>`** . All other facets like **`<minInclusive>`** , **`<maxInclusive>`** , **`<minLength>`** are imported as column attributes. Enumeration values are also imported as column attributes.

3.2.2.32.14 Primitive types

The table below lists Primitive XML Schema types, examples, and the corresponding data type in SAP Data Services. The constraining facets used are shown in bold.

XML Schema type	Example	Data type
AnyURI	http://www.example.com/	Varchar(len) : len = *length* (in chars)
Base64Binary	GpM7	Varchar(len) : len = *length* (in octets)
Boolean	{true, false, 0, 1}	Varchar(5)
Date	CCYY-MM-DD	Datetime
DateTime	Format = CCYY-MM-DD HH:MM:SS	Datetime
Decimal	7.999	Decimal(p, s) : p = *totalDigits*, a maximum of 28 and s = *fractionDigits*, default =28,2
Double	64 bit floating point	Double (In the software there is no difference between real and double)
Duration	P1Y2M3DT10H30M	Varchar(64)
Float	32 bit floating point, 12.78e-2	Real
gDay		Varchar(12)
gMonth		Varchar(12)
gMonthDay		Varchar(12)
gYear		Varchar(12)
gYearMonth	Gregorian CCYY-MM	Varchar(12)
HexBinary	0FB7	Varchar(len) : len = *length* (in octets)
Notation		N/A
Qname	po:USAddress	Varchar(len) : len = *length* (in chars)
String	"Hello World"	Varchar(len) : len = *length* (in characters)
Time	HH:MM:SS	Datetime

3.2.2.32.15 Derived types

The table below lists pre-defined Derived XML Schema types, examples, and the corresponding data type in SAP Data Services. The constraining facets used are shown in bold.

XML Schema type	Example	Data type
NormalizedString	[No tab/CR/LF in string]	Varchar(len) : len = *length* (in characters)
Token		Varchar(len) : len = *length* (in characters)
Language	En-GB, en-US, fr	Varchar(len): len = *length* (in characters)
NMTOKEN	US, Brésil	Varchar(len): len = *length* (in characters)
NMTOKENS	Brésil Canada Mexique	Varchar(len): len = *length* (in characters)
Name	ShipTo	Varchar(len): len = *length* (in characters)
NCName	USAddress	Varchar(len): len = *length* (in characters)
ID		Varchar(len): len = *length* (in characters)
IDREF		Varchar(len): len = *length* (in characters)
IDREFS		Varchar(len): len = *length* (in characters)
ENTITY		Varchar(len): len = *length* (in characters)
ENTITIES		Varchar(len): len = *length* (in characters)
Integer		Int
NonPositiveInteger		Int
NegativeInteger		Int
Long		Decimal 28,0
Int		Int
Short		Int
Byte		Int
NonNegativeInteger		Int
UnsignedLong		Long
UnsignedShort		Int
UnsigedByte		Int
PositiveInteger		Int
AnyType (ur-type)	unspecified type	Varchar(255)

3.2.2.32.16 User-defined types

User-defined types are XML Schema attributes with a non-XML Schema name space. The XML Schema W3C standard uses a SimpleType element for a user-defined type.

When SAP Data Services finds a user-defined type it finds the base type and uses it to assign a data type for the element. For example: If element X has type TelephoneNumber, its type in the software is `varchar(8)`.

Some simple types are based on other simple types. In such cases the software traces back to the base type.

3.2.2.32.17 List types

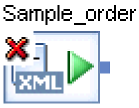
XML Schemas have list types. When it encounters a list, SAP Data Services makes that list's corresponding data type a `varchar(1024)`. All the elements of the list are placed in the value of that column as a string (exactly as it is represented in the XML).

3.2.2.32.18 Union types

A union type enables an attribute or element value to be one or more instances of one type drawn from the union of multiple primitive type and list types. When it encounters a union, SAP Data Services makes that union's corresponding data type a `varchar (1024)`.

3.2.2.32.19 Metadata

If you delete an XML Schema from the object library, XML sources or targets that are based on this format are invalid. SAP Data Services marks the source or target objects with an icon that indicates the calls are no longer valid.



To restore the invalid objects, you must delete the source or target and replace it with a source or target based on an existing XML Schema.

3.2.2.32.20 Error checking

SAP Data Services allows you to control whether it checks each incoming XML file or message for validity against the imported XML Schema. Select *Enable Validation* for an XML source or target in its editor. If you choose to check each XML file or message, the software uses the XML Schema imported and stored in the repository rather than a XML Schema specified by a given XML file or message. If a file or message is invalid relative to the XML Schema, the job produces an error and shuts down.

A typical example of when the software throws validation errors is when either a required element is missing or a new and unexpected element is present in the input. This is true of both the source and target. Consider the following examples:

- A element is defined in the XML Schema with enumeration values of "Black", "White", "StainlessSteal", and "Almond." If the mapping of that element from the XML document yields "Red" that would be incorrect XML. But the XML file target generates the XML regardless. If validation is enabled, then this error is detected.
- If an element's whitespace attribute is set to `collapse`, the software does not change the data in sources or targets to respect this setting. The whitespace attribute is not supported in the software.

During development, you might validate all messages to test for error conditions with representative messages. During production, you might choose to accept rare invalid messages and risk ambiguous or incorrect data.

The software supports XML Schema legal naming such as allowing multiple elements and attributes to have the same name. However, name conflicts should be identified and tested before you import an XML Schema. The software cannot detect naming conflicts and may not report accurate errors which could later lead to runtime errors.

3.2.2.33 XML template

Class

Single-use

Access

To insert as a target:

- Select the XML Template icon in the tool palette, then click the data flow diagram in the workspace.

To view options:

- Click the name of the XML template in the workspace or in the project area. This opens the object editor.

Description

Use an XML template to create an XML file that matches a particular input schema. The XML template does not require and does not produce a corresponding XML Schema or DTD format. Likewise when it generates XML, it does not create column attributes if they are present in its input schema.

Thus, you can use the XML template to produce an XML file without predefining an XML format. You can use an XML template as a target in a batch or real-time job. In an XML template, all data types are converted to varchar.

After adding an XML template to a data flow, specify the name and location of the file. In the XML template target file editor, specify the file in the *XML file* box.

> ℹ Note
>
> When using XML templates in real-time jobs, deselect the *Delete and recreate file* option in the target editor. This option is selected by default when you create an XML target.

Related Information

Target XML files, messages, and templates [page 994]

3.3 Smart editor

This section provides details about options available in the Designer smart editor. Use the smart editor to create scripts, expressions, and custom functions without having to type the names of existing elements like column, function, and variable names.

Related Information

Scripting Language [page 1709]
Custom functions [page 1694]

3.3.1 Accessing the smart editor

Access and use the embedded smart editor as a pane within any object editor in the Designer, or open the smart editor as a separate, full-size window.

For example, use the *Mapping* tab in a query to access smart editor:

1. Drag a column from an input schema into an output schema to enable the smart editor.

2. Enter text and select options using the smart editor's right-click menu, or click the ellipsis button to open the full-size smart editor window.

   > **i Note**
   >
   > You cannot add comments to a mapping clause in a Query transform. For example, the following syntax is not supported on the Mapping tab:

   ```
   table.column # comment
   ```

   The job will not run and you cannot successfully export it. Use the object description or workspace annotation feature instead.

When you open the smart editor window, the context of the object from which you opened it is displayed in the title bar.

You can open the smart editor from the following locations:

- Query Editor *Mapping* tab
- Query Editor *From* tab
- Query Editor *Where* tab
- Script Editor
- Conditional Editor
- While Loop Editor
- Custom Function Editor
- Function wizard, "Define Input Parameter(s)" page
- SQL - Transform Editor
- Case Editor

3.3.2 Smart editor options

3.3.2.1 Smart editor toolbar

In addition to standard toolbar icons (Open, Save, Print, Undo, Redo, Cut, Copy, Paste, Find, Replace, and Help), the smart editor toolbar also includes special icons to speed up your editing experience. Special smart editor toolbar icons include:

Icon	Description
Show/Hide Editor Library	Toggle to hide or show the Editor Library pane.
Show/Hide keypad	Toggle to hide or show an editing keypad.
Open selection list	Click to show a list of scripting options. Scroll and select the option you want. Double-click or press Enter/Return to add the option to your script.
Function wizard	Click to open the Function wizard window.

Icon	Description
Validate	Click to check your script for errors.

3.3.2.2 Editor Library pane

Use the *Show/Hide Editor Library* icon in the toolbar to show or hide the smart editor library. The library:

- Displays functions, variables, and data using Tabs.
- Allows you to search each tab using the Find option.

3.3.2.2.1 Tabs

The *Functions* tab displays existing functions in SAP Data Services: built-in, custom, and imported.

The *Variables* tab displays variables, parameters, data type formats, and right-click menu options that can be used in the current context. For example, if you open the smart editor to create a custom function, the *Variables* tab will include options on its right-click menu that you can use to insert, delete, and define properties for new parameters and local variables.

The *Data* tab displays the schemas of data flow sources including nested schemas for the current context. For example, if you open the smart editor from an object in a data flow, such as a WHERE clause of a query, schemas are displayed for connected sources. If you open the smart editor from a script object, the *Data* tab is not displayed.

3.3.2.2.2 Find option

You can search or browse through each tab to find the content you want to include in your script or expression.

3.3.2.3 Editor pane

3.3.2.3.1 Syntax coloring

When you type in the editor pane, the text changes color indicating the type of script language element it represents:

- Quoted strings are shown in pink
- Keywords in blue
- Comments in green
- Functions, operators, and variables are shown in black

3.3.2.3.2 Selection list and tool tips

You can use the smart editor with or without showing the editor library. The same list of context-based items available for use when the library is shown is also available in the editor when the selection list is enabled. The selection list shows these items in alphabetical order instead of grouping them into the categories shown in the library. In addition, the selection list displays keywords available for the context in which the editor is opened.

When the selection list is enabled, you can open it from the tool bar. The selection list also opens automatically when it recognizes a string pattern as you type into the editor.

3.3.2.3.2.1 To use the selection list and a tool tip

1. Right-click the editor, view the menu, and make sure that the *Enable Selection List* and *Enable Tool Tip* items are selected.
2. In the editor, enter at least three characters, or the dollar sign variable symbol ($).

   The selection list opens over the editor and highlights the first item (in this alphabetized list) that matches the characters you entered.

   Alternatively, you can click the Open Selection list icon in the tool bar.
3. Double-click an item in the selection list to insert the item in the editor and view an associated tool tip.

   The tool tip displays the same description, definition, or syntax that you would see if the item were selected from the editor library.
4. Complete the script or expression using these tools.

   For example, if you are completing a look-up function, the tool tip will remain on the screen so that you can follow the syntax of the function. If you enter an input value of the wrong data type, the tool tip closes, indicating an error.

3.3.2.3.3 Right-click menu and toolbar

The right-click menu and the tool bar share many commands.

Menu	Toolbar	Key Command
	Open	
	Save As	
	Print	Ctrl + P
Undo	Undo	Ctrl + Z
Redo	Redo	Ctrl + Y
Cut	Cut	Ctrl + X
Copy	Copy	Ctrl + C

Menu	Toolbar	Key Command
Paste	Paste	Ctrl + V
Select All		Ctrl + A
Find	Find	Ctrl + F
Replace	Replace	Ctrl + H
Validate	Validate	
Enable ToolTips		
Enable Selection List		
	Show/Hide Editor library	
	Show/Hide keypad	
	Open selection list	Alt+Down
	Function wizard	
	Help	

Important things to remember:

- *Enable ToolTips* and *Enable Selection List* can only be selected using the right-click menu.
- The library, key pad, selection list, and function wizard can be opened from the tool bar.
- Keyboard shortcuts are available for most commands.

3.3.2.3.4 Validation

The smart editor has an embedded error display that includes a script error highlight feature. If validation can occur for the current context, the *Validate* option will be available from the tool bar and right-click menu.

3.3.2.3.4.1 To validate

1. Select the Validate icon in the tool bar or right-click and select *Validate*.

   If errors occur, they are listed in a separate pane below the editor.
2. Double-click each error.
3. The editor redraws to show you where the error occurred in your text.

i Note

If the *Validate* option is not displayed, the expression must be validated in the context of the whole object. Close the full-size smart editor window. The expression is shown on the embedded smart editor. From the Designer menu select ▶ *Debug* ▶ *Validate* ◀.

Related Information

Debugging and Validation [page 1717]

3.3.3 To browse for a function

1. Expand the nodes to find the function you need:
   - Built-in functions are grouped by type
   - Custom functions are listed under the Custom node
   - Imported functions and stored procedures are listed under the name of the datastore used to import them.
2. Click a function and read its description and syntax in the yellow area below the tabs.
3. When you have the function you need, place it into the editor.

3.3.4 To search for a function

1. Select the position in the editor where you want to place the function.
2. In the *Functions* tab of the editor library, select the *Find* node.
3. Enter a string such as `loo`.
4. Press *Enter* or *Tab*.

   All functions that contain the string are returned under the node.
5. To place the function into the editor, do one of the following:
   - double-click
   - drag-and-drop
   - right-click the function and select *Enter*
   - select the function and press *Enter* or *Tab*

3.4 Data Types

Data types are internal storage formats used to store values. A data type implies a default format for displaying and entering values. *Expressions* are a combination of constants, operators, functions, and variables that evaluate to a value of a given data type.

This section discusses how SAP Data Services processes, converts, and evaluates data types.

3.4.1 Descriptions of data types

Data types are internal storage formats used to store values. Data types also imply certain default formats for displaying and entering values. In SAP Data Services:

- Data read from sources is converted to the appropriate SAP Data Services data types.
- Data loaded to targets is converted from their SAP Data Services data types to types appropriate for the target.

The software recognizes the following data types:

- *date* [page 1027]
- *datetime* [page 1029]
- *decimal* [page 1030]
- *double* [page 1030]
- *int (integer)* [page 1031]
- *interval* [page 1031]
- *long* [page 1032]
- *numeric* [page 1035]
- *real* [page 1036]
- *time* [page 1036]
- *timestamp* [page 1037]
- *varchar* [page 1038]

All of these data types allow NULL values.

3.4.1.1 date

The date data type defines calendar dates.

SAP Data Services automatically converts date values to and from the formats used by an external DBMS. Conversion operations from strings to dates, or from dates to strings or numbers require you to specify the format of the date value. To specify a date format, generate a string from the following codes and other literal strings or punctuation.

Date format code	Description	Example
DD	2-digit day of the month value (1-31)	The 2nd day of the month: `02`
MM	2-digit month number (1-12)	The month of March: `03`
MONTH	Full name of the month	The first month of the year: `JANUARY`
MON	Abbreviated, three-character name of month	The first month of the year: `JAN`
YY	2-digit year A `YY` less than 15 is interpreted as being 20 **<yy>** ; for example, 10 would be interpreted as being the year 2010. A `YY` greater than or equal to 15 is interpreted as being 19 **<yy>** ; for example, 35 would be interpreted as being the year 1935. To change the value that the software uses to interpret 2-digit year dates, change the *Century Change Year* value in the Data options. (Select ▶ *Tools* ▶ *Options* ▶ to open the *Options* window, and then select *General* under the *Data* category). The value must be a positive integer between 0 and 99.	The year 1998: `98`
YYYY	4-digit year	The year 1999: `1999`

You can perform various operations on dates such as add and subtract date, datetime, interval, and time values.

The following examples show the use of date formats with functions. The value of the variable `MyDate` is the first day of 1996.

> **Note**
>
> If you use lower case to type “mon” or “month”, the resulting value of `to_char` will be in lower case (For example, jan or january). If you use upper case for “MON” or “MONTH”, the resulting value of `to_char` will be in upper case (For example, JAN or JANUARY).

Example	Output
`to_char($MyDate, 'YYYY.MM.DD')`	1996.01.01

Example	Output
`to_char($MyDate, 'MONTH DD, YYYY')`	JANUARY 01, 1996
`to_char($MyDate, 'DD/MM/YY')`	01/01/96
`to_date('01/01/96','DD/MM/YY')`	1996.01.01 stored as a date
`to_date('01/01/19','DD/MM/YY')`	2019.01.01 stored as a date

Related Information

Date arithmetic [page 1039]

3.4.1.2 datetime

The datetime data type defines calendar dates and times.

SAP Data Services manages date operations in the format used by your DBMS. Conversion operations to or from datetime values require you to specify the format of the datetime. This data type behaves like a concatenation of two data items: The rules for the datetime type are the date rules for the date part, and the time rules for the time part.

If a date field is converted to a datetime value, the default time added to the value is 00:00:00. If a time is converted to a datetime value, the default date added to the value is 0000.01.01. You can also add and subtract date, datetime, interval, and time values.

When converting datetime values to strings, you can choose the sections of the value not to convert by excluding them from the format description. For example, to convert a datetime value to a string containing only the time, specify the function parameters as follows:

```
to_char($MyDateTime, 'hh24:mi:ss.ff')
```

For Oracle, if you load datetime data from SAP Data Services into a char field in an Oracle table, Oracle puts the data in its default datetime format—which includes only date values—and loses the time from the value.

Related Information

Date arithmetic [page 1039]

3.4.1.3 decimal

The decimal data type defines exact decimal numbers.

When specifying a decimal data type in Data Services, you indicate the following characteristics of the type:

Precision: The total number of digits in the value.

Scale: The number of digits to the right of the decimal point.

In the software, the following relations must hold for precision and scale:

1 <= precision <= 96

0 <= scale <= precision

The decimal value can have a plus or minus sign indicating a positive or negative value. The sign can appear before or after the value with any number of blanks between the value and the sign. Unsigned values are considered to be nonnegative. The sign does not count as part of precision.

Leading zeros are permitted in the integer digit, and trailing zeros are permitted in the fraction part.

Input that is more precise than the data type of the column or variable in which it is stored is rounded. Input out of range (absolute value is too large) causes a runtime error.

> i Note
>
> Data Services uses a maximum of 28 precision. Data Services does not enforce precision (that is, having a larger number will not cause an error). Instead, Data Services will round any number more than 28.

The decimal data type and the numeric data type are identical in the software.

> i Note
>
> When you import a table from an Oracle datastore and the native column data type is NUMBER (without any specific precision and scale) the software imports the column as Decimal (28,7) by default. You can override the default Precision and Scale values for an Oracle table at the database level by entering the values in the Advanced section of the Create New DataStore option.

Related Information

Create New Datastore: Oracle options [page 893]

3.4.1.4 double

The double data type defines an 8-byte floating point value, with radix, exponent range, and precision of the platform on which SAP Data Services is running.

3.4.1.5 int (integer)

The int data type defines a 4-byte signed binary integer.

The int value can have a plus or minus sign indicating a positive or negative value. The sign can appear before or after the value with any number of blanks between the value and the sign. Unsigned values are considered to be nonnegative.

3.4.1.6 interval

The `interval` data type defines differences between dates or times. The value is in days unless you specify another unit, such as in a conversion function.

SAP Data Services provides conversion functions to make interval values accessible:`interval_to_char` and `num_to_interval`.

You can add and subtract date, datetime, interval, and time values.

This data type allows NULL values.

Related Information

Date arithmetic [page 1039]

3.4.1.7 Limitations for long and blob

In general, you cannot use long or blob columns in comparisons, calculations, or data type conversions (except for long_to_varchar and varchar_to_long).

Therefore, you cannot use long or blob in the following situations:

- Join, key, compare, or pivot columns
- SQL functions, for example substr
- Expressions and conditions
- SELECT lists of queries containing GROUP BY clauses
- SELECT lists of queries with the Distinct Rows option enabled
- GROUP BY, ORDER BY, or WHERE clauses
- Input or output parameters or return type of functions, for example lookup
- Variable data types
- Work flow and data flow input and output parameters
- Debug filters

The following table shows some of these limitations by transform.

Transform	Do not use long or blob column data in
Case	case condition
Hierarchy_Flattening	parent or child columns
History_Preserving	compare columns
Pivot	pivot transform
Table_Comparison	primary key columns or compare column
Query transform	WHERE, GROUP BY, ORDER BY, or DISTINCT

SAP Information Steward also ignores the auto-correct load option for target tables that contain a long or blob column. The software resets the option and issues a warning message at run time to indicate that the auto-correct load option has been disabled.

i Note

To use large object data types with Informix datastores, you must first configure the Informix ODBC options. For more information, refer to the Informix datastore options.

Related Information

Informix [page 875]

3.4.1.7.1 long

SAP Data Services uses long to represent character-based large objects (clob). The software also converts several other database-specific large object types such as longvarchar and text to the long data type. The Data Services long data type supports mapping from all databases.

The software stores long columns either in memory or in the file system during the data flow execution depending on the size of the long value.

File format considerations for long

You can define long data type columns in Data Services delimited files, XML files, and XML messages. The long data can be in the file or can reference an external file. The notation for this external file is <<**`<filename>`**>>. The software automatically generates the file name.

For example, consider a comma-delimited file format that contains the following database columns:

Column name	Data type
ProductNo	integer

Column name	Data type
Description	long
Picture	blob

In Example 1, the long data appears in the file, but in Example 2, it references a file. The file name designates a path relative to the original input/output file or an absolute path.

Example 1:

```
7369,WidgetA transforms questionable data into trusted sources through a single
environment.,<<pictures\WidgetA.jpg>>
```

Example 2:

```
7499,<<descriptions\WidgetC_descr.txt>>,<<C:\Widgets\pictures\WidgetC.jpg>>
```

Limitations for long

The following limitations exist for long data types:

- The software does not convert between long and any other data types except varchar. You can only convert long to or from varchar using the varchar_to_long() or long_to_varchar() functions.
- Long can be stored in blob.
- When loading a long or longraw column to an Oracle target, the software always extracts and loads the data in separate steps, so it cannot push down the SELECT and load operations in one statement. This restriction does not apply to the Oracle clob, nclob, or blob columns.

Long and blob data types share many of the same limitations (see "Related Topics").

Related Information

Limitations for long and blob [page 1031]
blob [page 1033]
Conversion to or from internal data types [page 1040]

3.4.1.7.2 blob

The binary large object (blob) data type stores any kind of data in binary format. It is commonly used for multimedia data such as images, audio, and video.

Blob columns are stored in the file system during the data flow execution.

File format considerations for blob

You can define blob data type columns in SAP Data Services fixed-width files, delimited files, XML files, and XML messages. You can define an unlimited number of blob columns in a file format, and the blob columns can appear in any order in a file format.

In fixed-width file formats:

- All blob columns are sized in bytes, not characters.
  - The minimum field size of a blob column is 1 byte.
  - The maximum field size is 32,768 bytes.
- Blob data is always inline with the rest of the data in the fixed-width file. The term *inline* means the data itself appears at the location where a specific column is expected.
  For example, consider a fixed-width file format with the following columns:

Column name	Data type
EmployeeNo	integer(4)
LastName	varchar(15)
FirstName	varchar(15)
Password	blob(10)

  In the following sample rows, the blob data (represented by '?'s) appears inline in the file.

7369	Washington	George	??????????
8272	Lincoln	Abraham	??????????

In delimited text files, XML files, and XML messages, blob columns always reference an external file. The notation for this external file is `<filename>`. The software automatically generates the file name.

For example, consider a comma-delimited file format that contains the following three columns:

Column name	Data type
ProductNo	integer
Description	long
Picture	blob

In the following sample row, the blob column references the external file.

```
7369,WidgetA transforms questionable data into trusted sources through a single
environment.,<<pictures\WidgetA.jpg>>
```

You can use blob data types in sources and targets and pass them through transforms.

- When the software reads blob data from fixed-width flat file, it does not trim the leading or trailing 0x00 bytes. It will not treat all 0x00s as Null. They will be stored as is.
- When the software loads a blob into a fixed-width flat file, if the size of the input blob data is not equal to the target blob field size, an error occurs. If the input blob consists of only 0x00s or is a NULL value, the software loads all 0x00s up to the size of the field size of the target blob column.

Database considerations for blob

Data Services can load blob columns to:

- Databases that support parameterized loading.
- Databases with API-based bulk loaders (not file-based bulk loaders), which include:

Database	Bulk loader
Oracle	API
DB2	CLI load
Microsoft SQL Server	Bulk load
SAP Sybase ASE	Bulk load

Limitations for blob

The following limitations exist for blob data types:

- There are no data type conversions between blob and any other data types.
- Blob cannot be stored in long.
- The NULL indicator is not supported for blob data.
- The Data Preview pane in the Designer cannot display blob data.
- The View Data utility shows the data for a blob column as `<blob>`.
- Blob and long data types share many of the same limitations (see "Related Topics").

Related Information

long [page 1032]

Conversion to or from internal data types [page 1040]

Limitations for long and blob [page 1031]

3.4.1.8 numeric

The `decimal` data type and the `numeric` data type are identical in SAP Data Services. See *decimal* [page 1030] for data type information.

3.4.1.9 real

The real data type defines a 4-byte floating point value, with radix, exponent range, and precision of the platform on which SAP Data Services is running.

The real value can have a plus or minus sign indicating a positive or negative value. The sign can appear before or after the value with any number of blanks between the value and the sign. Unsigned values are considered to be nonnegative.

Databases store real values as a 32-bit approximation of the number. Because of this approximation, comparison results are unpredictable when a real value is used in an equality or inequality comparison.

Therefore, it is recommended that you do not use a real value in a WHERE clause. Real values appear in WHERE clauses that the software generates when a column of type real is used:

- As a compare column in the Table_Comparison transform
- In the Map_Operation transform with an opcode of update or delete
- Explicitly in the WHERE clause of a Query transform

In some cases, columns of type real might unintentionally appear in the WHERE clause of these transforms. For example, when no compare columns are specified in a Table_Comparison transform, the transform uses all columns of the table as compare columns. Similarly, if the source of a Map_Operation transform does not have primary key specified and the opcode is update or delete, the transform uses all source columns in the WHERE clause of the UPDATE or DELETE statement.

Use caution when using the `real` data type in these transforms.

For more information, consult the appropriate reference material for Windows NT.

3.4.1.10 time

The time data type defines times of the day, with no calendar date.

SAP Data Services manages time operations in the format used by your database manager. Conversion operations to or from times require you to specify the format of the time value. To specify a time format, generate a string from the following codes and other literal strings or punctuation.

Time format code	Description
HH24	2-digit hour of the day (0-23)
MI	2-digit minute (0-59)
SS	2-digit second (0-59)

The following examples show the use of time formats with functions. The value of the variable `MyTime` is 25 minutes after 8 in the evening.

Example	Output
`to_char($MyTime, 'HH24:MI:SS.FF')`	`20:25:00`

Example	Output
`to_char($MyTime, 'HH24:MI')`	`20:25`

You can add and subtract date, datetime, interval, and time values.

Related Information

Date arithmetic [page 1039]

3.4.1.11 timestamp

The `timestamp` data type supports the `timestamp` (with no zone information) data type in Oracle 9i. The `timestamp` data type incorporates up to a 9-digit sub-second.

Arithmetic

Add or subtract timestamp values. The resulting data type from addition or subtraction operations depends on the operation and data types involved. See *Date arithmetic* [page 1039] for details.

Conversion between timestamp and character strings

You can convert between timestamp values and character values using the to_date and to_char functions. These functions have a format called FF which indicates the sub-second digits. For example, valid function calls are:

```
to_date ('2002.02.26 01234004 09:03:25','yyy.mm.dd ff hh24:mi:ss')

to_char (timestamp_column, 'yyyy.mm.dd hh24:mi:ss.ff')
```

Use the FF format for datetime columns to access sub-seconds. For example, a DB2 timestamp column is mapped to datetime in SAP Data Services. This column contains micro-second. You can access these sub-seconds using the FF format.

Limitations

You cannot use timestamp columns in the SQL transform or in an Oracle stored procedure.

To use a timestamp column in the SQL transform, convert the timestamp column in the select list of the SQL transform to a character format using the to_char function and convert it back to timestamp using the to_date function.

To use a timestamp column in an Oracle stored procedure, convert input and output timestamp parameters in the stored procedure to char, using the to_char function and convert the output parameter back to timestamp in SAP BusienssObjects Data Services using the to_date function. Alternatively, you can convert the input parameter back to timestamp in the stored procedure using the Oracle to_timestamp function.

3.4.1.12 varchar

When specifying a varchar data type, indicate the following characteristic of the type:

Characteristic	Description
Length	Number of characters that the variable or column can hold. Length must be greater than zero. There is no maximum allowable value for the length.

Character strings longer than the number of characters defined for the column or variable are truncated on the right to the length of the data type. Only the required number of characters is used to store strings shorter than length.

SAP Data Services provides functions to convert values to and from strings; to join strings together, use the concatenation operator (||). This data type allows NULL values.

The software conforms to the ANSI SQL-92 varchar standard and treats varchar data as follows:

- Keeps trailing blanks in character values that you insert into varchar columns.
- Keeps trailing blanks when you read from sources with string data types. If you want to remove trailing blanks from your input data, you must use the rtrim or rtrim_blanks function.
- Ignores trailing blanks when you compare varchar data in transforms (Case, Query, and Table_Comparison) and functions (decode, ifthenelse, lookup, lookup_ext, lookup_seq).

  Note

  Not all database servers follow the ANSI standard for trailing blanks in insert, select, and compare operations. Therefore, if the software pushes down the insert, select, and compare operations to the database servers, the operations might return different results than when the software evaluates them. For the most current information on the treatment of trailing blanks, refer to the documentation for the specific database server.

- The ANSI standard treats an empty string as a zero length varchar value.

  Note

  The software treats an empty string differently, depending on the source type. For example, Oracle treats an empty string as a NULL value, but DB2 and Microsoft SQL Server treat an empty string as a zero-length varchar value. For the most current information on the treatment of empty strings, refer to the documentation for your specific database server.

- When using the Equal (=) or Not Equal (<>) operators to compare a value with a NULL constant, the comparison always evaluates to FALSE. Use the IS NULL and IS NOT NULL operators to test for NULL values in the WHERE clause of the Query transform, the lookup_ext function, and the SAP Data Services scripting language.

If you currently run the software pre-version 11.5.0 scripts and data flows, it is recommended that you migrate them to use the ANSI varchar behavior because the previous varchar behavior will not be supported in a future version.

The software supports reading, transforming, and loading National Language Supported (NLS) data from different language locales using the varchar data type. The software supports national character-set data types in the following databases:

Database	Version	National character-set data type
DB2	7.0 and higher	graphic, vargraphic
MS SQL Server	7.0 and higher	nchar, nvarchar
Oracle	9i and higher	nchar, nvarchar2

When the software encounters a national character-set data type in an expression, it binds the column with the data type recommended by the database. Likewise, when using the Metadata Exchange command in the Designer, the data type used in the database (not Data Services' `varchar` data type) is passed on to an SAP BusinessObjects universe.

The engine reads and loads national character-set data types seamlessly without the need for you to configure a locale for a database client and its datastore for the columns that use these data types.

3.4.2 Data type conversion

This section discusses how Data Services processes various data types—conversions during arithmetic operations and between data types.

3.4.2.1 Date arithmetic

Data Services performs some implicit data type conversions on `date`, `time`, `datetime`, `timestamp`, and `interval` values when performing date arithmetic. The following table describes these conversions:

Operation	Return type
DATE + INTERVAL	DATE
TIME + INTERVAL	TIME

Operation	Return type
DATETIME + INTERVAL	DATETIME
INTERVAL + INTERVAL	INTERVAL
DATE - DATE	INTERVAL
DATE - INTERVAL	DATE
TIME - TIME	INTERVAL
TIME - INTERVAL	TIME
INTERVAL - INTERVAL	INTERVAL
DATETIME - DATE	INTERVAL
DATETIME - TIME	INTERVAL
DATETIME - DATETIME	INTERVAL
DATETIME - INTERVAL	DATETIME
TIMESTAMP + TIMESTAMP	INTERVAL
TIMESTAMP - TIMESTAMP	INTERVAL
TIMESTAMP + INTERVAL	TIMESTAMP
TIMESTAMP - INTERVAL	TIMESTAMP

3.4.2.2 Conversion to or from internal data types

Data Services performs data type conversions when it imports metadata from external sources or targets into the repository and when it loads data into an external table or file. The software uses its own conversion functions rather than those specific to the database or application that is the source of the data.

Additionally, if you use a template table or Data_Transfer table as a target, the software converts from internal data types to those of the respective DBMS.

3.4.2.2.1 Unsupported data types

Data Services can read, load, and invoke stored procedures involving unknown data types provided that your database servers can convert from VARCHAR to the native (unknown) data type and from the native (unknown) data type to VARCHAR. Data Services might have a problem loading VARCHAR to a physical CLOB column if the native database does not support that conversion (for example, bulk loading or auto-correct load could fail).

When the software encounters a column assigned to an unsupported data type, it does not import the metadata for the column and indicates an error. The file errorlog.txt contains an entry indicating the column that is ignored. To include the column in your job, convert the data type to one supported by the software before importing the metadata for the table.

> ℹ Note
>
> Use the varchar_to_long function to convert a VARCHAR data type to a LONG datatype before loading physical CLOB. If from a prior installation, you are using a VARCHAR column in the physical schema for loading, this will still work.

3.4.2.2.2 Attunity Streams

The following table shows the conversion from Attunity Streams data types to Data Services data types when Data Services imports metadata from an Attunity Streams source or target into the repository.

Attunity Streams data type	Converts to Data Services data type
bigint	double ℹ Note Because int is only four bytes, data is lost during the conversion.
double	double
float	double
long varchar	Converted to long only if imported using an ODBC datastore.
real	real
date	datetime
decimal	decimal
integer	int
smallint	int
time	time
timestamp	datetime
varchar	varchar

3.4.2.2.3 Cobol copybook

The following table shows the conversion from COBOL copybook data types to Data Services data types when Data Services imports metadata from a COBOL copybook source or target into the repository.

COBOL copybook data type	Converts to Data Services data type
computational	decimal
comp	decimal

COBOL copybook data type	Converts to Data Services data type
computational-1	float
comp-1	float
computational-2	double
comp-2	double
computational-3	decimal
comp-3	decimal
computational-4	decimal
comp-4	decimal
computational-5	decimal
comp-5	decimal

HP Neoview data type	Converts to or from Data Services data type
date	date
time	time
timestamp	timestamp
interval	not supported

The following table shows the conversion from internal data types to HP Neoview data types in template tables or Data_Transfer transform tables.

Data Services data type	HP Neoview data type in template table
blob	not supported
date	date
datetime	timestamp
decimal	decimal
double	double precision
int	int
interval	float
long	varchar
numeric	Decimal: if precision is < = 18 Numeric: if precision is > 18
real	float
time	time
varchar	varchar
timestamp	timestamp

3.4.2.2.6 IBM DB2

The following table shows the conversion between DB2 data types and Data Services data types when Data Services imports metadata from a DB2 source or target into the repository and when it loads data into an external table or file.

DB2 data type	Converts to or from Data Services data type
bigint	int Note Because int is only four bytes, data is lost during the conversion to Data Services data type.
blob	blob

DB2 data type	Converts to or from Data Services data type
character	varchar
clob	long
date	date
dbclob	long
decimal	decimal
double	double
float	double
graphic	varchar
integer	int
long varchar	long
long vargraphic	long
real	real
smallint	int
time	time
timestamp	datetime
varchar	varchar
vargraphic	varchar

The following table shows the conversion from internal data types to DB2 data types in template tables or Data_Transfer transform tables.

Data Services data type	DB2 data type in template table
blob	blob
date	date
datetime	date
decimal	decimal
double	double
int	int
interval	real
long	clob
numeric	character
real	real
time	time
varchar	varchar
timestamp	date

3.4.2.2.7 Informix

The following table shows the conversion between Informix data types and Data Services data types when Data Services imports metadata from an Informix source or target into the repository and when it loads data into an external table or file.

Informix data type	Converts to or from Data Services data type
blob	blob
byte	blob
char	varchar
character	varchar
character varying	not supported
clob	long
date	date
datetime	datetime
dec	decimal
decimal	decimal
double	double
float	double
int	integer
integer	integer
money	decimal

real	double
time	date
varchar	varchar2
timestamp	timestamp

3.4.2.2.14 SAP HANA

The following table shows the conversion between SAP HANA data types and Data Services data types when Data Services imports metadata from an SAP HANA source or target into the repository and when it loads data into an external table or file.

SAP HANA data type	Converts to Data Services data type
integer	int
tinyint	int
smallint	int

SAP HANA data type	Converts to Data Services data type
bigint	decimal
char	varchar
nchar	varchar
varchar	varchar
nvarchar	varchar
decimal or numeric	decimal
float	double
real	real
double	double
date	date
time	time
timestamp	datetime
clob	long
nclob	long
blob	blob
binary	blob
varbinary	blob

The following table shows the conversion from internal data types to SAP HANA data types in template tables.

Data Services data type	Converts to SAP HANA data type
blob	blob
date	date
datetime	timestamp
decimal	decimal
double	double
int	integer
interval	real
long	clob/nclob
real	decimal
time	time
timestamp	timestamp
varchar	varchar/nvarchar

3.4.2.2.15 SQL Anywhere

The following table shows the conversion between SAP Sybase SQL Anywhere data types and Data Services data types when Data Services imports metadata from a SQL Anywhere source or target into the repository and when it loads data into an external table or file.

SQL Anywhere data type	Converts to or from Data Services data type
BIT	int
[UNSIGNED] TINYINT	int
[UNSIGNED] SMALLINT	int
INT or INTEGER	int
UNSIGNED INT or INTEGER	decimal(10,0)
BIGINT	decimal(19,0)
UNSIGNED BIGINT	decimal(20,0)
DEC or DECIMAL	decimal
NUMERIC	decimal
FLOAT(1-24) or FLOAT	real
FLOAT(25-53)	double
REAL	real
DOUBLE [PRECISION]	double
SMALLMONEY	decimal(10,4)
MONEY	decimal(19,4)
CHAR	varchar
NCHAR	varchar
VARCHAR	varchar
NVARCHAR	varchar
LONG VARCHAR	long
LONG NVARCHAR	long
TEXT (LONG VARCHAR)	long
NTEXT (LONG NVARCHAR)	long
XML	long
UNIQUEIDENTIFIERSTR (CHAR(26))	varchar(36)
DATE	date
TIME	time
SMALLDATETIME	datetime
DATETIME	datetime
TIMESTAMP	datetime

SQL Anywhere data type	Converts to or from Data Services data type
BINARY	blob
IMAGE	blob
LONG BINARY	blob
VARBINARY	blob
UNIQUEIDENTIFIER	blob

The following table shows the conversion from internal data types to SQL Anywhere data types in template tables or Data_Transfer transform tables.

Data Services data type	SQL Anywhere data type in template table
blob	LONG BINARY
date	DATE
datetime	DATETIME
decimal	DECIMAL
double	DOUBLE
int	INTEGER
interval	REAL
long	LONG VARCHAR/LONG NVARCHAR
real	REAL
time	TIME
timestamp	DATETIME
varchar	VARCHAR/NVARCHAR

Note

When using SQL Anywhere:

- TIMESTAMP supports six-digit sub-seconds (i.e. milliseconds)
- DECIMAL supports precision up to 96 due to ACTADECIMAL_MAXPRECISION (SQL Anywhere supports precision up to 127)
- VARCHAR columns support max length of 32767 characters
- LONG columns support a maximum length of 2GB characters

3.4.2.2.16 SAP Sybase ASE

The following table shows the conversion between SAP SAP Sybase ASE data types and Data Services data types when Data Services imports metadata from a Sybase ASE source or target into the repository and when it loads data into an external table or file.

SAP Sybase ASE data type	Converts to or from Data Services data type
binary	not supported
bit	int
char	varchar
datetime	datetime
decimal	decimal

timestamp	timestamp

3.4.2.2.18 Teradata

The following table shows the conversion between Teradata data types and Data Services data types when Data Services imports metadata from a Teradata source or target into the repository and when it loads data into an external table or file.

Teradata data types	Converts to or from Data Services data type
blob	blob
byteint	int
clob	long
char varying (n)	varchar(n)
char [(n)]	varchar(n)
date	date
decimal	decimal
double precision	float

Teradata data types	Converts to or from Data Services data type
float	float
int	int
long varchar	long
long vargraphic	long
numeric	decimal
real	float
smallint	int
time	time
timestamp	datetime
varchar < 32000	varchar
varchar >= 32000	long
varbyte < 32000	not supported
varbyte >= 32000	blob

The following table shows the conversion from internal data types to Teradata data types in template tables or Data_Transfer transform tables.

Data Services data type	Teradata data type in template table
blob	blob
date	date
datetime	timestamp
decimal	decimal
double	N/A
int	int
interval	N/A
long	long varchar
numeric	N/A
real	N/A
time	time
varchar	varchar
timestamp	N/A

3.4.2.3 Conversion of data types within expressions

When possible, SAP Data Services optimizes data flows by pushing expressions down to an underlying database manager. In a single transaction, the software can push down expressions so that they are performed by the underlying database manager. However, when the software evaluates an expression which includes operands of more than one data type, the software attempts to convert the operands to the same data type first. (Except for national character-set data types which can be pushed down while others in an expression are not. For more information about supported national character-set data types, see *varchar* [page 1038]).

When a conversion is required, the software provides a message at validation.

If the conversion is illegal, the software provides an error and you must remove the mismatch before executing the job.

If the conversion is legal, the software provides a warning indicating that it will not interrupt job execution.

Note

When the software converts a data type to evaluate an expression, the results might not be what you expect. To avoid legal but incorrect conversions, always validate before executing and examine the circumstance of any data type conversion warnings.

3.4.2.4 Conversion among number data types

SAP Data Services uses a type-promotion algorithm to evaluate expressions that contain more than one number data type. Number data types are ranked from highest to lowest, as follows:

- decimal
- double
- real
- int

If the software encounters expressions that have more than one number data type among the operands, it converts all of the operands to the data type of the operand with the highest ranking type.

For example, if A is an `int` and B is a `double`, the expression `A+B` is evaluated by first converting A to `double` and then adding the two `double` values. The result is type `double`.

If in addition to A and B, you multiply the result by a `decimal` number C, then `(A+B)*C` is evaluated by first converting `(A+B)` to decimal, and then performing the indicated operations on the two `decimal` values. The result is type `decimal`.

For addition, subtraction, and multiplication, the operation result will be equal to the higher of the two operands. For example:

```
int + double = double
```

The following algorithm is used for division:

Numerator data type	Denominator data type			
	int	real	double	decimal(p,s1)
int	double	double	double	decimal(p,s1)
real	double	double	double	decimal(p,s1)

Numerator data type	Denominator data type			
	int	real	double	decimal(p,s1)
double	double	double	double	decimal(p,s1)
decimal(p,s2)	decimal(p,s2)	decimal(p,s2)	decimal(p,s2)	decimal(p,max(10,s1,s2))

Conversion among decimals of different scale or precision

If decimals of two different scales are included in a single expression, the software uses the higher of the two scales. For example:

```
decimal(5,4) * decimal(7,2) = decimal(7,2)
```

Expect a loss of precision when operating on two `decimals` of different scale values. For example, when adding a `decimal(28, 26)` to a `decimal(28,1)`, the resulting decimal value has the lower of the two scale values:

```
400000.5 + 40.00005 = 400040.5
```

The least scale for division involving a decimal is 10.

Conversions between strings and numbers

When the software encounters a string where a number would normally be expected (for example, in mathematical operations or functions that expect numeric arguments), it will attempt to convert the string to a number.

For multiplication and division operations, operands are converted to numbers. Other promotion algorithms are shown in the following table.

Table 140: Addition

Provided data type	Data type required to evaluate the expression		
	Number	Date/time	String
Number	OK (promoted)	Number to interval	String to number
Date/time	Number to interval	Illegal	String to interval
String	String to number	String to interval	String to real

Table 141: Subtraction

Provided data type	Data type required to evaluate the expression			
	Number	Date/time	String	Interval
Number	OK (promoted)	Illegal	String to number	Interval to number
Date/time	Number to interval	OK	String to interval	OK

Provided data type	Data type required to evaluate the expression			
	Number	Date/time	String	Interval
String	String to number	String to datetime	String to real	String to number
Interval	Number to interval	Illegal	String to interval	OK

Table 142: Comparison

Provided data type	Data type required to evaluate the expression			
	Number	Date/time	String	Interval
Number	OK (promoted)	Illegal	String to number	OK
Date/time	Illegal	OK	Illegal	Illegal
String	Illegal	String to datetime	OK	String to interval
Interval	OK	Illegal	String to interval	OK

Conversions between strings and dates

For Oracle, if you load datetime data from SAP Data Services into a char field in an Oracle table, Oracle puts the data in its default datetime format—which includes only date values—and loses the time from the value.

3.4.2.5 Conversion between explicit data types

You can use functions to convert data from one type to another:

- *interval_to_char* [page 1578]
- *julian_to_date* [page 1591]
- *num_to_interval* [page 1635]
- *to_char* [page 1676]
- *to_date* [page 1678]
- *to_decimal* [page 1679]

You can also import database-specific functions to perform data type conversions.

3.4.2.6 Conversion between native data types

A Data Quality transform can get and set field data in a format other than the declared data type. For example, if the input field is varchar, it can be mapped to an int data type field, as long as the varchar field contains all digits. However, certain conversions are not supported depending on the data type and field content.

Note

When a data type is mapped to an input or output field that is an invalid data type, the transform issues a verification error.

Example

The USA Regulatory Address Cleanse transform has a varchar type input field named Postcode_Full. Varchar field types can write to any kind of data type as long as the data is formatted correctly, and contains all digits. The Postcode_Full field could be integer because the field contains numbers. However, the Postcode_Full field could not be date type because it does not conform to the date format.

The remaining portion of this section lists each field type and the applicable and invalid data types for each.

3.4.2.6.1 date

Input: A transform can read from a date input field to the following data types:

- date
- character
- datetime

Output: A transform may write to the following data types from a date data type:

- date
- character
- datetime

Invalid input and output data types for date:

- integer
- double
- decimal

3.4.2.6.2 datetime

Input: A transform can read from a datetime input field to the following data types:

- datetime
- character
- date (with possible truncation)
- time (with possible truncation)

Output: A transform may write to the following data types from a datetime data type:

- datetime
- character

- date (with possible truncation)
- time (with possible truncation)

Invalid input and output data types for datetime:

- integer
- double
- decimal

3.4.2.6.3 decimal

Input: A transform can read from a decimal input field to the following data types:

- decimal
- character
- integer (data may be truncated)
- double (data may be truncated)

Output: A transform may write to the following data types from a decimal data type:

- decimal
- character
- integer (with possible truncation)
- double (with possible truncation)

Invalid input and output data types for decimal:

- date
- time
- datetime

3.4.2.6.4 double

Input: A transform can read from a double input field and write to the following data types:

- double
- character
- decimal (with possible truncation)
- integer (with possible truncation)

Output: A transform may write to the following data types from a double data type:

- double
- character
- decimal (with possible truncation)
- integer (with possible truncation)

Invalid input and output data types for double:

- date
- time
- datetime

3.4.2.6.5 int (integer)

Input: A transform can read from an int (integer) input field to the following data types:

- integer
- character
- decimal
- double

Output: A transform may write to the following data types from an int data type:

- integer
- character
- double
- decimal

Invalid input and output data types for int:

- date
- time
- datetime

3.4.2.6.6 varchar

Input: A transform may read input varchar data to any other supported data type. However, if the varchar data is not formatted correctly for the data type, the results are undefined. For example, if a varchar data type is converted to integer, it must contain all digits to convert correctly.

Output: A transform may write any supported data type to a varchar data type. The transform automatically converts the field contents to varchar data.

> Note
>
> The data may be truncated if the output field is not long enough.

3.5 Transforms

A transform is a step in a data flow that acts on a data set. Built-in Data Services transforms are available through the object library.

3.5.1 Operation codes

Data Services maintains operation codes that describe the status of each row in each data set described by the inputs to and outputs from objects in data flows. The operation codes indicate how each row in the data set would be applied to a target table if the data set were loaded into a target. The operation codes are as follows:

Operation Code	Description
NORMAL	Creates a new row in the target. All rows in a data set are flagged as NORMAL when they are extracted by a source table or file. If a row is flagged as NORMAL when loaded into a target table or file, it is inserted as a new row in the target. Most transforms operate only on rows flagged as NORMAL.
INSERT	Creates a new row in the target. Rows can be flagged as INSERT by the Table_Comparison transform to indicate that a change occurred in a data set as compared with an earlier image of the same data set. The Map_Operation transform can also produce rows flagged as INSERT. Only History_Preserving and Key_Generation transforms can accept data sets with rows flagged as INSERT as input.
DELETE	Is ignored by the target. Rows flagged as DELETE are not loaded. Rows can be flagged as DELETE in the Map_Operation and Table Comparison transforms. Only the History_Preserving, transform with the *Preserve delete row(s) as update row(s)* option selected, can accept data sets with rows flagged as DELETE.
UPDATE	Overwrites an existing row in the target table. Rows can be flagged as UPDATE by the Table_Comparison transform to indicate that a change occurred in a data set as compared with an earlier image of the same data set. The Map_Operation transform can also produce rows flagged as UPDATE. Only History_Preserving and Key_Generation transforms can accept data sets with rows flagged as UPDATE as input.

3.5.2 Descriptions of transforms

The transforms described in this section are available from the object library on the *Transforms* tab.

The transforms that you can use depend on the Data Services package that you have purchased. If a transform belongs to a package that you have not purchased, it is unavailable and cannot be used in a Data Services job.

Transforms are grouped into the following categories:

- Data Integrator: Transforms that allow you to extract, transform, and load data. These transform help ensure data integrity and maximize developer productivity for loading and updating data warehouse environment.

- Data Quality: Transforms that help you improve the quality of your data. These transforms can parse, standardize, correct, enrich, match and consolidate your customer and operational information assets.
- Platform: Transforms that are needed for general data movement operations. These transforms allow you to generate, map and merge rows from two or more sources, create SQL query operations (expressions, lookups, joins, and filters), perform conditional splitting, and so on.
- Text Data Processing: Transforms that help you extract specific information from your text. These transforms can parse large volumes of text, allowing you to identify and extract entities and facts, such as customers, products, locations, and financial information relevant to your organization.

Table 143: Data Integrator transforms

Transform	Description
Data_Transfer	Allows a data flow to split its processing into two sub data flows and push down resource-consuming operations to the database server.
Date_Generation	Generates a column filled with date values based on the start and end dates and increment that you provide.
Effective_Date	Generates an additional "effective to" column based on the primary key's "effective date."
Hierarchy_Flattening	Flattens hierarchical data into relational tables so that it can participate in a star schema. Hierarchy flattening can be both vertical and horizontal.
History_Preserving	Converts rows flagged as UPDATE to UPDATE plus INSERT, so that the original values are preserved in the target. You specify in which column to look for updated data.
Key_Generation	Generates new keys for source data, starting from a value based on existing keys in the table you specify.
Map_CDC_Operation	Sorts input data, maps output data, and resolves before- and after-images for UPDATE rows. While commonly used to support Oracle changed-data capture, this transform supports any data stream if its input requirements are met.
Pivot (Columns to Rows)	Rotates the values in specified columns to rows. (Also see Reverse Pivot.)
Reverse Pivot (Rows to Columns)	Rotates the values in specified rows to columns.
Table_Comparison	Compares two data sets and produces the difference between them as a data set with rows flagged as INSERT and UPDATE.
XML_Pipeline	Processes large XML inputs in small batches.

Table 144: Data Quality transforms

Transform	Description
Address Lookup	Completes and populates addresses with minimal data, and can offer suggestions for possible matches.
Associate	Compares group numbers to find associated matches from different Match transforms.
Country_ID	Parses input data and then identifies the country of destination for each record.

Transform	Description
Data_Cleanse	Identifies and parses name, title, and firm data, phone numbers, Social Security numbers, dates, and e-mail addresses. It can assign gender, add prenames, generate Match standards, and convert input sources to a standard format. It can also parse and manipulate various forms of international data, as well as operational and product data.
DSF2 Walk Sequencer	Adds delivery sequence information to your data, which you can use with presorting software to qualify for walk-sequence discounts.
Geocoder	Identifies and appends geographic information to address data such as latitude and longitude.
Global_Address_Cleanse	Identifies, parses, validates, and corrects global address data, such as primary number, primary name, primary type, directional, secondary identifier, and secondary number.
Match	Compares records, based on your criteria, or business rules, to find matching records in your data.
USA_Regulatory_Address_Cleanse	Identifies, parses, validates, and corrects USA address data according to the U.S. Coding Accuracy Support System (CASS).
User_Defined	Does just about anything that you can write Python code to do. You can use the User-Defined transform to create new records and data sets, or populate a field with a specific value, just to name a few possibilities.

Table 145: Platform transforms

Transform	Description
Case	Simplifies branch logic in data flows by consolidating case or decision making logic in one transform. Paths are defined in an expression table.
Map_Operation	Modifies data based on current operation codes and mapping expressions. The operation codes can then be converted between data manipulation operations.
Merge	Unifies rows from two or more sources into a single target.
Query	Retrieves a data set that satisfies conditions that you specify. A Query transform is similar to a SQL SELECT statement.
Row_Generation	Generates a column filled with integer values starting at zero and incrementing by one to the end value you specify.
SQL	Performs the indicated SQL query operation.
Validation	Ensures that the data at any stage in the data flow meets your criteria. You can filter out or replace data that fails your criteria.

Table 146: Text Data Processing transforms

Transform	Description
Entity_Extraction	Extracts information (entities and facts) from unstructured data and creates structured data that can be used by various business intelligence tools.

i Note

For all transforms, to refresh a target schema after making changes to transform options, choose *View* ▸ *Refresh* or press *F5*.

3.5.3 Data Integrator transforms

3.5.3.1 Data_Transfer

Writes the data from a source or the output from another transform into a transfer object and subsequently reads data from the transfer object. The transfer type can be a relational database table or file.

Use the Data_Transfer transform to push down operations to the database server when the transfer type is a database table. You can push down resource-consuming operations such as joins, GROUP BY, and sorts.

Related Information

Performance Optimization Guide: Splitting a data flow into sub data flows [page 2153]
Target options [page 1072]

3.5.3.1.1 Data inputs

The data input is from a source or the output data set from another transform with rows flagged with the NORMAL operation code. This data is referred to as the *input data set*.

The input data set must not contain hierarchical (nested) data.

3.5.3.1.2 Editor

Use the Data_Transfer editor to specify the transfer type and options associated with that type. Depending on the transfer type you select, additional tabs appear.

- When *Transfer type* is `Table` and *Database type* is any RDBMS (such as `Oracle` or `Microsoft SQL Server`), additional tabs are Options, Bulk Loader Options, Pre-Load Commands, and Post-Load Commands.

The Options tab displays the DDL to create the table. You can modify this CREATE TABLE statement to add clauses such as EXTENTSIZE. You can also save this DDL to execute later.

3.5.3.1.3 Target options

The tabs that appears on the target editor depends on the transfer type that you specify.

3.5.3.1.3.1 General tab

Transfer type	Option	Description
File, Table, or Automatic	*Enable transfer*	Enables or disables the execution of the Data_Transfer transform. It is selected by default. You might want to disable this transform if you are tuning performance and you want to see the effect of the Data_Transfer transform. Note When you run the job in debug mode, Data Services automatically disables all Data_Transfer transforms.
File	*File options: File name*	Name of the flat file that you want to use as transfer for sub data flows. The file does not need to exist.
File	*File options: Root directory*	The name of the root directory that will contain the file to use for transfer. If your default Job Server and Designer reside on the same computer, you can use the browse button (ellipses) to find the *Root directory*. If your default Job Server does not reside on your local computer, you must manually enter the path to your *Root directory*. You can use a global variable or parameter for the pathname.
File, Table, or Automatic	*Join rank*	Indicates the rank of the output data set relative to other tables and files joined in a data flow. The software joins sources with higher join ranks before joining sources with lower join ranks. Join rank specified in the Query transform editor FROM tab overrides any join rank specified in a source. For new jobs, specify the join rank only in the Query transform editor. Must be a non-negative integer. Default value is 0.

Transfer type	Option	Description
Table - relational	*Table options: Array fetch size*	Indicates the number of rows retrieved in a single request to a source database. The default value is 1000. Higher numbers reduce requests, lowering network traffic, and possibly improve performance. The maximum value is 5000. This option is available for source tables from DB2, Informix, ODBC, Oracle, and SQL Server datastores. When retrieving a column with an Oracle long data type, Data Services automatically sets Array Fetch Size to 1. If a column has an Oracle long data type, Data Services can only retrieve one row at a time.
Table - relational	*Table options: Database type*	Select an item in the *Database type* box to set the content of additional tabs on the Data_Transfer transform editor to match the specific options for that database type. This option allows you to quickly set target option values in data flows. If your target datastore has multiple configurations, the target editor lists database types that you defined for your datastore configuration. To add or remove items in this list, edit the datastore configuration information in the datastore editor. Data Services allows you to use target table editor option values from any datastore configuration: ● If the datastore has only one configuration, then the initial values for the target table editor are defaults set by Designer for that database type or version. ● If the datastore has more than one configuration and there are different database types/versions, then Data Services determines the initial values for the additional database types/versions from the *Use values from* box in the Create New Configuration dialog (a sub-dialog of the datastore editor). ● If you also select the *Restore values if they already exist* check box (in the Create New Configuration dialog), Data Services looks for previously defined values that once existed for that database type or version. It is possible for a data flow to contain target table editor values for a database type or version, even if its datastore configuration was deleted. Data Services retains all target table editor values saved with every datastore configuration. If such values exist, then it restores those values. Otherwise, it gets the values from the configuration you select from the *Use values from* option.

Transfer type	Option	Description
		For example, suppose you set a configuration for Oracle 8i. When you edit the target table editor options, you change the *Rows Per Commit* default value of 1000 to 500. Later you add a new datastore configuration for a Microsoft SQL Server 2000 database to your original datastore and set the *Use values from* option to Oracle 8i. In this case, the target table editor settings for SQL Server inherit the value 500 for *Rows per Commit* because this was the value set in the Oracle 8i configuration.
Table - relational	*Table options: Table name*	Name of the database table that you want to use as transfer for sub data flows. Specify the table name with the following format: `<datastorename.ownername.tablename>` You can click the browse button (ellipses) to display your datastores. Select a table name from the list or type in the name of a new table.
File, Table, or Automatic	*Transfer type*	Choose one of the following transfer types to temporarily store the data of each sub data flow: ● *Table:* Database table from an existing datastore. If you choose this type, specify the Table options below (*Table name*, *Database type*, and *Array fetch size*). ● *File:* A flat file. If you choose this type, specify the File options below (*Root directory* and *File name*). ● *Automatic:* The Data Services optimizer chooses the transfer type from: ○ Your datastores that selected the *Enable automatic data transfer* check box, or ○ The pageable cache directory that you specify in the Server Manager. The Data Services optimizer chooses the transfer type and location that could provide the optimal performance, based on subsequent operations that the data flow contains. For example, if an ORDER BY follows the Data_Transfer transform, the optimizer might pick the database datastore that contains the data so that the ORDER BY can be pushed down to the database. If the data flow does not contain an ORDER BY, GROUP BY, DISTINCT, join, or any expression that can be pushed down, the Optimizer chooses the pageable cache directory. If multiple files are available (one on

Transfer type	Option	Description
		each job server in a server group), the optimizer chooses the directory that is local to the data flow process.

3.5.3.1.3.2 Options tab

Transfer type	Option	Description
Table - relational database	*Data definition language (DDL)*	You can edit or save the SQL CREATE TABLE statement that Data Services generates. You might want to add extra parameters (such as table space name or extent size) or type in your own DDL statement. Data Services saves the DDL and uses it at job execution time.
Table - relational database	*Delete data before loading*	Deletes the existing data in the table before loading. Defaults to selected. Clear this checkbox to append data to the existing data in the table.
Table - relational database	*Drop and re-create before loading*	Drops the existing table and creates a new one with the same name before loading. Defaults to selected. Note Unlike a template table, you can use bulk loading options for a transfer table even when the *Drop and re-create before loading* is checked.
Table - relational database	*Enable partitioning*	(Displayed only if the transfer table is either physically partitioned or logically partitioned) Enables Data Services to use the partition information in this transfer table. If you select *Enable partitioning*, Data Services transfers data using the number of partitions in the table as the maximum number of parallel instances. If you select *Enable partitioning*, you cannot select *Number of Loaders*.
Table - relational database	*Generate default DDL*	Click this button to display the SQL CREATE TABLE statement that Data Services generates.
Table - relational database	*Number of loaders*	Loading with one loader is known as "single loader loading." Loading when the number of loaders is greater than one is known as "parallel loading." The default number of loaders is 1. You can specify any number of loaders.

Transfer type	Option	Description
		If you select *Number of Loaders*, you cannot select *Enable partitioning*. When parallel loading, each loader receives the number of rows indicated in the Rows per commit option, in turn, and applies the rows in parallel with the other loaders. For example, if you choose a Rows per commit of 1000 and set the number of loaders to 3, the first 1000 rows are sent to the first loader. The second 1000 rows are sent to the second loader, the third 1000 rows to the third loader, and the next 1000 rows back to the first loader.
Table - relational database	*Rows per commit*	Specifies the transaction size in number of rows. If set to 1000, Data Services sends a commit to the underlying database every 1000 rows. This option is not available for targets in real time jobs.

3.5.3.1.3.3 Bulk Loader Options tab

Transfer type	Option	Description
Table - relational database	-	Available options depend on the database in which the table is defined. See *Target tables* [page 963].

3.5.3.1.3.4 Pre-Load Commands and Post-Load Commands tabs

Transfer type	Option	Description
Table - relational database	-	Specify SQL commands that Data Services executes before starting a load or after finishing a load into a transfer table. When a data flow is called, Data Services opens all the objects (queries, transforms, sources, and targets) in the data flow. Next, Data Services runs the target's preload script. Therefore, Data Services executes any preload SQL commands before processing any transform. ℹ Note Because Data Services executes the SQL commands as a unit of transaction, you should not include transaction commands in preload or postload SQL statements.

Transfer type	Option	Description
		Both the *Pre Load Commands* tab and the *Post Load Commands* tab contain a *SQL Commands* box and a *Value* box. The *SQL Commands* box contains command lines. When you first open the tab, an empty line appears. To edit a line, select the line in the *SQL Commands* box. The text for the SQL command appears in the *Value* box. Edit the text in that box. To add a new line, determine the desired position for the new line, select the existing line immediately before or after the desired position, right-click, and choose *Insert Before* to insert a new line before the selected line, or choose *Insert After* to insert a new line after the selected line. Finally, type the SQL command in the *Value* box. To delete a line, select the line in the *SQL Commands* box, right click, and choose *Delete*. You can include variables and parameters in preload or postload SQL statements. Put the variables and parameters in either brackets, braces, or quotes. Data Services translates each statement differently, writing a statement that depends on the variable or parameter type. <table><tr><th>Entered statement</th><th>Variable value</th><th>Written statement</th></tr><tr><td>[$X]</td><td>5</td><td>5</td></tr><tr><td>[$X]</td><td>John Smith</td><td>John Smith</td></tr><tr><td>{$X}</td><td>5</td><td>5</td></tr><tr><td>{$X}</td><td>John Smith</td><td>John Smith</td></tr><tr><td>'$X'</td><td>5</td><td>5</td></tr><tr><td>'$X'</td><td>John Smith</td><td>John Smith</td></tr></table> You cannot use Pre Load and Post Load SQL commands in a real-time job.

3.5.3.1.4 Data outputs

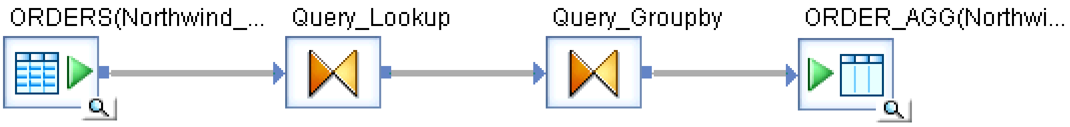
A data set with the same schema and the same operation code as the input data set. If a subsequent ORDER BY or GROUP BY is pushed down to the database, the output rows are in the ORDER BY (or GROUP BY) order.

Data Services automatically splits the data flow into sub data flows and executes them serially. The sub data flow names use the following format, where `<n>` is the number of the sub data flow:

```
<dataflowname_n>
```

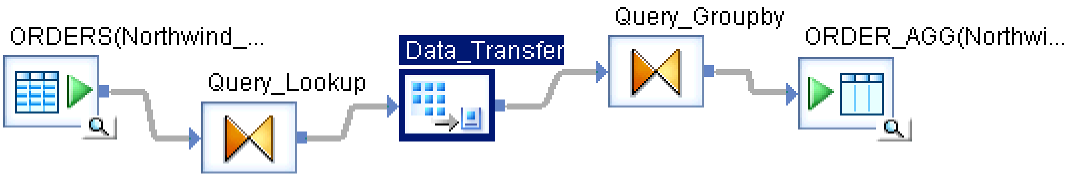
3.5.3.1.5 Example

This simple data flow contains a Query transform that does a lookup of sales subtotals and groups the results by country and region.



Suppose the GROUP BY operation processes millions of rows. Data Services cannot push the GROUP BY operation down to the database because the Query before it contains a **<lookup_ext>** function which Data Services cannot push down. You can add a **<Data_Transfer>** transform to split the **<lookup_ext>** function and the GROUP BY operation into two sub data flows to enable Data Services to push the GROUP BY to the target database.

1. Delete the connecting line between the two Query transforms.
2. Drag the Data_Transfer transform from the object library to the data flow in the work space and connect it to the two Query transforms.



3. Open the Data_Transfer transform editor and select the transfer type.

   This example selects Table for Transfer type.
4. In the Table options area, click the browse button for *Table name* and double-click the datastore that you want to contain the data to transfer to the second sub data flow.
5. Specify the transfer table in the Input table for Data_Transfer window.
   a) Enter the name of the table that will contain the data to transfer. The table does not need to exist.
   b) In the *Owner name* text box, type either the owner name or an alias.
   If you specify an alias for the owner, the *CREATE TABLE* statement in the *Options* tab shows the alias name in square brackets. When you execute the job, Data Services replaces the alias name with the owner name.
   c) Click *OK*.
6. You can change the default value for *Array fetch size*.
7. When you execute the job, Data Services displays messages for each sub data flow. For the sample GROUP BY data flow, the following messages display for the data flow and sub data flows:

   Job **<LookupGroup_Orders_Job>** is started. Process to execute data flow**<LookupGroup_Orders_DF>** is started. Starting sub data flow **<LookupGroup_Orders_DF_1>** on job server host <SJ-Comput>, port <3508>. Distribution level <Job>. Process to execute sub data flow **<LookupGroup_Orders_DF_1>** is started. Sub data flow **<LookupGroup_Orders_DF_1>** is started. Cache statistics for sub data flow

<<**LookupGroup_Orders_DF_1>** are not available to be used for optimization and need to be collected before they can be used. Sub data flow **<LookupGroup_Orders_DF_1>** using PAGEABLE Cache with <1280 MB> buffer pool. Sub data flow **<LookupGroup_Orders_DF_1>** is completed successfully. Process to execute sub data flow **<LookupGroup_Orders_DF_1>** is completed. Starting sub data flow **<LookupGroup_Orders_DF_2>** on job server host <SJ-Comput>, port <3508>. Distribution level <Job>. Process to execute sub data flow **<LookupGroup_Orders_DF_2>** is started. Sub data flow **<LookupGroup_Orders_DF_2>** is started. Cache statistics determined that sub data flow <LookupGroup_Orders_DF_2> uses <0> caches with a total size of <0> bytes. This is less than (or equal to) the virtual memory <1610612736> bytes available for caches. Statistics is switching the cache type to IN MEMORY. Sub data flow **<LookupGroup_Orders_DF_2>** using IN MEMORY Cache. Sub data flow **<LookupGroup_Orders_DF_2>** is completed successfully. Process to execute sub data flow **<LookupGroup_Orders_DF_2>** is completed. Process to execute data flow **<LookupGroup_Orders_DF>** is completed. Job **<LookupGroup_Orders_Job>** is completed successfully.

3.5.3.2 Date_Generation

Produces a series of dates incremented as you specify.

Use this transform to produce the key values for a time dimension target. From this generated sequence you can populate other fields in the time dimension (such as day_of_week) using functions in a query.

3.5.3.2.1 Data inputs

None.

3.5.3.2.2 Options

Option	Description
Cache	Indicates whether the software should read the required data from the source and load it into memory or pageable cache. Because an inner source of a join must be read for each row of an outer source, you might want to cache a source when it is used as an inner source in a join. Options are:

Option	Description
	- *Yes*: The source is always cached unless it is the outer-most source in a join. - *No*: The source is never cached. The default is *Yes*. Cache specified in the Query transform editor FROM tab overrides any cache specified in a source. For new jobs, specify the cache only in the Query transform editor.
End date	The last date in the output sequence. Use the same format used for *Start date* to specify this date.
Increment	The interval between dates in the output sequence. Select *Daily*, *Monthly*, or *Weekly*.
Join rank	Indicates the rank of the output data set relative to other tables and files joined in a data flow. The software joins sources with higher join ranks before joining sources with lower join ranks. Join rank specified in the Query transform editor FROM tab overrides any join rank specified in a source. For new jobs, specify the join rank only in the Query transform editor. Must be a non-negative integer. Default value is 0.
Start date	The first date in the output sequence. Specify this date using the following format: YYYY.MM.DD where `YYYY` is a year value, `MM` is a month value, and `DD` is a day value.

3.5.3.2.3 Data outputs

A data set with a single column named `DI_GENERATED_DATE` containing the date sequence. The rows generated are flagged as INSERT.

The Date_Generation transform does not generate hierarchical data.

Generated dates can range from 1900.01.01 through 9999.12.31.

3.5.3.2.4 Example

To create a time dimension target with dates from the beginning of the year 1997 to the end of the year 2000, place a Date_Generation transform, a query, and a target in a data flow. Connect the output of the

Date_Generation transform to the query, and the output of the query to the target. Inside the Date_Generation transform, specify the following Options. You can also specify a variable for these options.

- *Start date*: 1997.01.01 (A variable can also be used.)
- *End date*: 2000.12.31 (A variable can also be used.)
- *Increment*: Daily (A variable can also be used.)

Inside the query, create two target columns and the field name, and define a mapping for these time dimension values:

- Business quarter: `BusQuarter`
  Function: quarter(Generated_date)
- Date number from start: `DateNum`
  Function: julian(generated_date) - julian(1997.01.01)

3.5.3.3 Effective_Date

Calculates an "effective-to" value for data that contains an effective date. The calculated effective-to date and an existing effective date produce a date range that allows queries based on effective dates to produce meaningful results.

3.5.3.3.1 Data inputs

Data that has an effective date column.

Effective dates allow you to indicate changes to information over time. The effective date value in each row of a data set indicates the date from which the data in the row is valid. As changes are made to the information, more rows are included to describe the information as it changes over time. Each row describing the set of information is distinguished from the others by the effective date of the row.

An example input data set might include a column that identifies the information being described (Project), a column that changes over time (Status), and an effective date:

Project	Effective date	Status
Cherry Lake	1999.06.22	Proposal
Cherry Lake	2003.01.12	Case
Hetch Hetchy Reservoir	1999.08.02	Proposal
Hetch Hetchy Reservoir	2003.05.06	Case

This transform description uses the term "related rows" to refer to a set of rows that describe the same information as it changes over time. There are two sets of related rows in the example above, described by the values in the Project column.

If the input data set allows duplicate effective dates, it might contain an effective sequence column to distinguish between related rows that also have the same effective date:

Project	Effective date	Effective sequence	Status
Cherry Lake	1999.06.22	0	Proposal
Cherry Lake	2002.01.12	0	Case
Hetch Hetchy Reservoir	1999.08.02	0	Proposal
Hetch Hetchy Reservoir	2002.10.17	0[a]	Proposal
Hetch Hetchy Reservoir	2002.10.17	1[a]	Case
Hetch Hetchy Reservoir	2003.05.06	0	Case
a. Project statuses are distinguished by the effective sequence.			

In the example, only the row with the largest sequence number is effective-dated by this transform. A query that selects the status of project "Hetch Hetchy Reservoir" on 2002.12.31 will return 'case' as a result. The input data set can contain only rows flagged as NORMAL.

The input data set can contain hierarchical data. The transform operates only on the rows at the top-level of the input data set, and passes nested data through to the output without change. Columns containing nested schemas cannot be used as transform parameters.

3.5.3.3.2 Editor

The Effective_Date transform editor includes:

- A Schema In pane on the left that shows the source schema
- A Schema Out pane on the right that shows the target schema
- An Effective Date tab that shows the transform options. You can drag column names from the source schema to fill in values for the *Effective Date column* and *Effective sequence column* options.

The target schema is generated in response to the values you choose in the transform options. To refresh the target schema after you make a change to the options, choose *View* > *Refresh* or press *F5*.

3.5.3.3.3 Options

Option	Description
Default effective to date value	A date assigned as the effective-to date for those rows with the highest effective date among related rows. You can also specify a variable for this option.
Effective date column	A column in the input data set of type `date` that contains the effective date. This column name is entered automatically if Data Services finds a column named `EFFDT` in the source. The column appears in the output schema with the name `EFFDT`. This field is required.
Effective sequence column	A column in the input data set that indicates the order in time of related rows that have duplicate effective dates. If no related rows also share effective dates, the sequence numbers are the same ('0' for example). If related rows do share the same effective dates, the sequence numbers are incremented as rows with conflicting effective dates are added. This transform returns only the row containing the maximum sequence number if there are related rows with the same effective date. This field is required only if the input data set allows duplicate effective dates.
Effective to column	The name of a date column added to the output schema that contains the effective-to date. The effective-to date for a row is equal to the effective date of the related row with the closest greater effective date. If no such row exists, the *Default effective to date* is used.

3.5.3.3.4 Data outputs

The transform output includes all of the columns from the source schema and the calculated effective-to date column. For example, given a default effective-to date of January 1, 2999, the input described in the data input section is transformed as follows:

Project	Effective date	Effective-to date	Status
Cherry Lake	1999.06.22	2003.01.12	Proposal
Cherry Lake	2003.01.12	2999.01.01[a]	Case
Hetch Hetchy Reservoir	1999.08.02	2002.10.17	Proposal

Project	Effective date	Effective-to date	Status
Hetch Hetchy Reservoir	2002.10.17	2003.05.06	Case
Hetch Hetchy Reservoir	2003.05.06	2999.01.01[a]	Case

a. The default effective-to date is used to close the effective date range.

In the case where an effective sequence column is necessary to produce a unique key—related rows contain the same effective date—the output from the Effective_Date transform includes a single row where the input had more than one. The row returned contains the largest sequence number:

Project	Effective date	Effective to date	Effective sequence	Status
Cherry Lake	1999.06.22	2003.01.12	0	Proposal
Cherry Lake	2003.01.12	2999.01.01	0	Case
Hetch Hetchy Reservoir	1999.08.02	2002.10.17	0	Proposal
Hetch Hetchy Reservoir	2002.10.17	2003.05.06	1[a]	Case
Hetch Hetchy Reservoir	2003.05.06	2999.01.01	0	Case

a. Data from the row with sequence 0 is omitted.

After the range of effective dates is generated for a set of data, you can use the effective-to date to filter appropriate records. For example, you can extract the subset of records valid as of today by selecting only those records whose effective-to column is later than today's date and effective-from column is earlier than today's date.

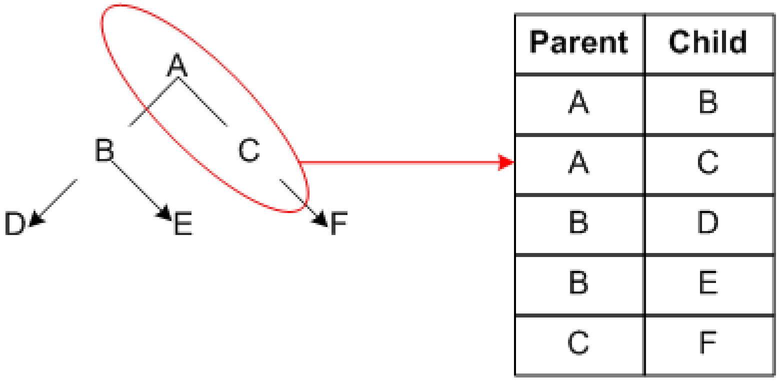
Nested schemas in the input are passed through without change.

3.5.3.4 Hierarchy_Flattening

Constructs a complete hierarchy from parent/child relationships, then produces a description of the hierarchy in vertically or horizontally flattened format.

3.5.3.4.1 Data inputs

Rows describing individual parent-child relationships.



Parent	Child
A	B
A	C
B	D
B	E
C	F

Each row must contain two columns that function as the keys of the parent and child in the relationship. The input can also include columns containing attributes describing the parent and/or child.
